DOUGLAS GIANCOLI

Pearson

Editorial Director: Jeanne Zalesky
Content Development: Margy Kuntz, Andrea Giancoli
Project Managers: Cynthia Rae Abbott, Elisa Mandelbaum, Francesca Monaco, Karen Misler, Rebecca Dunn
Production Vendor: CodeMantra
Interior Composition: Preparé Italia, Battipaglia (SA), Italy
Copyeditor: Joanna Dinesmore
Proofreaders: Andrea Giancoli, Carol Reitz, and Clare Romeo
Art House: Lachina Creative
Design Managers: Mark Ong, Derek Bacchus, Emily Friel, SPi Global
Rights & Permissions Manager: Ben Ferrini
SPi Global Photo Researcher: Eric Schrader and Mary Teresa Giancoli
Manufacturing Buyer: Stacey Wienberger

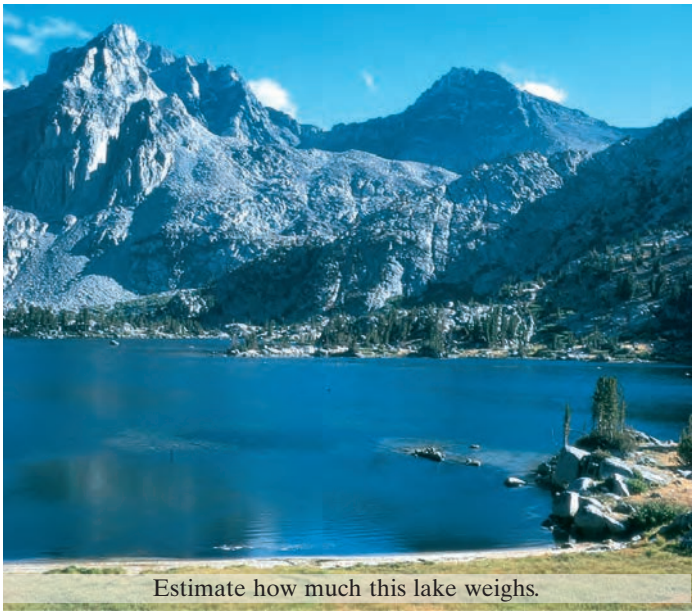
Giancoli, Douglas C., author.
Title: Physics for scientists & engineers with modern physics/Douglas C. Giancoli.
Other titles: Physics for scientists and engineers with modern physics
Description: Fifth edition. | Upper Saddle River, N.J. : Pearson Education, Inc., [2019] | Includes bibliographical references and index.
Contents: Introduction, measurement, estimating — Describing motion: kinematics in one dimension — Kinematics in two or three dimensions; vectors — Dynamics: Newton's laws of motion — Using Newton's laws: friction, circular motion, drag forces — Gravitation and Newton's synthesis — Work and energy — Conservation of energy — Linear momentum — Rotational motion — Angular momentum; general rotation — Static equilibrium; elasticity and fracture — Fluids — Oscillations — Wave motion — Sound — Temperature, thermal expansion, and the ideal gas law — Kinetic theory of gases — Heat and the first law of thermodynamics — Second law of thermodynamics — Electric charge and electric field — Gauss's law — Electric potential — Capacitance, dielectrics, electric energy storage — Electric currents and resistance — DC circuits — Magnetism — Sources of magnetic field — Electromagnetic induction and Faraday's law — Inductance, electromagnetic oscillations, and AC circuits — Maxwell's equations and electromagnetic waves — Light: reflection and refraction — Lenses and optical instruments — The wave nature of light: interference and polarization — Diffraction — The special theory of relativity — Early quantum theory and models of the atom — Quantum mechanics — Quantum mechanics of atoms — Molecules and solids — Nuclear physics and radioactivity — Nuclear energy; effects and uses of radiation — Elementary particles — Astrophysics and cosmology.
Identifiers: LCCN 2019015435 | ISBN 9780134378053 (v.1) | ISBN 0134378059 (v.1)
Subjects: LCSH: Physics--Textbooks.
Classification: LCC QC21.3 .G539 2019 | DDC 530--dc23 LC record available at https://lccn.loc.gov/2019015435



ISBN 10: 0-321-99227-X; ISBN 13: 978-0-32-199227-7 (Student Edition)
ISBN 10: 0-134-37806-7; ISBN 13: 978-13-437806-0 (Classic Student Edition)
ISBN 10: 0-134-37808-3; ISBN 13: 978-0-13-437808-4 (Looseleaf Edition)

Applications List xii
Preface xvi
To Students xx
Use of Color xxi

Estimate how much this lake weighs.

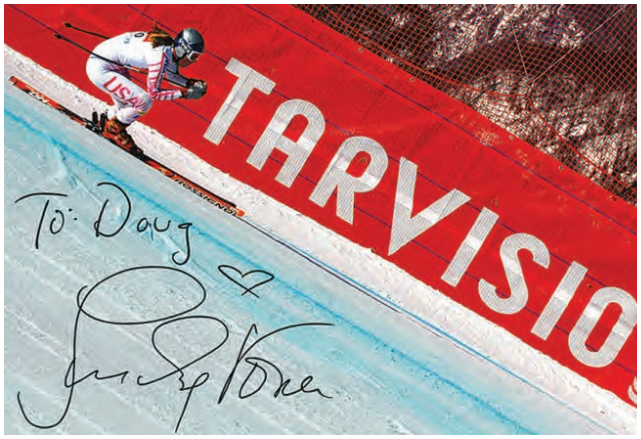
**1 Introduction, Measurement, Estimating 1**

1–1 How Science Works 2
1–2 Models, Theories, and Laws 3
1–3 Measurement and Uncertainty; Significant Figures 3
1–4 Units, Standards, and the SI System 6
1–5 Converting Units 9
1–6 Order of Magnitude: Rapid Estimating 11
*1–7 Dimensions and Dimensional Analysis 14
Questions, MisConceptions, Problems 15–19

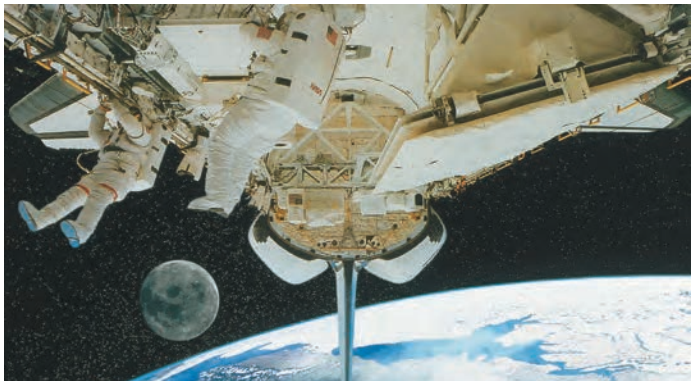
**2 Describing Motion: Kinematics in One Dimension 20**

2–1 Reference Frames and Displacement 21
2–2 Average Velocity 22
2–3 Instantaneous Velocity 24
2–4 Acceleration 27
2–5 Motion at Constant Acceleration 30
2–6 Solving Problems 33
2–7 Freely Falling Objects 37
*2–8 Variable Acceleration; Integral Calculus 43
Questions, MisConceptions, Problems 45–53

**3 Kinematics in Two or Three Dimensions; Vectors 54**



3–1 Vectors and Scalars 55
3–2 Addition of Vectors—Graphical Methods 55
3–3 Subtraction of Vectors, and Multiplication of a Vector by a Scalar 57
3–4 Adding Vectors by Components 58
3–5 Unit Vectors 62
3–6 Vector Kinematics 62
3–7 Projectile Motion 65
3–8 Solving Problems Involving Projectile Motion 67
3–9 Relative Velocity 73
Questions, MisConceptions, Problems 76–84



**4 Dynamics: Newton's Laws of Motion 85**

4–1 Force 86
4–2 Newton's First Law of Motion 86
4–3 Mass 88
4–4 Newton's Second Law of Motion 88
4–5 Newton's Third Law of Motion 91
4–6 Weight—the Force of Gravity; and the Normal Force 94
4–7 Solving Problems with Newton's Laws: Free-Body Diagrams 97
4–8 Problem Solving—A General Approach 104
Questions, MisConceptions, Problems 105–115

**5 Using Newton's Laws: Friction, Circular Motion, Drag Forces 116**

5–1 Using Newton's Laws with Friction 117
5–2 Uniform Circular Motion—Kinematics 123
5–3 Dynamics of Uniform Circular Motion 126
5–4 Highway Curves: Banked and Unbanked 130
5–5 Nonuniform Circular Motion 133
*5–6 Velocity-Dependent Forces: Drag and Terminal Velocity 134
Questions, MisConceptions, Problems 136–144

## 6 Gravitation and Newton's Synthesis 145

6–1 Newton's Law of Universal Gravitation 146
6–2 Vector Form of Newton's Law of Universal Gravitation 149
6–3 Gravity Near the Earth's Surface 149
6–4 Satellites and "Weightlessness" 152
6–5 Planets, Kepler's Laws, and Newton's Synthesis 155
6–6 Moon Rises an Hour Later Each Day 161
6–7 Types of Forces in Nature 161
*6–8 Gravitational Field 162
*6–9 Principle of Equivalence; Curvature of Space; Black Holes 163
Questions, MisConceptions, Problems 165–171

## 7 Work and Energy 172

7–1 Work Done by a Constant Force 173
7–2 Scalar Product of Two Vectors 176
7–3 Work Done by a Varying Force 177
7–4 Kinetic Energy and the Work-Energy Principle 181
Questions, MisConceptions, Problems 186–193

## 8 Conservation of Energy 194

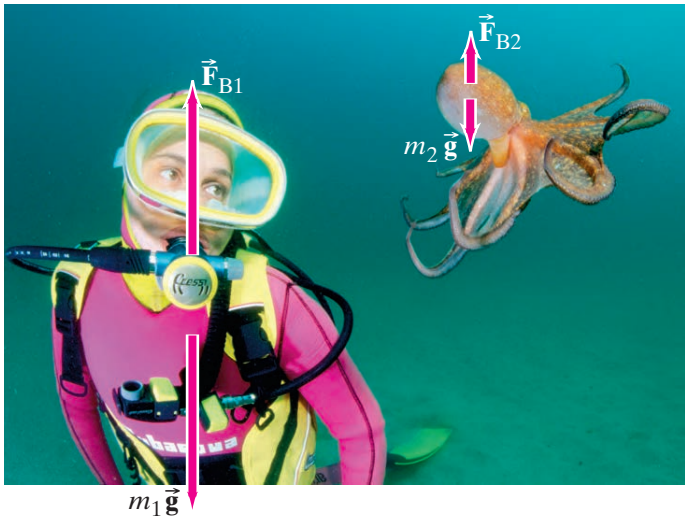
8–1 Conservative and Nonconservative Forces 195
8–2 Potential Energy 197
8–3 Mechanical Energy and Its Conservation 200
8–4 Problem Solving Using Conservation of Mechanical Energy 201
8–5 The Law of Conservation of Energy 207
8–6 Energy Conservation with Dissipative Forces: Solving Problems 208
8–7 Gravitational Potential Energy and Escape Velocity 210
8–8 Power 213
8–9 Potential Energy Diagrams; Stable and Unstable Equilibrium 215
*8–10 Gravitational Assist (Slingshot) 216
Questions, MisConceptions, Problems 218–226

## 9 Linear Momentum 227

9–1 Momentum and Its Relation to Force 228
9–2 Conservation of Momentum 230
9–3 Collisions and Impulse 234
9–4 Conservation of Energy and Momentum in Collisions 235
9–5 Elastic Collisions in One Dimension 236
9–6 Inelastic Collisions 239
9–7 Collisions in 2 or 3 Dimensions 241
9–8 Center of Mass (CM) 244
9–9 Center of Mass and Translational Motion 248
*9–10 Systems of Variable Mass; Rocket Propulsion 251
Questions, MisConceptions, Problems 254–263

## 10 Rotational Motion 264

10–1 Angular Quantities 265
10–2 Vector Nature of Angular Quantities 270
10–3 Constant Angular Acceleration 270
10–4 Torque 271
10–5 Rotational Dynamics; Torque and Rotational Inertia 274
10–6 Solving Problems in Rotational Dynamics 276
10–7 Determining Moments of Inertia 279
10–8 Rotational Kinetic Energy 281
10–9 Rotation plus Translational Motion; Rolling 283
*10–10 Why Does a Rolling Sphere Slow Down? 289
Questions, MisConceptions, Problems 291–301



## 11 Angular Momentum; General Rotation 302

11–1 Angular Momentum—Objects Rotating About a Fixed Axis 303
11–2 Vector Cross Product; Torque as a Vector 307
11–3 Angular Momentum of a Particle 309
11–4 Angular Momentum and Torque for a System of Particles; General Motion 310
11–5 Angular Momentum and Torque for a Rigid Object 312
11–6 Conservation of Angular Momentum 315
*11–7 The Spinning Top and Gyroscope 317
11–8 Rotating Frames of Reference; Inertial Forces 318
*11–9 The Coriolis Effect 319
Questions, MisConceptions, Problems 322–330

## 12 Static Equilibrium; Elasticity and Fracture 331

12–1 The Conditions for Equilibrium 332
12–2 Solving Statics Problems 334
*12–3 Applications to Muscles and Joints 339
12–4 Stability and Balance 341
12–5 Elasticity; Stress and Strain 342
12–6 Fracture 345
*12–7 Trusses and Bridges 347
*12–8 Arches and Domes 350
Questions, MisConceptions, Problems 353–364

## 13 Fluids 365

13–1 Phases of Matter 366
13–2 Density and Specific Gravity 366
13–3 Pressure in Fluids 367
13–4 Atmospheric Pressure and Gauge Pressure 371
13–5 Pascal's Principle 371
13–6 Measurement of Pressure; Gauges and the Barometer 372
13–7 Buoyancy and Archimedes' Principle 374
13–8 Fluids in Motion; Flow Rate and the Equation of Continuity 378
13–9 Bernoulli's Equation 380
13–10 Applications of Bernoulli's Principle: Torricelli, Airplanes, Baseballs, Blood Flow 382
13–11 Viscosity 385
*13–12 Flow in Tubes: Poiseuille's Equation, Blood Flow 385
*13–13 Surface Tension and Capillarity 386
*13–14 Pumps, and the Heart 388
Questions, MisConceptions, Problems 390–398

## 14 Oscillations 399

14–1 Oscillations of a Spring 400
14–2 Simple Harmonic Motion 402
14–3 Energy in the Simple Harmonic Oscillator 408
14–4 Simple Harmonic Motion Related to Uniform Circular Motion 410
14–5 The Simple Pendulum 411
*14–6 The Physical Pendulum and the Torsion Pendulum 412
14–7 Damped Harmonic Motion 414
14–8 Forced Oscillations; Resonance 417
Questions, MisConceptions, Problems 420–427

## 15 Wave Motion 428

15–1 Characteristics of Wave Motion 429
15–2 Types of Waves: Transverse and Longitudinal 431
15–3 Energy Transported by Waves 435
15–4 Mathematical Representation of a Traveling Wave 437
*15–5 The Wave Equation 440
15–6 The Principle of Superposition 441
15–7 Reflection and Transmission 443
15–8 Interference 444
15–9 Standing Waves; Resonance 446
15–10 Refraction 449
15–11 Diffraction 450
Questions, MisConceptions, Problems 452–459

## 16 Sound 460

16–1 Characteristics of Sound 461
16–2 Mathematical Representation of Longitudinal Waves 462
16–3 Intensity of Sound: Decibels 464
16–4 Sources of Sound: Vibrating Strings and Air Columns 467
*16–5 Quality of Sound, and Noise; Superposition 472
16–6 Interference of Sound Waves; Beats 473
16–7 Doppler Effect 476
*16–8 Shock Waves and the Sonic Boom 480
*16–9 Applications: Sonar, Ultrasound, and Medical Imaging 481
Questions, MisConceptions, Problems 484–491

## 17 Temperature, Thermal Expansion, and the Ideal Gas Law 492

17–1 Atomic Theory of Matter 493
17–2 Temperature and Thermometers 495
17–3 Thermal Equilibrium and the Zeroth Law of Thermodynamics 497
17–4 Thermal Expansion 497
*17–5 Thermal Stresses 501
17–6 The Gas Laws and Absolute Temperature 502
17–7 The Ideal Gas Law 503
17–8 Problem Solving with the Ideal Gas Law 504
17–9 Ideal Gas Law in Terms of Molecules: Avogadro's Number 506
*17–10 Ideal Gas Temperature Scale—a Standard 507
Questions, MisConceptions, Problems 509–515

## 18 Kinetic Theory of Gases 516

18–1 The Ideal Gas Law and the Molecular Interpretation of Temperature 516
18–2 Distribution of Molecular Speeds 520
18–3 Real Gases and Changes of Phase 522
18–4 Vapor Pressure and Humidity 524
18–5 Temperature Decrease of Boiling Water with Altitude 526
18–6 Van der Waals Equation of State 527
18–7 Mean Free Path 528
18–8 Diffusion 530
Questions, MisConceptions, Problems 532–537

## 19 Heat and the First Law of Thermodynamics 538

19–1 Heat as Energy Transfer 539
19–2 Internal Energy 540
19–3 Specific Heat 541
19–4 Calorimetry—Solving Problems 542
19–5 Latent Heat 545
19–6 The First Law of Thermodynamics 549
19–7 Thermodynamic Processes and the First Law 551
19–8 Molar Specific Heats for Gases, and the Equipartition of Energy 556
19–9 Adiabatic Expansion of a Gas 559
19–10 Heat Transfer: Conduction, Convection, Radiation 560
Questions, MisConceptions, Problems 568–575

## 20 Second Law of Thermodynamics 576

20–1 The Second Law of Thermodynamics—Introduction 577
20–2 Heat Engines 578
20–3 The Carnot Engine; Reversible and Irreversible Processes 580
20–4 Refrigerators, Air Conditioners, and Heat Pumps 584
20–5 Entropy 587
20–6 Entropy and the Second Law of Thermodynamics 590
20–7 Order to Disorder 593
20–8 Unavailability of Energy; Heat Death 594
20–9 Statistical Interpretation of Entropy and the Second Law 595
*20–10 Thermodynamic Temperature; Third Law of Thermodynamics 597
20–11 Thermal Pollution, Global Warming, and Energy Resources 598
Questions, MisConceptions, Problems 601–608

## 21 Electric Charge and Electric Field 609

21–1 Static Electricity; Electric Charge and Its Conservation 610
21–2 Electric Charge in the Atom 611
21–3 Insulators and Conductors 611
21–4 Induced Charge; the Electroscope 612
21–5 Coulomb's Law 613
21–6 The Electric Field 618
21–7 Electric Field Calculations for Continuous Charge Distributions 622
21–8 Field Lines 626
21–9 Electric Fields and Conductors 627
21–10 Motion of a Charged Particle in an Electric Field 628
21–11 Electric Dipoles 629
*21–12 Electric Forces in Molecular Biology: DNA Structure and Replication 631
Questions, MisConceptions, Problems 634–642

## 22 Gauss's Law 643

22–1 Electric Flux 644
22–2 Gauss's Law 645
22–3 Applications of Gauss's Law 647
*22–4 Experimental Basis of Gauss's and Coulomb's Laws 652
Questions, MisConceptions, Problems 653–659

## 23 Electric Potential 660

23–1 Electric Potential Energy and Potential Difference 661
23–2 Relation between Electric Potential and Electric Field 664
23–3 Electric Potential Due to Point Charges 666
23–4 Potential Due to Any Charge Distribution 669
23–5 Equipotential Lines and Surfaces 670
23–6 Potential Due to Electric Dipole; Dipole Moment 671
23–7 $\vec{\mathbf{E}}$ Determined from $V$ 672
23–8 Electrostatic Potential Energy; the Electron Volt 674
23–9 Digital; Binary Numbers; Signal Voltage 676
*23–10 TV and Computer Monitors 679
*23–11 Electrocardiogram (ECG or EKG) 682
Questions, MisConceptions, Problems 684–691

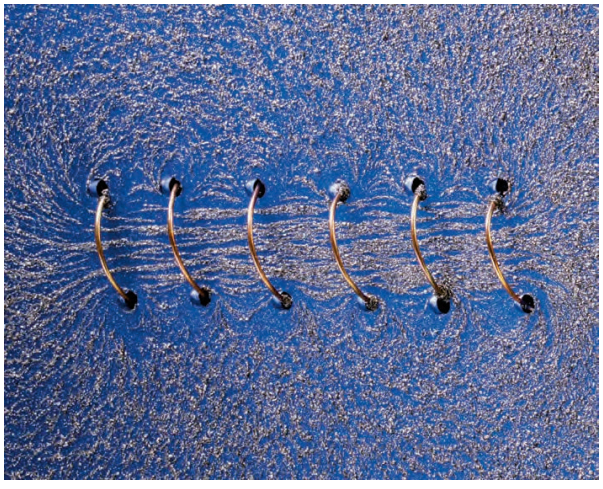
## 24 Capacitance, Dielectrics, Electric Energy Storage 692

24–1 Capacitors 692
24–2 Determination of Capacitance 694
24–3 Capacitors in Series and Parallel 698
24–4 Storage of Electric Energy 700
24–5 Dielectrics 703
*24–6 Molecular Description of Dielectrics 706
Questions, MisConceptions, Problems 708–716

## 25 Electric Current and Resistance 717

25–1 The Electric Battery 718
25–2 Electric Current 720
25–3 Ohm's Law: Resistance and Resistors 722
25–4 Resistivity 724
25–5 Electric Power 726
25–6 Power in Household Circuits 729
25–7 Alternating Current 730
25–8 Microscopic View of Electric Current 732
*25–9 Superconductivity 735
*25–10 Electrical Conduction in the Human Nervous System 736
Questions, MisConceptions, Problems 739–746

## 26 DC Circuits 747



26–1 EMF and Terminal Voltage 748
26–2 Resistors in Series and in Parallel 749
26–3 Kirchhoff's Rules 754
26–4 EMFs in Series and in Parallel; Charging a Battery 757
26–5 *RC* Circuits—Resistor and Capacitor in Series 759
26–6 Electric Hazards and Safety 764
26–7 Ammeters and Voltmeters—Measurement Affects Quantity Measured 767
Questions, MisConceptions, Problems 771–781

## 27 Magnetism 782

27–1 Magnets and Magnetic Fields 782
27–2 Electric Currents Produce Magnetic Fields 785
27–3 Force on an Electric Current in a Magnetic Field; Definition of $\vec{\mathbf{B}}$ 786
27–4 Force on an Electric Charge Moving in a Magnetic Field 788
27–5 Torque on a Current Loop; Magnetic Dipole Moment 793
27–6 Applications: Motors, Loudspeakers, Galvanometers 795
27–7 Discovery and Properties of the Electron 797
27–8 The Hall Effect 799
27–9 Mass Spectrometer 800
Questions, MisConceptions, Problems 802–810

## 28 Sources of Magnetic Field 811

28–1 Magnetic Field Due to a Straight Wire 812
28–2 Force between Two Parallel Wires 813
28–3 Definitions of the Ampere and the Coulomb 814
28–4 Ampère's Law 815
28–5 Magnetic Field of a Solenoid and a Toroid 819
28–6 Biot-Savart Law 821
28–7 Magnetic Field Due to a Single Moving Charge 824
28–8 Magnetic Materials—Ferromagnetism 824
28–9 Electromagnets and Solenoids—Applications 826
28–10 Magnetic Fields in Magnetic Materials; Hysteresis 827
*28–11 Paramagnetism and Diamagnetism 828
Questions, MisConceptions, Problems 830–837

## 29 Electromagnetic Induction and Faraday's Law 838

29–1 Induced EMF 839
29–2 Faraday's Law of Induction; Lenz's Law 840
29–3 EMF Induced in a Moving Conductor 845
29–4 Electric Generators 846
29–5 Back EMF and Counter Torque; Eddy Currents 848
29–6 Transformers and Transmission of Power 851
29–7 A Changing Magnetic Flux Produces an Electric Field 854
*29–8 Information Storage: Magnetic and Semiconductor 856
*29–9 Applications of Induction: Microphone, Seismograph, GFCI 858
Questions, MisConceptions, Problems 860–868

## 30 Inductance, Electromagnetic Oscillations, and AC Circuits 869

30–1 Mutual Inductance 870
30–2 Self-Inductance; Inductors 872
30–3 Energy Stored in a Magnetic Field 874
30–4 *LR* Circuits 875
30–5 *LC* Circuits and Electromagnetic Oscillations 877
30–6 *LC* Oscillations with Resistance (*LRC* Circuit) 880
30–7 AC Circuits and Reactance 881
30–8 *LRC* Series AC Circuit; Phasor Diagrams 885
30–9 Resonance in AC Circuits 887
30–10 Impedance Matching 888
*30–11 Three-Phase AC 889
Questions, MisConceptions, Problems 890–897

## 31 Maxwell's Equations and Electromagnetic Waves 898

31–1 Changing Electric Fields Produce Magnetic Fields; Displacement Current 899
31–2 Gauss's Law for Magnetism 902
31–3 Maxwell's Equations 903
31–4 Production of Electromagnetic Waves 903
31–5 Electromagnetic Waves, and Their Speed, Derived from Maxwell's Equations 905
31–6 Light as an Electromagnetic Wave and the Electromagnetic Spectrum 909
31–7 Measuring the Speed of Light 912
31–8 Energy in EM Waves; the Poynting Vector 913
31–9 Radiation Pressure 915
31–10 Radio and Television; Wireless Communication 917
Questions, MisConceptions, Problems 921–925

## 32 Light: Reflection and Refraction 926

32–1 The Ray Model of Light 927
32–2 Reflection; Image Formation by a Plane Mirror 927
32–3 Formation of Images by Spherical Mirrors 931
32–4 Seeing Yourself in a Magnifying Mirror (Concave) 936
32–5 Convex (Rearview) Mirrors 938
32–6 Index of Refraction 939
32–7 Refraction: Snell's Law 939
32–8 The Visible Spectrum and Dispersion 941
32–9 Total Internal Reflection; Fiber Optics 943
*32–10 Refraction at a Spherical Surface 946
Questions, MisConceptions, Problems 949–957

## 33 Lenses and Optical Instruments 958

33–1 Thin Lenses; Ray Tracing and Focal Length 959
33–2 The Thin Lens Equation 962
33–3 Combinations of Lenses 966
33–4 Lensmaker's Equation 968
33–5 Cameras: Film and Digital 970
33–6 The Human Eye; Corrective Lenses 975
33–7 Magnifying Glass 979
33–8 Telescopes 980
33–9 Compound Microscope 983
33–10 Aberrations of Lenses and Mirrors 984
Questions, MisConceptions, Problems 986–994

## 34 The Wave Nature of Light: Interference and Polarization 995

34–1 Waves vs. Particles; Huygens' Principle and Diffraction 996
34–2 Huygens' Principle and the Law of Refraction; Mirages 997
34–3 Interference–Young's Double-Slit Experiment 998
*34–4 Intensity in the Double-Slit Interference Pattern 1002
34–5 Interference in Thin Films 1004
34–6 Michelson Interferometer 1010
34–7 Polarization 1010
*34–8 Liquid Crystal Displays (LCD) 1014
*34–9 Scattering of Light by the Atmosphere 1015
34–10 Brightness: Lumens and Luminous Intensity 1016
*34–11 Efficiency of Lightbulbs 1016
Questions, MisConceptions, Problems 1018–1024

## 35 Diffraction 1025

35–1 Diffraction by a Single Slit or Disk 1026
*35–2 Intensity in Single-Slit Diffraction Pattern 1028
*35–3 Diffraction in the Double-Slit Experiment 1031
35–4 Interference vs. Diffraction 1033
35–5 Limits of Resolution; Circular Apertures 1033
35–6 Resolution of Telescopes and Microscopes; the $\lambda$ Limit 1035
35–7 Resolution of the Human Eye and Useful Magnification 1037
35–8 Diffraction Grating 1037
35–9 The Spectrometer and Spectroscopy 1040
*35–10 Peak Widths and Resolving Power for a Diffraction Grating 1041
35–11 X-Rays and X-Ray Diffraction 1043
*35–12 X-Ray Imaging and Computed Tomography (CT Scan) 1045
*35–13 Specialty Microscopes and Contrast 1048
Questions, MisConceptions, Problems 1049–1054

## 36 The Special Theory of Relativity 1055

36–1 Galilean–Newtonian Relativity 1056
36–2 The Michelson–Morley Experiment 1058
36–3 Postulates of the Special Theory of Relativity 1061
36–4 Simultaneity 1062
36–5 Time Dilation and the Twin Paradox 1064
36–6 Length Contraction 1070
36–7 Four-Dimensional Space–Time 1072
36–8 Galilean and Lorentz Transformations 1072
36–9 Relativistic Momentum 1077
36–10 The Ultimate Speed 1079
36–11 $E = mc^2$; Mass and Energy 1080
36–12 Doppler Shift for Light 1085
36–13 The Impact of Special Relativity 1086
Questions, MisConceptions, Problems 1088–1094

## 37 Early Quantum Theory and Models of the Atom 1095

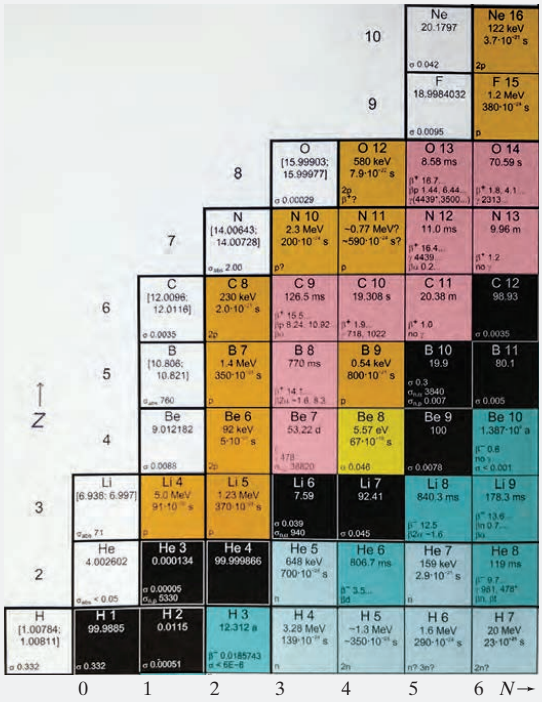
37–1 Blackbody Radiation; Planck's Quantum Hypothesis 1096
37–2 Photon Theory of Light and the Photoelectric Effect 1098
37–3 Energy, Mass, and Momentum of a Photon 1101
37–4 Compton Effect 1102
37–5 Photon Interactions; Pair Production 1104
37–6 Wave–Particle Duality; the Principle of Complementarity 1105
37–7 Wave Nature of Matter 1106
37–8 Electron Microscopes 1108
37–9 Early Models of the Atom 1110
37–10 Atomic Spectra: Key to the Structure of the Atom 1111
37–11 The Bohr Model 1113
37–12 de Broglie's Hypothesis Applied to Atoms 1120
Questions, MisConceptions, Problems 1121–1127

## Appendices

**A Mathematical Formulas A–1**
**B Derivatives and Integrals A–6**
**C Numerical Integration A–8**
**D More on Dimensional Analysis A–12**
**E Gravitational Force Due to a Spherical Mass Distribution A–13**
**F Differential Form of Maxwell's Equations A–16**
**G Selected Isotopes A–18**

Answers to Odd-Numbered Problems A–23
Index A–47
Photo Credits A–77

## 38 Quantum Mechanics 1128



38–1 Quantum Mechanics—A New Theory 1129
38–2 The Wave Function and Its Interpretation; the Double-Slit Experiment 1129
38–3 The Heisenberg Uncertainty Principle 1131
38–4 Philosophic Implications; Probability Versus Determinism 1135
38–5 The Schrödinger Equation in One Dimension—Time-Independent Form 1136
*38–6 Time-Dependent Schrödinger Equation 1138
38–7 Free Particles; Plane Waves and Wave Packets 1140
38–8 Particle in an Infinitely Deep Square Well Potential (a Rigid Box) 1142
38–9 Finite Potential Well 1147
38–10 Tunneling through a Barrier 1149
Questions, MisConceptions, Problems 1152–1157

## 39 Quantum Mechanics of Atoms 1158

39–1 Quantum-Mechanical View of Atoms 1159
39–2 Hydrogen Atom: Schrödinger Equation and Quantum Numbers 1159
39–3 Hydrogen Atom Wave Functions 1163
39–4 Multielectron Atoms; the Exclusion Principle 1166
39–5 Periodic Table of Elements 1167
39–6 X-Ray Spectra and Atomic Number 1169
*39–7 Magnetic Dipole Moment; Total Angular Momentum 1171
39–8 Fluorescence and Phosphorescence 1174
39–9 Lasers 1175
*39–10 Holography 1178
Questions, MisConceptions, Problems 1180–1185

## 40 Molecules and Solids 1186

40–1 Bonding in Molecules 1187
40–2 Potential-Energy Diagrams for Molecules 1189
40–3 Weak (van der Waals) Bonds 1192
40–4 Molecular Spectra 1196
40–5 Bonding in Solids 1202
40–6 Free-Electron Theory of Metals; Fermi Energy 1203
40–7 Band Theory of Solids 1208
40–8 Semiconductors and Doping 1210
40–9 Semiconductor Diodes, LEDs, OLEDs 1212
40–10 Transistors: Bipolar and MOSFETs 1218
40–11 Integrated Circuits, 10-nm Technology 1219
Questions, MisConceptions, Problems 1220–1225

## 41 Nuclear Physics and Radioactivity 1226

41–1 Structure and Properties of the Nucleus 1227
41–2 Binding Energy and Nuclear Forces 1230
41–3 Radioactivity 1233
41–4 Alpha Decay 1234
41–5 Beta Decay 1237
41–6 Gamma Decay 1239
41–7 Conservation of Nucleon Number and Other Conservation Laws 1240
41–8 Half-Life and Rate of Decay 1240
41–9 Decay Series 1245
41–10 Radioactive Dating 1246
41–11 Detection of Particles 1248
Questions, MisConceptions, Problems 1250–1255

## 42 Nuclear Energy; Effects and Uses of Radiation 1256

42–1 Nuclear Reactions and the Transmutation of Elements 1257
42–2 Cross Section 1260
42–3 Nuclear Fission; Nuclear Reactors 1261
42–4 Nuclear Fusion 1266
42–5 Passage of Radiation Through Matter; Biological Damage 1271
42–6 Measurement of Radiation—Dosimetry 1272
*42–7 Radiation Therapy 1276
*42–8 Tracers in Research and Medicine 1277
*42–9 Emission Tomography: PET and SPECT 1278
*42–10 Nuclear Magnetic Resonance (NMR); Magnetic Resonance Imaging (MRI) 1279
Questions, MisConceptions, Problems 1283–1288

## 43 Elementary Particles 1289

43–1 High-Energy Particles and Accelerators 1290
43–2 Beginnings of Elementary Particle Physics—Particle Exchange 1296
43–3 Particles and Antiparticles 1299
43–4 Particle Interactions and Conservation Laws 1300
43–5 Neutrinos 1302
43–6 Particle Classification 1304
43–7 Particle Stability and Resonances 1306
43–8 Strangeness? Charm? Towards a New Model 1307
43–9 Quarks 1308
43–10 The Standard Model: QCD and Electroweak Theory 1311
43–11 Grand Unified Theories 1314
43–12 Strings and Supersymmetry 1317
Questions, MisConceptions, Problems 1318–1231

## 44 Astrophysics and Cosmology 1322

44–1 Stars and Galaxies 1323
44–2 Stellar Evolution: Birth and Death of Stars, Nucleosynthesis 1326
44–3 Distance Measurements 1332
44–4 General Relativity: Gravity and the Curvature of Space 1334
44–5 The Expanding Universe: Redshift and Hubble's Law 1338
44–6 The Big Bang and the Cosmic Microwave Background 1342
44–7 The Standard Cosmological Model: Early History of the Universe 1345
44–8 Inflation: Explaining Flatness, Uniformity, and Structure 1348
44–9 Dark Matter and Dark Energy 1350
44–10 Large-Scale Structure of the Universe 1353
44–11 Gravitational Waves—LIGO 1354
44–12 Finally . . . 1354
Questions, MisConceptions, Problems 1356–1360

## Appendices

**A Mathematical Formulas A–1**
**B Derivatives and Integrals A–6**
**C Numerical Integration A–8**
**D More on Dimensional Analysis A–12**
**E Gravitational Force Due to a Spherical Mass Distribution A–13**
**F Differential Form of Maxwell's Equations A–16**
**G Selected Isotopes A–18**

Answers to Odd-Numbered Problems A–23

# Applications (Selected) to Medicine and Biology and to Engineering, Environment, Everyday Life, Etc.

(Entries with a star * include material new to this edition)

**Chapter 1**
Viruses attack cell 7
Heartbeats in a lifetime 12
Number of nucleons in human body 17
Lung capacity 19
Building collapse 2, 332, 346–7
The 8000-m peaks 9
Making estimates: volume of a lake 11
Page thickness 12
Building height by triangulation 12
Earth radius estimate 13, 18
Fermi estimates 13
Particulate pollution 18
Global positioning satellite 18
Computer chips 18

**Chapter 2**
Airport runway design 32
*Car air bag inflation time 32, 254
Car braking distance 35, 183
CD bit size, bit rate, playing time 48, 53
*Baseball 49, 82, 83, 84, 172
Basketball 50, 83, 109
Golf putt, uphill or down 52
Rapid transit system 53

**Chapter 3**
Helicopter supply drop 54, 72, 83
*Sports 54, 65, 69, 71, 76, 77, 79, 80, 81, 82, 83, 84
Kicked football 69, 71
Truck escape lane 79, 110
Golf on the Moon 82
Extreme sports 83

**Chapter 4**
How we can walk 92
Whiplash 106
*Force heart exerts 107
Rocket 85, 92, 108, 233, 252, 395
Skater pushoff 91
What force accelerates a car 92
You weigh less in a falling elevator 96
Hockey 98
Elevator, discomfort 101, 108
Mechanical advantage, pulley 102, 188
Accelerometer 102
*Sports 106, 107, 108, 109, 110, 112
*Bear sling 106, 355
Tug of war 106, 255
Car accident "*g*'s" 107
Optical tweezers 108, 916, 923
*Tightrope walker 109
Basketball shot 109
Mountain climbers 110, 114, 115, 193, 370
City planning, cars on hill 112
Bicycling 112, 114
Supermarket ramp design 113
Doomsday asteroid 114, 262
*Car stuck in mud 115

**Chapter 5**
Centrifugation 126
Skiing 116, 121, 136
Push or pull a sled? 120
Skier speed in air vs. on snow 121
*Simulating gravity 126, 136, 141, 168, 171
*Uranium enrichment, reactor, bomb 126
Ferris wheel 129
Avoid skidding on a curve 130–2
Banked highway curves 132
Cross-country skiing friction 136
Rotating space station 136, 141, 168
*Rotor ride 137, 143
Airplane bank/turn 137, 144
Roller coaster upside down 141
Car flying up off road 141
Rock climbing friction 143

**Chapter 6**
Weightlessness 154–5
*Astronauts in orbit 145, 155, 165
Gravity on tall peaks 150
Oil and mineral exploration 150, 165, 167
Satellites, spacecraft 145, 152–5, 168, 169
Geostationary satellites 153
Free fall, for athletes 155
Planets 155–8, 167
Determining the Sun's mass 158
Planets around other stars 158, 250, 262
*Ocean tides 159, 165, 170
Lagrange point 160
*Moon's orbit, periods, phases, diagram 161, 169
*Eclipses 161
Curved space 163–4
Black holes 164, 167
White dwarfs 167
Comets, asteroids, moons 168, 169, 171
GPS 169
Milky Way Galaxy 171

**Chapter 7**
Baseball pitch 172
Car stopping distance $\propto v^2$ 183
Lever 187, 334
*Pulley 188
Jet catapults 189
Bicycle, sprockets (teeth) 192, 299
Climbing rope stretch 193

**Chapter 8**
Stair-climbing power 213
*ATP 216
Hike *over* logs 218
Pole vault 194, 203–4, (189)
Downhill ski runs 194
Roller coaster 198, 202, 209
Escape velocity from Earth or Moon 212
Power needs of car 214
Efficiency of engine 215
*Gravitational assist 216–7, 224, 263
High jump 220
Bungee jump 221
Lunar module landing 222
Escape velocity from solar system 223
Ski jump 225
Long jump 225

**Chapter 9**
Impulse in fall: break a leg? 257
Billiard balls 227, 230, 237, 242
Tennis serve 229, 234
Rocket propulsion 233, 252, 395
Rifle recoil 233
Karate blow 235
Nuclear reactors 238
Nuclear collisions 238, 239, 241, 243
Ballistic pendulum, speed measured 240
Distant planet discovery 250, 262
Conveyor belt 253
Car crashworthiness 261
Asteroid danger 262
Force wind exerts 263
Bowling 263

**Chapter 10**
Acuity of bird's eye 266
Centrifuge 271
*Biceps, triceps, torque 273, 295, 339
Situps 291
Fast mammal 291
Rotating carnival rides 264, 267, 268
Tire iron extension 272
Flywheel, energy 282, 301
Yo-yo 287
Braking forces on a car 288–9
Bicycle odometer 291
Tightrope walking 291
*Total solar eclipse 293
Wrench torque 294
Hammer throw 296
CD rotation frequency 298
Bicycle gears 299
Cue stick, ball roll 300
*Bicycle turn angle 301

**Chapter 11**
Rotating skaters/divers 302, 304, 330
Neutron star collapse 305, 330
Strange spinning bike wheel 307, 314

Automobile wheel balancing 314–5
Precessing top 317–8
Gyroscope 318
Hurricanes, cyclones, typhoons 321, 394
*Anticyclonic weather 321
Precession of the equinoxes 327
SUV rollover 328
Baseball bat sweet spot 330

**Chapter 12**
*Forces in muscles & joints 339, 358, (273)
*What can make an athlete 339
*Forces on the spine and back pain 340
Human balance with loads 342
*Bone fracture 346, 359, 364
Buildings, statics 331–352
Lever, mechanical advantage 334
Balancing a seesaw 335
Cantilever 336
Fracture 345–7
Tragic collapse 346–7, (332)
Trusses and bridges 347–9, 363
Architecture: arches and domes 350–2
*Forces in a dome 352

**Chapter 13**
Pressure in cells 371
Blood flow 380, 384, 386
Human circulatory system 380
Blood loss to brain, TIA 384
*Air flow in animal burrow 384
Heart disease, artery clogging 386
Walking on water, insect 387
Heart as a pump 388–9
*Blood pressure measurement 389
Blood transfusion 395, 396
Water supply pressure 369
Atmospheric pressure decrease with elevation 370
Altitude where air pressure is half 370
Finger holds water in straw 371
Hydraulic lift 372
Hydraulic brakes 372
Pressure gauges 372–3
Barometer 373
Suction 374
Hydrometer 377
Continental drift, plate tectonics 378
*Lake level change, rock thrown overboard 378, 390
Helium balloon lift 378
Heating duct 380
Hot-water heating system flow 382
Perfume atomizer 383
Airplane wing lift 383
Sailing upwind 383
Baseball curve 384
Why smoke goes up a chimney 384
Soaps and detergents 387
Pumps 388–9, (374)
Siphon 390
Hydraulic press 393
Rocket thrust 395
Reynolds number 395
Barrel broken by thin liquid column 397

**Chapter 14**
Spider web oscillations 405
Human leg as pendulum 424
Shock absorbers 399, 415
Unwanted floor vibrations 406
Loudspeaker 406–7
*Pendulum clock 412, 421, 424
Geology 412, 415
Measure *g* with pendulum 412
Earthquake dampers 415
Child on a swing, resonance 417–8
Resonance damage 418
*Q*-value 419, 425, 896
Bungee jumper 422
*Metronome 424
Natural stride 424
Tall building sway 426

**Chapter 15**
Echolocation by bats, dolphins, whales 434
Water waves 428, 435
Sound wave 431, 460 *ff*
Geology 435, 452, 457
Earthquake waves 435, 437, 450, 453
Square wave 442
*Cell phone signal 451
AM and FM radio wave bending 452
Fish and fisher: internal reflection 456
Seismic reflection: oil prospecting 457
Coffee spill 457
Tsunami 459

**Chapter 16**
Wide range of human hearing 464
Sensitivity of the ear 467, (466)
Bats use Doppler 479
Doppler blood-flow meter 479, 491
Ultrasound medical imaging 482–3
*Doppler ultrasound imaging 483
Stringed instruments 460, 468–9
Wind instruments 460, 469–72
Piano strings 460, 468, 469
Distance from lightning, seconds 461
Autofocusing camera 462
Loudspeaker output 465
Musical scale 468
Guitar, violin 468, 469, 484, 487
Organ pipes 471–2
Tuning with beats 475–6
Doppler in weather forecasting 480
*Radar speed gun 480
Galaxy redshift 480
Sonic boom; sound barrier 481, 489
Sonar: depth in sea, Earth "soundings" 481–2, 489
Signal-to-noise ratio 486, 490, 679
Quartz oscillator clock 487
Motion sensor 489
Audio gain 490

**Chapter 17**
Life under ice 500–1
Molecules in one breath 507, 514
Snorkels are short 515
*Hot air balloon 492, 515
Expansion joints 495, 498, 501
Do holes expand? 499
Opening a tight lid 499
Gas tank overflow 500
Highway buckling 501
Closed jars in fires 503
Mass (weight) of air in a room 505
Cold and hot tire pressure 506
Thermostat 509
Pyrex glass 509
*Tape measure inaccuracy 510, 513
Scuba 512, 513, 514, 515
Potato chip bag puff up 513

**Chapter 18**
KE of molecules in cells 519
Humidity, and comfort 525–6
Chromatography 531
Diffusion in living organisms 531–2, 536
Temperature effect on chemical reactions 521
Evaporation cools 524, 548
Humidity, weather 526
*Temperature decrease of boiling water with altitude 526–7
Pressure cooker 535

**Chapter 19**
Working off Calories 540
Measuring Calorie content 545, 570
Evaporation and body temperature 548–9, (524)
Body heat: convection by blood 563, 574
Body's radiative heat loss 564
Room comfort: cool air, warm walls 565
Medical thermography 567
Avoid plants freezing 568
Eating snow makes you colder 571
Heat conduction to skin, blood capillaries 573
Leaf's energy absorption 575
Metabolizing fat 575
Cold tile, warm rugs 561
Heat loss through windows 562
Thermal windows (two panes) 562
How clothing insulates 562
*R*-values of thermal insulation 562
Ocean currents and wind 563
Convective home heating 563
Dark vs. light clothing 564
Radiation from the sun, seasons 566
Astronomy—size of a star 566
Goose down loft 568
Thermos bottle 568
Emergency blanket 568
Air parcels, weather, adiabatic lapse rate 573

**Chapter 20**
Biological development, evolution 594
*Trees offsetting $CO_2$ buildup 608
Steam engine 576, 578, 582, 606
Internal combustion engines 578–80, 583–4
Engine efficiency 582–3
Refrigerators, air conditioners 584–6, 603
Heat pump 586–7, 603
*SEER rating 587
Thermal pollution, climate 598–600
*Carbon footprint 598
Energy resources 599, 605–6
Solar, thermal, wind energy 599, 605
Diesel engine 607, (575)
Stirling cycle 607
Jet engine, Brayton cycle 607
Dehumidifier 608, (537)

**Chapter 21**
Inside a cell: kinetic theory plus electrostatic force 631
DNA structure, replication 631–3, 640
Static electricity 609, 610, 635, 640
Photocopiers and printers 619
Electrical shielding, safety 628

**Chapter 23**
Electrocardiogram (ECG) 660, 682–3, 779
Dipoles in molecular biology 672
Heart beat, depolarization process 682–3
Common voltages $10^{-4}$ V to $10^{8}$ V 663
Breakdown voltage 666
Lightning rods 666
*Supply voltage, signal voltage 676
*Digital, bits, bytes, binary numbers 676
*Analog-to-digital converter (ADC) 676
*Morse code 676
*Bit-rate, TV transmission 676, 678–9, 682
*Data compression, jpeg 677–8
*Quantization error 677
*Sampling rate, bit depth 677
*Digital-to-analog converter (DAC) 677, 780
*Bandwidth 678
*Noise, bit flips 678–9
*Digital error correction, parity bit 678
*Bit error rate 679
*Signal-to-noise ratio (S/N) 679
*TV and computer monitors 679–82
*Digital TV, pixels, subpixels 680
*Flat screens, HD 680–1
*Addressing pixels 680–1
*Data stream 681
*Active matrix, TFT, data lines 681–2
*TV refresh rate 682
Oscilloscope 682
*ASCII code 688
Photocell 689

**Chapter 24**
Capacitor shocks, burns 703
Heart defibrillator 703, 712, 764
Capacitor use as power backup, surge protector, memory 692, 695
Condenser microphone 695
Computer key 695
Camera flash energy 701
Electrostatic air cleaner 710
Tiny distance measurement 710
Coaxial cable 714, 818, 874, 911
*Dynamic random access memory (DRAM) 716, 857

**Chapter 25**
Electrical conduction in human nervous system, neurons 736–8
Action potential 737
Battery construction, terminals 718–9
*Electric cars 720, 744
Battery connections 721, 724
Loudspeaker wire thickness 725
Heating element 726–8
Resistance thermometer 726
Lightning bolt 728, (690, 716)
Household circuits, shorts 729–30
Fuses, circuit breakers 729, 766
Safety—wires getting hot 729, 764–6
Extension cord danger 730
Hair dryer 732
Strain gauge 746

**Chapter 26**
*Blood sugar phone app 747
Heart pacemaker 764
Electricity dangers to humans 764–6
Ventricular fibrillation 764
Two-speed fan 752–3
Car battery charging 757
*Jump-starting a car, safely 758–9
*RC*: sawtooth, flashers, wipers 763, 780
Hazards, electric safety 764–6
Proper grounding, plugs 765–6
Leakage current 766
Dangerous downed power line 766
Ammeters, voltmeters, ohmmeters 767–9
Meter connection, corrections 768–9, 781
*Measurement affects quantity measured 769
Voltage divider 774
Solar panel 778
Potentiometer and bridge circuits 778–9
Car battery corrosion 780
Digital-to-analog converter (DAC) 780, (677)

**Chapter 27**
Electromagnetic blood pump 802
Blood flow rate, Hall effect 807
Use of a compass 784
Magnetic declination 784
Maps and true north 784
Aurora borealis 792
Electric motors, DC and AC 795–6
Loudspeakers and headsets 796

**Chapter 28**
Coaxial cable 818, 874, 911
Solenoid switches: doorbell, car starter 826
Magnetic circuit breakers 826
Relay (magnetic) 830

**Chapter 29**
EM blood-flow measurement 845
Induction stove 842
Generators, power plants 846–7
Alternators, in cars 848
Motor overload 849
Eddy-current damping 850, 861
Airport metal detector 850
Transformers, power transmission 851–3
Cell phone charger 852
Car ignition system 852
*Wireless electric power transmission 854
Inductive charger 854
Magnetic information storage 856
*Semiconductor memory 857–8
*RAM, DRAM 857
*Bit-line & word-line 857
*Writing and reading memory 857
*Volatile and non volatile memory 858
*Flash memory, MOSFET, MRAM 858
Microphone 858
Card reader, magnetic strip 858
Seismograph 859
Ground fault circuit interrupter (GFCI) 859
Shielded cable 861
Recycling solid waste 861

**Chapter 30**
*Electric car inductive charging 869
Surge protection 877
Capacitors as filters 884, 896, 897
Loudspeaker cross-over 884
Impedance matching 888
3-phase AC 889
*Q*-value 896, (419, 425)
Filter circuit 896

**Chapter 31**
Optical tweezers 916, 923
*TV from the Moon 898, 920, 924
Wireless devices, transmission 898, 917–20
Antennas 911, 919
Phone call time lag 912
*Solar sail 916, 925
Radio and TV 917–9
AM and FM 918
Cell phones, remotes, cable TV, satellite TV 920
*GPS 924
Solar power use 924

**Chapter 32**
Medical endoscope, bronchoscope, colonoscope 945
How tall a mirror do you need 930
Seeing yourself in a magnifying mirror (concave) 936–7
Convex (rearview mirrors) 938
Optical illusions 939, 998
Apparent water depth 939–40, 941
Rainbows 942, 957
Colors underwater 943
Diamonds sparkle 944
Prism binoculars 944
Fiber optic cables 945, 954, 956
*High-frequency trading, interception 945
Solar cooker 951
Washing machine water level detector 956
Road reflectors 957

**Chapter 33**
Human eye 975–8
Fovea, denser in cones 976, 1037
Near- and far-sighted 976–8
Corrective lenses 976–7, 987
Contact lenses 978
Seeing underwater 978
Light microscopes 983–4, 1048
Where your eye can see a lens image 961
Cameras, film and digital 970–5
*CCD, CMOS sensors, potential well 970–1
*Bayer pixels, Fovean 971
Digital artifacts 971
Camera adjustments, *f*-stop 971–3
Depth of field 973
*Resolution, compression, JPEG, raw 973–4
Telephoto, wide angle 975
Optical vs. digital zoom 975
Magnifying glass 979–80
Telescopes 980–2
*Microscopes 983–4, 1048
Lens aberrations 984–5
Film projector 989
Pinhole camera 990

**Chapter 34**
Soap bubbles, oil films, colors 995, 1004–8
Highway mirages 998
Lens coatings 1008–9
Polarizing sunglasses 1012–13
Liquid crystal displays, TV and computer screens 1014–5
Sky color 1015–6
*Lightbulb efficiency, LED 1016–7
Stealth aircraft coating 1022
CD bits, pits & lands 1024

**Chapter 35**
Resolution of eye 1035, 1037
Useful magnification 1037
Spectroscopy in biology 1041
X-ray diffraction in biology 1044
Medical imaging: X-rays, CT 1045–7
*Interference microscope 1048
*Phase-contrast microscope 1048
Hubble space telescope 1034–5
Telescope and microscope resolution 1035–7
X-rays 1043–7
Tomography 1045–7

**Chapter 36**
Space travel 1067–8
Global position system (GPS) 1068–9
Fantasy supertrain 1071
Radar speed gun 1092

**Chapter 37**
Electron microscope image: blood vessel, clot, retina, viruses 1095, 1109, (7)
Photosynthesis 1102
Measuring bone density 1103
Electron microscopes (EM), TEM, SEM 1109, 1151, (1095)
Photocells 1098
Photodiodes, soundtracks 1101

**Chapter 38**
Scanning tunneling electron microscope 1151
Atomic force microscope 1151

**Chapter 39**
Fluorescence analysis 1174–5
Medical uses of lasers, surgery 1178, 1183
Neon lights 1158
Fluorescent lightbulbs 1175
Lasers 1175–9, 1216
Bar code readers 1177
DVD, CD, Blu-ray 1177–8
Holography 1178–9

**Chapter 40**
Cell energy—ATP 1192
Weak bonds, DNA 1192–4
Protein synthesis 1194–6
*Pulse oximeter 1216
Computer processor chips 1186
Transparent objects 1210
Zener diode voltage regulator 1213–4, 1225
Rectifiers 1214
*Photovoltaic cells 1214–5
*LED displays, bulbs 1215–6
TV remote 1215, 1225
*Solid-state lighting 1215–6
**pn* diode laser 1216
*OLED, AMOLED displays 1216–7
Amplifiers 1218
*MOSFET switch 1218–9
*Technology generation 1219

**Chapter 41**
Earliest life 1248
Radiation film badges 1249, 1274
Smoke detector 1237
Radioactive activity and safety 1243–4
Carbon-14 dating 1246–7
Archeological & geological dating 1246–8
Oldest Earth rocks 1248
Geiger counter 1248
Rubidium-strontium dating 1253
Tritium dating 1254
*Mass excess, mass defect 1254

**Chapter 42**
Biological radiation damage 1271–6
Radiation dosimetry, RBE 1272–6
Radon exposure 1274, 1276
Natural radioactive background 1274
Radiation exposure, film badge 1274
Radiation sickness 1274
Whole-body dose 1275
Radiation therapy 1276–7
Proton therapy 1277
Radioactive tracers 1277–8
Gamma camera 1278
Medical imaging, PET, SPECT, MRI 1278–82
*Brain PET scan using cell phone 1279
Imaging resolutions compared 1282
Radiation and thyroid 1286
Nuclear reactors, power plants 1256, 1263–5, 1269–71
Breeder reactors 1265
Manhattan project 1266
Nuclear fusion 1266–71
Why stars shine 1267–9
Thermonuclear devices 1269
Fusion energy reactors 1269–71

**Chapter 43**
Linacs and tumor irradiation 1294

**Chapter 44**
Stars and galaxies 1323–32
Black holes 1331, 1337–8
Big Bang storyline 1345–8

# Preface

## New Stuff!

1. **MisConceptual Questions**, 10 or 15 at the end of each chapter. The multiple-choice answers include common misconceptions as well as correct responses. Pedagogically, asking students to think, to consider the options, is more effective than just telling them what is valid and what is wrong. (These are in addition to the one at the start of each chapter.
2. **Digital** is all around us. Yet that word is not always used carefully. In this new edition we have 20 new pages describing the basics from the ground up. **Binary** numbers, *bits* and *bytes*, are introduced in Chapter 23 along with analog-to-digital conversion (ADC), and vice versa, including *digital audio* and how video screens work. Also information **compression**, *sampling rate*, *bit depth*, *pixel addressing*, *digital transmission* and, in later chapters, information **storage** (RAM, DRAM, flash), *digital cameras* and their *sensors* (CCD, CMOS).
3. **Gravitational Assist** (Slingshot) to accelerate spacecraft (Chapter 8).
4. **Magnetic field** of a **single moving charge**, rarely treated (and if it is, maybe not well), and it shows the need for relativity theory.
5. Seeing **yourself** in a **magnifying mirror** (concave), angular magnification and blurriness with a paradox. Also **convex** (rearview) **mirrors** (Chapter 32).
6. Pedagogical clarification on defining **potential energy**, and energy itself (Chapter 8), and on hundreds of other topics.
7. The **Moon** rises an hour later each day (Chapter 6), its *phases*, *periods*, and diagram.
8. Efficiency of **lightbulbs** (Chapter 34).
9. **Idealization** vs. reality emphasized—such as PV diagrams (Chapter 19) as an idealized approximation.
10. Many new Problems ($\sim$ 500) plus new Questions as well as the 500 or so MisConceptual Questions (point 1 above).
11. Many new worked-out Examples.
12. More **math** steps included in derivations and Examples.
13. **State** of a system and *state variables* clarified (Chapter 17).
14. Contemporary physics: Gravitational waves, LIGO and Virgo, Higgs, WIMPS, OLEDS and other semiconductor physics, nuclear fusion updates, neutrino-less double beta decay.
15. New SI units (Chapter 1, Chapter 21, Tables).
16. *Boiling* temperature of water vs. *elevation* (Chapter 18).
17. Modern physics in earlier classical Chapters (sometimes in Problems): Light-years, observable universe (Chapter 1); optical tweezers (Chapter 4); uranium enrichment (Chapter 5); black holes and curved space, white dwarfs (Chapter 6); crystal structure (Chapter 7); Yukawa potential, Lennard-Jones potential (Chapter 8); neutrons, nuclear reactors, moderator, nuclear collisions, radioactive decay, neutron star collapse (Chapter 9); galaxy redshift (Chapter 16); gas diffusion of uranium (Chapter 18); quarks (Chapter 21); liquid-drop model of nucleus, Geiger counter, Van de Graaff (Chapter 23); transistors (Chapters 23, 29); isotopes, cyclotron (Chapter 27); MOSFET (Chapter 29); semiconductor (camera sensor), photon (Chapter 33); line spectra, X-ray crystallography (Chapter 35).
18. Second law of thermodynamics and heat energy reorganized (Chapter 20).
19. **Symmetry** emphasized throughout.
20. *Uranium enrichment*, % needed in reactors, bombs (Chapters 5, 42).
21. Mass excess, mass defect (Chapter 41).
22. The *mole*, more careful definition (Chapter 17).
23. Liquid-gas ambiguity above critical temperature (Chapter 18).
24. Measurement affects quantity measured, new emphasis.

**25.** New **Applications**:

- Ocean Tides (Chapter 6)
- Anticyclonic weather (Chapter 11)
- Jump starting a car safely (Chapter 26)
- Light bulb efficiency (Chapter 34)
- Specialty microscopes and contrast (Chapter 35)
- Forces on Muscles and Joints (Chapter 12)
- Doppler ultrasound imaging (Chapter 16)
- Lake level change when rock thrown from boat (Chapter 13)
- Skier speed on snow vs. flying through the air (Chapter 5)
- Inductive charging (Chapter 29)
- Human body internal heat transfer is convection (blood) (Chapter 19)
- Blood pressure measurement (Chapter 13)
- Sports (lots)
- Voltage divider (Chapter 26, Problems)
- Flat screen TV (Chapters 23, 34, 40)
- Carbon footprint and climate (Chapter 20)
- Electrocardiogram (Chapter 23)
- Wireless from the Moon unimaginable (Chapter 31)
- Why snorkels are short (Chapter 17 Problem)
- Electric cars (Chapter 25)
- Digital (Chapters 23, 29, 33, 40) includes (in addition to details in point 2 above) quantization error, digital error correction, noise, bit error rate, digital TV data stream, refresh rate, active matrix, thin film transistors, digital memory, bit-line, reading and writing of memory cells (MOSFET), floating gate, volatile and nonvolatile memory, Bayer, JPEG, ASCII code, and more.

## Seeing the World through Eyes that Know Physics

I was motivated to write a textbook different from others which typically present physics as a sequence of facts, like a catalog. Instead of beginning formally and dogmatically, I aim to begin each topic with everyday observations and experiences the students can relate to: start with specifics, the real world, and then go to the great generalizations and the more formal aspects of the physics, showing why we believe what we believe. This approach reflects how science is actually practiced.

The aim is to give students a thorough understanding of the basic concepts of physics in all its aspects, from mechanics to modern physics. Also important is to show students how useful physics is in their own everyday lives and in their future professions by means of interesting applications to biology, medicine, engineering, architecture, and more.

Much effort has gone into approaches for the practical techniques of solving problems: worked-out Examples, Problem Solving sections, and Problem Solving Strategies.

Chapter 1 is *not* a throwaway. It is fundamental to physics to realize that every measurement has an *uncertainty*, and how significant figures are used. Being able to make rapid *estimates* is a powerful tool useful for every student, and used throughout the book starting in Chapter 1 (you can estimate the Earth's radius!).

Mathematics can be an obstacle to students. I have aimed at including all steps in a derivation. Important mathematical tools, such as addition of vectors and vector product, are incorporated in the text where first needed, so they come with a context rather than in a forbidding introductory Chapter. Appendices contain a basic math review, derivatives and integrals, plus some more advanced topics including numerical integration, gravitational field of spherical mass distribution, Maxwell's equations in differential form, and a Table of selected nuclear isotopes (carefully updated, as are the Periodic Table and the Fundamental Constants found inside the back and front covers).

Some instructors may find this book contains more material than can be covered in their courses. The text offers great flexibility. Sections marked with a star * may be considered optional. These contain slightly more advanced

## Versions of this Book

**Complete version**: 44 Chapters including 9 Chapters of modern physics.

**Classic version**: 37 Chapters, 35 on classical physics, plus one each on relativity and quantum theory.

**3 Volume version**: Available separately or packaged together

**Volume 1**: Chapters 1–20 on mechanics, including fluids, oscillations, waves, plus heat and thermodynamics.

**Volume 2**: Chapters 21–35 on electricity and magnetism, plus light and optics.

**Volume 3**: Chapters 36–44 on modern physics: relativity, quantum theory, atomic physics, condensed matter, nuclear physics, elementary particles, cosmology and astrophysics.

physics material, or material not usually covered in typical courses, or interesting applications; they contain no material needed in later Chapters (except perhaps in later optional Sections). For a brief course, all optional material could be dropped as well as significant parts of Chapters 13, 16, 26, 30, and 35, and selected parts of Chapters 9, 12, 19, 20, 33. Topics not covered in class can be a valuable resource for outside study by students. Indeed, this text can serve as a useful reference for years because of its wide range of coverage.

## Thanks

Many physics professors provided input or direct feedback on every aspect of this textbook. They are listed below, and I owe each a debt of gratitude.

Edward Adelson, The Ohio State University
Lorraine Allen, United States Coast Guard Academy
Zaven Altounian, McGill University
Leon Amstutz, Taylor University
Kim Arvidsson, Schreiner University
Philip S. Baringer, Kansas University
Bruce Barnett, Johns Hopkins University
Michael Barnett, Lawrence Berkeley Lab
Anand Batra, Howard University
David Branning, Trinity College
Bruce Bunker, University of Notre Dame
Wayne Carr, Stevens Institute of Technology
Charles Chiu, University of Texas Austin
Roger N. Clark, U. S. Geological Survey
Russell Clark, University of Pittsburgh
Robert Coakley, University of Southern Maine
David Curott, University of North Alabama
Biman Das, SUNY Potsdam
Bob Davis, Taylor University
Kaushik De, University of Texas Arlington
Michael Dennin, University of California Irvine
Kathryn Dimiduk, Cornell University
John DiNardo, Drexel University
Scott Dudley, United States Air Force Academy
John Essick, Reed College
Cassandra Fesen, Dartmouth College
Leonard Finegold, Drexel University
Alex Filippenko, University of California Berkeley
Richard Firestone, Lawrence Berkeley Lab
Tom Furtak, Colorado School of Mines
Gill Gabelmann, Washburn University
Gabriel Orebi Gann, University of California Berkeley
Edward Gibson, California State University Sacramento
John Hamilton, University of Hawai'i – Hilo
John Hardy, Texas A&M
J. Erik Hendrickson, University of Wisconsin-Eau Claire
Charles Hibbard, Lowell High School
Dr. Laurent Hodges, Iowa State University
David Hogg, New York University
Mark Hollabaugh, Normandale Community College
Russell Holmes, University of Minnesota Twin Cities
William Holzapfel, University of California Berkeley
Bob Jacobsen, University of California Berkeley
Arthur W. John, Northeastern University
David Jones, Florida International University
Andrew N. Jordan, University of Rochester
Teruki Kamon, Texas A&M
Thomas Hemmick, State University of New York Stonybrook
Daryao Khatri, University of the District of Columbia
Woo-Joong Kim, Seattle University
John Kinard, Greenwood High School
Jay Kunze, Idaho State University
Jim LaBelle, Dartmouth College
Andrei Linde, Stanford University
M.A.K. Lodhi, Texas Tech
Lisa Madewell, University of Wisconsin
Ponn Maheswaranathan, Winthrop University
Bruce Mason, University of Oklahoma
Mark Mattson, James Madison University
Linda McDonald, North Park College
Raj Mohanty, Boston University
Giuseppe Molesini, Isituto Nazionale di ottica Florence
Lisa K. Morris, Washington State University
Richard Muller, University of California Berkeley
Blaine Norum, University of Virginia
Lauren Movatne, Reedley College
Alexandria Oakes, Eastern Michigan University
Ralph Oberly, Marshall University
Michael Ottinger, San Juan College
Lyman Page, Princeton
Laurence Palmer, University of Maryland
Bruce Partridge, Haverford College
R. Daryl Pedigo, University of Washington
Robert Pelcovitz, Brown University
Saul Perlmutter, University of California Berkeley
Vahe Peroomian, UCLA
Harvey Picker, Trinity College
Amy Pope, Clemson University
James Rabchuk, Western Illinois University
Michele Rallis, Ohio State University
Andrew Resnick, Cleveland State University
Paul Richards, University of California Berkeley
Peter Riley, University of Texas Austin
Dennis Rioux, University of Wisconsin Oshkosh
John Rollino, Rutgers University
Larry Rowan, University of North Carolina Chapel Hill
Arthur Schmidt, Northwestern University
Cindy Schwarz, Vassar College
Peter Sheldon, Randolph-Macon Woman's College
James Siegrist, University of California Berkeley
Christopher Sirola, University of Southern Mississippi
Earl Skelton, Georgetown University
George Smoot, University of California Berkeley
Stanley Sobolewski, Indiana University of Pennsylvania
Mark Sprague, East Carolina University
Michael Strauss, University of Oklahoma
Leo Takahashi, Pennsylvania State University
Richard Taylor, University of Oregon
Oswald Tekyi-Mensah, Alabama State University
Ray Turner, Clemson University
Som Tyagi, Drexel University
David Vakil, El Camino College
Robert Webb, Texas A&M
Robert Weidman, Michigan Technological University
Edward A. Whittaker, Stevens Institute of Technology
Lisa M. Will, San Diego City College
Suzanne Willis, Northern Illinois University
Michael Winokur, University of Wisconsin-Madison
Stanley George Wojcicki, Stanford University
Mark Worthy, Mississippi State University
Edward Wright, UCLA
Todd Young, Wayne State College

I owe special thanks to Prof. Bob Davis for much valuable input, and especially for working out all the Problems and producing the Solutions Manual for all Problems, as well as for providing the answers to odd-numbered Problems at the back of the book. Many thanks also to J. Erik Hendrickson who collaborated with Bob Davis on the solutions, and to the team they managed (Michael Ottinger, John Kinard, David Jones, Kristi Hatch, Lisa Will).

I am especially grateful to Profs. Lorraine Allen, Kathryn Dimiduk, Michael Strauss, Cindy Schwarz, Robert Coakley, Robert Pelcovitz, Mark Hollabaugh, Charles Hibbard, and Michael Winokur, who helped root out errors and offered significant improvements and clarifications.

For Chapters 43 and 44 on Particle Physics and Cosmology and Astrophysics, I was fortunate to receive generous input from some of the top experts in the field, to whom I owe a debt of gratitude: Saul Perlmutter, George Smoot, Richard Muller, Alex Filippenko, Paul Richards, Gabriel Orebi Gann, James Siegrist, and William Holzapfel (UC Berkeley), Andreí Linde (Stanford U.), Lyman Page (Princeton), Edward Wright (UCLA), Michael Strauss (University of Oklahoma), and Bob Jacobsen (UC Berkeley).

I also wish to thank many others at the University of California, Berkeley, Physics Department for helpful discussions, and for hospitality. Thanks also to Prof. Tito Arecchi at the Istituto Nazionale di Ottica, Florence, Italy.

Finally, I am grateful to the many people at Pearson Education with whom I worked on this project, especially Jeanne Zalesky and Paul Corey, and the perspicacious editors Margy Kuntz and Andrea Giancoli.

The final responsibility for all errors lies with me. I welcome comments, corrections, and suggestions as soon as possible to benefit students for the next reprint.

## About the Author

Doug Giancoli obtained his BA in physics (summa cum laude) from UC Berkeley, his MS in physics at MIT, and his PhD in elementary particle physics back at UC Berkeley. He spent 2 years as a post-doctoral fellow at UC Berkeley's Virus Lab developing skills in molecular biology and biophysics.

His mentors include Nobel winners Emilio Segrè, Barry Barish, and Donald Glaser.

He has taught a wide range of undergraduate courses, traditional as well as innovative ones, and works to improve his textbooks meticulously, seeking ways to provide a better understanding of physics for students.

Doug loves the outdoors, especially climbing peaks. He says climbing peaks is like learning physics: it takes effort and the rewards are great.

# Students Advice

## HOW TO STUDY

1. Read the Chapter. Learn new vocabulary and notation. Respond to questions and exercises as they occur. Follow carefully the steps of worked-out Examples and derivations. Avoid time looking at a screen. Paper is better than pixels when it comes to learning and thinking.
2. Attend all class meetings. Listen. Take notes. Ask questions (everyone wants to, but maybe you will have the courage). You will get more out of class if you read the Chapter first.
3. Read the Chapter again, paying attention to details. Follow derivations and worked-out Examples. Absorb their logic. Answer Exercises and as many of the end-of-Chapter Questions as you can, and all MisConceptual Questions.
4. Solve at least 10 to 20 end-of-Chapter Problems, especially those assigned. In doing Problems you may find out what you learned and what you didn't. Discuss them with other students. Problem solving is one of the great learning tools. Don' t just look for a formula—it might be the wrong one.

## NOTES ON THE FORMAT AND PROBLEM SOLVING

1. Sections marked with a star (*) may be considered optional or advanced. They can be omitted without interrupting the main flow of topics. No later material depends on them except possibly later starred Sections. They may be fun to read, though.
2. The customary **conventions** are used: symbols for quantities (such as $m$ for mass) are italicized, whereas units (such as m for meter) are not italicized. Symbols for vectors are shown in boldface with a small arrow above: $\vec{\mathbf{F}}$.
3. Few equations are valid in all situations. Where practical, the **range of validity** of important equations are stated in square brackets next to the equation. The equations that represent the great laws of physics are displayed with a tan background, as are a few other indispensable equations.
4. At the end of each Chapter is a set of **Questions** you should try to answer. Attempt all the multiple-choice **MisConceptual Questions**, which are intendend to get common misconceptions "out on the table" by including them as responses (temptations) along with correct answers. Most important are **Problems** which are ranked as Level I, II, or III, according to estimated difficulty. Level I Problems are easiest, Level II are standard Problems, and Level III are "challenge problems." These ranked Problems are arranged by Section, but Problems for a given Section may depend on earlier material too. There follows a group of **General Problems**, not arranged by Section or ranked. Problems that relate to optional Sections are starred (*). Answers to odd-numbered Problems are given at the end of the book.
5. Being able to solve **Problems** is a crucial part of learning physics, and provides a powerful means for understanding the concepts and principles. This book contains many aids to problem solving: (a) worked-out **Examples**, including an Approach and a Solution, which should be studied as an integral part of the text; (b) some of the worked-out Examples are **Estimation Examples**,which show how rough or approximate results can be obtained even if the given data are sparse (see Section 1-6); (c) **Problem Solving Strategies** placed throughout the text to suggest a step-by-step approach to problem solving for a particular topic—but the basics remain the same; most of these "Strategies" are followed by an Example that is solved by explicitly following the suggested steps; (d) special problem-solving Sections; (e) "Problem Solving" marginal notes which refer to hints within the text for solving Problems; (f) **Exercises** within the text that you should work out immediately, and then check your response against the answer given at the bottom of the last page of that Chapter; (g) the Problems themselves at the end of each Chapter.
6. **Conceptual Examples** pose a question which hopefully starts you to think about a response. Give yourself a little time to come up with your own response before reading the Response given.
7. Math review, plus additional topics, are found in **Appendices**. **Useful data**, **conversion factors**, and math **formulas** are found inside the front and back covers.

# USE OF COLOR

## Vectors

A general vector

resultant vector (sum) is slightly thicker

components of any vector are dashed

Displacement ($\vec{\mathbf{D}}$, $\vec{\mathbf{r}}$)

Velocity ($\vec{\mathbf{v}}$)

Acceleration ($\vec{\mathbf{a}}$)

*This page intentionally left blank*

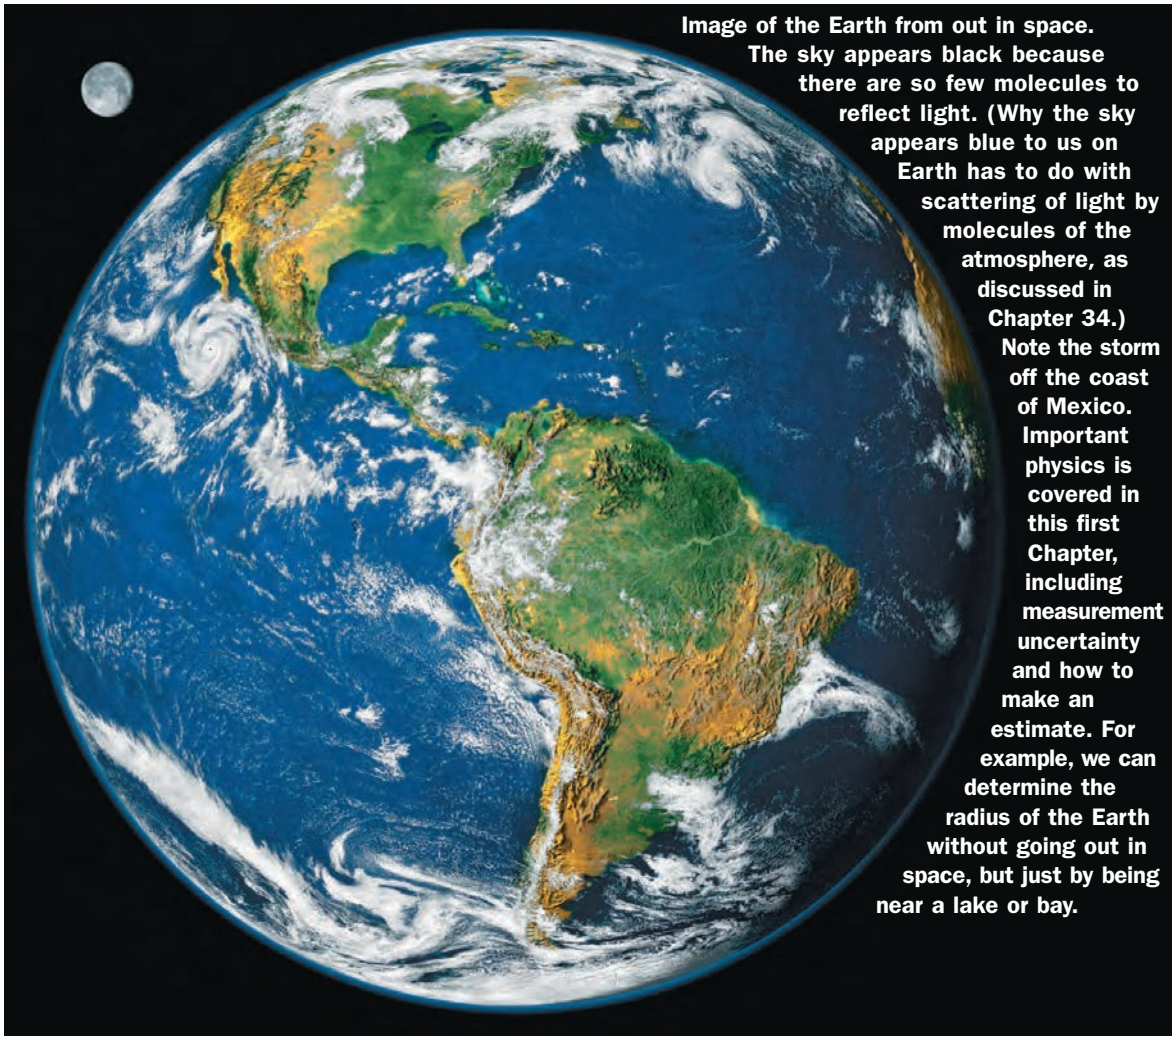

Image of the Earth from out in space. The sky appears black because there are so few molecules to reflect light. (Why the sky appears blue to us on Earth has to do with scattering of light by molecules of the atmosphere, as discussed in Chapter 34.) Note the storm off the coast of Mexico. Important physics is covered in this first Chapter, including measurement uncertainty and how to make an estimate. For example, we can determine the radius of the Earth without going out in space, but just by being near a lake or bay.

CHAPTER 1

# Introduction, Measurement, Estimating

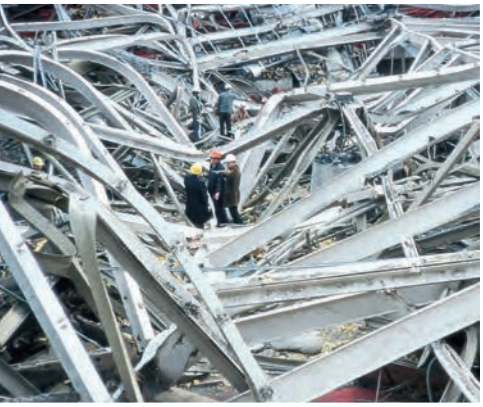
## CHAPTER-OPENING QUESTIONS—Guess now!

**1.** How many $cm^3$ are in $1.0\,m^3$?

**(a)** 10. **(b)** 100. **(c)** 1000. **(d)** 10,000. **(e)** 100,000. **(f)** 1,000,000.

**2.** Suppose you wanted to actually measure the radius of the Earth, at least roughly, rather than taking other people's word for what it is. Which response below describes the best approach?

**(a)** Use an extremely long measuring tape.
**(b)** It is only possible by flying high enough to see the actual curvature of the Earth.
**(c)** Use a standard measuring tape, a stepladder, and a large smooth lake.
**(d)** Use a laser and a mirror on the Moon or on a satellite.
**(e)** Give up; it is impossible using ordinary means.



[*We start each Chapter with a Question—sometimes two. Try to answer right away. Don't worry about getting the right answer now—the idea is to get your preconceived notions out on the table. If they are misconceptions, we expect them to be cleared up as you read the Chapter. You will get another chance at the Question later in the Chapter when the appropriate material has been covered. These Chapter-Opening Questions will also help you see the power and usefulness of physics.*]

## CONTENTS

1–1 How Science Works
1–2 Models, Theories, and Laws
1–3 Measurement and Uncertainty; Significant Figures
1–4 Units, Standards, and the SI System
1–5 Converting Units
1–6 Order of Magnitude: Rapid Estimating
*1–7 Dimensions and Dimensional Analysis

**⚠ CAUTION**

*Science is not static. It changes and develops*

Physics is the most basic of the sciences. It deals with the behavior and structure of matter. The field of physics is usually divided into *classical physics* which includes motion, fluids, heat, sound, light, electricity and magnetism; and *modern physics* which includes the topics of relativity, atomic structure, condensed matter, nuclear physics, elementary particles, and cosmology and astrophysics. We will cover all these topics in this book, beginning with motion (or mechanics, as it is often called) and ending with the most recent results in our study of the cosmos.

An understanding of physics is wonderfully useful for anyone making a career in science or technology. Engineers, for example, must know how to calculate the forces within a structure to design it so that it remains standing (Fig. 1–1a). Indeed, in Chapter 12 we will see a worked-out Example of how a simple physics calculation—or even intuition based on understanding the physics of forces—would have saved hundreds of lives (Fig. 1–1b). We will see many examples in this book of how physics is useful in many fields, and in everyday life.

## 1–1 How Science Works

There is a real physical world out there. We could just walk through it, not thinking much about it. Or, we can instead examine it carefully. That is what scientists do. The aim of science is the search for order in our observations of the physical world so as to provide a deeper picture or description of this world around us. Sometimes we just want to understand how things work.

Some people seem to think that science is a mechanical process of collecting facts and devising theories. But it is not so simple. Science is a creative activity, and in many ways resembles other creative activities of the human mind.

One important aspect of science is **observation** of events (which great writers and artists also do), and includes the design and carrying out of experiments. But observation and experiment require imagination, because scientists can never include everything in a description of what they observe. In other words, scientists must make judgments about what is relevant in their observations and experiments.

Consider, for example, how two great minds, Aristotle (384–322 B.C.) and Galileo (1564–1642), interpreted motion along a horizontal surface. Aristotle noted that objects given an initial push along the ground (or on a level tabletop) always slow down and stop. Consequently, Aristotle argued, the natural state of an object is to be at rest. Galileo, in his reexamination of horizontal motion in the 1600s, had the idea that friction is a kind of force like a push or a pull; and he imagined that if friction could be eliminated, an object given an initial push along a horizontal surface would continue to move indefinitely without stopping. He concluded that for an object to be in motion was *just as natural* as for it to be at rest. By inventing a new approach, Galileo founded our modern view of motion (Chapters 2, 3, and 4), and he did so with a leap of the imagination. Galileo made this leap conceptually, without actually eliminating friction.

Observation, with careful experimentation and measurement, is one side of the scientific process. The other side is the invention or creation of **theories** to explain and order the observations. Theories are never derived directly from observations. Observations may help inspire a theory, and theories are accepted or rejected based on the results of observation and experiment.

Theories are inspirations that come from the minds of humans. For example, the idea that matter is made up of atoms (the atomic theory) was not arrived at by direct observation of atoms. Rather, the idea sprang from creative minds. The theory of relativity, the electromagnetic theory of light, and Newton's law of universal gravitation were likewise the result of human imagination.

The great theories of science may be compared, as creative achievements, with great works of art or literature. But how does science differ from these other creative activities? One important difference is that science requires **testing** of its ideas or theories to see if their predictions are borne out by experiment.

But theories are not "proved" by testing. First of all, no measuring instrument is perfect, so exact confirmation is not possible. Furthermore, it is not possible to test a theory in every single possible circumstance. Hence a theory cannot be absolutely verified.

Indeed, the history of science tells us that long-held theories can often be replaced by new ones.

## 1–2 Models, Theories, and Laws

When scientists are trying to understand a particular aspect of the physical world, they often make use of a **model**. A model, in the scientist's sense, is a kind of analogy or mental image of the phenomena in terms of something we are familiar with. One example is the wave model of light. We cannot see waves of light as we can water waves. But it is valuable to think of light as made up of waves because experiments indicate that light behaves in many respects as water waves do.

The purpose of a model is to give us an approximate mental or visual picture—something to hold on to—when we cannot see what actually is happening in the real world. Models often give us a deeper understanding: the analogy to a known system (for instance, water waves in the above example) can suggest new experiments to perform and can provide ideas about what other related phenomena might occur.

You may wonder what the difference is between a theory and a model. Usually a model is relatively simple and provides a structural similarity to the phenomena being studied. A **theory** is broader, more detailed, and can give quantitatively testable predictions, often with great precision.

It is important not to confuse a model or a theory with the real world and the phenomena themselves. Theories are descriptions of the physical world, and they are made up by us. Theories are *invented*—usually by very smart people.

**CAUTION**
*Theories and laws are NOT discovered. They are invented*

Scientists give the title **law** to certain concise but general statements about how nature behaves (that energy is conserved, for example). Sometimes the statement takes the form of a relationship or equation between quantities (such as Newton's second law, $F = ma$).

To be called a law, a statement must be found experimentally valid over a wide range of observed phenomena. For less general statements, the term **principle** is often used (such as Archimedes' principle). We use "theory" to describe a more general picture of a large group of phenomena.

Scientific laws are different from political laws, which are *prescriptive*: they tell us how we ought to behave. Scientific laws are *descriptive*: they do not say how nature *should* behave, but rather are meant to describe how nature *does* behave. As with theories, laws cannot be tested in the infinite variety of cases possible. So we cannot be sure that any law is absolutely true. We use the term "law" when its validity has been tested over a wide range of situations, and when any limitations and the range of validity are clearly understood.

Scientists normally do their research as if the accepted laws and theories were true. But they are obliged to keep an open mind in case new information should alter the validity of any given law or theory. In other words, laws of physics, or the "laws of nature", represent our descriptions of reality and are not inalterable facts that last forever. Laws are not lying there in nature, waiting to be discovered. We humans, the brightest humans, invent the laws using observations and intuition as a basis. And we hope our laws provide a good description of nature, and at a minimum give us a reliable approximation of how nature really behaves.

## 1–3 Measurement and Uncertainty; Significant Figures

In the quest to understand the world around us, scientists seek to find relationships among physical quantities that can be measured.

### Uncertainty

Reliable measurements are an important part of physics. But no measurement is absolutely precise. There is an uncertainty associated with every measurement. Among the most important sources of uncertainty, other than blunders, are the limited accuracy of every measuring instrument and the inability to read

**FIGURE 1–2** Measuring the width of a board with a centimeter ruler. The uncertainty is about $\pm 1$ mm.

an instrument (such as a ruler) beyond some fraction of the smallest division shown. For example, if you were to use a centimeter ruler to measure the width of a board (Fig. 1–2), the result could be claimed to be precise to about 0.1 cm (1 mm), the smallest division on the ruler, although half of this value might be a valid claim as well. The reason is that it is difficult for the observer to estimate (or *interpolate*) between the smallest divisions. Furthermore, the ruler itself may not have been manufactured to an accuracy very much better than this.

When giving the result of a measurement, it is important to state the **estimated uncertainty** in the measurement. For example, the width of a board might be written as $8.8 \pm 0.1$ cm. The $\pm 0.1$ cm ("plus or minus 0.1 cm") represents the estimated uncertainty in the measurement, so that the actual width most likely lies between 8.7 and 8.9 cm. The **percent uncertainty** is the ratio of the uncertainty to the measured value, multiplied by 100. For example, if the measurement is 8.8 and the uncertainty about 0.1 cm, the percent uncertainty is

$$\frac{0.1}{8.8} \times 100\% \approx 1\%,$$

where $\approx$ means "is approximately equal to."

Often the uncertainty in a measured value is not specified explicitly. In such cases, scientists follow a general rule that

> **uncertainty in a numerical value is assumed to be *one or a few units* in the last digit specified.**

For example, if a length is given as 5.6 cm, the uncertainty is assumed to be about 0.1 cm or 0.2 cm, or possibly 0.3 cm. It is important in this case that you do not write 5.60 cm, for this implies an uncertainty on the order of 0.01 or 0.02 cm; it assumes that the length is probably between about 5.58 cm and 5.62 cm, when actually you believe it is between about 5.4 and 5.8 cm.

## Significant Figures

The number of reliably known digits in a number is called the number of **significant figures**. Thus there are four significant figures in the number 23.21 cm and two in the number 0.062 cm (the zeros in the latter are merely place holders that show where the decimal point goes). The number of significant figures may not always be clear. Take, for example, the number 80. Are there one or two significant figures? We need words here: If we say it is *roughly* 80 km between two cities, there is only one significant figure (the 8) since the zero is merely a place holder. If there is no suggestion that the 80 is a rough approximation, then we can often assume (as we will in this book) that it has two significant figures: so it is 80 km within an accuracy of about 1 or 2 km. If it is precisely 80 km, to within $\pm 0.1$ or $\pm 0.2$ km, then we need to write 80.0 km (three significant figures).

When specifying numerical results, you should avoid the temptation to keep more digits in the final answer than is justified: see boldface statement above. For example, to calculate the area of a rectangle 11.3 cm by 6.8 cm, the result of multiplication would be 76.84 $cm^2$. But this answer can not be accurate to the implied 0.01 $cm^2$ uncertainty. Why? Because (using the outer limits of the assumed uncertainty for each measurement) the result could be between $11.2 \text{ cm} \times 6.7 \text{ cm} = 75.04 \text{ cm}^2$ and $11.4 \text{ cm} \times 6.9 \text{ cm} = 78.66 \text{ cm}^2$. At best, we can quote the answer as 77 $cm^2$, which implies an uncertainty of about 1 or 2 $cm^2$. The other two digits (in the number 76.84 $cm^2$) must be dropped (rounded off) because they are not significant. As a rough general **significant figures rule**,

**PROBLEM SOLVING**
*Significant figures rule: Number of significant figures in final result should be same as the least significant input value*

> *the final result of a multiplication or division should have no more digits than the numerical value with the fewest significant figures.*

In our example, 6.8 cm has the least number of significant figures, namely two. Thus the result 76.84 $cm^2$ needs to be rounded off to 77 $cm^2$.

**EXERCISE A** The area of a rectangle 4.5 cm by 3.25 cm is correctly given by (*a*) 14.625 $cm^2$; (*b*) 14.63 $cm^2$; (*c*) 14.6 $cm^2$; (*d*) 15 $cm^2$.

When *adding* or *subtracting* numbers, the final result should contain no more decimal places than the number with the fewest decimal places. For example, the result of subtracting 0.57 from 3.6 is 3.0 (not 3.03). Similarly $36 + 8.2 = 44$, not 44.2.

Be careful not to confuse significant figures with the number of decimal places. Significant figures are related to the expected uncertainty in any measured quantity.

**PROBLEM SOLVING**
*Significant figures when adding and subtracting*

**EXERCISE B** For each of the following numbers, state the number of significant figures and the number of decimal places: (*a*) 1.23; (*b*) 0.123; (*c*) 0.0123.

Keep in mind when you use a calculator that all the digits it produces may not be significant. When you divide 2.0 by 3.0, the proper answer is 0.67, and not 0.666666666 as calculators give (Fig. 1–3a). Digits should not be quoted in a result unless they are truly significant figures. However, to obtain the most accurate result, you should normally *keep one or more extra significant figures throughout a calculation, and round off only in the final result*. (With a calculator, you can keep all its digits in intermediate results.) Calculators can also give too few significant figures. For example, when you multiply $2.5 \times 3.2$, a calculator may give the answer as simply 8. See Fig. 1–3b. But the answer is accurate to two significant figures, so the proper answer is 8.0.[†]

**CAUTION**
*Calculators err with significant figures*

**PROBLEM SOLVING**
*Report only the proper number of significant figures in the final result. But keep extra digits during the calculation*

(a) (b)

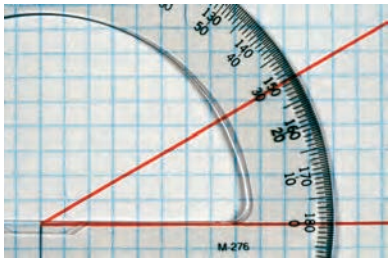

**FIGURE 1–3** These two calculators show the wrong number of significant figures. In (a), 2.0 was divided by 3.0. The correct final result should be stated as 0.67. In (b), 2.5 was multiplied by 3.2. The correct result is 8.0.

**CONCEPTUAL EXAMPLE 1–1** **Significant figures.** Using a protractor (Fig. 1–4), you measure an angle to be 30°. (*a*) How many significant figures should you quote in this measurement? (*b*) Use a calculator to find the cosine of the angle you measured.

**RESPONSE** (*a*) If you look at a protractor, you will see that the precision with which you can measure an angle is about one degree (certainly not 0.1°). So you can quote two significant figures, namely 30° (not 30.0°). (*b*) If you enter cos 30° in your calculator, you will get a number like 0.866025403. But the angle you entered is known only to two significant figures, so its cosine is correctly given by 0.87; you must round your answer to two significant figures.

**NOTE** Trigonometric functions, like cosine, are reviewed in Appendix A.

**FIGURE 1–4** Example 1–1. A protractor used to measure an angle.

**EXERCISE C** Do 0.00324 and 0.00056 have the same number of significant figures?

## Scientific Notation

We commonly write numbers in "powers of ten," or "scientific" notation—for instance 36,900 as $3.69 \times 10^4$, or 0.0021 as $2.1 \times 10^{-3}$. One advantage of scientific notation is that it allows the number of significant figures to be clearly expressed. For example, it is not clear whether 36,900 has three, four, or five significant figures. With powers of ten notation the ambiguity can be avoided: if the number is known to three significant figures, we write $3.69 \times 10^4$, but if it is known to four, we write $3.690 \times 10^4$.

[†]Be careful also about other digital read-outs. If a digital bathroom scale shows 85.6, do not assume the uncertainty is $\pm 0.1$ or $\pm 0.2$; the scale was likely manufactured with an accuracy of perhaps only 1% or so: that is, $\pm 1$ or $\pm 2$. For digital scientific instruments, also be careful: the instruction manual should state the accuracy.

**EXERCISE D** Write each of the following in scientific notation and state the number of significant figures for each: (*a*) 0.0258, (*b*) 42,300, (*c*) 344.50.

### Percent Uncertainty versus Significant Figures

The significant figures rule is only approximate, and in some cases may underestimate the accuracy (or uncertainty) of the answer. Suppose for example we divide 97 by 92:

$$\frac{97}{92} = 1.05 \approx 1.1.$$

Both 97 and 92 have two significant figures, so the rule says to give the answer as 1.1. Yet the numbers 97 and 92 both imply an uncertainty of $\pm 1$ if no other uncertainty is stated. Both $92 \pm 1$ and $97 \pm 1$ imply an uncertainty of about 1% ($1/92 \approx 0.01 = 1\%$). But the final result to two significant figures is 1.1, with an implied uncertainty of $\pm 0.1$, which is an uncertainty of $0.1/1.1 \approx 0.1 \approx 10\%$. In this case it is better to give the answer as 1.05 (which is three significant figures). Why? Because 1.05 implies an uncertainty of $\pm 0.01$ which is $0.01/1.05 \approx 0.01 \approx 1\%$, just like the uncertainty in the original numbers 92 and 97.

SUGGESTION: Use the significant figures rule, but consider the % uncertainty too, and add an extra digit if it gives a more realistic estimate of uncertainty.

### Approximations

Much of physics involves approximations, often because we do not have the means to solve a problem precisely. For example, we may choose to ignore air resistance or friction in doing a Problem even though they are present in the real world, and then our calculation is only an estimate or approximation. In doing Problems, we should be aware of what approximations we are making, and be aware that the precision of our answer may not be nearly as good as the number of significant figures given in the result.

### Accuracy versus Precision

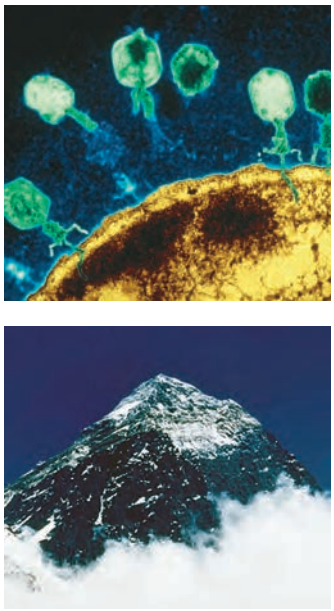
There is a technical difference between "precision" and "accuracy." **Precision** in a strict sense refers to the repeatability of the measurement using a given instrument. For example, if you measure the width of a board many times, getting results like 8.81 cm, 8.85 cm, 8.78 cm, 8.82 cm (interpolating between the 0.1 cm marks as best as possible each time), you could say the measurements give a *precision* a bit better than 0.1 cm. **Accuracy** refers to how close a measurement is to the true value. For example, if the ruler shown in Fig. 1–2 was manufactured with a 2% error, the accuracy of its measurement of the board's width (about 8.8 cm) would be about 2% of 8.8 cm or about $\pm 0.2$ cm. Estimated uncertainty is meant to take both accuracy and precision into account.

## 1–4 Units, Standards, and the SI System

The measurement of any quantity is made relative to a particular standard or **unit**, and this unit must be specified along with the numerical value of the quantity. For example, we can measure length in British units such as inches, feet, or miles, or in the metric system in centimeters, meters, or kilometers. To specify that the length of a particular object is 18.6 is insufficient. The unit *must* be given, because 18.6 meters is very different from 18.6 inches or 18.6 millimeters.

For any unit we use, such as the meter for distance or the second for time, we need to define a **standard** which defines exactly how long one meter or one second is. It is important that standards be chosen that are readily reproducible so that anyone needing to make a very accurate measurement can refer to the standard in the laboratory and communicate results with other scientists.

## Length



The first truly international standard was the **meter** (abbreviated m) established as the standard of **length** by the French Academy of Sciences in the 1790s. The standard meter was originally chosen to be one ten-millionth of the distance from the Earth's equator to either pole,[†] and a platinum rod to represent this length was made. (One meter is, very roughly, the distance from the tip of your nose to the tip of your finger, with arm and hand stretched out horizontally.) In 1889, the meter was defined more precisely as the distance between two finely engraved marks on a particular bar of platinum–iridium alloy. In 1960, to provide greater precision and reproducibility, the meter was redefined as 1,650,763.73 wavelengths of a particular orange light emitted by the gas krypton-86.

In 1983 the meter was again redefined, this time in terms of the speed of light (whose best measured value in terms of the older definition of the meter was 299,792,458 m/s, with an uncertainty of 1 m/s). The new definition reads: "The meter is the length of path traveled by light in vacuum during a time interval of 1/299,792,458 of a second." The new definition of the meter has the effect of giving the speed of light the exact value of 299,792,458 m/s. [The newer definitions provided greater precision than the 2 marks on the old platinum bar.]

*New definition of the meter*

British units of length (inch, foot, mile) are now defined in terms of the meter. The **inch** (in.) is defined as exactly 2.54 centimeters (cm; 1 cm = 0.01 m). One **foot** is exactly 12 in., and 1 **mile** is 5280 ft. Other conversion factors are given in the Table on the inside of the front cover of this book. Table 1–1 below presents some typical lengths, from very small to very large, rounded off to the nearest power of 10. (We call this rounded off value the **order of magnitude**.) See also Fig. 1–5. (Note that the abbreviation for inches (in.) is the only one with a period, to distinguish it from the word "in".) [The **nautical mile** = 6076 ft = 1852 km is used by ships on the open sea and was originally defined as 1/60 of a degree latitude on Earth's surface. A speed of 1 **knot** is 1 nautical mile per hour.]

**FIGURE 1–5** Some lengths: (a) viruses (about $10^{-7}$ m long) attacking a cell; (b) Mt. Everest's height is on the order of $10^4$ m (8850 m, to be precise).

(a)

(b)

## Time

The standard unit of **time** is the **second** (s). For many years, the second was defined as 1/86,400 of a mean solar day (24 h/day × 60 min/h × 60 s/min = 86,400 s/day). The standard second can be defined more precisely in terms of the frequency of radiation emitted by cesium atoms when they pass between two particular states. [Specifically, one second is the time required for 9,192,631,770 periods of this radiation. This number was chosen to keep "one second" the same as in the old definition.] There are, by definition, 60 s in one minute (min) and 60 minutes in one hour (h). Table 1–2 presents a range of time intervals, rounded off to the nearest power of 10.

[†]Modern measurements of the Earth's circumference reveal that the intended length is off by about one-fiftieth of 1%. Not bad!

**TABLE 1–1 Some Typical Lengths or Distances (order of magnitude)**

| Length (or Distance) | Meters (approximate) |
|---|---|
| Neutron or proton (diameter) | $10^{-15}$ m |
| Atom (diameter) | $10^{-10}$ m |
| Virus [see Fig. 1–5a] | $10^{-7}$ m |
| Sheet of paper (thickness) | $10^{-4}$ m |
| Finger width | $10^{-2}$ m |
| Football field length | $10^{2}$ m |
| Height of Mt. Everest [see Fig. 1–5b] | $10^{4}$ m |
| Earth diameter | $10^{7}$ m |
| Earth to Sun | $10^{11}$ m |
| Earth to nearest star | $10^{16}$ m |
| Earth to nearest galaxy | $10^{22}$ m |
| Earth to farthest galaxy visible | $10^{26}$ m |

**TABLE 1–2 Some Typical Time Intervals (order of magnitude)**

| Time Interval | Seconds (approximate) |
|---|---|
| Lifetime of very unstable subatomic particle | $10^{-23}$ s |
| Lifetime of radioactive elements | $10^{-22}$ s to $10^{28}$ s |
| Lifetime of muon | $10^{-6}$ s |
| Time between human heartbeats | $10^{0}$ s (= 1 s) |
| One day | $10^{5}$ s |
| One year | $3 \times 10^{7}$ s |
| Human life span | $2 \times 10^{9}$ s |
| Length of recorded history | $10^{11}$ s |
| Humans on Earth | $10^{14}$ s |
| Life on Earth | $10^{17}$ s |
| Age of Universe | $4 \times 10^{17}$ s |

**TABLE 1–3 Some Masses**

| Object | Kilograms (approximate) |
|---|---|
| Electron | $10^{-30}$ kg |
| Proton, neutron | $10^{-27}$ kg |
| DNA molecule | $10^{-17}$ kg |
| Bacterium | $10^{-15}$ kg |
| Mosquito | $10^{-5}$ kg |
| Plum | $10^{-1}$ kg |
| Human | $10^{2}$ kg |
| Ship | $10^{8}$ kg |
| Earth | $6 \times 10^{24}$ kg |
| Sun | $2 \times 10^{30}$ kg |
| Galaxy | $10^{41}$ kg |

## Mass

The standard unit of **mass** is the **kilogram** (kg). The standard mass has been, since 1889, a particular platinum–iridium cylinder, kept at the International Bureau of Weights and Measures near Paris, France, whose mass is defined as exactly 1 kg. A range of masses is presented in Table 1–3. [For practical purposes, a 1 kg mass weighs about 2.2 pounds on Earth.]

1 metric **ton** is 1000 kg. In the British system of units, 1 ton is 2000 pounds.

When dealing with atoms and molecules, we usually use the **unified atomic mass unit** (u or amu). In terms of the kilogram,

$$1\,\text{u} = 1.6605 \times 10^{-27}\,\text{kg}.$$

(Precise values of this and other numbers are given inside the front cover.) The **density** of a uniform object is its mass divided by its volume, commonly expressed in $\text{kg/m}^3$.

## Unit Prefixes

In the metric system, the larger and smaller units are defined in multiples of 10 from the standard unit, and this makes calculation particularly easy. Thus 1 kilometer (km) is 1000 m, 1 centimeter is $\frac{1}{100}$ m, 1 millimeter (mm) is $\frac{1}{1000}$ m or $\frac{1}{10}$ cm, and so on. The *prefixes* "centi-," "kilo-," and others are listed in Table 1–4 and can be applied not only to units of length but to units of volume, mass, or any other unit. For example, a centiliter (cL) is $\frac{1}{100}$ liter (L), and a kilogram (kg) is 1000 grams (g). An 8.2-megapixel camera has a detector with 8,200,000 pixels (individual "picture elements").

In common usage, $1\,\mu\text{m}$ $(= 10^{-6}\,\text{m})$ is called 1 **micron**.

**PROBLEM SOLVING**

*Always use a consistent set of units*

## Systems of Units

When dealing with the laws and equations of physics it is very important to use a consistent set of units. Several systems of units have been in use over the years. Today the most important is the **Système International** (French for International System), which is abbreviated SI. In SI units, the standard of length is the meter, the standard for time is the second, and the standard for mass is the kilogram. This system used to be called the MKS (meter-kilogram-second) system.

A second metric system is the **cgs system**, in which the centimeter, gram, and second are the standard units of length, mass, and time, as abbreviated in the title. The **British engineering system** (although more used in the U.S. than Britain) has as its standards the foot for length, the pound for force, and the second for time.

We use SI units almost exclusively in this book, although we often define the cgs and British units when a new quantity is introduced. In the SI, there have traditionally been seven *base* quantities, each defined in terms of a standard; seven is the smallest number of base quantities consistent with a full description of the physical world. See Table 1–5. All other quantities[†] can be defined in terms of seven base quantities; see the Table inside the front cover which lists many quantities and their units in terms of base units.

**TABLE 1–4 Metric (SI) Prefixes**

| Prefix | Abbreviation | Value |
|---|---|---|
| yotta | Y | $10^{24}$ |
| zetta | Z | $10^{21}$ |
| exa | E | $10^{18}$ |
| peta | P | $10^{15}$ |
| tera | T | $10^{12}$ |
| giga | G | $10^{9}$ |
| mega | M | $10^{6}$ |
| kilo | k | $10^{3}$ |
| hecto | h | $10^{2}$ |
| deka | da | $10^{1}$ |
| deci | d | $10^{-1}$ |
| centi | c | $10^{-2}$ |
| milli | m | $10^{-3}$ |
| micro[†] | $\mu$ | $10^{-6}$ |
| nano | n | $10^{-9}$ |
| pico | p | $10^{-12}$ |
| femto | f | $10^{-15}$ |
| atto | a | $10^{-18}$ |
| zepto | z | $10^{-21}$ |
| yocto | y | $10^{-24}$ |

[†]$\mu$ is the Greek letter "mu."

## *A New SI

As always in science, new ideas and approaches can produce better precision and closer correspondence with the real world. Even for units and standards.

International organizations on units have proposed further changes that should make standards more readily available and reproducible. To cite one example, the standard kilogram (see above) has been found to have changed slightly in mass (contamination is one cause).

The new redefinition of SI standards follows the method already used for the meter as being related to the defined value of the speed of light, as we mentioned on page 7 under "Length." For example, the charge on the electron, $e$, instead of being a measured value, becomes *defined* as a certain value (its current value), and the unit of electric charge (the coulomb) follows from that. All units then become based on

[†]Some exceptions are for angle (radians—see Chapter 10), solid angle (steradian), and sound level (bel or decibel, Chapter 16).

*Some Sections of this book, such as this subsection, may be considered *optional* at the discretion of the instructor and they are marked with an asterisk (*). See the Preface for more details.

defined fundamental constants like $e$ and the speed of light. Seven is still the number of basic standards. The new definitions maintain the values of the traditional definitions: the "new" meter is the same length as the "old" meter. The new definitions do not change our understanding of what length, time, or mass means.

For us, using this book, the difference between the new SI and the traditional SI is highly technical and does not affect the physics we study. We include the traditional SI because there is some good physics in explaining it. [The Table of Fundamental Constants inside the front cover would look slightly different using the new SI. The value of the charge $e$ on the electron, for example, is *defined*, and so would have no uncertainty attached to it; instead, our Table inside the front cover includes the traditional SI measured uncertainty (updated) of $\pm 98 \times 10^{-29}$ C.]

**TABLE 1–5**
**Traditional SI Base Quantities**

| Quantity | Unit | Unit Abbreviation |
|---|---|---|
| Length | meter | m |
| Time | second | s |
| Mass | kilogram | kg |
| Electric current | ampere | A |
| Temperature | kelvin | K |
| Amount of substance | mole | mol |
| Luminous intensity | candela | cd |

# 1–5 Converting Units

Any quantity we measure, such as a length, a speed, or an electric current, consists of a number *and* a unit. Often we are given a quantity in one set of units, but we want it expressed in another set of units. For example, suppose we measure that a shelf is 21.5 inches wide, and we want to express this in centimeters. We must use a **conversion factor**, which in this case is, *by definition*, exactly

$$1 \text{ in.} = 2.54 \text{ cm}$$

or, written another way,

$$1 = 2.54 \text{ cm/in.}$$

Since multiplying by the number one does not change anything, the width of our shelf, in cm, is

$$21.5 \text{ inches} = (21.5 \cancel{\text{in.}}) \times \left(2.54 \frac{\text{cm}}{\cancel{\text{in.}}}\right) = 54.6 \text{ cm}.$$

Note how the units (inches in this case) cancelled out (thin red lines). A Table containing many unit conversions is found inside the front cover of this book. Let's consider some Examples.

**EXAMPLE 1–2** **The 8000-m peaks.** There are only 14 peaks whose summits are over 8000 m above sea level. They are the highest peaks in the world (Fig. 1–6 and Table 1–6) and are referred to as "eight-thousanders." What is the elevation, in feet, of an elevation of 8000 m?

**APPROACH** We need to convert meters to feet, and we can start with the conversion factor 1 in. = 2.54 cm, which is exact. That is, 1 in. = 2.5400 cm to any number of significant figures, because it is *defined* to be.

**SOLUTION** One foot is defined to be 12 in., so we can write

$$1 \text{ ft} = (12 \cancel{\text{in.}})\left(2.54 \frac{\text{cm}}{\cancel{\text{in.}}}\right) = 30.48 \text{ cm} = 0.3048 \text{ m},$$

which is exact. Note how the units cancel (colored slashes). We can rewrite this equation to find the number of feet in 1 meter:

$$1 \text{ m} = \frac{1 \text{ ft}}{0.3048} = 3.28084 \text{ ft}.$$

(We could carry the result to 6 significant figures because 0.3048 is exact, 0.304800 · · · .) We multiply this equation by 8000.0 (to have five significant figures):

$$8000.0 \text{ m} = (8000.0 \cancel{\text{m}})\left(3.28084 \frac{\text{ft}}{\cancel{\text{m}}}\right) = 26{,}247 \text{ ft}.$$

An elevation of 8000 m is 26,247 ft above sea level.

**NOTE** We could have done the unit conversions all in one line:

$$8000.0 \text{ m} = (8000.0 \cancel{\text{m}})\left(\frac{100 \cancel{\text{cm}}}{1 \cancel{\text{m}}}\right)\left(\frac{1 \cancel{\text{in.}}}{2.54 \cancel{\text{cm}}}\right)\left(\frac{1 \text{ ft}}{12 \cancel{\text{in.}}}\right) = 26{,}247 \text{ ft}.$$

The key is to multiply conversion factors, each equal to one (= 1.0000), and to make sure which units cancel.

**FIGURE 1–6** The world's second highest peak, K2, whose summit is considered the most difficult of the "8000-ers." Example 1–2.

**PHYSICS APPLIED**
*The world's tallest peaks*

**TABLE 1–6 The 8000-m Peaks**

| Peak | Height (m) |
|---|---|
| Mt. Everest | 8850 |
| K2 | 8611 |
| Kangchenjunga | 8586 |
| Lhotse | 8516 |
| Makalu | 8462 |
| Cho Oyu | 8201 |
| Dhaulagiri | 8167 |
| Manaslu | 8156 |
| Nanga Parbat | 8125 |
| Annapurna | 8091 |
| Gasherbrum I | 8068 |
| Broad Peak | 8047 |
| Gasherbrum II | 8035 |
| Shisha Pangma | 8013 |

The first two equations in Example 1–2 on the previous page show how to change from feet to meters, or meters to feet. For practical purposes

$$1\,\text{m} \;=\; 3.28\,\text{ft} \;\approx\; 3.3\,\text{ft}$$

which means that we can change any distance or height in meters to feet by multiplying by 3 and adding 10% (0.1). For example, a 3000-m-high peak in feet is 9000 ft + 900 ft ≈ 10,000 ft.

**TABLE 1–6 The 8000-m Peaks**

| Peak | Height (m) |
|---|---|
| Mt. Everest | 8850 |
| K2 | 8611 |
| Kangchenjunga | 8586 |
| Lhotse | 8516 |
| Makalu | 8462 |
| Cho Oyu | 8201 |
| Dhaulagiri | 8167 |
| Manaslu | 8156 |
| Nanga Parbat | 8125 |
| Annapurna | 8091 |
| Gasherbrum I | 8068 |
| Broad Peak | 8047 |
| Gasherbrum II | 8035 |
| Shisha Pangma | 8013 |

**EXERCISE E** The names and elevations of the 14 eight-thousand-meter peaks in the world (see Example 1–2) are given in Table 1–6, repeated here. They are all in the Himalaya mountain range in India, Pakistan, Tibet, and China. Determine the elevation of the world's three highest peaks in feet.

**EXAMPLE 1–3 Apartment area.** You have seen a nice apartment whose floor area is 880 square feet $(\text{ft}^2)$. What is its area in square meters?

**APPROACH** We use the same conversion factor, 1 in. = 2.54 cm, but this time we have to use it twice.

**SOLUTION** Because 1 in. = 2.54 cm = 0.0254 m, then

$$1\,\text{ft}^2 \;=\; (12\,\text{in.})^2(0.0254\,\text{m/in.})^2 \;=\; 0.0929\,\text{m}^2.$$

So

$$880\,\text{ft}^2 \;=\; (880\,\text{ft}^2)(0.0929\,\text{m}^2/\text{ft}^2) \;\approx\; 82\,\text{m}^2.$$

**NOTE** As a rule of thumb, an area given in $\text{ft}^2$ is roughly 10 times the number of square meters (more precisely, about 10.8×).

*Rule of thumb: Floor area in $\text{ft}^2$ is about 10× area in $\text{m}^2$: $100\,\text{m}^2 \approx 1000\,\text{ft}^2$*

**EXERCISE F** One **hectare** is defined as $1.000 \times 10^4\,\text{m}^2$. There are 640 **acres** in a square mile. Both units are used for land area. (*a*) How many acres are in one hectare? (*b*) What would be an easy everyday rule-of-thumb conversion factor?

**EXAMPLE 1–4 Speeds.** Where the posted speed limit is 55 miles per hour (mi/h or mph), what is this speed (*a*) in meters per second (m/s) and (*b*) in kilometers per hour (km/h)?

**APPROACH** We again use the conversion factor 1 in. = 2.54 cm, and we recall that there are 5280 feet in a mile and 12 inches in a foot; also, one hour contains (60 min/h) × (60 s/min) = 3600 s/h.

**SOLUTION** (*a*) We can write 1 mile as

$$1\,\text{mi} \;=\; (5280\,\cancel{\text{ft}})\left(12\,\frac{\cancel{\text{in.}}}{\cancel{\text{ft}}}\right)\left(2.54\,\frac{\cancel{\text{cm}}}{\cancel{\text{in.}}}\right)\left(\frac{1\,\text{m}}{100\,\cancel{\text{cm}}}\right)$$
$$= \;1609\,\text{m}.$$

We also know that 1 hour contains 3600 s, so

$$55\,\frac{\text{mi}}{\text{h}} \;=\; \left(55\,\frac{\cancel{\text{mi}}}{\cancel{\text{h}}}\right)\left(1609\,\frac{\text{m}}{\cancel{\text{mi}}}\right)\left(\frac{1\,\cancel{\text{h}}}{3600\,\text{s}}\right) \;=\; 25\,\frac{\text{m}}{\text{s}},$$

where we rounded off to two significant figures.

(*b*) Now we use 1 mi = 1609 m = 1.609 km; then

$$55\,\frac{\text{mi}}{\text{h}} \;=\; \left(55\,\frac{\cancel{\text{mi}}}{\text{h}}\right)\left(1.609\,\frac{\text{km}}{\cancel{\text{mi}}}\right) \;=\; 88\,\frac{\text{km}}{\text{h}}.$$

**NOTE** Each conversion factor is equal to one. You can look up most conversion factors in the Table inside the front cover.

**PROBLEM SOLVING**
*Conversion factors = 1*

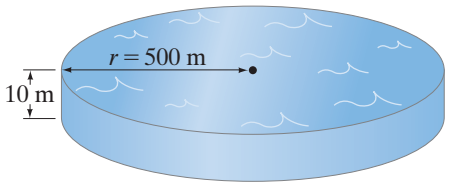
**EXERCISE G** Return to the first Chapter-Opening Question, page 1, and answer it again now. Try to explain why you may have answered differently the first time.

**PROBLEM SOLVING**
*Unit conversion is wrong if units do not cancel*

When changing units, you can avoid making an error in the use of conversion factors by checking that units cancel out properly. For example, in our conversion of 1 mi to 1609 m in Example 1–4(*a*), if we had incorrectly used the factor $\left(\frac{100\,\text{cm}}{1\,\text{m}}\right)$ instead of $\left(\frac{1\,\text{m}}{100\,\text{cm}}\right)$, the centimeter units would not have cancelled out; we would not have ended up with meters.

# 1–6 Order of Magnitude: Rapid Estimating

This is an exciting and powerful Section that will be useful throughout this book, and in real life. We will see how to make approximate calculations of quantities you may never have dreamed you could do.



Also, we are sometimes interested only in an approximate value for a quantity, maybe because an accurate calculation would take more time than it is worth or requires data that are not available. In other cases, we may want to make a rough estimate in order to check a calculation made on a calculator, to make sure that no blunders were made when the numbers were entered.

**PROBLEM SOLVING**
*How to make a rough estimate*

A rough estimate can be made by rounding off all numbers to one significant figure and its power of 10, and after the calculation is made, again keeping only one significant figure. Such an estimate is called an **order-of-magnitude estimate** and can be accurate within a factor of 10, and often better. In fact, the phrase "order of magnitude" is sometimes used to refer simply to the power of 10.

(a)

(b)

**FIGURE 1–7** Example 1–5. (a) How much water is in this lake? (Photo is one of the Rae Lakes in the Sierra Nevada of California.) (b) Model of the lake as a cylinder. [We could go one step further and estimate the mass or weight of this lake. We will see later that water has a density of 1000 kg/m$^3$, so this lake has a mass of about $(10^3\,\text{kg/m}^3)(10^7\,\text{m}^3) \approx 10^{10}\,\text{kg}$, which is about 10 billion kg or 10 million metric tons. (A metric ton is 1000 kg, about 2200 lb, slightly larger than a British ton, 2000 lb.)]

**EXAMPLE 1–5** **ESTIMATE** **Volume of a lake.** Estimate how much water there is in a particular lake, Fig. 1–7a, which is roughly circular, about 1 km across, and you guess it has an average depth of about 10 m.

**APPROACH** No lake is a perfect circle, nor can lakes be expected to have a perfectly flat bottom. We are only estimating here. To estimate the volume, we can use a simple model of the lake as a cylinder: we multiply the average depth of the lake times its roughly circular surface area, as if the lake were a cylinder (Fig. 1–7b).

**PHYSICS APPLIED**
*Estimating the volume (or mass) of a lake; see also Fig. 1–7*

**SOLUTION** The volume $V$ of a cylinder is the product of its height $h$ times the area of its base: $V = h\pi r^2$, where $r$ is the radius of the circular base.[†] The radius $r$ is $\frac{1}{2}\,\text{km} = 500\,\text{m}$, so the volume is approximately

$$V = h\pi r^2 \approx (10\,\text{m}) \times (3) \times (5 \times 10^2\,\text{m})^2 \approx 8 \times 10^6\,\text{m}^3 \approx 10^7\,\text{m}^3,$$

where $\pi$ was rounded off to 3. So the volume is on the order of $10^7\,\text{m}^3$, ten million cubic meters. Because of all the estimates that went into this calculation, the order-of-magnitude estimate $(10^7\,\text{m}^3)$ is probably better to quote than the $8 \times 10^6\,\text{m}^3$ figure.

**NOTE** To express our result in U.S. gallons, we see in the Table on the inside front cover that $1\,\text{liter} = 10^{-3}\,\text{m}^3 \approx \frac{1}{4}\,\text{gallon}$. Hence, the lake contains about $(8 \times 10^6\,\text{m}^3)(1\,\text{gallon}/4 \times 10^{-3}\,\text{m}^3) \approx 2 \times 10^9$ gallons of water.

[†]Formulas like this for volume, area, etc., are found inside the back cover of this book.

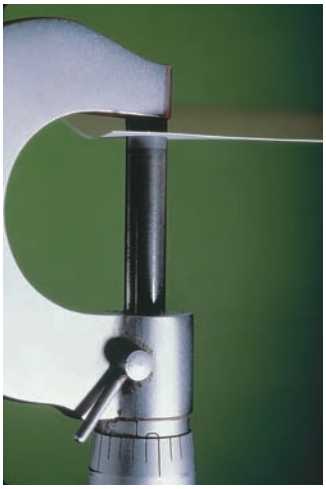


**FIGURE 1–8** Example 1–6. Micrometer used for measuring small thicknesses.

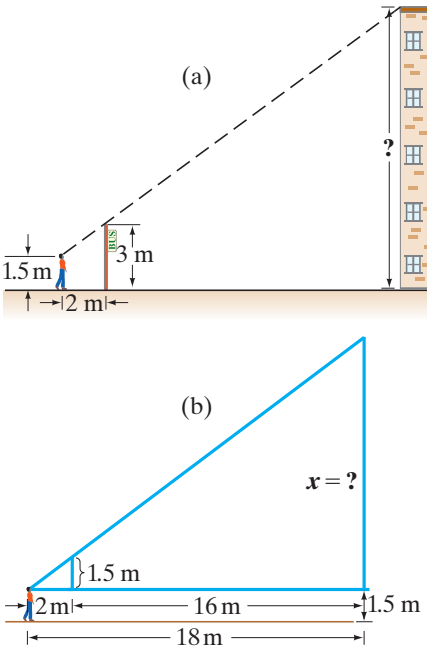
**EXAMPLE 1–6 ESTIMATE** **Thickness of a sheet of paper.** Estimate the thickness of a page of this book.

**APPROACH** At first you might think that a special measuring device, a micrometer (Fig. 1–8), is needed to measure the thickness of one page since an ordinary ruler can not be read so finely. But we can use a trick or, to put it in physics terms, make use of a *symmetry*: we can make the reasonable assumption that all the pages of this book are equal in thickness.



**SOLUTION** We can use a ruler to measure hundreds of pages at once. If you measure the thickness of the first 500 pages of this book (page 1 to page 500), you might get something like 1.5 cm. Note that 500 numbered pages, counted front and back, is 250 separate pieces of paper. So one sheet must have a thickness of about

$$\frac{1.5\text{ cm}}{250\text{ sheets}} \approx 6 \times 10^{-3}\text{ cm} = 6 \times 10^{-2}\text{ mm},$$

or less than a tenth of a millimeter (0.1 mm).

It cannot be emphasized enough how important it is to draw a diagram when solving a physics Problem, as the next Example shows.

**FIGURE 1–9** Example 1–7. Diagrams are really useful!

**EXAMPLE 1–7 ESTIMATE** **Height by triangulation.** Estimate the height of the building shown in Fig. 1–9, by "triangulation," with the help of a bus-stop pole and a friend.

**APPROACH** By standing your friend next to the pole, you estimate the height of the pole to be 3 m. You next step away from the pole until the top of the pole is in line with the top of the building, Fig. 1–9a. You are 5 ft 6 in. tall, so your eyes are about 1.5 m above the ground. Your friend is taller, and when she stretches out her arms, one hand touches you and the other touches the pole, so you estimate that distance as 2 m (Fig. 1–9a). You then pace off the distance from the pole to the base of the building with big, 1-m-long steps, and you get a total of 16 steps or 16 m.

**SOLUTION** Now you draw, to scale, the diagram shown in Fig. 1–9b using these measurements. You can measure, right on the diagram, the last side of the triangle to be about $x \approx 13$ or 14 m. Alternatively, you can use similar triangles to obtain the height $x$:

$$\frac{1.5\text{ m}}{2\text{ m}} = \frac{x}{18\text{ m}},$$

so

$$x \approx 13\tfrac{1}{2}\text{ m}.$$

Finally you add in your eye height of 1.5 m above the ground to get your final result: the building is about 15 m tall.

**EXAMPLE 1–8 ESTIMATE** **Total number of heartbeats.** Estimate the total number of beats a typical human heart makes in a lifetime.

**APPROACH** A typical resting heart rate is 70 beats/min. But during exercise it can be a lot higher. A reasonable average might be 80 beats/min.

**SOLUTION** One year, in seconds, is $(24\text{ h/d})(3600\text{ s/h})(365\text{ d}) \approx 3 \times 10^7\text{ s}$. If an average person lives 70 years $= (70\text{ yr})(3 \times 10^7\text{ s/yr}) \approx 2 \times 10^9\text{ s}$, then the total number of heartbeats would be about

$$\left(80\frac{\text{beats}}{\text{min}}\right)\left(\frac{1\text{ min}}{60\text{ s}}\right)(2 \times 10^9\text{ s}) \approx 3 \times 10^9,$$

or 3 billion.

**EXAMPLE 1–9 ESTIMATE** **Estimating the radius of Earth.** Believe it or not, you can estimate the radius of the Earth without having to go into space (see the photograph on page 1). If you have ever been on the shore of a large lake, you may have noticed that you cannot see the beaches, piers, or rocks at water level across the lake on the opposite shore. The lake seems to bulge out between you and the opposite shore—a good clue that the Earth is round. Suppose you climb a stepladder and discover that when your eyes are 10 ft (3.0 m) above the water, you can just see the rocks at water level on the opposite shore. From a map, you estimate the distance to the opposite shore as $d \approx 6.1$ km. Use Fig. 1–10 with $h = 3.0$ m to estimate the radius $R$ of the Earth.

**APPROACH** We use simple geometry, including the theorem of Pythagoras, $c^2 = a^2 + b^2$, where $c$ is the length of the hypotenuse of any right triangle, and $a$ and $b$ are the lengths of the other two sides.

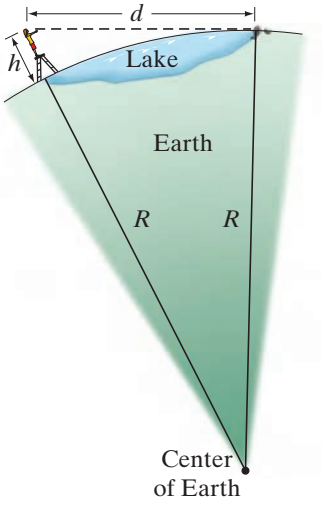
**SOLUTION** For the right triangle of Fig. 1–10, the two sides are the radius of the Earth $R$ and the distance $d = 6.1$ km $= 6100$ m. The hypotenuse is approximately the length $R + h$, where $h = 3.0$ m. By the Pythagorean theorem,

$$\begin{aligned} R^2 + d^2 &\approx (R + h)^2 \\ &\approx R^2 + 2hR + h^2. \end{aligned}$$

We solve algebraically for $R$, after cancelled $R^2$ on both sides:

$$\begin{aligned} R \approx \frac{d^2 - h^2}{2h} &= \frac{(6100\,\text{m})^2 - (3.0\,\text{m})^2}{6.0\,\text{m}} \\ &= 6.2 \times 10^6\,\text{m} \\ &= 6200\,\text{km}. \end{aligned}$$

**NOTE** Precise measurements give 6380 km. But look at your achievement! With a few simple rough measurements and simple geometry, you made a good estimate of the Earth's radius. You did not need to go out in space, nor did you need a very long measuring tape.[†]



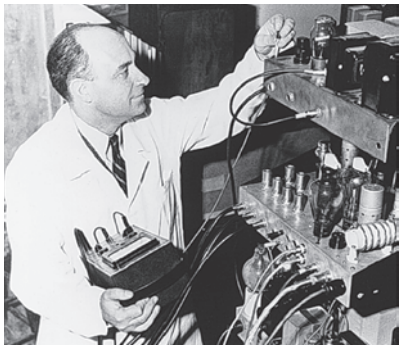


**FIGURE 1–10** Example 1–9, but not to scale. You can just barely see rocks at water level on the opposite shore of a lake 6.1 km wide if you stand on a stepladder.

**EXERCISE H** Return to the second Chapter-Opening Question, page 1, and answer it again now. Try to explain why you may have answered differently the first time.

Another type of estimate, this one made famous by Enrico Fermi (1901–1954, Fig. 1–11), was to show his students how to estimate the number of piano tuners in a city, such as Chicago or San Francisco. To get a rough order-of-magnitude estimate of the number of piano tuners today in San Francisco, a city of about 800,000 inhabitants, we can proceed by estimating the number of functioning pianos, how often each piano is tuned, and how many pianos each tuner can tune. To estimate the number of pianos in San Francisco, we note that certainly not everyone has a piano. A guess of 1 family in 3 having a piano would correspond to 1 piano per 12 persons, assuming an average family of 4 persons.

As an order of magnitude, let's say 1 piano per 10 people. This is certainly more reasonable than 1 per 100 people, or 1 per every person, so let's proceed with the estimate that 1 person in 10 has a piano, or about 80,000 pianos in San Francisco. Now a piano tuner needs an hour or two to tune a piano. So let's estimate that a tuner can tune 4 or 5 pianos a day. A piano ought to be tuned every 6 months or a year—let's say once each year. A piano tuner tuning 4 pianos a day, 5 days a week, 50 weeks a year can tune about 1000 pianos a year. So San Francisco, with its (very) roughly 80,000 pianos, needs about 80 piano tuners. This is, of course, only a rough estimate.[‡] It tells us that there must be many more than 10 piano tuners, and surely not as many as 1000.

**FIGURE 1–11** Enrico Fermi. Fermi contributed significantly to both theoretical and experimental physics, a feat almost unique in modern times.

**PROBLEM SOLVING**
*Estimating how many piano tuners there are in a city*

[†]As a teenager I had a summer job washing dishes at a camp located 350 m above famous Lake Tahoe in California. Starting the drive down to Lake Tahoe, the beaches across the lake were visible. But approaching the level of Lake Tahoe, the beaches across the lake were no longer visible! I realized that Lake Tahoe was bulging up in the middle, blocking the view. ("The Earth is round.")

[‡]A search on the internet (done after this calculation) reveals over 50 listings. Each of these listings may employ more than one tuner, but on the other hand, each may also do repairs as well as tuning. In any case, our estimate is reasonable.

## *1–7 Dimensions and Dimensional Analysis

When we speak of the **dimensions** of a quantity, we are referring to the type of base units that make it up. The dimensions of area, for example, are always length squared, abbreviated $[L^2]$ using square brackets; the units can be square meters, square feet, cm$^2$, and so on. Velocity, on the other hand, can be measured in units of km/h, m/s, or mi/h, but the dimensions are always a length $[L]$ divided by a time $[T]$: that is, $[L/T]$.

The formula for a quantity may be different in different cases, but the dimensions remain the same. For example, the area of a triangle of base $b$ and height $h$ is $A = \frac{1}{2}bh$, whereas the area of a circle of radius $r$ is $A = \pi r^2$. The formulas are different in the two cases, but the dimensions of area are always $[L^2]$.

Dimensions can be used as a help in working out relationships, a procedure referred to as **dimensional analysis**. One useful technique is the use of dimensions to check if a relationship is *incorrect*. Note that we add or subtract quantities only if they have the same dimensions (we don't add centimeters and hours); and the quantities on each side of an equals sign must have the same dimensions. (In numerical calculations, the units must also be the same on both sides of an equation.)

For example, suppose you derived the equation $v = v_0 + \frac{1}{2}at^2$, where $v$ is the velocity of an object after a time $t$, $v_0$ is the object's initial velocity, and the object undergoes an acceleration $a$. Let's do a dimensional check to see if this equation could be correct or is surely incorrect. Note that numerical factors, like the $\frac{1}{2}$ here, do not affect dimensional checks. We write a dimensional equation as follows, remembering that the dimensions of velocity are $[L/T]$ and (as we shall see in Chapter 2) the dimensions of acceleration are $[L/T^2]$:

$$\left[\frac{L}{T}\right] \stackrel{?}{=} \left[\frac{L}{T}\right] + \left[\frac{L}{T^2}\right][T^2]$$
$$\stackrel{?}{=} \left[\frac{L}{T}\right] + [L].$$

The dimensions are incorrect: on the right side, we have the sum of quantities whose dimensions are not the same. Thus we conclude that an error was made in the derivation of the original equation.

A dimensional check can only tell you when a relationship is wrong. It can not tell you if it is completely right. For example, a dimensionless numerical factor (such as $\frac{1}{2}$ or $2\pi$) could be missing.

Dimensional analysis can also be used as a quick check on an equation you are not sure about. For example, consider a simple pendulum of length $\ell$. Suppose that you can't remember whether the equation for the period $T$ (the time to make one back-and-forth swing) is $T = 2\pi\sqrt{\ell/g}$ or $T = 2\pi\sqrt{g/\ell}$, where $g$ is the acceleration due to gravity and, like all accelerations, has dimensions $[L/T^2]$. (Do not worry about these formulas—the correct one will be derived in Chapter 11; what we are concerned about here is a person's recalling whether it contains $\ell/g$ or $g/\ell$.) A dimensional check shows that the former $(\ell/g)$ is correct:

$$[T] = \sqrt{\frac{[L]}{[L/T^2]}} = \sqrt{[T^2]} = [T],$$

whereas the latter $(g/\ell)$ is not:

$$[T] \neq \sqrt{\frac{[L/T^2]}{[L]}} = \sqrt{\frac{1}{[T^2]}} = \frac{1}{[T]}.$$

The constant $2\pi$ has no dimensions and so can't be checked using dimensions.

Further uses of dimensional analysis are found in Appendix D.

*Some Sections of this book, such as this one, may be considered *optional* at the discretion of the instructor, and they are marked with an asterisk (*). See the Preface for more details.

**EXAMPLE 1–10 Planck length.** The smallest meaningful measure of length is called the "Planck length," and is defined in terms of three fundamental constants in nature: the speed of light $c = 3.00 \times 10^8\,\text{m/s}$, the gravitational constant $G = 6.67 \times 10^{-11}\,\text{m}^3/\text{kg}\cdot\text{s}^2$, and Planck's constant $h = 6.63 \times 10^{-34}\,\text{kg}\cdot\text{m}^2/\text{s}$. The Planck length $\lambda_P$ ($\lambda$ is the Greek letter "lambda") is given by the following combination of these three constants:

$$\lambda_P = \sqrt{\frac{Gh}{c^3}}.$$

Show that the dimensions of $\lambda_P$ are length $[L]$, and find the order of magnitude of $\lambda_P$.

**APPROACH** We rewrite the above equation in terms of dimensions. The dimensions of $c$ are $[L/T]$, of $G$ are $[L^3/MT^2]$, and of $h$ are $[ML^2/T]$.

**SOLUTION** The dimensions of $\lambda_P$ are

$$\sqrt{\frac{[L^3/MT^2][ML^2/T]}{[L^3/T^3]}} = \sqrt{[L^2]} = [L]$$

which is a length. Good. The value of the Planck length is

$$\lambda_P = \sqrt{\frac{Gh}{c^3}} = \sqrt{\frac{(6.67 \times 10^{-11}\,\text{m}^3/\text{kg}\cdot\text{s}^2)(6.63 \times 10^{-34}\,\text{kg}\cdot\text{m}^2/\text{s})}{(3.00 \times 10^8\,\text{m/s})^3}} \approx 4 \times 10^{-35}\,\text{m},$$

which is on the order of $10^{-34}$ or $10^{-35}\,\text{m}$.

**NOTE** Some recent theories (Chapters 43 and 44) suggest that the smallest particles (quarks, leptons) have sizes on the order of the Planck length, $10^{-35}\,\text{m}$. These theories also suggest that the "Big Bang," with which the Universe is believed to have begun, started from an initial size on the order of the Planck length.

# Summary

[*The Summary that appears at the end of each Chapter in this book gives a brief overview of the main ideas of the Chapter. The Summary* cannot *serve to give an understanding of the material, which can be accomplished only by a detailed reading of the Chapter.*]

Physics, like other sciences, is a creative endeavor. It is not simply a collection of facts. Important **theories** are created with the idea of explaining **observations**. To be accepted, theories are **tested** by comparing their predictions with the results of actual experiments. Note that, in general, a theory cannot be "proved" in an absolute sense.

Scientists often devise models of physical phenomena. A **model** is a kind of picture or analogy that helps to describe the phenomena in terms of something we already know about. A **theory**, often developed from a model, is usually deeper and more complex than a simple model.

A scientific **law** is a concise statement, often expressed in the form of an equation, which quantitatively describes a wide range of phenomena.

**Measurements** play a crucial role in physics, but can never be perfectly precise. It is important to specify the **uncertainty** of a measurement either by stating it directly using the $\pm$ notation, and/or by keeping only the correct number of **significant figures**.

Physical quantities are always specified relative to a particular standard or **unit**, and the unit used should always be stated. The commonly accepted set of units today is the **Système International** (SI), in which the standard units of length, mass, and time are the **meter**, **kilogram**, and **second**.

When converting units, check all **conversion factors** for correct cancellation of units.

Making rough, **order-of-magnitude estimates** is a very useful technique in science as well as in everyday life.

[*The **dimensions** of a quantity refer to the combination of base quantities that comprise it. Velocity, for example, has dimensions of [length/time] or $[L/T]$. Working with only the dimensions of the various quantities in a given relationship—this technique is called **dimensional analysis**—makes it possible to check a relationship for correct form.]

# Questions

1. What are the merits and drawbacks of using a person's foot as a standard? Consider both (*a*) a particular person's foot, and (*b*) any person's foot. Keep in mind that it is advantageous that fundamental standards be accessible (easy to compare to), invariable (do not change), indestructible, and reproducible.
2. What is wrong with this road sign:

   Memphis 7 mi (11.263 km)?
3. Why is it incorrect to think that the more digits you include in your answer, the more accurate it is?
4. For an answer to be complete, units need to be specified. Why?
5. You measure the radius of a wheel to be 4.16 cm. If you multiply by 2 to get the diameter, should you write the result as 8 cm or as 8.32 cm? Justify your answer.
6. Express the sine of 30.0° with the correct number of significant figures.
7. List assumptions useful to estimate the number of car mechanics in (*a*) San Francisco, (*b*) your hometown, and then make the estimates.

# MisConceptual Questions

[List all answers that are valid.]

**1.** The laws of physics
(*a*) are permanent and unalterable.
(*b*) are part of nature and are waiting to be discovered.
(*c*) can change, but only because of evidence that convinces the community of physicists.
(*d*) apply to physics but not necessarily to chemistry or other fields.
(*e*) were basically complete by 1900, and have undergone only minor revisions since.
(*f*) are accepted by all major world countries, and cannot be changed without international treaties.

**2.** How should we write the result of the following calculation, being careful about significant figures?

$$(3.84\text{ s})(37\text{ m/s}) + (5.3\text{ s})(14.1\text{ m/s}) =$$

(*a*) 200 m.
(*b*) 210 m.
(*c*) 216.81 m.
(*d*) 217 m.
(*e*) 220 m.

**3.** Four students use different instruments to measure the length of the same pen. Which measurement implies the greatest precision?
(*a*) 160.0 mm.
(*b*) 16.0 cm.
(*c*) 0.160 m.
(*d*) 0.00016 km.
(*e*) Need more information.

**4.** The number 0.0078 has how many significant figures?
(*a*) 1.
(*b*) 2.
(*c*) 3.
(*d*) 4.

**5.** How many significant figures does $1.362 + 25.2$ have?
(*a*) 2.
(*b*) 3.
(*c*) 4.
(*d*) 5.

**6.** Accuracy represents
(*a*) repeatability of a measurement, using a given instrument.
(*b*) how close a measurement is to the true value.
(*c*) an ideal number of measurements to make.
(*d*) how poorly an instrument is operating.

**7.** Precision represents
(*a*) repeatability of a measurement, using a given instrument.
(*b*) how close a measurement is to the true value.
(*c*) an ideal number of measurements to make.
(*d*) how poorly an instrument is operating.

**8.** To convert from $\text{ft}^2$ to $\text{yd}^2$, you should
(*a*) multiply by 3.
(*b*) multiply by 1/3.
(*c*) multiply by 9.
(*d*) multiply by 1/9.
(*e*) multiply by 6.
(*f*) multiply by 1/6.

**9.** Which is *not* true about an order-of-magnitude estimation?
(*a*) It gives you a rough idea of the answer.
(*b*) It can be done by keeping only one significant figure.
(*c*) It can be used to check if an exact calculation is reasonable.
(*d*) It may require making some reasonable assumptions in order to calculate the answer.
(*e*) It will always be accurate to at least two significant figures.

***10.** $[L^2]$ represents the dimensions for which of the following?
(*a*) $\text{cm}^2$.
(*b*) square feet.
(*c*) $\text{m}^2$.
(*d*) All of the above.

# Problems

[*The Problems at the end of each Chapter are ranked* I, II, *or* III *according to estimated difficulty, with* (I) *Problems being easiest. Level* III *are meant as challenges for the best students. The Problems are arranged by Section, meaning that the reader should have read up to and including that Section, but not only that Section—Problems often depend on earlier material. Next is a set of "General Problems" not arranged by Section and not ranked.*]

## 1–3 Measurement, Uncertainty, Significant Figures

(Note: *In Problems, assume a number like* 6.4 *is accurate to* $\pm 0.1$; *and* 950 *is accurate to* 2 *significant figures* ($\pm 10$) *unless* 950 *is said to be "precisely" or "very nearly"* 950, *in which case assume* $950 \pm 1$.)

**1.** (I) How many significant figures do each of the following numbers have: (*a*) 777, (*b*) 81.60, (*c*) 7.03, (*d*) 0.03, (*e*) 0.0086, (*f*) 6465, and (*g*) 8700?

**2.** (I) Write the following numbers in powers of 10 notation: (*a*) 5.859, (*b*) 21.8, (*c*) 0.0068, (*d*) 328.65, (*e*) 0.219, (*f*) 444.

**3.** (I) Write out the following numbers in full with the correct number of zeros: (*a*) $8.69 \times 10^5$, (*b*) $9.1 \times 10^3$, (*c*) $2.5 \times 10^{-1}$, (*d*) $4.76 \times 10^2$, and (*e*) $3.62 \times 10^{-5}$.

**4.** (II) What is the percent uncertainty in the measurement $3.25 \pm 0.35$ m?

**5.** (II) Time intervals measured with a physical stopwatch typically have an uncertainty of about 0.2 s, due to human reaction time at the start and stop moments. What is the percent uncertainty of a hand-timed measurement of (*a*) 4.5 s, (*b*) 45 s, (*c*) 4.5 min?

**6.** (II) Add $(9.2 \times 10^3\text{ s}) + (6.3 \times 10^4\text{ s}) + (0.008 \times 10^6\text{ s})$.

**7.** (II) Multiply $4.079 \times 10^2$ m by $0.057 \times 10^{-1}$ m, taking into account significant figures.

**8.** (II) What, approximately, is the percent uncertainty for a measurement given as $1.27\text{ m}^2$?

**9.** (II) For small angles $\theta$, the numerical value of $\sin\theta$ is approximately the same as the numerical value of $\tan\theta$. Find the largest angle for which sine and tangent agree to within two significant figures.

**10.** (II) A report stated that "a survey of 215 students found that 37.2% had bought a sugar-rich soft drink the day before." (*a*) How many students bought a soft drink? (*b*) What is wrong with the original statement?

**11.** (II) A watch manufacturer claims that its watches gain or lose no more than 9 seconds in a year. How accurate are these watches, expressed as a percentage?

**12.** (III) What is the area, and its approximate uncertainty, of a circle of radius $5.1 \times 10^4$ cm?

**13.** (III) What, roughly, is the percent uncertainty in the volume of a spherical beach ball of radius $r = 0.64 \pm 0.04$ m?

## 1–4 and 1–5 Units, Standards, SI, Converting Units

**14.** (I) Write the following as full (decimal) numbers without prefixes on the units: (*a*) 286.6 mm, (*b*) 74 $\mu$V, (*c*) 430 mg, (*d*) 47.2 ps, (*e*) 22.5 nm, (*f*) 2.50 gigavolts.

15. (I) Express the following using the prefixes of Table 1–4: (*a*) $3 \times 10^6$ volts, (*b*) $2 \times 10^{-6}$ meters, (*c*) $5 \times 10^3$ days, (*d*) $18 \times 10^2$ bucks, and (*e*) $9 \times 10^{-7}$ seconds.

16. (I) Determine your own height in meters, and your mass in kg.

17. (II) To the correct number of significant figures, use the information inside the front cover of this book to determine the ratio of (*a*) the surface area of Earth compared to the surface area of the Moon, (*b*) the volume of Earth compared to the volume of the Moon.

18. (II) Would a driver traveling at 15 m/s in a 35 mi/h zone be exceeding the speed limit? Why or why not?

19. (II) The age of the universe is thought to be about 14 billion years. Assuming two significant figures, write this in powers of 10 in (*a*) years, (*b*) seconds.

20. (II) The Sun, on average, is 93 million miles from Earth. How many meters is this? Express (*a*) using powers of 10, and (*b*) using a metric prefix (km).

21. (II) Express the following sum with the correct number of significant figures: $1.90\,\text{m} + 142.5\,\text{cm} + 6.27 \times 10^5\,\mu\text{m}$.

22. (II) A typical atom has a diameter of about $1.0 \times 10^{-10}$ m. (*a*) What is this in inches? (*b*) Approximately how many atoms are along a 1.0-cm line, assuming they just touch?

23. (II) Determine the conversion factor between (*a*) km/h and mi/h, (*b*) m/s and ft/s, and (*c*) km/h and m/s.

24. (II) What is the conversion factor between (*a*) $\text{ft}^2$ and $\text{yd}^2$, (*b*) $\text{m}^2$ and $\text{ft}^2$?

25. (II) A **light-year** is the distance light travels in one year $\left(\text{at speed} = 2.998 \times 10^8\,\text{m/s}\right)$. (*a*) How many meters are there in 1.00 light-year? (*b*) An **astronomical unit** (AU) is the average distance from the Sun to Earth, $1.50 \times 10^8$ km. How many AU are there in 1.00 light-year?

26. (II) How much longer (percentage) is a one-mile race than a 1500-m race ("the metric mile")?

27. (II) How many wavelengths of orange krypton-86 light (Section 1–4) would fit into the thickness of one page of this book? See Example 1–6.

28. (II) Using the French Academy of Sciences' original definition of the meter, calculate Earth's circumference and radius in *those* meters. Give % error relative to today's accepted values (inside front cover).

29. (II) A passenger jet uses about 12 liters of fuel per km of flight. What is that value expressed as miles per gallon?

30. (II) American football uses a *field* that is 100.0 yd long, whereas a *soccer field* is 100.0 m long. Which field is longer, and by how much (give yards, meters, and percent)?

31. (II) (*a*) How many seconds are there in 1.00 year? (*b*) How many nanoseconds are there in 1.00 year? (*c*) How many years are there in 1.00 second?

32. (II) Use Table 1–3 to estimate the total number of protons or neutrons in (*a*) a bacterium, (*b*) a DNA molecule, (*c*) the human body, (*d*) our Galaxy.

33. (II) The diameter of the planet Mercury is 4879 km. (*a*) What is the surface area of Mercury? (*b*) How many times larger is the surface area of the Earth?

34. (III) A standard baseball has a circumference of approximately 23 cm. If a baseball had the same mass per unit volume (see Tables in Section 1–4) as a neutron or a proton, about what would its mass be?

## 1–6 Order-of-Magnitude Estimating

(Note: *Remember that for rough estimates, only round numbers are needed both as input to calculations and as final results.*)

35. (I) Estimate the order of magnitude (power of 10) of: (*a*) 3200, (*b*) $86.30 \times 10^3$, (*c*) 0.076, and (*d*) $15.0 \times 10^8$.

36. (II) Estimate how many books can be shelved in a college library with 6500 $\text{m}^2$ of floor space. Assume 8 shelves high, having books on both sides, with corridors 1.5 m wide. Assume books are about the size of this one, on average.

37. (II) Estimate how many hours it would take to run (at 10 km/h) across the U.S. from New York to California.

38. (II) Estimate the number of liters of water a human drinks in a lifetime.

39. (II) Estimate the number of *cells* in an adult human body, given that a typical cell has a diameter of about 10 $\mu$m, and the human body has a density of about 1000 $\text{kg/m}^3$.

40. (II) Estimate how long it would take one person to mow a football field using an ordinary home lawn mower (Fig. 1–12). (State your assumptions, such as the mower moves with a 1-km/h speed, and has a 0.5-m width.)

**FIGURE 1–12**
Problem 40.

41. (II) Estimate the number of gallons of gasoline consumed by the total of all automobile drivers in the U.S., per year.

42. (II) Estimate the number of dentists (*a*) in San Francisco and (*b*) in your town or city.

43. (II) Estimate how many kilograms of laundry soap are used in the U.S. in one year (and therefore pumped out of washing machines with the dirty water). Assume each load of laundry takes 0.1 kg of soap.

44. (II) How big is a *ton* (1000 kg)? That is, what is the volume of something that weighs a ton? To be specific, estimate the diameter of a 1-ton rock, but first make a wild guess: will it be 1 ft across, 3 ft, or the size of a car? [*Hint*: Rock has mass per volume about 3 times that of water, which is 1 kg per liter $\left(10^3\,\text{cm}^3\right)$ or 62 lb per cubic foot.]

45. (II) A hiking trail is 270 km long through varying terrain. A group of hikers cover the first 49 km in two and a half days. Estimate how much time they should allow for the rest of the trip.

46. (II) Estimate how many days it would take to walk around the circumference of the Earth, assuming 12 h walking per day at 4 km/h.

47. (II) Estimate the number of jelly beans in the jar of Fig. 1–13.

**FIGURE 1–13**
Problem 47. Estimate the number of jelly beans in the jar.

**48.** (II) Estimate the number of bus drivers (*a*) in Washington, D.C., and (*b*) in your town.

**49.** (III) You are in a hot air balloon, 300 m above the flat Texas plains. You look out toward the horizon. How far out can you see—that is, how far is your horizon? The Earth's radius is about 6400 km.

**50.** (III) I agree to hire you for 30 days. You can decide between two methods of payment: either (1) $1000 a day, or (2) one penny on the first day, two pennies on the second day and continue to double your daily pay each day up through day 30. Use quick estimation to make your decision, and justify it.

**51.** (III) The rubber worn from tires mostly enters the atmosphere as *particulate pollution*. Estimate how much rubber (in kg) is put into the air in the United States every year. To get started, a good estimate for a tire tread's depth is 1 cm when new, and rubber has a mass of about 1200 kg per $m^3$ of volume.

**52.** (III) Many sailboats are docked at a marina 4.4 km away on the opposite side of a lake. You stare at one of the sailboats because, when you are lying flat at the water's edge, you can just see its deck but none of the side of the sailboat. You then go to that sailboat on the other side of the lake and measure that the deck is 1.5 m above the level of the water. Using Fig. 1–14, where $h = 1.5$ m, estimate the radius $R$ of the Earth.

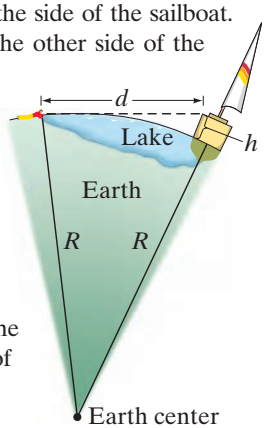

**FIGURE 1–14** Problem 52. You see a sailboat across a lake (not to scale). $R$ is the radius of the Earth. Because of the curvature of the Earth, the water "bulges out" between you and the boat.

**53.** (III) You are lying on a beach, your eyes 20 cm above the sand. Just as the Sun sets, fully disappearing over the horizon, you immediately jump up, your eyes now 150 cm above the sand, and you can again just see the top of the Sun. If you count the number of seconds $(= t)$ until the Sun fully disappears again, you can estimate the *Earth's radius*. But for this Problem, use the known radius of the Earth to calculate the time $t$.

### *1–7 Dimensions

***54.** (I) What are the dimensions of density, which is mass per volume?

***55.** (II) The speed $v$ of an object is given by the equation $v = At^3 - Bt$, where $t$ refers to time. (*a*) What are the dimensions of $A$ and $B$? (*b*) What are the SI units for the constants $A$ and $B$?

***56.** (II) Three students derive the following equations in which $x$ refers to distance traveled, $v$ the speed, $a$ the acceleration $(m/s^2)$, $t$ the time, and the subscript zero $(_0)$ means a quantity at time $t = 0$. Here are their equations: (*a*) $x = vt^2 + 2at$, (*b*) $x = v_0 t + \frac{1}{2}at^2$, and (*c*) $x = v_0 t + 2at^2$. Which of these could possibly be correct according to a dimensional check, and why?

***57.** (II) (*a*) Show that the following combination of the three fundamental constants of nature that we used in Example 1–10 (that is $G$, $c$, and $h$) forms a quantity with the dimensions of time:

$$t_P = \sqrt{\frac{Gh}{c^5}}.$$

This quantity, $t_P$, is called the **Planck time** and is thought to be the earliest time, after the creation of the Universe, at which the currently known laws of physics can be applied. (*b*) Estimate the order of magnitude of $t_P$ using values given inside the front cover (or Example 1–10).

## General Problems

**58.** **Global positioning satellites (GPS)** can be used to determine your position with great accuracy. If one of the satellites is 20,000 km from you, and you want to know your position to $\pm 2$ m, what percent uncertainty in the distance is required? How many significant figures are needed in the distance?

**59.** One mole of atoms consists of $6.02 \times 10^{23}$ individual atoms. If a mole of atoms were spread uniformly over the Earth's surface, how many atoms would there be per square meter?

**60.** **Computer chips** (Fig. 1–15) can be etched on circular silicon wafers of thickness 0.300 mm that are sliced from a solid cylindrical silicon crystal of length 25 cm. If each wafer can hold 750 chips, what is the maximum number of chips that can be produced from one entire cylinder?

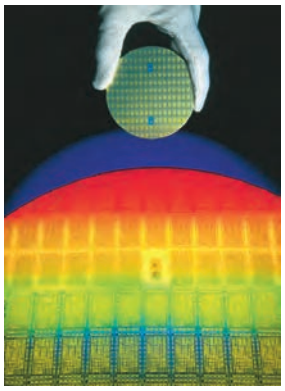

**FIGURE 1–15** Problem 60. The wafer held by the hand is shown below, enlarged and illuminated by colored light. Visible are rows of integrated circuits (chips).

**61.** If you used only a keyboard to enter data, how many years would it take to fill up a *hard drive* in a computer that can store 1.0 terabytes $(1.0 \times 10^{12}$ bytes) of data? Assume 40-hour work weeks, and that you can type 150 characters per minute, and that one byte is one keyboard character.

**62.** An average family of four uses roughly 1200 L (about 300 gallons) of water per day $(1\text{ L} = 1000\text{ cm}^3)$. How much depth would a lake lose per year if it covered an area of 60 $km^2$ with uniform depth and supplied a local town with a population of 40,000 people? Consider only population uses, and neglect evaporation, rain, creeks and rivers.

**63.** A certain compact disc (CD) contains 783.216 megabytes of digital information. Each byte consists of exactly 8 bits. When played, a CD player reads the CD's information at a constant rate of 1.4 megabits per second. How many minutes does it take the player to read the entire CD?

**64.** An *angstrom* (symbol Å) is a unit of length, defined as $10^{-10}$ m, which is on the order of the diameter of an atom. (*a*) How many nanometers are in 1.0 angstrom? (*b*) How many femtometers or fermis (the common unit of length in nuclear physics) are in 1.0 angstrom? (*c*) How many angstroms are in 1.0 m? (*d*) How many angstroms are in 1.0 light-year (see Problem 25)?

**65.** A typical adult human lung contains about 300 million tiny cavities called alveoli. Estimate the average diameter of a single alveolus.

**66.** Hold a pencil in front of your eye at a position where its blunt end just blocks out the Moon (Fig. 1–16). Make appropriate measurements to estimate the diameter of the Moon, given that the Earth–Moon distance is $3.8 \times 10^5$ km.

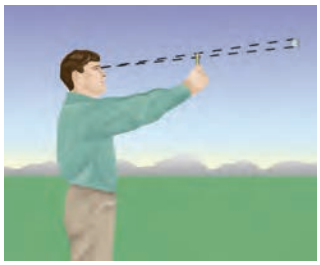

**FIGURE 1–16**
Problem 66. How big is the Moon?

**67.** A storm dumps 1.0 cm of rain on a city 5 km wide and 7 km long in a 2-h period. How many metric tons (1 metric ton $= 10^3$ kg) of water fell on the city? ($1\ \text{cm}^3$ of water has a mass of $1\ \text{g} = 10^{-3}$ kg.) How many gallons of water was this?

**68.** Greenland's ice sheet covers over $1.7 \times 10^6\ \text{km}^2$ and is approximately 2.5 km thick. If it were to melt completely then by how much would you expect the ocean to rise? Assume $\frac{2}{3}$ of Earth's surface is ocean. See Tables inside front and back covers.

**69.** Noah's ark was ordered to be 300 cubits long, 50 cubits wide, and 30 cubits high. The cubit was a unit of measure equal to the length of a human forearm, elbow to the tip of the longest finger. Express the dimensions of Noah's ark in meters, and estimate its volume ($\text{m}^3$).

**70.** One liter ($1000\ \text{cm}^3$) of oil is spilled onto a smooth lake. If the oil spreads out uniformly until it makes an oil slick just one molecule thick, with adjacent molecules just touching, estimate the diameter of the oil slick. Assume the oil molecules have a diameter of $2 \times 10^{-10}$ m.

**71.** If you walked north along one of Earth's lines of longitude until you had changed latitude by 1 minute of arc (there are 60 minutes per degree), how far would you have walked (in miles)? This distance is a *nautical mile* (page 7).

**72.** Determine the percent uncertainty in $\theta$, and in $\sin\theta$, when (*a*) $\theta = 15.0° \pm 0.5°$, (*b*) $\theta = 75.0° \pm 0.5°$.

**73.** Jim stands beside a wide river and wonders how wide it is. He spots a large rock on the bank directly across from him. He then walks upstream 85 strides and judges that the angle between him and the rock, which he can still see, is now at an angle of 30° downstream (Fig. 1–17). Jim measures his stride to be about 0.8 m long. Estimate the width of the river.

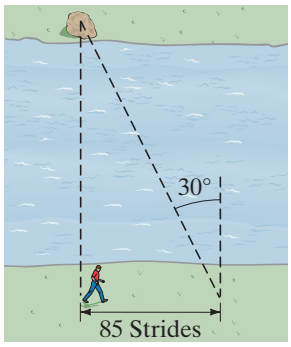

**FIGURE 1–17**
Problem 73.

**74.** Make a rough estimate of the volume of your body (in $\text{m}^3$).

**75.** Estimate the number of plumbers in San Francisco.

**76.** Estimate the ratio (order of magnitude) of the mass of a human to the mass of a DNA molecule. [*Hint*: Check the Tables in this Chapter.]

**77.** The following formula estimates an average person's lung capacity $V$ (in liters, where $1\ \text{L} = 10^3\ \text{cm}^3$):

$$V = 4.1H - 0.018A - 2.7,$$

where $H$ and $A$ are the person's height (in meters) and age (in years), respectively. In this formula, what are the units of the numbers 4.1, 0.018, and 2.7?

**78.** The density of an object is defined as its mass divided by its volume. Suppose a rock's mass and volume are measured to be 6 g and $2.8325\ \text{cm}^3$. To the correct number of significant figures, determine the rock's density (mass/volume).

**79.** Recent findings in astrophysics suggest that the observable universe can be modeled as a sphere of radius $R = 13.7 \times 10^9$ light-years $= 13.0 \times 10^{25}$ m with an average total mass density of about $1 \times 10^{-26}\ \text{kg/m}^3$. Only about 4% of total mass is due to "ordinary" matter (such as protons, neutrons, and electrons). Estimate how much ordinary matter (in kg) there is in the observable universe. (For the light-year, see Problem 25.)

## ANSWERS TO EXERCISES

**A:** (*d*).
**B:** All three have three significant figures; the number of decimal places is (*a*) 2, (*b*) 3, (*c*) 4.
**C:** No: they have three and two, respectively.
**D:** (*a*) $2.58 \times 10^{-2}$, 3; (*b*) $4.23 \times 10^4$, 3 (probably); (*c*) $3.4450 \times 10^2$, 5.
**E:** Mt. Everest, 29,035 ft; K2, 28,251 ft; Kangchenjunga, 28,169 ft.
**F:** (*a*) 2.47 acres in 1 hectare; (*b*) $2\frac{1}{2}$ or even just 2 acres in 1 hectare.
**G:** (*f*) 1,000,000; that is, one million.
**H:** (*c*).

A space shuttle has released a parachute to reduce its speed quickly. The directions of the shuttle's velocity and acceleration are shown by the green ($\vec{\mathbf{v}}$) and gold ($\vec{\mathbf{a}}$) arrows.

Motion is described using the concepts of velocity and acceleration. In the case shown here, the velocity $\vec{\mathbf{v}}$ is to the right, in the direction of motion. The acceleration $\vec{\mathbf{a}}$ is in the opposite direction from the velocity $\vec{\mathbf{v}}$, which means the object is slowing down.

We examine in detail motion with constant acceleration, including the vertical motion of objects falling under gravity.

CHAPTER 2

# Describing Motion: Kinematics in One Dimension

## CONTENTS

2–2 Average Velocity
2–3 Instantaneous Velocity
2–4 Acceleration
2–5 Motion at Constant Acceleration
2–6 Solving Problems
2–7 Freely Falling Objects
*2–8 Variable Acceleration; Integral Calculus

## CHAPTER-OPENING QUESTION—Guess now!

[*Don't worry about getting the right answer now—you will get another chance later in the Chapter. See also page 1 of Chapter 1 for more explanation.*]

Two small heavy balls have the same diameter but one weighs twice as much as the other. The balls are dropped from a second-story balcony at the exact same time. The time to reach the ground below will be:

**(a)** twice as long for the lighter ball as for the heavier one.
**(b)** longer for the lighter ball, but not twice as long.
**(c)** twice as long for the heavier ball as for the lighter one.
**(d)** longer for the heavier ball, but not twice as long.
**(e)** nearly the same for both balls.

The motion of objects—baseballs, automobiles, joggers, and even the Sun and Moon—is an obvious part of everyday life. It was not until the sixteenth and seventeenth centuries that our modern understanding of motion was established. Many individuals contributed to this understanding, particularly Galileo Galilei (1564–1642) and Isaac Newton (1642–1727).

The study of the motion of objects, and the related concepts of force and energy, form the field called **mechanics**. Mechanics is customarily divided into two parts: **kinematics**, which is the description of how objects move, and **dynamics**, which deals with force and why objects move as they do. This Chapter and the next deal with kinematics.

For now we only discuss objects that move without rotating (Fig. 2–1a). Such motion is called **translational motion**. In this Chapter we will be concerned with describing an object that moves along a straight-line path, which is one-dimensional translational motion. In Chapter 3 we will describe translational motion in two (or three) dimensions along paths that are not straight. (Rotation, shown in Fig. 2–1b, is discussed in Chapters 10 and 11.)

We will often use the concept, or *model*, of an idealized **particle** which is considered to be a mathematical **point** with no spatial extent (no size). A point particle can undergo only translational motion. The particle model is useful in many real situations where we are interested only in translational motion and the object's size is not significant. For example, we might consider a billiard ball, or even a spacecraft traveling toward the Moon, as a particle for many purposes.

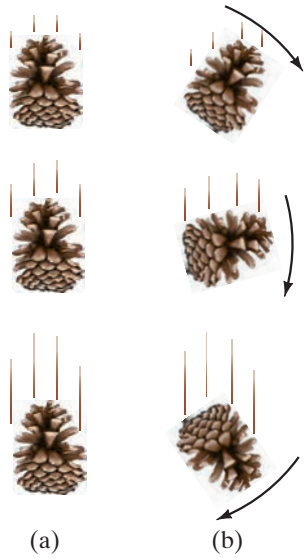

**FIGURE 2–1** A falling pinecone undergoes (a) pure translation; (b) it is rotating as well as translating.

## 2–1 Reference Frames and Displacement

Any measurement of position, distance, or speed must be made with respect to a **reference frame**, or **frame of reference**. For example, while you are on a train traveling at 80 km/h, suppose a person walks past you toward the front of the train at a speed of, say, 5 km/h (Fig. 2–2). This 5 km/h is the person's speed with respect to the train as frame of reference. With respect to the ground, that person is moving at a speed of 80 km/h + 5 km/h = 85 km/h. It is always important to specify the frame of reference when stating a speed. In everyday life, we usually mean "with respect to the Earth" without even thinking about it, but the reference frame must be specified whenever there might be confusion.

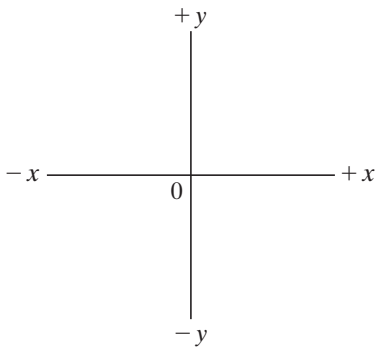

**FIGURE 2–2** A person walks toward the front of a train at 5 km/h. The train is moving at 80 km/h with respect to the ground, so the walking person's speed, relative to the ground, is 85 km/h.

When specifying the motion of an object, it is important to specify not only the speed but also the direction of motion. Often we can specify a direction by using north, east, south, and west, and by "up" and "down." In physics, we often draw a set of **coordinate axes**, as shown in Fig. 2–3, to represent a frame of reference. We can always place the origin 0, and the directions of the $x$ and $y$ axes, as we like for convenience. The $x$ and $y$ axes are always perpendicular to each other. The **origin** is where $x = 0$, $y = 0$. Objects positioned to the right of the origin of coordinates (0) on the $x$ axis have an $x$ coordinate which we almost always choose to be positive; objects at points to the left of 0 have a negative $x$ coordinate. The position along the $y$ axis is usually considered positive when above 0, and negative when below 0, although the reverse convention can be used if convenient. Any point on the $xy$ plane can be specified by giving its $x$ and $y$ coordinates. In three dimensions, a $z$ axis perpendicular to the $x$ and $y$ axes is added.

For one-dimensional motion, we often choose the $x$ axis as the line along which the motion takes place. Then the **position** of an object at any moment is given by its $x$ coordinate. If the motion is vertical, as for a dropped object, we usually use the $y$ axis.

**FIGURE 2–3** Standard set of $xy$ coordinate axes, sometimes called "rectangular coordinates." [Also called *Cartesian coordinates*, after René Descartes (1596–1650), who invented them.]

**⚠ CAUTION**

*The displacement may not equal the total distance traveled*

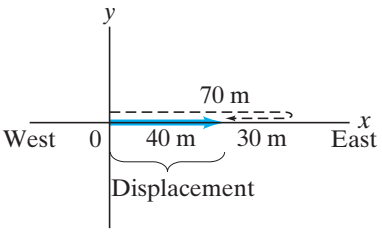

**FIGURE 2–4** A person walks 70 m east, then 30 m west. The total distance traveled is 100 m (path is shown dashed in black); but the displacement, shown as a solid blue arrow, is 40 m to the east.

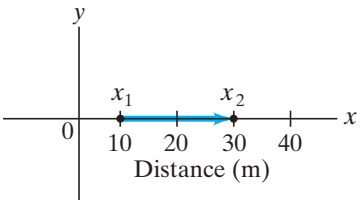
**FIGURE 2–5** The arrow represents the displacement $x_2 - x_1$. Distances are in meters.



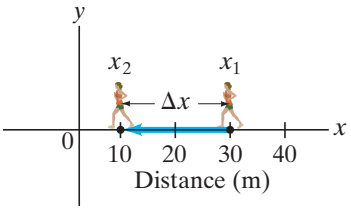


**FIGURE 2–6** For the displacement $\Delta x = x_2 - x_1 = 10.0\,\text{m} - 30.0\,\text{m}$, the displacement vector points left.

We need to make a distinction between the **distance** an object has traveled and its **displacement**, which is defined as the *change in position* of the object.

That is, *displacement is how far the object is from its starting point*. To see the distinction between total distance and displacement, imagine a person walking 70 m to the east and then turning around and walking back (west) a distance of 30 m (see Fig. 2–4). The total distance traveled is 70 m + 30 m = 100 m, but the displacement is only 40 m since the person is now only 40 m from the starting point.

Displacement is a quantity that has both *magnitude* and *direction*. Such quantities are called **vectors**, and are represented by arrows in diagrams. For example, in Fig. 2–4, the blue arrow represents the displacement whose magnitude is 40 m and whose direction is to the right (east).

We will deal with vectors more fully in Chapter 3. For now, we deal only with motion in one dimension, along a line. In this case, vectors which point in one direction will be positive (usually to the right along the $x$ axis). Vectors that point in the opposite direction will have a negative sign in front of their magnitude.

Consider the motion of an object over a particular time interval. Suppose that at some initial time, call it $t_1$, the object is on the $x$ axis at the position $x_1$ in the coordinate system shown in Fig. 2–5. At some later time, $t_2$, suppose the object has moved to position $x_2$. The displacement of our object is $x_2 - x_1$, and is represented by the arrow pointing to the right in Fig. 2–5. It is convenient to write

$$\Delta x = x_2 - x_1,$$

where the symbol $\Delta$ (Greek letter delta) means "change in." Then $\Delta x$ means "the change in $x$," or "change in position," which is in fact the displacement. The **change in** any quantity means the *final* value of that quantity, minus the *initial* value. Suppose $x_1 = 10.0\,\text{m}$ and $x_2 = 30.0\,\text{m}$, as in Fig. 2–5. Then

$$\Delta x = x_2 - x_1 = 30.0\,\text{m} - 10.0\,\text{m} = 20.0\,\text{m},$$

so the displacement is 20.0 m in the positive direction, Fig. 2–5.

Now consider an object moving to the left as shown in Fig. 2–6. Here the object, a person, starts at $x_1 = 30.0\,\text{m}$ and walks to the left to the point $x_2 = 10.0\,\text{m}$. In this case her displacement is

$$\Delta x = x_2 - x_1 = 10.0\,\text{m} - 30.0\,\text{m} = -20.0\,\text{m},$$

and the blue arrow representing the vector displacement points to the left. For one-dimensional motion along the $x$ axis, a vector pointing to the right is positive, whereas a vector pointing to the left has a negative sign.

**EXERCISE A** An ant starts at $x = 20\,\text{cm}$ on a piece of graph paper and walks along the $x$ axis to $x = -20\,\text{cm}$. It then turns around and walks back to $x = -10\,\text{cm}$. Determine (a) the ant's displacement and (b) the total distance traveled.

## 2–2 Average Velocity

An important aspect of the motion of a moving object is how *fast* it is moving—its speed or velocity.

The term "speed" refers to how far an object travels in a given time interval, regardless of direction. If a car travels 240 kilometers (km) in 3 hours (h), we say its average speed was 80 km/h. In general, the **average speed** of an object is defined as *the total distance traveled along its path divided by the time it takes to travel this distance*:

$$\text{average speed} = \frac{\text{distance traveled}}{\text{time elapsed}}. \qquad \textbf{(2–1)}$$

The terms "velocity" and "speed" are often used interchangeably in ordinary language. But in physics we make a distinction between the two. Speed is simply a positive number, with units. **Velocity**, on the other hand, is used to signify both the *magnitude* (numerical value) of how fast an object is moving and also the *direction* in which it is moving. Velocity is therefore a *vector*.

There is a second difference between speed and velocity: namely, the *average velocity* is defined in terms of *displacement*, rather than total distance traveled:

$$\text{average velocity} = \frac{\text{displacement}}{\text{time elapsed}} = \frac{\text{final position} - \text{initial position}}{\text{time elapsed}}.$$

**CAUTION**
*Average speed is not necessarily equal to the magnitude of the average velocity*

Average speed and average velocity have the same magnitude when the motion is all in one direction. In other cases, they may differ: recall the walk we described earlier, in Fig. 2–4, where a person walked 70 m east and then 30 m west. The total distance traveled was 70 m + 30 m = 100 m, but the displacement was 40 m. Suppose this walk took 70 s to complete. Then the average speed was:

$$\frac{\text{distance}}{\text{time elapsed}} = \frac{100\text{ m}}{70\text{ s}} = 1.4\text{ m/s}.$$

The magnitude of the average velocity, on the other hand, was:

$$\frac{\text{displacement}}{\text{time elapsed}} = \frac{40\text{ m}}{70\text{ s}} = 0.57\text{ m/s}.$$

In everyday life, we are usually interested in average speed. If this second equation on average velocity seems strange, we will see its usefulness in the next Section.

To discuss one-dimensional motion of an object in general, suppose that at some moment in time, call it $t_1$, the object is on the $x$ axis at position $x_1$ in a coordinate system, and at some later time, $t_2$, suppose it is at position $x_2$. The **elapsed time** (= change in time) is $\Delta t = t_2 - t_1$. During this time interval the displacement of our object is $\Delta x = x_2 - x_1$. Then the **average velocity**, defined as *the displacement divided by the elapsed time*, can be written

$$\bar{v} = \frac{x_2 - x_1}{t_2 - t_1} = \frac{\Delta x}{\Delta t}, \qquad \text{[average velocity]} \quad \textbf{(2–2)}$$

where $v$ stands for velocity and the bar $(^{-})$ over the $v$ is a standard symbol meaning "average."

**CAUTION**
*Time interval = elapsed time*

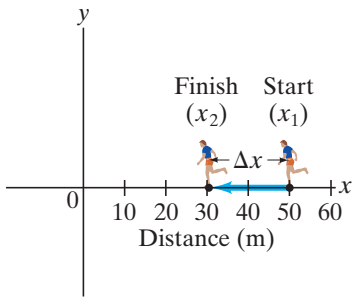
It is always important to choose (and state) the *elapsed time*, or **time interval**, $t_2 - t_1$, the time that passes during our chosen period of observation.

**EXAMPLE 2–1** **Runner's average velocity.** The position of a runner is plotted as moving along the $x$ axis of a coordinate system. During a 3.00-s time interval, the runner's position changes from $x_1 = 50.0\text{ m}$ to $x_2 = 30.5\text{ m}$, as shown in Fig. 2–7. What is the runner's average velocity?

**APPROACH** We want to find the average velocity, which is the displacement divided by the elapsed time.

**SOLUTION** The displacement is

$$\Delta x = x_2 - x_1 = 30.5\text{ m} - 50.0\text{ m} = -19.5\text{ m}.$$



In this case the displacement is negative.

The elapsed time, or time interval, is given as $\Delta t = 3.00\text{ s}$. The average velocity (Eq. 2–2) is

$$\bar{v} = \frac{\Delta x}{\Delta t} = \frac{-19.5\text{ m}}{3.00\text{ s}} = -6.50\text{ m/s}.$$

The displacement and average velocity are negative: that is, the runner is moving to the left along the $x$ axis, as indicated by the arrow in Fig. 2–7. The runner's average velocity is 6.50 m/s to the left.

**FIGURE 2–7** Example 2–1. A person runs from $x_1 = 50.0\text{ m}$ to $x_2 = 30.5\text{ m}$. The displacement is $-19.5\text{ m}$.

For one-dimensional motion in the usual case of the $+x$ axis to the right, if $x_2$ is less than $x_1$, then the object is moving to the left, and $\Delta x = x_2 - x_1$ is less than zero. The sign of the displacement, and thus of the average velocity, indicates the direction: the average velocity is positive for an object moving to the right along the $x$ axis and negative when the object moves to the left. The direction of the average velocity is always the same as the direction of the displacement.

**PROBLEM SOLVING**
*+ or − sign can signify the direction for linear motion*

**EXAMPLE 2–2** **Distance a cyclist travels.** How far can a cyclist travel in 2.5 h along a straight road if her average velocity is 18 km/h?

**APPROACH** We want to find the distance traveled, which in this case equals the displacement $\Delta x$, so we solve Eq. 2–2 for $\Delta x$.

**SOLUTION** In Eq. 2–2, $\bar{v} = \Delta x/\Delta t$, we multiply both sides by $\Delta t$ and obtain

$$\Delta x = \bar{v}\,\Delta t = (18\,\text{km/h})(2.5\,\text{h}) = 45\,\text{km}.$$

**EXAMPLE 2–3** **Car changes speed.** A car travels at a constant 50 km/h for 100 km. It then speeds up to 100 km/h and is driven another 100 km. What is the car's average speed for the 200-km trip?

**APPROACH** At 50 km/h, the car takes 2.0 h to travel 100 km. At 100 km/h, it takes only 1.0 h to travel 100 km. We use the definition of average velocity, Eq. 2–2.

**SOLUTION** Average velocity (Eq. 2–2) is

$$\bar{v} = \frac{\Delta x}{\Delta t} = \frac{100\,\text{km} + 100\,\text{km}}{2.0\,\text{h} + 1.0\,\text{h}} = 67\,\text{km/h}.$$

**NOTE** Averaging the two speeds, $(50\,\text{km/h} + 100\,\text{km/h})/2 = 75\,\text{km/h}$, gives a wrong answer. Can you see why? You must use the definition of $\bar{v}$, Eq. 2–2.

## 2–3 Instantaneous Velocity

**FIGURE 2–8** Car speedometer showing mi/h in white, and km/h in orange.

If you drive a car along a straight road for 150 km in 2.0 h, the magnitude of your average velocity is 75 km/h. It is unlikely, though, that you were moving at precisely 75 km/h at every instant. To describe this situation we need the concept of *instantaneous velocity*, which is the velocity at any instant of time. (Its magnitude is the number, with units, indicated by a speedometer, Fig. 2–8.) More precisely, the **instantaneous velocity** at any moment is defined as *the average velocity over an infinitesimally short time interval*. That is, Eq. 2–2 is to be evaluated in the limit of $\Delta t$ becoming extremely small, approaching zero. We can write the definition of instantaneous velocity, $v$, for one-dimensional motion as

$$v = \lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t}. \qquad \text{[instantaneous velocity]} \quad \textbf{(2–3)}$$

The notation $\lim_{\Delta t \to 0}$ means the ratio $\Delta x/\Delta t$ is to be evaluated in the limit of $\Delta t$ approaching zero. But we do not simply set $\Delta t = 0$ in this definition, for then $\Delta x$ would also be zero, and we would not be able to evaluate it. Rather, we consider the *ratio* $\Delta x/\Delta t$, as a whole. As we let $\Delta t$ approach zero, $\Delta x$ approaches zero as well. But the ratio $\Delta x/\Delta t$ approaches some definite value, which is the instantaneous velocity at a given instant.

In Eq. 2–3, the limit as $\Delta t \to 0$ is written in calculus notation as $dx/dt$ and is called the **derivative** of $x$ with respect to $t$:

$$v = \lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt}. \qquad \textbf{(2–4)}$$

This equation is the definition of instantaneous velocity for one-dimensional motion.

For instantaneous velocity we use the symbol $v$, whereas for average velocity we use $\bar{v}$, with a bar above. In the rest of this book, when we use the term "velocity" it will refer to instantaneous velocity. When we want to speak of the average velocity, we will make this clear by including the word "average."

Note that the *instantaneous speed* always equals the magnitude of the instantaneous velocity. Why? Because as the time interval becomes infinitesimally small ($\Delta t \to 0$), an object has no time to change speed or direction, and so the distance traveled and the magnitude of the displacement have to be the same.

If an object moves at a uniform (that is, constant) velocity during a particular time interval, then its instantaneous velocity at any instant is the same as its average velocity (see Fig. 2–9a). But in many situations this is not the case. For example, a car may start from rest, speed up to 50 km/h, remain at that velocity for a time, then slow down to 20 km/h in a traffic jam, and finally stop at its destination after traveling a total of 15 km in 30 min. This trip is plotted on the graph of Fig. 2–9b. Also shown on the graph is the average velocity (dashed line), which is $\bar{v} = \Delta x/\Delta t = 15\,\text{km}/0.50\,\text{h} = 30\,\text{km/h}$.

To better understand instantaneous velocity, let us consider a graph of the position versus time ($x$ vs. $t$) of a particle moving along the $x$ axis, as shown in Fig. 2–10. (Note that this is different from showing the "path" of a particle moving in two dimensions on an $x$ vs. $y$ plot.) The particle is at position $x_1$ at time $t_1$, and at position $x_2$ at time $t_2$. $P_1$ and $P_2$ represent these two points on the graph. A straight line drawn from point $P_1\,(x_1, t_1)$ to point $P_2\,(x_2, t_2)$ forms the hypotenuse of a right triangle whose sides are $\Delta x$ and $\Delta t$. The ratio $\Delta x/\Delta t$ is the **slope** of the straight line $P_1P_2$. But $\Delta x/\Delta t$ is also the average velocity of the particle during the time interval $\Delta t = t_2 - t_1$. Therefore, we conclude that the average velocity of a particle during any time interval $\Delta t = t_2 - t_1$ is equal to the slope of the straight line (or *chord*) connecting the two points $(x_1, t_1)$ and $(x_2, t_2)$ on an $x$ vs. $t$ graph.

Consider now a time $t_i$, intermediate between $t_1$ and $t_2$, at which time the particle is at $x_i$ (Fig. 2–11). The slope of the straight line $P_1P_i$ is less than the slope of $P_1P_2$ in this case. Thus the average velocity during the time interval $t_i - t_1$ is less than during the time interval $t_2 - t_1$.

Now let us imagine that we take the point $P_i$ in Fig. 2–11 to be closer and closer to point $P_1$. That is, we let the interval $t_i - t_1$, which we now call $\Delta t$, become smaller and smaller. The slope of the line connecting the two points becomes closer and closer to the slope of a line tangent to the curve at point $P_1$. The average velocity (equal to the slope of the chord) thus approaches the slope of the tangent at point $P_1$. The definition of the instantaneous velocity (Eq. 2–3) is the limiting value of the average velocity as $\Delta t$ approaches zero. Thus the *instantaneous velocity equals the slope of the tangent to the x vs. t curve* at that point (which we can simply call "the slope of the curve" at that point).

Because the velocity at any instant equals the slope of the tangent to the $x$ vs. $t$ graph at that instant, we can obtain the velocity at any instant from such a graph. For example, in Fig. 2–12 (which shows the same curve as in Figs. 2–10 and 2–11), the slope continually increases as our object moves from $x_1$ to $x_2$, so the velocity is increasing. For times after $t_2$, however, the slope begins to decrease and in fact reaches zero (so $v = 0$) where $x$ has its maximum value, at point $P_3$ in Fig. 2–12. Beyond this point, the slope is negative, as for point $P_4$. The velocity is therefore negative, which makes sense since $x$ is now decreasing—the particle is moving to the left on a standard $xy$ plot, toward decreasing values of $x$.

If an object moves with constant velocity over a particular time interval, its instantaneous velocity is equal to its average velocity. The graph of $x$ vs. $t$ in this case will be a straight line whose slope equals the velocity. The curve of Fig. 2–10 has no straight sections, so there are no time intervals when the velocity is constant.

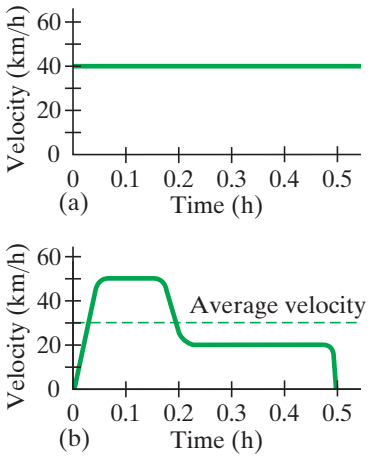


**FIGURE 2–9** Velocity of a car as a function of time: (a) at constant velocity; (b) with velocity varying in time.

**FIGURE 2–10** Graph of a particle's position $x$ vs. time $t$. The slope of the straight line $P_1P_2$ represents the average velocity of the particle during the time interval $\Delta t = t_2 - t_1$.

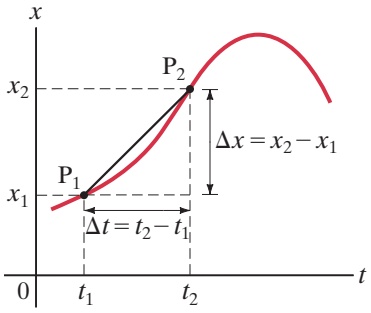

**FIGURE 2–11** Same position vs. time curve as in Fig. 2–10, but including an intermediate time $t_i$. Note that the average velocity over the time interval $t_i - t_1$ (which is the slope of $P_1P_i$) is less than the average velocity over the time interval $t_2 - t_1$. The slope of the thin line tangent to the curve at point $P_1$ equals the instantaneous velocity at time $t_1$.

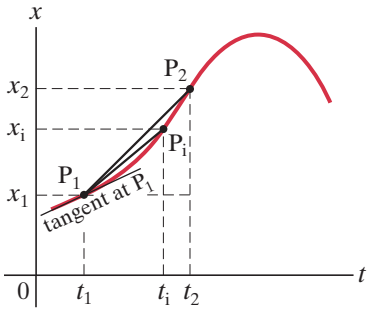

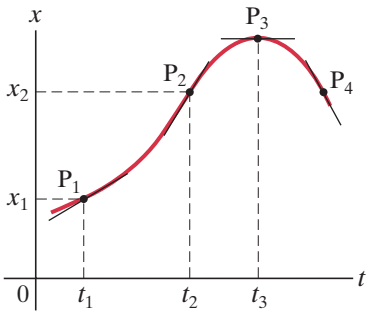

**FIGURE 2–12** Same $x$ vs. $t$ curve as in Figs. 2–10 and 2–11, but here showing the slope at four different points: At $P_3$, the slope is zero, so $v = 0$. At $P_4$ the slope is negative, so $v < 0$.

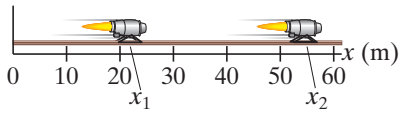
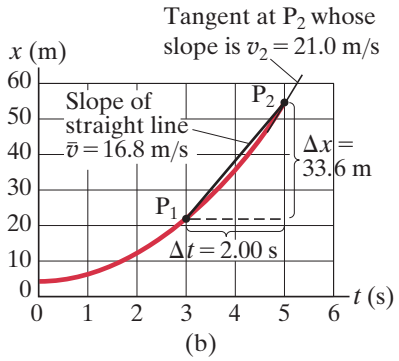


**EXERCISE B** What is your speed at the instant you turn around to move in the opposite direction? (*a*) Depends on how quickly you turn around; (*b*) always zero; (*c*) always negative; (*d*) none of the above.

The derivatives of various functions are studied in calculus courses, and you can find a review in this book in Appendix B. The derivatives of polynomial functions (which we use a lot) are:



$$\frac{d}{dt}\left(Ct^n\right) = nCt^{n-1} \quad \text{and} \quad \frac{dC}{dt} = 0,$$

where $C$ is any constant.

**FIGURE 2–13** Example 2–4.
(a) Engine traveling on a straight track.
(b) Graph of $x$ vs. $t$: $x = At^2 + B$.

(a)

(b)

**EXAMPLE 2–4** **Given $x$ as a function of $t$.** A jet engine moves along an experimental track (which we call the $x$ axis) as shown in Fig. 2–13a. We will treat the engine as if it were a particle. Its position as a function of time is given by the equation $x = At^2 + B$, where $A = 2.10\,\text{m/s}^2$ and $B = 2.80\,\text{m}$, and this equation is plotted in Fig. 2–13b. (*a*) Determine the displacement of the engine during the time interval from $t_1 = 3.00\,\text{s}$ to $t_2 = 5.00\,\text{s}$. (*b*) Determine the average velocity during this time interval. (*c*) Determine the magnitude of the instantaneous velocity at $t = 5.00\,\text{s}$.

**APPROACH** (*a*) We substitute values for $t_1$ and $t_2$ in the given equation for $x$ to obtain $x_1$ and $x_2$. (*b*) The average velocity can be found from Eq. 2–2. (*c*) To find the instantaneous velocity, we take the derivative of the given $x$ equation with respect to $t$ using the formulas given above.

**SOLUTION** (*a*) At $t_1 = 3.00\,\text{s}$, the position (point $P_1$ in Fig. 2–13b) is

$$x_1 = At_1^2 + B = (2.10\,\text{m/s}^2)(3.00\,\text{s})^2 + 2.80\,\text{m} = 21.7\,\text{m}.$$

At $t_2 = 5.00\,\text{s}$, the position ($P_2$ in Fig. 2–13b) is

$$x_2 = (2.10\,\text{m/s}^2)(5.00\,\text{s})^2 + 2.80\,\text{m} = 55.3\,\text{m}.$$

The displacement is thus

$$x_2 - x_1 = 55.3\,\text{m} - 21.7\,\text{m} = 33.6\,\text{m}.$$

(*b*) The magnitude of the average velocity can then be calculated as

$$\bar{v} = \frac{\Delta x}{\Delta t} = \frac{x_2 - x_1}{t_2 - t_1} = \frac{33.6\,\text{m}}{2.00\,\text{s}} = 16.8\,\text{m/s}.$$

This equals the slope of the straight line joining points $P_1$ and $P_2$ shown in Fig. 2–13b.

(*c*) The instantaneous velocity at $t = t_2 = 5.00\,\text{s}$ equals the slope of the tangent to the curve at point $P_2$ shown in Fig. 2–13b. We could measure this slope off the graph to obtain $v_2$. But we can calculate $v$ more precisely for any time $t$, using the given formula

$$x = At^2 + B,$$

which is the engine's position $x$ as a function of time $t$. We take the derivative of $x$ with respect to time (see formulas at top of this page):

$$v = \frac{dx}{dt} = \frac{d}{dt}\left(At^2 + B\right) = 2At.$$

We are given $A = 2.10\,\text{m/s}^2$, so for $t = t_2 = 5.00\,\text{s}$,

$$v_2 = 2At = 2(2.10\,\text{m/s}^2)(5.00\,\text{s}) = 21.0\,\text{m/s}.$$

# 2–4 Acceleration

An object whose velocity is changing is said to be accelerating. For instance, a car whose velocity increases in magnitude from zero to 80 km/h is accelerating. Acceleration specifies how rapidly the velocity of an object is changing.

## Average Acceleration

**Average acceleration** is defined as the change in velocity divided by the time taken to make this change:

$$\text{average acceleration} = \frac{\text{change of velocity}}{\text{time elapsed}}.$$

In symbols, the average acceleration over a time interval $\Delta t = t_2 - t_1$ during which the velocity changes by $\Delta v = v_2 - v_1$ is defined as

$$\bar{a} = \frac{v_2 - v_1}{t_2 - t_1} = \frac{\Delta v}{\Delta t}. \qquad \textbf{(2–5)}$$

Because velocity is a vector, acceleration is a vector too. But for one-dimensional motion, we need only use a plus or minus sign to indicate acceleration direction relative to a chosen coordinate axis.

**EXAMPLE 2–5** **Average acceleration.** A car accelerates along a straight road from rest to 90 km/h in 5.0 s, Fig. 2–14. What is the magnitude of its average acceleration?

**APPROACH** Average acceleration is the change in velocity divided by the elapsed time, 5.0 s. The car starts from rest, so $v_1 = 0$. The final velocity is $v_2 = 90\,\text{km/h} = 90 \times 10^3\,\text{m}/3600\,\text{s} = 25\,\text{m/s}$.

**SOLUTION** From Eq. 2–5, the average acceleration is

$$\bar{a} = \frac{v_2 - v_1}{t_2 - t_1} = \frac{25\,\text{m/s} - 0\,\text{m/s}}{5.0\,\text{s}} = 5.0\,\frac{\text{m/s}}{\text{s}}.$$

This is read as "five meters per second per second" and means that, on average, the velocity changed by 5.0 m/s during each second. That is, assuming the acceleration was constant, during the first second the car's velocity increased from zero to 5.0 m/s. During the next second its velocity increased by another 5.0 m/s, reaching a velocity of 10.0 m/s at $t = 2.0$ s, and so on. See Fig. 2–14.

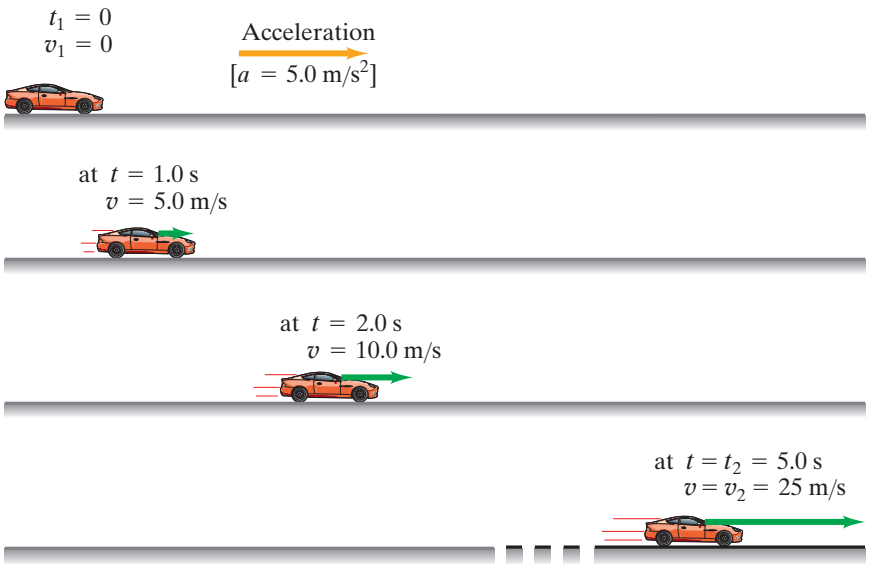


**FIGURE 2–14** Example 2–5. The car is shown at the start with $v_1 = 0$ at $t_1 = 0$. The car is shown three more times, at $t = 1.0$ s, $t = 2.0$ s, and at the end of our time interval, $t_2 = 5.0$ s. The green arrows represent the velocity vectors, whose length represents the magnitude of the velocity at that moment and get longer with time. The acceleration vector is the orange arrow, whose magnitude is constant and is found to equal 5.0 m/s$^2$. Distances are not to scale.

We almost always write the units for acceleration as $m/s^2$ (meters per second squared) instead of m/s/s. This is possible because:

$$\frac{m/s}{s} = \frac{m}{s \cdot s} = \frac{m}{s^2}.$$

According to the calculation in Example 2–5, the velocity changed on average by 5.0 m/s during each second, for a total change of 25 m/s over the 5.0 s; the average acceleration was $5.0\ m/s^2$.

Note that *acceleration* tells us how quickly the *velocity* changes, whereas *velocity* tells us how quickly the *position* changes.

**⚠ CAUTION**
*Distinguish velocity from acceleration*

**⚠ CAUTION**
*If v or a is zero, is the other zero too?*

**CONCEPTUAL EXAMPLE 2–6** **Velocity and acceleration.** (*a*) If the velocity of an object is zero, does it mean that the acceleration is zero? (*b*) If the acceleration is zero, does it mean that the velocity is zero? Think of some examples.

**RESPONSE** A zero velocity does not necessarily mean that the acceleration is zero, nor does a zero acceleration mean that the velocity is zero. (*a*) For example, when you put your foot on the gas pedal of your car which is at rest, the velocity starts from zero but the acceleration is not zero since the velocity of the car changes. (How else could your car start forward if its velocity weren't changing—that is, accelerating?) (*b*) As you cruise along a straight highway at a constant velocity of 100 km/h, your acceleration is zero: $a = 0$, $v \neq 0$.

**EXERCISE C** A powerful car is advertised to go from zero to 60 mi/h in 5.4 s. What does this say about the car: (*a*) it is fast (high speed); or (*b*) it accelerates well?

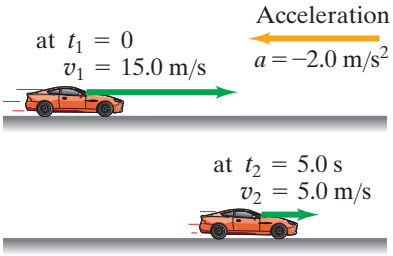

**FIGURE 2–15** Example 2–7, showing the position of the car at times $t_1$ and $t_2$, as well as the car's velocity represented by the green arrows. We calculate that the acceleration vector (orange) points to the left as the car slows down while moving to the right.

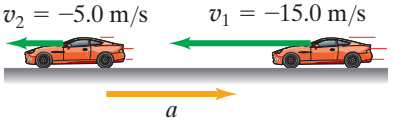
**EXAMPLE 2–7** **Car slowing down.** An automobile is moving to the right along a straight highway, which we choose to be the positive *x* axis (Fig. 2–15). Then the driver puts on the brakes. If the initial velocity (when the driver hits the brakes) is $v_1 = 15.0$ m/s, and it takes 5.0 s to slow down to $v_2 = 5.0$ m/s, what was the car's average acceleration?

**APPROACH** We put the given initial and final velocities, and the elapsed time, into Eq. 2–5 for $\bar{a}$.

**SOLUTION** In Eq. 2–5, we call the initial time $t_1 = 0$, and set $t_2 = 5.0$ s. (Note that our choice of $t_1 = 0$ doesn't affect the calculation of $\bar{a}$ because only $\Delta t = t_2 - t_1$ appears in Eq. 2–5.) Then

$$\bar{a} = \frac{5.0\ m/s - 15.0\ m/s}{5.0\ s} = -2.0\ m/s^2.$$



The negative sign appears because the final velocity is less than the initial velocity. In this case the direction of the acceleration is to the left (in the negative *x* direction)—even though the velocity is always pointing to the right. We say that the acceleration is $2.0\ m/s^2$ to the left, and it is shown in Fig. 2–15 as an orange arrow.

**FIGURE 2–16** The car of Example 2–7, now moving to the *left* and decelerating. The acceleration is

$$a = \frac{v_2 - v_1}{\Delta t}$$

$$a = \frac{(-5.0\ m/s) - (-15.0\ m/s)}{5.0\ s}$$

$$= \frac{-5.0\ m/s + 15.0\ m/s}{5.0\ s} = +2.0\ m/s^2.$$

## "Deceleration"

When an object is slowing down, we sometimes say it is **decelerating**. In physics, the concept of acceleration is all we need: it can be + or −. But if the word "deceleration" is used, be careful: deceleration does *not* mean that the acceleration is necessarily negative, as in Example 2–7. The velocity of an object moving to the right along the positive *x* axis is positive; if the object is slowing down (as in Fig. 2–15), the acceleration *is* negative. But the same car moving to the left (decreasing *x*), and slowing down, has positive acceleration that points to the right, as shown in Fig. 2–16. We have a deceleration whenever the magnitude of the velocity is decreasing; thus the *velocity and acceleration point in opposite directions* when there is deceleration.

**EXERCISE D** A car moves along the $x$ axis. What is the sign of the car's acceleration if it is moving in the positive $x$ direction with ($a$) increasing speed or ($b$) decreasing speed? What is the sign of the acceleration if the car moves in the negative $x$ direction with ($c$) increasing speed or ($d$) decreasing speed?

## Instantaneous Acceleration

The **instantaneous acceleration**, $a$, is defined as the *limiting value of the average acceleration as we let* $\Delta t$ *approach zero*:

$$a = \lim_{\Delta t \to 0} \frac{\Delta v}{\Delta t} = \frac{dv}{dt}. \qquad \textbf{(2–6)}$$

This limit, $dv/dt$, is the derivative of $v$ with respect to $t$. We will use the term "acceleration" to refer to the instantaneous value. If we want to discuss the average acceleration, we will always include the word "average."

If we draw a graph of the velocity, $v$, vs. time, $t$, as shown in Fig. 2–17, then the *average* acceleration over a time interval $\Delta t = t_2 - t_1$ is represented by the slope of the straight line connecting the two points $P_1$ and $P_2$ in Fig. 2–17. [Compare this to the position vs. time graph of Fig. 2–10 for which the slope of the straight line represents the average velocity.] The *instantaneous* acceleration at any time, say $t_1$, is the slope of the tangent to the $v$ vs. $t$ curve at time $t_1$, which is also shown in Fig. 2–17. In Fig. 2–17, as we go from time $t_1$ to time $t_2$ the velocity continually increases, but the acceleration (the rate at which the velocity changes) is decreasing since the slope of the curve is decreasing.

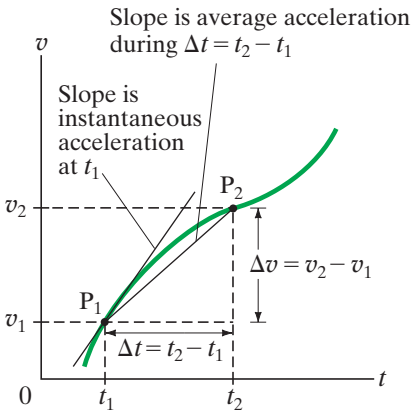


**FIGURE 2–17** A graph of velocity $v$ vs. time $t$. The average acceleration over a time interval $\Delta t = t_2 - t_1$ is the slope of the straight line $P_1P_2$: $\bar{a} = \Delta v/\Delta t$. The instantaneous acceleration at time $t_1$ is the slope of the $v$ vs. $t$ curve at that instant.

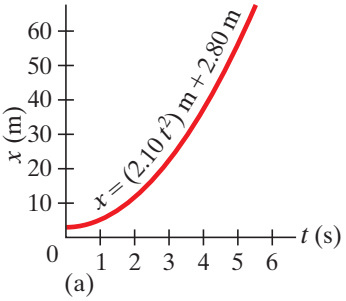
**EXAMPLE 2–8** **Acceleration given $x(t)$.** A particle is moving in a straight line so that its position is given by the relation $x = (2.10\,\text{m/s}^2)t^2 + (2.80\,\text{m})$, as in Example 2–4. Calculate ($a$) its average acceleration during the time interval from $t_1 = 3.00\,\text{s}$ to $t_2 = 5.00\,\text{s}$, and ($b$) its instantaneous acceleration as a function of time.

**APPROACH** To determine acceleration, we first must find the velocity at $t_1$ and $t_2$ by differentiating $x$: $v = dx/dt$. Then we use Eq. 2–5 to find the average acceleration, and Eq. 2–6 to find the instantaneous acceleration.

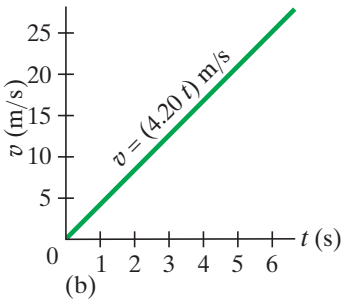
**SOLUTION** ($a$) The velocity at any time $t$ is

$$v = \frac{dx}{dt} = \frac{d}{dt}\left[(2.10\,\text{m/s}^2)t^2 + 2.80\,\text{m}\right] = (4.20\,\text{m/s}^2)t,$$

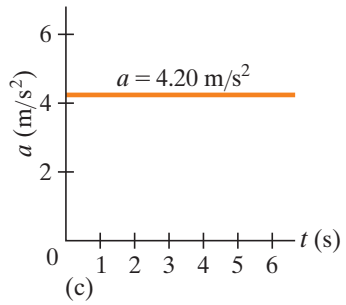
as we already saw in Example 2–4*c*. Therefore, at time $t_1 = 3.00\,\text{s}$, $v_1 = (4.20\,\text{m/s}^2)(3.00\,\text{s}) = 12.6\,\text{m/s}$ and at $t_2 = 5.00\,\text{s}$, $v_2 = 21.0\,\text{m/s}$. Therefore,



$$\bar{a} = \frac{\Delta v}{\Delta t} = \frac{21.0\,\text{m/s} - 12.6\,\text{m/s}}{5.00\,\text{s} - 3.00\,\text{s}} = 4.20\,\text{m/s}^2.$$



($b$) With $v = (4.20\,\text{m/s}^2)t$, the instantaneous acceleration at any time is



$$a = \frac{dv}{dt} = \frac{d}{dt}\left[(4.20\,\text{m/s}^2)t\right] = 4.20\,\text{m/s}^2.$$

The acceleration in this case is constant; it does not depend on time. Figure 2–18 shows graphs of (a) $x$ vs. $t$ (the same as Fig. 2–13b), (b) $v$ vs. $t$, which is linearly increasing as calculated above, and (c) $a$ vs. $t$, which is a horizontal straight line because $a$ = constant.

**FIGURE 2–18** Example 2–8. Graphs of (a) $x$ vs. $t$, (b) $v$ vs. $t$, and (c) $a$ vs. $t$ for the motion $x = At^2 + B$. Note that $v$ increases linearly with $t$ and that the acceleration $a$ is constant. Also, $v$ is the slope of the $x$ vs. $t$ curve, whereas $a$ is the slope of the $v$ vs. $t$ curve.

Like velocity, acceleration is a rate. The velocity of an object is the rate at which its displacement changes with time; its acceleration, on the other hand, is the rate at which its velocity changes with time. In a sense, acceleration is a "rate of a rate."

This can be expressed in equation form: since $a = dv/dt$ and $v = dx/dt$, then

$$a = \frac{dv}{dt} = \frac{d}{dt}\left(\frac{dx}{dt}\right) = \frac{d^2x}{dt^2}.$$

Here $d^2x/dt^2$ is the *second derivative* of $x$ with respect to time: we first take the derivative of $x$ with respect to time $(dx/dt)$, and then we again take the derivative with respect to time, $(d/dt)(dx/dt)$, to get the acceleration.

**EXERCISE E** The position of a particle is given by the following equation:

$$x = (2.00\,\text{m/s}^3)t^3 + (2.50\,\text{m/s})t.$$

What is the acceleration of the particle at $t = 2.00$ s? Choose one: (*a*) 13.0 m/s$^2$; (*b*) 22.5 m/s$^2$; (*c*) 24.0 m/s$^2$; (*d*) 2.00 m/s$^2$; (*e*) 21.0 m/s$^2$.

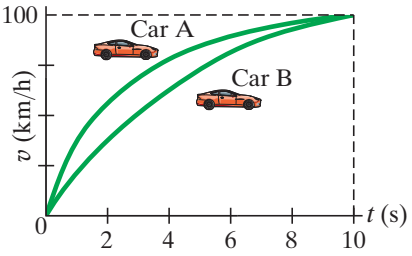


**FIGURE 2–19** Example 2–9.

**CONCEPTUAL EXAMPLE 2–9** **Analyzing with graphs.** Figure 2–19 shows the velocity as a function of time for two cars accelerating from 0 to 100 km/h in a time of 10.0 s. Compare for the two cars: (*a*) the average acceleration; (*b*) the instantaneous acceleration; and (*c*) the total distance traveled.

**RESPONSE** (*a*) Average acceleration is $\Delta v/\Delta t$. Both cars have the same $\Delta v$ (100 km/h) and the same $\Delta t$ (10.0 s), so the average acceleration is the same for both cars. (*b*) Instantaneous acceleration is the slope of the tangent to the $v$ vs. $t$ curve. For about the first 4 s, the top curve is steeper than the bottom curve, so car A has a greater instantaneous acceleration during this interval. The bottom curve is steeper during the last 6 s, so car B has the larger acceleration during this period. (*c*) Except at $t = 0$ and $t = 10.0$ s, car A is always going faster than car B. Since it is going faster, it will go farther in the same time. Notice what marvelous information we can get from a graph.

## 2–5 Motion at Constant Acceleration

We now examine motion in a straight line when the magnitude of the acceleration is constant. In this case, the instantaneous and average acceleration are equal. We use the definitions of average velocity and acceleration to derive a set of valuable equations that relate $x$, $v$, $a$, and $t$ when $a$ is constant, allowing us to determine any one of these variables if we know the others.

Notation in physics varies from book to book; and different instructors use different notation. We are now going to change our notation, to simplify it a bit for our discussion here of motion at **constant acceleration**. First we choose the initial time in any discussion to be zero, and we call it $t_0$. That is, $t_1 = t_0 = 0$. (This is effectively starting a stopwatch at $t_0$.) We can then let $t_2 = t$ be the elapsed time. The initial position $(x_1)$ and the initial velocity $(v_1)$ of an object will now be represented by $x_0$ and $v_0$, since they represent $x$ and $v$ at $t = 0$. At time $t$ the position and velocity will be called $x$ and $v$ (rather than $x_2$ and $v_2$). The average velocity during the time interval $t - t_0$ will be (Eq. 2–2)

$$\bar{v} = \frac{\Delta x}{\Delta t} = \frac{x - x_0}{t - t_0} = \frac{x - x_0}{t}$$

since we chose $t_0 = 0$. The acceleration, assumed constant in time, is $a = \Delta v/\Delta t$ (Eq. 2–5), so

$$a = \frac{v - v_0}{t}.$$

A common problem is to determine the velocity of an object after any elapsed time $t$, when we are given the object's constant acceleration. We can solve such problems by solving for $v$ in the last equation: first we multiply both sides by $t$, which gives $at = v - v_0$, and then

$$v = v_0 + at. \qquad \text{[constant acceleration]} \quad \textbf{(2–7)}$$

If an object, such as a motorcycle, starts from rest $(v_0 = 0)$ and accelerates

at $4.0\,\text{m/s}^2$, then after an elapsed time $t = 6.0\,\text{s}$ its velocity will be $v = 0 + at = (4.0\,\text{m/s}^2)(6.0\,\text{s}) = 24\,\text{m/s}$.

Next, let us see how to calculate the position $x$ of an object after a time $t$ when it undergoes constant acceleration. The definition of average velocity (Eq. 2–2) is $\bar{v} = (x - x_0)/t$, which we can rewrite by multiplying both sides by $t$:

$$x = x_0 + \bar{v}t. \qquad \textbf{(2–8)}$$

Because the velocity increases at a uniform rate, the average velocity, $\bar{v}$, will be midway between the initial and final velocities:

$$\bar{v} = \frac{v_0 + v}{2}. \qquad \text{[constant acceleration]} \quad \textbf{(2–9)}$$

**CAUTION**
*Average velocity, but only if $a$ = constant*

(Careful: Equation 2–9 is not necessarily valid if the acceleration is not constant.) We combine the last two Equations with Eq. 2–7 and find, starting with Eq. 2–8,

$$\begin{aligned} x &= x_0 + \bar{v}t \\ &= x_0 + \left(\frac{v_0 + v}{2}\right)t \\ &= x_0 + \left(\frac{v_0 + v_0 + at}{2}\right)t \end{aligned}$$

or

$$x = x_0 + v_0 t + \tfrac{1}{2}at^2. \qquad \text{[constant acceleration]} \quad \textbf{(2–10)}$$

Equations 2–7, 2–9, and 2–10 are three of the four most useful equations for motion at constant acceleration. We now derive the fourth equation, which is useful in situations where the time $t$ is not known. We substitute Eq. 2–9 into Eq. 2–8:

$$x = x_0 + \bar{v}t = x_0 + \left(\frac{v + v_0}{2}\right)t.$$

Next we solve Eq. 2–7 for $t$, obtaining

$$t = \frac{v - v_0}{a},$$

and substituting this into the previous equation we have

$$x = x_0 + \left(\frac{v + v_0}{2}\right)\left(\frac{v - v_0}{a}\right) = x_0 + \frac{v^2 - v_0^2}{2a}.$$

We solve this for $v^2$ and obtain

$$v^2 = v_0^2 + 2a(x - x_0), \qquad \text{[constant acceleration]} \quad \textbf{(2–11)}$$

which is the other useful equation we sought.

We now have four equations relating position, velocity, acceleration, and time, when the acceleration $a$ is constant. We collect these *kinematic equations for constant acceleration* here in one place for further reference (the tan background is used to emphasize their importance):

$$v = v_0 + at \qquad [a = \text{constant}] \quad \textbf{(2–12a)}$$

$$x = x_0 + v_0 t + \tfrac{1}{2}at^2 \qquad [a = \text{constant}] \quad \textbf{(2–12b)}$$

$$v^2 = v_0^2 + 2a(x - x_0) \qquad [a = \text{constant}] \quad \textbf{(2–12c)}$$

$$\bar{v} = \frac{v + v_0}{2}. \qquad [a = \text{constant}] \quad \textbf{(2–12d)}$$

*Kinematic equations for constant acceleration (we'll use them a lot)*

These useful equations are not valid unless $a$ is a constant. In many cases we can set $x_0 = 0$, and this simplifies the above equations a bit. Note that $x$ represents position (not distance), and that $x - x_0$ is the displacement, whereas $t$ is the elapsed time.

Equations 2–12 are useful also when $a$ is approximately constant, in order to obtain reasonable estimates.

PHYSICS APPLIED
*Airport design*

**EXAMPLE 2–10** **Runway design.** You are designing an airport for small planes. One kind of airplane that might use this airfield must reach a speed before takeoff of at least 27.8 m/s (100 km/h), and can accelerate at 2.00 m/s$^2$. (*a*) If the runway is 150 m long, can this airplane reach the required speed for takeoff? (*b*) If not, what minimum length must the runway have?

**APPROACH** Assuming the plane's acceleration is constant, we use the kinematic equations for constant acceleration. In (*a*), we want to find $v$, and we are given:

| Known | Wanted |
|---|---|
| $x_0 = 0$ | $v$ |
| $v_0 = 0$ | |
| $x = 150\text{ m}$ | |
| $a = 2.00\text{ m/s}^2$ | |

**SOLUTION** (*a*) Of the four kinematic equations on page 31, Eq. 2–12c will give us $v$ when we know $v_0$, $a$, $x$, and $x_0$:

$$\begin{aligned} v^2 &= v_0^2 + 2a(x - x_0) \\ &= 0 + 2(2.00\text{ m/s}^2)(150\text{ m}) = 600\text{ m}^2/\text{s}^2 \\ v &= \sqrt{600\text{ m}^2/\text{s}^2} = 24.5\text{ m/s}. \end{aligned}$$

PROBLEM SOLVING
*Equations 2–12 are valid only when the acceleration is constant, which we assume in this Example*

This runway length is *not* sufficient, because the minimum speed is not reached. (*b*) Now we want to find the minimum runway length, $x - x_0$, for a plane to reach $v = 27.8\text{ m/s}$, given $a = 2.00\text{ m/s}^2$. We again use Eq. 2–12c, but rewritten as

$$(x - x_0) = \frac{v^2 - v_0^2}{2a} = \frac{(27.8\text{ m/s})^2 - 0}{2(2.00\text{ m/s}^2)} = 193\text{ m}.$$

A 200-m runway is more appropriate for this plane.

**NOTE** We did this Example as if the plane were a particle, so we round off our answer to 200 m.

PHYSICS APPLIED
*Car safety—air bags*

**EXAMPLE 2–11** **ESTIMATE** **Air bags.** Suppose you want to design an air bag system that can protect the driver at a speed of 100 km/h (60 mph) if the car hits a brick wall. Estimate how fast the air bag must inflate (Fig. 2–20) to effectively protect the driver. How does the use of a seat belt help the driver?

**FIGURE 2–20** Example 2–11. An air bag deploying on impact.

**APPROACH** We assume the acceleration is roughly constant, so we can use Eqs. 2–12. Both Eqs. 2–12a and 2–12b contain $t$, our desired unknown. They both contain $a$, so we must first find $a$, which we can do using Eq. 2–12c if we know the distance $x$ over which the car crumples. A rough estimate might be about 1 meter. We choose the time interval to start at the instant of impact with the car moving at $v_0 = 100\text{ km/h}$, and to end when the car comes to rest ($v = 0$) after traveling 1 m.

**SOLUTION** We convert the given initial speed to SI units: $100\text{ km/h} = 100 \times 10^3\text{ m}/3600\text{ s} = 28\text{ m/s}$. We then find the acceleration from Eq. 2–12c:

$$a = -\frac{v_0^2}{2x} = -\frac{(28\text{ m/s})^2}{2.0\text{ m}} = -390\text{ m/s}^2.$$

This enormous acceleration takes place in a time given by (Eq. 2–12a):

$$t = \frac{v - v_0}{a} = \frac{0 - 28\text{ m/s}}{-390\text{ m/s}^2} = 0.07\text{ s}.$$

To be effective, the air bag would need to inflate faster than this.

What does the air bag do? It spreads the force over a large area of the chest (to avoid puncture of the chest by the steering wheel). The seat belt keeps the person in a stable position directly in front of the expanding air bag.

**EXERCISE F** A car starts from rest and accelerates at a constant $10\,\text{m/s}^2$ during a $\frac{1}{4}$-mile (402 m) race. How fast is the car going at the finish line? (*a*) 8040 m/s; (*b*) 90 m/s; (*c*) 81 m/s; (*d*) 804 m/s.

## 2–6 Solving Problems

Before doing more worked-out Examples, let us look at how to approach problem solving. First, it is important to note that physics is *not* a collection of equations to be memorized. Simply searching for an equation that might work can lead you to a wrong result and will not help you understand physics (Fig. 2–21). A better approach is to use the following (rough) procedure, which we present as a special "Problem Solving Strategy." (Other such Problem Solving Strategies will be found throughout the book.)

**FIGURE 2–21** Read each Chapter of this book, study it by reading it again carefully, and work the Problems using your reasoning abilities.

### PROBLEM SOLVING

**1.** Read and **reread** the whole problem carefully before trying to solve it.

**2.** Decide what **object** (or objects) you are going to study, and for what **time interval**. You can often choose the initial time to be $t = 0$.

**3.** **Draw** a **diagram** or picture of the situation, with coordinate axes wherever applicable. [You can place the origin of coordinates and the axes wherever you like to make your calculations easier. You also choose which direction is positive and which is negative. Usually we choose the $x$ axis to the right as positive.]

**4.** Write down what quantities are "**known**" or "given," and then what you *want* to know ("unknowns"). Consider quantities both at the beginning and at the end of the chosen time interval. You may need to "translate" language into physical terms, such as "starts from rest" means $v_0 = 0$.

**5.** Think about which **principles of physics** apply in this problem. Use common sense and your own experiences. Then plan an approach.

**6.** Consider which **equations** (and/or definitions) relate the quantities involved. Before using them, be sure their **range of validity** includes your problem (for example, Eqs. 2–12 are valid only when the acceleration is constant). If you find an applicable equation that involves only known quantities and one desired unknown, **solve** the equation algebraically for the unknown. Sometimes several sequential calculations, or a combination of equations, may be needed. It is often preferable to solve algebraically for the desired unknown before putting in numerical values.

**7.** Carry out the **calculation** if it is a numerical problem. Keep one or two extra digits during the calculations, but round off the final answer(s) to the correct number of significant figures (Section 1–3).

**8.** Think carefully about the result you obtain: Is it **reasonable**? Does it make sense according to your own intuition and experience? A good check is to do a rough **estimate** using only powers of 10, as discussed in Section 1–6. Often it is preferable to do a rough estimate at the *start* of a numerical problem because it can help you focus your attention on finding a path toward a solution.

**9.** A very important aspect of doing problems is keeping track of **units**. An equals sign implies the units on each side must be the same, just as the numbers must. If the units do not balance, a mistake has been made. This can serve as a **check** on your solution (but it only tells you if you're wrong, not if you're right). Always use a consistent set of units.

**PROBLEM SOLVING**
*"Starting from rest" means $v = 0$ at $t = 0$ [i.e., $v_0 = 0$]*

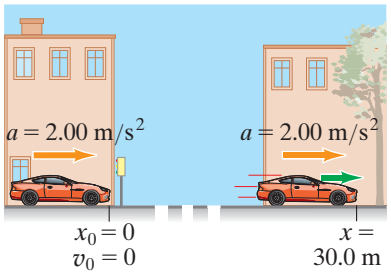

**FIGURE 2–22** Example 2–12. (Not to scale.)

| Known | Wanted |
|---|---|
| $x_0 = 0$ | $t$ |
| $x = 30.0\ \text{m}$ | |
| $a = 2.00\ \text{m/s}^2$ | |
| $v_0 = 0$ | |

**EXAMPLE 2–12** **Acceleration of a car.** How long does it take a 4.0-m-long car to cross a 26.0-m-wide intersection after the light turns green, if the car accelerates from rest at a constant $2.00\ \text{m/s}^2$? The car has to travel $26.0\ \text{m} + 4.0\ \text{m} = 30.0\ \text{m}$ to clear the intersection.

**APPROACH** We follow the Problem Solving Strategy on the previous page.

**SOLUTION**

1. **Reread** the problem. Be sure you understand what it asks for (here, a time interval: "how long does it take").
2. The **object** under study is the car. We need to choose the **time interval** during which we look at the car's motion: we choose $t = 0$, the initial time, to be the moment the car starts to accelerate from rest $(v_0 = 0)$; the time $t$ is the instant the car has traveled the full 30.0 m of the intersection.
3. **Draw a diagram**: the situation is shown in Fig. 2–22 where the car is shown moving along the positive $x$ axis. We choose $x_0 = 0$ at the front bumper of the car before it starts to move.
4. The "**knowns**" and the "wanted" information are shown in the Table in the margin. Note that "starting from rest" means $v = 0$ at $t = 0$; that is, $v_0 = 0$. The wanted time $t$ is how long it takes the car to travel 30.0 m.
5. The **physics**: the car, starting from rest $(\text{at } t_0 = 0)$, increases in speed as it covers more distance. The acceleration is constant, so we can use the kinematic equations, Eqs. 2–12.
6. **Equations**: we want to find the time, given the distance and acceleration; Eq. 2–12b $\left(x = x_0 + v_0 t + \frac{1}{2}at^2\right)$ is perfect since the only unknown quantity is $t$. Setting $v_0 = 0$ and $x_0 = 0$ in Eq. 2–12b, we have
$$x = \tfrac{1}{2}at^2.$$
We solve for $t$
$$t = \sqrt{\frac{2x}{a}}.$$
7. The **calculation**:
$$t = \sqrt{\frac{2x}{a}} = \sqrt{\frac{2(30.0\ \text{m})}{2.00\ \text{m/s}^2}} = 5.48\ \text{s}.$$
This is our answer. Note that the units come out correctly.

**PROBLEM SOLVING**
*Check your answer*

8. We can check the **reasonableness** of the answer by doing an alternate calculation: we use our result in step 7 and check if the distance traveled turns out to be 30.0 m. First we find the final velocity (Eq. 2–12a),
$$v = at = (2.00\ \text{m/s}^2)(5.48\ \text{s}) = 10.96\ \text{m/s},$$
and then find the distance traveled using the definition of average velocity (see Eq. 2–8).
$$x = x_0 + \bar{v}t = 0 + \tfrac{1}{2}(10.96\ \text{m/s} + 0)(5.48\ \text{s}) = 30.0\ \text{m},$$
which checks with our given distance.
9. We checked the **units** in step 7, and they came out correctly (seconds).

**NOTE** In steps 6 and 7, when we took the square root, we should have written $t = \pm\sqrt{2x/a} = \pm 5.48\ \text{s}$. Mathematically there are two solutions. But the second solution, $t = -5.48\ \text{s}$, is a time *before* our chosen time interval and makes no sense physically. We say it is "unphysical" and ignore it.

**PROBLEM SOLVING**
*"Unphysical" solutions*

We explicitly followed the steps of the Problem Solving Strategy in Example 2–12. In upcoming Examples, we will use our usual "Approach" and "Solution" to avoid being wordy.

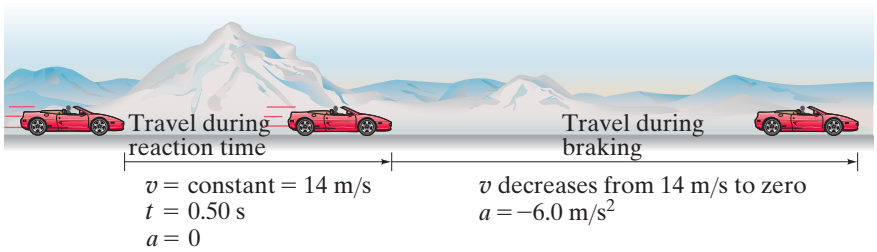

**FIGURE 2–23** Example 2–13: stopping distance for a braking car.

**EXAMPLE 2–13** ESTIMATE **Braking distances.** Estimate the minimum stopping distance for a car, which is important for traffic safety and traffic design. The problem is best dealt with in two parts, two separate time intervals. (1) The first time interval begins when the driver decides to hit the brakes, and ends when the foot touches the brake pedal. This is the "reaction time" during which the speed is constant, so $a = 0$. (2) The second time interval is the actual braking period when the vehicle slows down ($a \neq 0$) and comes to a stop. The stopping distance depends on the reaction time of the driver, the initial speed of the car (the final speed is zero), and the deceleration of the car. For a dry road and good tires, good brakes can decelerate a car at a rate of about 5 m/s² to 8 m/s². Calculate the total stopping distance for an initial velocity of 50 km/h ($= 14$ m/s $\approx 31$ mi/h) and assume the acceleration of the car is $-6.0$ m/s² (the minus sign appears because the velocity is taken to be in the positive $x$ direction and its magnitude is decreasing). Reaction time for typical drivers varies from perhaps 0.3 s to about 1.0 s; take it to be 0.50 s.

PHYSICS APPLIED
*Car stopping distances*

**APPROACH** During the "reaction time," part (1), the car moves at constant speed of 14 m/s, so $a = 0$. Once the brakes are applied, part (2), the acceleration is $a = -6.0$ m/s² and is constant over this time interval. For both parts $a$ is constant, so we can use Eqs. 2–12.

**SOLUTION** Part (1). We take $x_0 = 0$ for the first time interval, when the driver is reacting (0.50 s): the car travels at a constant speed of 14 m/s so $a = 0$. See Fig. 2–23 and the Table in the margin. To find $x$, the position of the car at $t = 0.50$ s (when the brakes are first applied), we cannot use Eq. 2–12c because $x$ is multiplied by $a$, which is zero. But Eq. 2–12b works:

$$x = v_0 t + 0 = (14\text{ m/s})(0.50\text{ s}) = 7.0\text{ m}.$$

Thus the car travels 7.0 m during the driver's reaction time, until the instant the brakes are applied. We will use this result as input to part (2).

Part (2). During the second time interval, the brakes are applied and the car is brought to rest. The initial position is $x_0 = 7.0$ m (result of part (1)), and other variables are shown in the second Table in the margin. Equation 2–12a doesn't contain $x$; Eq. 2–12b contains $x$ but also the unknown $t$. Equation 2–12c, $v^2 - v_0^2 = 2a(x - x_0)$, is what we want; after setting $x_0 = 7.0$ m, we solve for $x$, the final position of the car (where it stops):

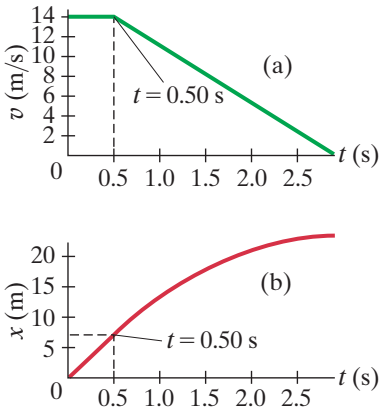
$$x = x_0 + \frac{v^2 - v_0^2}{2a}$$

$$= 7.0\text{ m} + \frac{0 - (14\text{ m/s})^2}{2(-6.0\text{ m/s}^2)} = 7.0\text{ m} + \frac{-196\text{ m}^2/\text{s}^2}{-12\text{ m/s}^2}$$

$$= 7.0\text{ m} + 16\text{ m} = 23\text{ m}.$$

The car traveled 7.0 m while the driver was reacting and another 16 m during the braking period before coming to a stop, for a total distance traveled of 23 m. Figure 2–24 shows graphs of (a) $v$ vs. $t$ (we were given that $v$ is constant from $t = 0$ until $t = 0.50$ s, and after $t = 0.50$ s it decreases linearly to zero), and (b) $x$ vs. $t$.

**NOTE** From the equation above for $x$, we see that the stopping distance after the driver hit the brakes $(= x - x_0)$ increases with the *square* of the initial speed, not just linearly with speed. If you are traveling twice as fast, it takes *four* times the distance to stop (when braking at the same rate, $a$).



*Part 1: Reaction time*

| Known | Wanted |
|---|---|
| $t = 0.50$ s | $x$ |
| $v_0 = 14$ m/s | |
| $v = 14$ m/s | |
| $a = 0$ | |
| $x_0 = 0$ | |

*Part 2: Braking*

| Known | Wanted |
|---|---|
| $x_0 = 7.0$ m | $x$ |
| $v_0 = 14$ m/s | |
| $v = 0$ | |
| $a = -6.0$ m/s² | |

**FIGURE 2–24** Example 2–13. Graphs of (*a*) $v$ vs. $t$ and (*b*) $x$ vs. $t$.

**EXAMPLE 2–14** **ESTIMATE** **Two Moving Objects: Police and Speeder.** A car speeding at 150 km/h (over 90 mph) passes a still police car which immediately takes off in hot pursuit. Using simple assumptions, such as that the speeder continues at constant speed, estimate how long it takes the police car to overtake the speeder. Then estimate the police car's speed at that moment and decide if the assumptions were reasonable.

**PROBLEM SOLVING**
*Guess the acceleration*

**APPROACH** When the police car takes off, it accelerates, and the simplest assumption is that its acceleration is constant. This may not be reasonable, but let's see what happens. We can estimate the acceleration if we have noticed automobile ads, which claim cars can accelerate from rest to 100 km/h in 5.0 s. So the average acceleration of the police car could be approximately

$$a_P = \frac{100\,\text{km/h}}{5.0\,\text{s}} = 20\,\frac{\text{km/h}}{\text{s}}\left(\frac{1000\,\text{m}}{1\,\text{km}}\right)\left(\frac{1\,\text{h}}{3600\,\text{s}}\right) = 5.6\,\text{m/s}^2.$$

**SOLUTION** We need to set up the kinematic equations to determine the unknown quantities, and since there are two moving objects, we need two separate sets of equations. We denote the speeding car's position by $x_S$ and the police car's position by $x_P$. Because we are interested in solving for the time when the two vehicles arrive at the same position on the road, we use Eq. 2–12b for each car ($x_0 = 0$ for both cars):

$$x_S = v_{0S}t + \tfrac{1}{2}a_S t^2 = (150\,\text{km/h})t + 0 = (42\,\text{m/s})t$$
$$x_P = v_{0P}t + \tfrac{1}{2}a_P t^2 = 0 + \tfrac{1}{2}(5.6\,\text{m/s}^2)t^2,$$

where we have set $v_{0P} = 0$ and $a_S = 0$ (speeder assumed to move at constant speed). We want the time when the cars meet, so we set $x_S = x_P$ and solve for $t$:

$$(42\,\text{m/s})t = (2.8\,\text{m/s}^2)t^2.$$

The solutions are

$$t = 0 \quad \text{and} \quad t = \frac{42\,\text{m/s}}{2.8\,\text{m/s}^2} = 15\,\text{s}.$$

The first solution corresponds to the instant the speeder passed the police car. The second solution tells us when the police car catches up to the speeder, 15 s later. This is our answer, but is it reasonable? The police car's speed at $t = 15$ s is

$$v_P = v_{0P} + a_P t = 0 + (5.6\,\text{m/s}^2)(15\,\text{s}) = 84\,\text{m/s}$$

or 300 km/h ($\approx$ 190 mi/h). Not reasonable, and highly dangerous.

**CAUTION**
*Initial assumptions need to be checked out for reasonableness*

**NOTE** More reasonable is to give up the assumption of constant acceleration. The police car surely cannot maintain constant acceleration at high speed. Also, the speeder, if a reasonable person, would slow down upon hearing the police siren. Figure 2–25 shows (a) $x$ vs. $t$ and (b) $v$ vs. $t$ graphs, based on the original assumption of $a_P$ = constant, whereas (c) shows $v$ vs. $t$ for more reasonable assumptions.

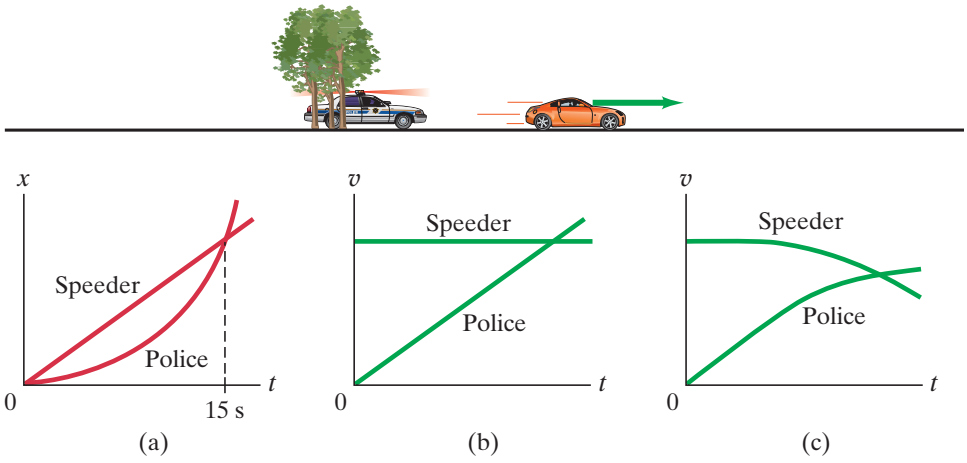


**FIGURE 2–25** Example 2–14.

**FIGURE 2–26** Painting of Galileo demonstrating to the Grand Duke of Tuscany his argument for the action of gravity being uniform acceleration. He used a wooden inclined plane (center) to slow down the action. A ball rolling down the plane still accelerates. Tiny bells placed at equal distances along the inclined plane would ring at shorter time intervals as the ball "fell," indicating that the speed was increasing.

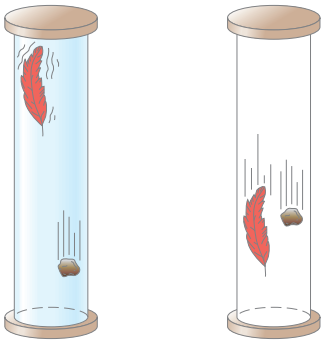
**FIGURE 2–27** Multiflash photograph of a falling apple, at equal time intervals. The apple falls farther during each successive interval, which means it is accelerating.

## 2–7 Freely Falling Objects

One of the most common examples of uniformly accelerated motion is that of an object allowed to fall freely near the Earth's surface. That a falling object is accelerating may not be obvious at first. And beware of thinking, as was widely believed before the time of Galileo (Fig. 2–26), that heavier objects fall faster than lighter objects and that the speed of fall is proportional to how heavy the object is. Wrong. *The speed of a falling object is* not *proportional to its mass*.

Galileo made use of his new technique of imagining what would happen in idealized (simplified) cases. For free fall, he postulated that *all objects would fall with the same constant acceleration in the absence of air or other resistance*. He showed that this postulate predicts that for an object falling from rest, the distance traveled will be proportional to the square of the time (Fig. 2–27); that is, $d \propto t^2$. We can see this from Eq. 2–12b for constant acceleration; but Galileo was the first to deduce this mathematical relation.

To support his claim that falling objects increase in speed as they fall, Galileo made use of a clever argument: a heavy stone dropped from a height of 2 m will drive a stake into the ground much further than if the same stone is dropped from a height of only 0.2 m. Clearly, the stone must be moving faster in the former case.



Galileo claimed that *all* objects, light or heavy, fall with the *same* acceleration, at least in the absence of air. If you hold a piece of paper flat and horizontal in one hand, and a heavier object like a baseball in the other, and release them at the same time as in Fig. 2–28a, the heavier object will reach the ground first. But if you repeat the experiment, this time crumpling the paper into a small wad, you will find (see Fig. 2–28b) that the two objects reach the floor at nearly the same time.

Galileo was sure that air acts as a resistance to very light objects that have a large surface area. But in many ordinary circumstances this air resistance is negligible. In a chamber from which the air has been removed, even light objects like a feather or a horizontally held piece of paper will fall with the same acceleration as any other object (see Fig. 2–29). Such a demonstration in vacuum was not possible in Galileo's time, which makes Galileo's achievement all the greater. Galileo is often called the "father of modern science," not only for the *content* of his science: astronomical discoveries, inertia, free fall; but also for his new methods of *doing* science: idealization and simplification, mathematization of theory, theories that have testable consequences, experiments to test theoretical predictions.

**FIGURE 2–28** (a) A ball and a light piece of paper are dropped at the same time. (b) Repeated, with the paper wadded up.

**FIGURE 2–29** A rock and a feather are dropped simultaneously (a) in air, (b) in a vacuum.

Galileo's specific contribution to our understanding of the motion of falling objects can be summarized as follows:

> **at a given location on the Earth and in the absence of air resistance, all objects fall with the same constant acceleration.**

We call this acceleration the **acceleration due to gravity** at the surface of the Earth, and we give it the symbol $g$. Its magnitude is approximately

$$g = 9.80\ \text{m/s}^2. \qquad \left[\begin{array}{l}\text{acceleration due to gravity}\\ \text{at surface of Earth}\end{array}\right]$$

In British units $g$ is about $32\ \text{ft/s}^2$. Actually, $g$ varies slightly according to latitude and elevation above sea level on the Earth's surface, but these variations are so small that we will ignore them for most purposes. (Acceleration of gravity out in space beyond the Earth's surface is treated in Chapter 6.) Air resistance acts to reduce the speed of a falling object, but this effect is often small, and we will neglect it for the most part. However, air resistance will be noticeable even on a reasonably heavy object if the velocity becomes large.[†]

Acceleration due to gravity is a vector, as is any acceleration, and its direction is downward toward the center of the Earth.

When dealing with freely falling objects we can make use of Eqs. 2–12, where for $a$ we use the value of $g$ given above. Also, since the motion is vertical we will substitute $y$ in place of $x$, and $y_0$ in place of $x_0$. We take $y_0 = 0$ unless otherwise specified. *It is arbitrary whether we choose y to be positive in the upward direction or in the downward direction; but we must be consistent about it throughout a problem's solution.*

**PROBLEM SOLVING**
*You can choose y to be positive either up or down*

**EXERCISE G** Return to the Chapter-Opening Question, page 20, and answer it again now, assuming minimal air resistance. Try to explain why you may have answered differently the first time.

**EXAMPLE 2–15** **Falling from a tower.** Suppose that a ball is dropped ($v_0 = 0$) from a tower. How far will it have fallen after a time $t_1 = 1.00\,\text{s}$, $t_2 = 2.00\,\text{s}$, and $t_3 = 3.00\,\text{s}$? Ignore air resistance.

**APPROACH** Let us take $y$ as positive downward, so the acceleration is $a = g = +9.80\ \text{m/s}^2$. We set $v_0 = 0$ and $y_0 = 0$. We want to find the position $y$ of the ball after three different time intervals. Equation 2–12b, with $x$ replaced by $y$, relates the given quantities ($t$, $a$, and $v_0$) to the unknown $y$.

**SOLUTION** We set $t = t_1 = 1.00\,\text{s}$ in Eq. 2–12b:

$$y_1 = v_0 t_1 + \tfrac{1}{2}at_1^2$$
$$= 0 + \tfrac{1}{2}at_1^2 = \tfrac{1}{2}(9.80\,\text{m/s}^2)(1.00\,\text{s})^2 = 4.90\,\text{m}.$$

The ball has fallen a distance of 4.90 m during the time interval $t = 0$ to $t_1 = 1.00\,\text{s}$. Similarly, after $2.00\,\text{s}$ $(= t_2)$, the ball's position is

$$y_2 = \tfrac{1}{2}at_2^2 = \tfrac{1}{2}(9.80\,\text{m/s}^2)(2.00\,\text{s})^2 = 19.6\,\text{m}.$$

Finally, after $3.00\,\text{s}$ $(= t_3)$, the ball's position is (see Fig. 2–30a)

$$y_3 = \tfrac{1}{2}at_3^2 = \tfrac{1}{2}(9.80\,\text{m/s}^2)(3.00\,\text{s})^2 = 44.1\,\text{m}.$$

**NOTE** Whenever we say "dropped," it means $v_0 = 0$. Note also the graph of $y$ vs. $t$ (Fig. 2–30b): the curve is not straight but bends upward because $y$ is proportional to $t^2$.

**NOTE** Because of air resistance, all of the distances in Fig. 2–30, $y_1$, $y_2$, $y_3$, would be smaller than shown (and as just calculated); but the difference will be small for a reasonably heavy (but small) object.

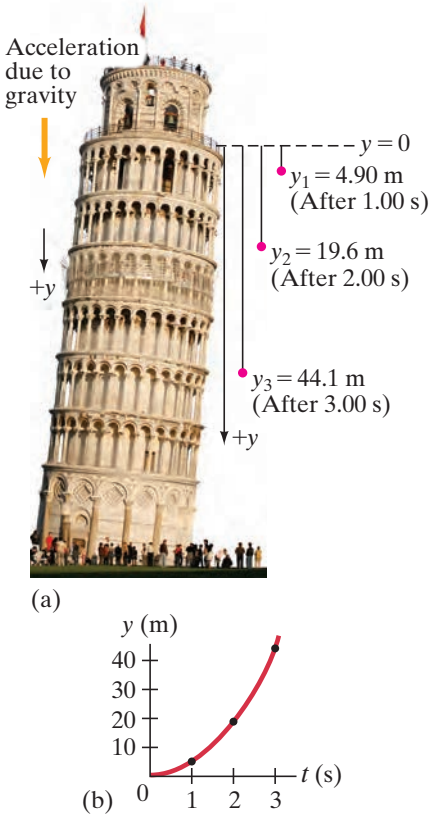


**FIGURE 2–30** Example 2–15. (a) An object dropped from a tower falls with progressively greater speed and covers greater distance with each successive second. (See also Fig. 2–27.) (b) Graph of $y$ vs. $t$ ($y$ is + downward).

[†]The speed of an object falling in air (or other fluid) does not increase indefinitely. If the object falls far enough, it will reach a maximum velocity called the **terminal velocity** due to air resistance. (Section 5–6 deals directly with air resistance.)

**EXAMPLE 2–16** **Thrown down from a tower.** Suppose the ball in Example 2–15 is *thrown* downward with an initial velocity of 3.00 m/s, instead of being dropped. (*a*) What then would be its position after 1.00 s and 2.00 s? (*b*) What would its speed be after 1.00 s and 2.00 s? Compare with the speeds of a dropped ball.

**APPROACH** Again we use Eq. 2–12b, but now $v_0$ is not zero, it is $v_0 = 3.00\,\text{m/s}$.

**SOLUTION** (*a*) At $t_1 = 1.00\,\text{s}$, the position of the ball as given by Eq. 2–12b is

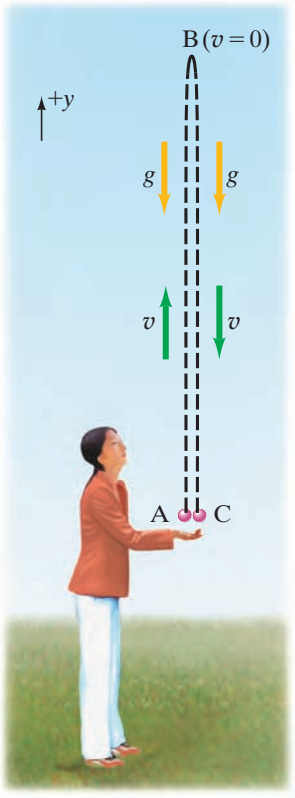
$$y = v_0 t + \tfrac{1}{2}at^2 = (3.00\,\text{m/s})(1.00\,\text{s}) + \tfrac{1}{2}(9.80\,\text{m/s}^2)(1.00\,\text{s})^2 = 7.90\,\text{m}.$$

At $t_2 = 2.00\,\text{s}$ (time interval $t = 0$ to $t = 2.00\,\text{s}$), the position is

$$y = v_0 t + \tfrac{1}{2}at^2 = (3.00\,\text{m/s})(2.00\,\text{s}) + \tfrac{1}{2}(9.80\,\text{m/s}^2)(2.00\,\text{s})^2 = 25.6\,\text{m}.$$

As expected, the ball falls farther each second than when it is dropped with $v_0 = 0$, Example 2–15.

(*b*) The velocity is obtained from Eq. 2–12a:



$$\begin{aligned} v &= v_0 + at \\ &= 3.00\,\text{m/s} + (9.80\,\text{m/s}^2)(1.00\,\text{s}) = 12.8\,\text{m/s} \quad [\text{at } t_1 = 1.00\,\text{s}] \\ &= 3.00\,\text{m/s} + (9.80\,\text{m/s}^2)(2.00\,\text{s}) = 22.6\,\text{m/s}. \quad [\text{at } t_2 = 2.00\,\text{s}] \end{aligned}$$

In Example 2–15, when the ball was dropped $(v_0 = 0)$, the first term $(v_0)$ in these equations was zero, so

$$\begin{aligned} v &= 0 + at \\ &= (9.80\,\text{m/s}^2)(1.00\,\text{s}) = 9.80\,\text{m/s} \quad [\text{at } t_1 = 1.00\,\text{s}] \\ &= (9.80\,\text{m/s}^2)(2.00\,\text{s}) = 19.6\,\text{m/s}. \quad [\text{at } t_2 = 2.00\,\text{s}] \end{aligned}$$

**NOTE** For both Examples 2–15 and 2–16 the speed increases linearly in time by 9.80 m/s during each second. But the speed of the downwardly thrown ball at any instant is always 3.00 m/s (its initial speed) greater than that of a dropped ball.

**FIGURE 2–31** An object thrown into the air leaves the thrower's hand at A, reaches its maximum height at B, and returns to the original position at C. Examples 2–17, 2–18, 2–19, 2–20, and 2–21.

**EXAMPLE 2–17** **Ball thrown upward.** A person throws a ball *upward* into the air with an initial velocity of 15.0 m/s. Calculate how high it goes. Ignore air resistance.

**APPROACH** We are not concerned here with the throwing action, but only with the motion of the ball *after* it leaves the thrower's hand (Fig. 2–31) at point A. Let us choose $y$ to be positive in the upward direction and negative in the downward direction. (This is a different convention from that used in Examples 2–15 and 2–16, and so illustrates our options.) The acceleration due to gravity is downward and so will have a negative sign, $a = -g = -9.80\,\text{m/s}^2$. As the ball rises, its speed decreases until it reaches the highest point (B in Fig. 2–31), where its speed is zero for an instant; then it descends, with increasing speed.

**SOLUTION** We consider the time interval from when the ball leaves the thrower's hand until the ball reaches the highest point. To determine the maximum height, we calculate the position of the ball when its velocity equals zero ($v = 0$ at the highest point). At $t = 0$ (point A in Fig. 2–31) we set $y_0 = 0$, $v_0 = 15.0\,\text{m/s}$, and $a = -9.80\,\text{m/s}^2$. At time $t$ (maximum height), $v = 0$, $a = -9.80\,\text{m/s}^2$, and we wish to find $y$. We use Eq. 2–12c, replacing $x$ with $y$: $v^2 = v_0^2 + 2ay$. We solve this equation for $y$:

$$y = \frac{v^2 - v_0^2}{2a} = \frac{0 - (15.0\,\text{m/s})^2}{2(-9.80\,\text{m/s}^2)} = 11.5\,\text{m}.$$

The ball reaches a height of 11.5 m above the hand.

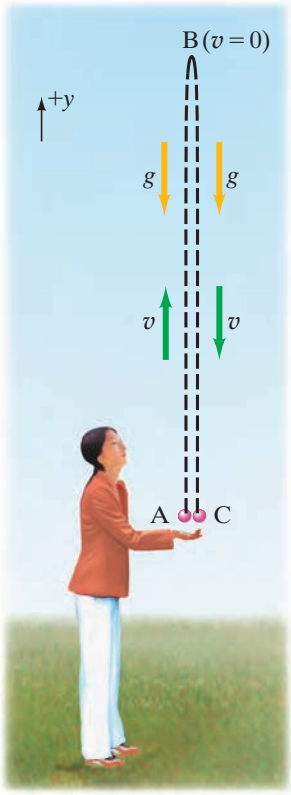


**FIGURE 2–31** (Repeated.) An object thrown into the air leaves the thrower's hand at A, reaches its maximum height at B, and returns to the original position at C. Examples 2–17, 2–18, 2–19, 2–20, and 2–21.

**EXAMPLE 2–18** **Ball thrown upward, II.** In Example 2–17, Fig. 2–31 (shown here again), how long is the ball in the air before it comes back to the hand?

**APPROACH** We need to choose a time interval to calculate how long the ball is in the air before it returns to the hand. We could do this calculation in two parts by first determining the time required for the ball to reach its highest point, and then determining the time it takes to fall back down. However, it is simpler to consider the time interval for the entire motion from A to B to C (Fig. 2–31) in one step and use Eq. 2–12b. We can do this because $y$ is position (or displacement from the origin), and not the total distance traveled. Thus, at both points A and C we have $y = 0$.

**SOLUTION** We use Eq. 2–12b with $a = -9.80\,\text{m/s}^2$ and find

$$y = y_0 + v_0 t + \tfrac{1}{2}at^2$$
$$0 = 0 + (15.0\,\text{m/s})t + \tfrac{1}{2}(-9.80\,\text{m/s}^2)t^2.$$

This equation can be factored (we factor out one $t$):

$$(15.0\,\text{m/s} - 4.90\,\text{m/s}^2\, t)\, t = 0.$$

There are two solutions:

$$t = 0 \quad \text{and} \quad t = \frac{15.0\,\text{m/s}}{4.90\,\text{m/s}^2} = 3.06\,\text{s}.$$

The first solution ($t = 0$) corresponds to the initial point (A) in Fig. 2–31, when the ball was first thrown from $y_0 = 0$. The second solution, $t = 3.06\,\text{s}$, corresponds to point C, when the ball has returned to $y = 0$. Thus the ball is in the air 3.06 s.

**NOTE** We have ignored air resistance in these last two Examples, which could be significant, so our result is only an approximation to a real, practical situation.

We did not consider the throwing action in these Examples. Why? Because during the throw, the thrower's hand is touching the ball and accelerating the ball at a rate unknown to us—the acceleration is *not* $g$. We consider only the time when the ball is in the air and the acceleration is equal to $g$.

Every quadratic equation (where the variable is squared) mathematically produces two solutions. In physics, sometimes only one solution corresponds to the real situation, as we saw in Example 2–12, in which case we ignore the "unphysical" solution. But here in Example 2–18, both solutions to our equation in $t^2$ are physically meaningful: $t = 0$ and $t = 3.06\,\text{s}$.

**CAUTION**

*Quadratic equations have two solutions. Sometimes only one corresponds to reality, sometimes both*

**CONCEPTUAL EXAMPLE 2–19** **Two possible misconceptions.** Give examples to show the error in these two common misconceptions: (1) that acceleration and velocity are always in the same direction, and (2) that an object thrown upward has zero acceleration at the highest point (B in Fig. 2–31).

**RESPONSE** Both are wrong. (1) Velocity and acceleration are *not* necessarily in the same direction. When the ball in Fig. 2–31 is moving upward, its velocity is positive (upward), whereas the acceleration is negative (downward). (2) At the highest point (B in Fig. 2–31), the ball has zero velocity for an instant. Is the acceleration also zero at this point? No. The velocity near the top of the arc points upward, then becomes zero for an instant (zero time) at the highest point, and then points downward. Gravity does not stop acting, so $a = -g = -9.80\,\text{m/s}^2$ even there. Thinking that $a = 0$ at point B would lead to the conclusion that upon reaching point B, the ball would stay there: if the acceleration (= rate of change of velocity) were zero, the velocity would stay zero at the highest point, and the ball would stay up there without falling. Remember: the acceleration of gravity always points down toward the center of the Earth, even when the object is moving up.

**CAUTION**

*(1) Velocity and acceleration are not always in the same direction; the acceleration (of gravity) always points down*
*(2) $a \neq 0$ even at the highest point of a trajectory*

**EXAMPLE 2–20** **Ball thrown upward, III.** Let us consider again the ball thrown upward of Examples 2–17 and 2–18, and make more calculations. Calculate (*a*) how much time it takes for the ball to reach the maximum height (point B in Fig. 2–31), and (*b*) the velocity of the ball when it returns to the thrower's hand (point C).

**APPROACH** Again we assume the acceleration is constant, so we can use Eqs. 2–12. We have the maximum height of 11.5 m and initial speed of 15.0 m/s from Example 2–17. Again we take $y$ as positive upward.

**SOLUTION** (*a*) We consider the time interval between the throw $(t_0 = 0, v_0 = 15.0\,\text{m/s})$ and the top of the path ($y = +11.5\,\text{m}$, $v = 0$), and we want to find $t$. The acceleration is constant at $a = -g = -9.80\,\text{m/s}^2$. Both Eqs. 2–12a and 2–12b contain the time $t$ with other quantities known. Let us use Eq. 2–12a with $a = -9.80\,\text{m/s}^2$, $v_0 = 15.0\,\text{m/s}$, and $v = 0$:

$$v = v_0 + at;$$

setting $v = 0$ gives $0 = v_0 + at$, which we rearrange to solve for $t$: $at = -v_0$ or

$$t = -\frac{v_0}{a} = -\frac{15.0\,\text{m/s}}{-9.80\,\text{m/s}^2} = 1.53\,\text{s}.$$

This is just half the time it takes the ball to go up and fall back to its original position [3.06 s, calculated in Example 2–18]. Thus it takes the *same time* to reach the maximum height as to fall back to the starting point. We might have guessed this from the *symmetry* of the motion. But be careful. When air resistance cannot be neglected, the symmetry is no longer perfect.

(*b*) To find the ball's velocity when it returns to the hand (point C), we consider the time interval from the throw $(t_0 = 0, v_0 = 15.0\,\text{m/s})$ until the ball's return to the hand, which occurs at $t = 3.06\,\text{s}$ (as calculated in Example 2–18). We use Eq. 2–12a again to find $v$ when $t = 3.06\,\text{s}$:

$$\begin{aligned} v &= v_0 + at \\ &= 15.0\,\text{m/s} - (9.80\,\text{m/s}^2)(3.06\,\text{s}) = -15.0\,\text{m/s}. \end{aligned}$$

**NOTE** The ball has the same speed (magnitude of velocity) when it returns to the starting point as it did initially, but in the opposite direction (this is the meaning of the negative sign). And, as we saw in part (*a*), the time is the same up as down. Thus the motion is *symmetrical* about the maximum height.

**PROBLEM SOLVING**
*Acceleration in g's*

The acceleration of objects such as rockets and fast airplanes is often given as a multiple of $g = 9.80\,\text{m/s}^2$. For example, an airplane pulling out of a dive (see Fig. 2–32) and undergoing 3.00 *g*'s would have an acceleration of $(3.00)(9.80\,\text{m/s}^2) = 29.4\,\text{m/s}^2$.

**FIGURE 2–32** Several airplanes, in formation, are just coming out of a downward dive.

**EXAMPLE 2–21** **Ball thrown upward, IV; the quadratic formula.** For the ball in Example 2–20, calculate at what time $t$ the ball passes a point 8.00 m above the person's hand. (See Fig. 2–31, repeated below.)

**APPROACH** We choose the time interval from the throw $(t_0 = 0,\ v_0 = 15.0\ \text{m/s})$ until the time $t$ (to be determined) when the ball is at position $y = 8.00\ \text{m}$, using Eq. 2–12b.

**SOLUTION** We want to find $t$, given $y = 8.00\ \text{m}$, $y_0 = 0$, $v_0 = 15.0\ \text{m/s}$, and $a = -9.80\ \text{m/s}^2$. We use Eq. 2–12b:

$$\begin{aligned} y &= y_0 + v_0 t + \tfrac{1}{2}at^2 \\ 8.00\ \text{m} &= 0 + (15.0\ \text{m/s})t + \tfrac{1}{2}(-9.80\ \text{m/s}^2)t^2. \end{aligned}$$

To solve any quadratic equation of the form $at^2 + bt + c = 0$, where $a$, $b$, and $c$ are constants ($a$ is not acceleration here), we use the **quadratic formula**:

$$t = \frac{-b \pm \sqrt{b^2 - 4ac}}{2a}.$$

We rewrite our $y$ equation just above in standard form, $at^2 + bt + c = 0$:

$$(4.90\ \text{m/s}^2)t^2 - (15.0\ \text{m/s})t + (8.00\ \text{m}) = 0.$$

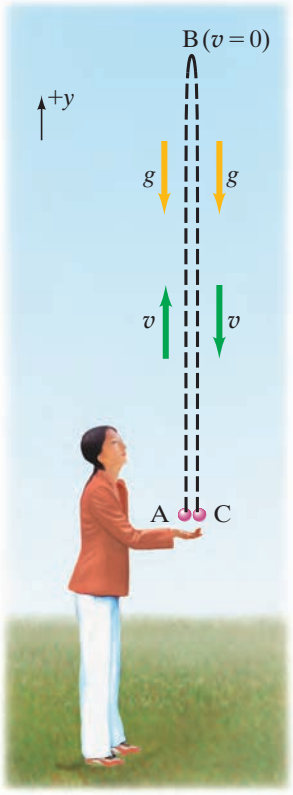
So the coefficient $a$ is $4.90\ \text{m/s}^2$, $b$ is $-15.0\ \text{m/s}$, and $c$ is 8.00 m. Putting these into the quadratic formula, we obtain

$$t = \frac{15.0\ \text{m/s} \pm \sqrt{(-15.0\ \text{m/s})^2 - 4(4.90\ \text{m/s}^2)(8.00\ \text{m})}}{2(4.90\ \text{m/s}^2)},$$

which gives us $t = 0.69\ \text{s}$ and $t = 2.37\ \text{s}$. Are both solutions valid? Yes, because the ball passes $y = 8.00\ \text{m}$ when it goes up $(t = 0.69\ \text{s})$ and again when it comes down $(t = 2.37\ \text{s})$.

**NOTE** Figure 2–33 shows graphs of ($a$) $y$ vs. $t$ and ($b$) $v$ vs. $t$ for the ball thrown upward in Fig. 2–31, incorporating the results of Examples 2–17, 2–18, 2–20, and 2–21.

**PROBLEM SOLVING**
*Quadratic formula is a very useful tool*



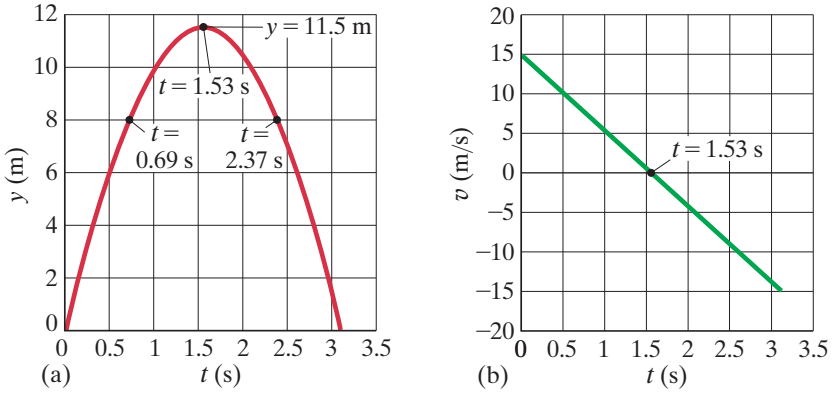


**FIGURE 2–31** (Repeated.) An object thrown into the air leaves the thrower's hand at A, reaches its maximum height at B, and returns to the original position at C. Examples 2–17, 2–18, 2–19, 2–20, and 2–21.

**FIGURE 2–33** Graphs of (a) $y$ vs. $t$, (b) $v$ vs. $t$, for a ball thrown upward, Examples 2–17, 2–18, 2–20, and 2–21.

**EXAMPLE 2–22** **Ball thrown upward at edge of cliff.** Suppose that the person of Examples 2–17, 2–18, 2–20, and 2–21 is standing on the edge of a cliff, so that the ball can fall to the base of the cliff 50.0 m below, as shown in Fig. 2–34. ($a$) How long does it take the ball to reach the base of the cliff? ($b$) What is the total distance traveled by the ball? Ignore air resistance (likely to be significant, so our result is an approximation).

**APPROACH** We again use Eq. 2–12b, but this time we set $y = -50.0\ \text{m}$, the bottom of the cliff, which is 50.0 m below the initial position $(y_0 = 0)$.

**SOLUTION** (*a*) We use Eq. 2–12b with $a = -9.80\,\text{m/s}^2$, $v_0 = 15.0\,\text{m/s}$, $y_0 = 0$, and $y = -50.0\,\text{m}$:

$$\begin{aligned} y &= y_0 + v_0 t + \tfrac{1}{2}at^2 \\ -50.0\,\text{m} &= 0 + (15.0\,\text{m/s})t - \tfrac{1}{2}(9.80\,\text{m/s}^2)t^2. \end{aligned}$$

Rewriting in the standard form we have

$$(4.90\,\text{m/s}^2)t^2 - (15.0\,\text{m/s})t - (50.0\,\text{m}) = 0.$$

Using the quadratic formula, we find as solutions $t = 5.07\,\text{s}$ and $t = -2.01\,\text{s}$. The first solution, $t = 5.07\,\text{s}$, is the answer we are seeking: the time it takes the ball to rise to its highest point and then fall to the base of the cliff. To rise and fall back to the top of the cliff took 3.06 s (Example 2–18); so it took an additional 2.01 s to fall to the base. But what is the meaning of the other solution, $t = -2.01\,\text{s}$? This is a time before the throw, when our calculation begins, so it isn't relevant here. It is outside our chosen time interval, and so is an *unphysical* solution just as in Example 2–12.

(*b*) For the total distance traveled, Example 2–17 told us that the ball moves up 11.5 m, falls 11.5 m back down to the top of the cliff; it then falls down another 50.0 m to the base of the cliff, for a total distance traveled of 2 (11.5 m) + 50.0 m = 73.0 m. Note that the *displacement*, however, was −50.0 m. Figure 2–34b shows the $y$ vs. $t$ graph for this situation.

**NOTE** The solution $t = -2.01\,\text{s}$ in part (*a*) could be meaningful in a different physical situation. Suppose that a person standing on top of a 50.0-m-high cliff sees a rock pass by her at $t = 0$ moving upward at 15.0 m/s; at what time did the rock leave the base of the cliff, and when did it arrive back at the base of the cliff? The equations will be precisely the same as for our original Example, and the answers $t = -2.01\,\text{s}$ and $t = 5.07\,\text{s}$ will be the correct answers. Note that we cannot put *all* the information for a problem into the mathematics, so we have to use common sense in interpreting results.

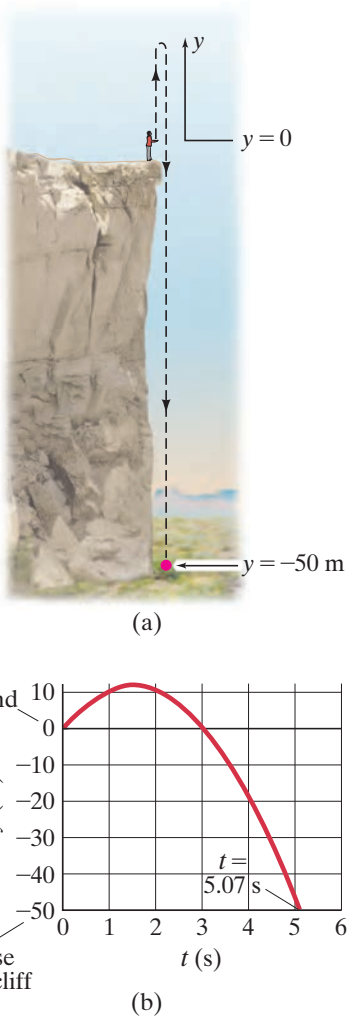

**FIGURE 2–34** Example 2–22. (*a*) A person stands on the edge of a cliff. A ball is thrown upward, and then falls back down past the thrower to the base of the cliff, 50.0 m below. (*b*) The $y$ vs. $t$ graph.

**EXERCISE H** Two balls are thrown from a cliff. One is thrown directly up, the other directly down, each with the same initial speed, and both hit the ground below the cliff. Which ball hits the ground at the greater speed: (*a*) the ball thrown upward, (*b*) the ball thrown downward, or (*c*) both the same? Ignore air resistance.

## *2–8 Variable Acceleration; Integral Calculus

In this brief optional Section we use integral calculus to derive the kinematic equations for constant acceleration, Eqs. 2–12a and b. We also show how calculus can be used when the acceleration is not constant. If you have not yet studied simple integration in your calculus course, you may want to postpone reading this Section until you have. We discuss integration in more detail in Section 7–3, where we begin to use it in the physics.

First we derive Eq. 2–12a, assuming as we did in Section 2–5 that an object has velocity $v_0$ at $t = 0$ and a constant acceleration $a$. We start with the definition of instantaneous acceleration, $a = dv/dt$, which we rewrite as

$$dv = a\,dt.$$

We take the definite integral of both sides of this equation, using the same notation we did in Section 2–5, from $v = v_0$ at $t_0 = 0$ to some velocity $v$ at time $t$:

$$\int_{v=v_0}^{v} dv = \int_{t_0=0}^{t} a\,dt$$

which gives, since $a$ = constant,

$$v - v_0 = at.$$

This is Eq. 2–12a, $v = v_0 + at$.

Next we derive Eq. 2–12b starting with the definition of instantaneous velocity, Eq. 2–4, $v = dx/dt$. We rewrite this as

$$dx = v\,dt$$

or

$$dx = (v_0 + at)dt$$

where we substituted in Eq. 2–12a.

Now we integrate from $x = x_0$ at $t_0 = 0$ to an arbitrary position $x$ at time $t$:

$$\int_{x=x_0}^{x} dx = \int_{t_0=0}^{t} (v_0 + at)dt$$

$$x - x_0 = \int_{t_0=0}^{t} v_0\,dt + \int_{t_0=0}^{t} at\,dt$$

$$x - x_0 = v_0 t + \tfrac{1}{2}at^2$$

since $v_0$ and $a$ are constants. This result is just Eq. 2–12b, $x = x_0 + v_0 t + \frac{1}{2}at^2$.

Finally let us use calculus to find velocity and displacement, given an acceleration that is not constant but varies in time.

**EXAMPLE 2–23** **Integrating a time-varying acceleration.** An experimental vehicle starts from rest $(v_0 = 0)$ at $t = 0$ and accelerates for a few seconds at a rate given by $a = (7.00\,\text{m/s}^3)t$. What is (*a*) its velocity and (*b*) its displacement 2.00 s later?

**APPROACH** We cannot use Eqs. 2–12 because $a$ is not constant. We integrate the acceleration $a = dv/dt$ over time to find $v$ as a function of time; and then integrate $v = dx/dt$ to get the displacement.

**SOLUTION** From the definition of acceleration, $a = dv/dt$, we have

$$dv = a\,dt.$$

We take the integral of both sides from $v = 0$ at $t = 0$ to velocity $v$ at an arbitrary time $t$:

$$\int_0^v dv = \int_0^t a\,dt$$

$$v = \int_0^t (7.00\,\text{m/s}^3)t\,dt$$

$$= (7.00\,\text{m/s}^3)\left(\frac{t^2}{2}\right)\Bigg|_0^t = (7.00\,\text{m/s}^3)\left(\frac{t^2}{2} - 0\right) = (3.50\,\text{m/s}^3)t^2.$$

At $t = 2.00$ s, $v = (3.50\,\text{m/s}^3)(2.00\,\text{s})^2 = 14.0$ m/s.

(*b*) To get the displacement, we assume $x_0 = 0$ and start with $v = dx/dt$ which we rewrite as $dx = v\,dt$. Then we integrate from $x = 0$ at $t = 0$ to position $x$ at time $t$:

$$\int_0^x dx = \int_0^t v\,dt$$

$$x = \int_0^{2.00\,\text{s}} (3.50\,\text{m/s}^3)t^2\,dt = (3.50\,\text{m/s}^3)\,\frac{t^3}{3}\Bigg|_0^{2.00\,\text{s}} = 9.33\,\text{m}.$$

In sum, at $t = 2.00$ s, $v = 14.0$ m/s and $x = 9.33$ m.

Some problems in kinematics can be solved using Numerical Integration, which is discussed in Appendix C.

# Summary

[*The Summary that appears at the end of each Chapter in this book gives a brief overview of the main ideas of the Chapter. The Summary* cannot *serve to give an understanding of the material, which can be accomplished only by a detailed reading of the Chapter.*]

**Kinematics** deals with the description of how objects move. The description of the motion of any object must always be given relative to some particular **reference frame**.

The **displacement** of an object is the change in position of the object.

**Average speed** is the distance traveled divided by the **elapsed time** or **time interval**, $\Delta t$, the time period over which we choose to make our observations. An object's **average velocity** over a particular time interval $\Delta t$ is its displacement $\Delta x$ during that time interval, divided by $\Delta t$:

$$\bar{v} = \frac{\Delta x}{\Delta t}. \qquad \textbf{(2–2)}$$

The **instantaneous velocity**, whose magnitude is the same as the *instantaneous speed*, is defined as the average velocity taken over an infinitesimally short time interval $(\Delta t \to 0)$:

$$v = \lim_{\Delta t \to 0} \frac{\Delta x}{\Delta t} = \frac{dx}{dt}, \qquad \textbf{(2–4)}$$

where $dx/dt$ is the derivative of $x$ with respect to $t$.

On a graph of position vs. time, the **slope** is equal to the instantaneous velocity.

Acceleration is the change of velocity per unit time. An object's **average acceleration** over a time interval $\Delta t$ is

$$\bar{a} = \frac{\Delta v}{\Delta t}, \qquad \textbf{(2–5)}$$

where $\Delta v$ is the change of velocity during the time interval $\Delta t$.

**Instantaneous acceleration** is the average acceleration taken over an infinitesimally short time interval:

$$a = \lim_{\Delta t \to 0} \frac{\Delta v}{\Delta t} = \frac{dv}{dt}. \qquad \textbf{(2–6)}$$

On a graph of velocity vs. time, the slope is equal to the instantaneous acceleration.

If an object has position $x_0$ and velocity $v_0$ at time $t = 0$ and moves in a straight line with **constant acceleration**, the velocity $v$ and position $x$ at a later time $t$ are related to the acceleration $a$, the initial position $x_0$, and the initial velocity $v_0$ by Eqs. 2–12:

$$\begin{aligned} v &= v_0 + at, \\ x &= x_0 + v_0 t + \tfrac{1}{2}at^2, \\ v^2 &= v_0^2 + 2a(x - x_0), \\ \bar{v} &= \frac{v + v_0}{2}. \end{aligned} \qquad \textbf{(2–12)}$$

Objects that move vertically near the surface of the Earth, either falling or having been projected vertically up or down, move with the constant downward **acceleration due to gravity**, whose magnitude is $g = 9.80\ \text{m/s}^2$ if air resistance can be ignored.

[*Integral calculus can be used to derive the kinematic Equations 2–12 and to solve Problems involving varying acceleration. Numerical integration is also a useful tool.]

# Questions

1. Does a car speedometer measure speed, velocity, or both? Explain.
2. Can an object have a varying speed if its velocity is constant? Can it have varying velocity if its speed is constant? If yes, give examples in each case.
3. When an object moves with constant velocity, does its average velocity during any time interval differ from its instantaneous velocity at any instant? Explain.
4. If one object has a greater speed than a second object, does the first necessarily have a greater acceleration? Explain, using examples.
5. Compare the acceleration of a motorcycle that accelerates from 80 km/h to 90 km/h with the acceleration of a bicycle that accelerates from rest to 10 km/h in the same time.
6. Can an object have a northward velocity and a southward acceleration? Explain.
7. Can the velocity of an object be negative when its acceleration is positive? What about vice versa? If yes, give examples.
8. Give an example where both the velocity and acceleration are negative.
9. Two cars emerge side by side from a tunnel. Car A is traveling with a speed of 60 km/h and has an acceleration of 40 km/h/min. Car B has a speed of 40 km/h and has an acceleration of 60 km/h/min. Which car is passing the other as they come out of the tunnel? Explain your reasoning.
10. Can an object be increasing in speed as its acceleration decreases? If so, give an example. If not, explain.
11. A baseball player hits a ball straight up into the air. It leaves the bat with a speed of 120 km/h. Ignoring air resistance, how fast would the ball be traveling when the catcher catches it (at the same height it left the bat)? Explain.
12. As a freely falling object speeds up, what is happening to its acceleration—does it increase, decrease, or stay the same? (*a*) Ignore air resistance. (*b*) Consider air resistance.
13. You travel from point A to point B in a car moving at a constant speed of 70 km/h. Then you travel the same distance from point B to another point C, moving at a constant speed of 90 km/h. Is your average speed 80 km/h for the entire trip from A to C? Explain why or why not.
14. Can an object have zero velocity and nonzero acceleration at the same time? Give examples.
15. Can an object have zero acceleration and nonzero velocity at the same time? Give examples.
16. Which of these motions is *not* at constant acceleration: a rock falling from a cliff, an elevator moving from the second floor to the fifth floor making stops along the way, a dish resting on a table? Explain your answers.
17. Discuss two conditions given in Section 2–7 for being able to use a constant acceleration of magnitude $g = 9.8\ \text{m/s}^2$. Give an example in which one of these conditions would not be met and would not even be a reasonable approximation of motion. [*Hint*: Carefully read Section 2–7, especially page 38.]

**18.** Describe in words the motion plotted in Fig. 2–35 in terms of velocity, acceleration, etc. [*Hint*: First try to duplicate the motion plotted by walking or moving your hand.]

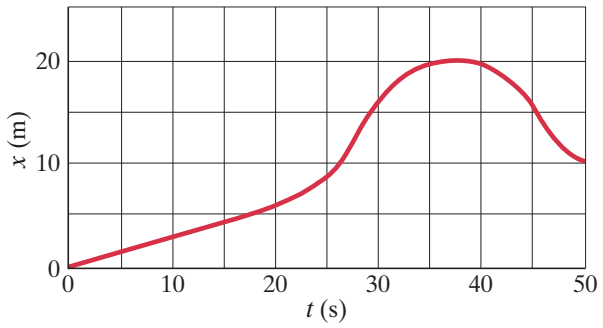

**FIGURE 2–35** Question 18.

**19.** Describe in words the motion of the object graphed in Fig. 2–36.

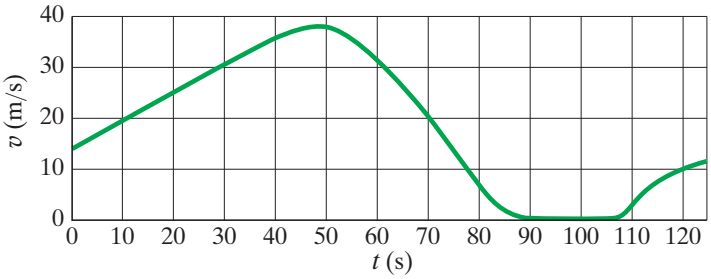

**FIGURE 2–36** Question 19.

# MisConceptual Questions

[List all answers that are valid, and ignore air resistance.]

**1.** In which of the following cases does a car have a negative velocity and a positive acceleration? A car that is traveling in the
(*a*) $-x$ direction at a constant 20 m/s.
(*b*) $-x$ direction increasing in speed.
(*c*) $+x$ direction increasing in speed.
(*d*) $-x$ direction decreasing in speed.
(*e*) $+x$ direction decreasing in speed.

**2.** At time $t = 0$ an object is traveling to the right along the $+x$ axis at a speed of 10.0 m/s with constant acceleration of $-2.0\ \text{m/s}^2$. Which statement is true?
(*a*) The object will slow down, eventually coming to a complete stop.
(*b*) The object cannot have a negative acceleration and be moving to the right.
(*c*) The object will continue to move to the right, slowing down but never coming to a complete stop.
(*d*) The object will slow down, momentarily stopping, then pick up speed moving to the left.

**3.** You drive 4 km at 30 km/h and then another 4 km at 50 km/h. What is your average speed for the whole 8-km trip?
(*a*) More than 40 km/h. (*c*) Less than 40 km/h.
(*b*) Equal to 40 km/h. (*d*) Not enough information.

**4.** Two cars start from rest and travel a distance $d$ with constant acceleration. The acceleration of car B is four times that of car A. After each has traveled distance $d$,
(*a*) car B is moving 16 times as fast as car A.
(*b*) car B is moving 8 times as fast as car A.
(*c*) car B is moving 4 times as fast as car A.
(*d*) car B is moving 2 times as fast as car A.

**5.** A rock is thrown straight up rising to a maximum height before falling back down.
(*a*) The acceleration is constant for the entire trip.
(*b*) The velocity is constant for the entire trip.
(*c*) The magnitudes of both the velocity and acceleration decrease on the way up and increase on the way down.
(*d*) The acceleration is constant for the entire trip except at the top where it is 0.

**6.** A ball is dropped from the top of a tall building. At the same instant, a second ball is thrown upward from ground level. When the two balls pass one another, one on the way up, the other on the way down, compare the magnitudes of their acceleration:
(*a*) The acceleration of the dropped ball is greater.
(*b*) The acceleration of the ball thrown upward is greater.
(*c*) The acceleration of both balls is the same.
(*d*) The acceleration changes during the motion, so you cannot predict the exact value when the two balls pass each other.
(*e*) The accelerations are in opposite directions.

**7.** You drop a rock off a bridge. When the rock has fallen 4 m, you drop a second rock. As the two rocks continue to fall, what happens to their velocities?
(*a*) Both increase at the same rate.
(*b*) The velocity of the first rock increases faster than the velocity of the second.
(*c*) The velocity of the second rock increases faster than the velocity of the first.
(*d*) Both velocities stay constant.

**8.** Two objects are dropped from a bridge, an interval of 1.0 s apart. During the time that both objects continue to fall, their separation
(*a*) decreases at first, but then stays constant.
(*b*) increases at first, but then stays constant.
(*c*) decreases.
(*d*) stays constant.
(*e*) increases.

**9.** A ball is thrown downward at a speed of 20 m/s. Choosing the $+y$ axis pointing up and neglecting air resistance, which equation(s) would correctly describe the motions? The acceleration due to gravity is $g = 9.8\ \text{m/s}^2$ downward.
(*a*) $v = (20\ \text{m/s}) - gt$.
(*b*) $y = y_0 + (-20\ \text{m/s})t - (1/2)gt^2$.
(*c*) $v^2 = (20\ \text{m/s})^2 - 2g(y - y_0)$.
(*d*) $(20\ \text{m/s}) = (v + v_0)/2$.
(*e*) All of the above.

**10.** A car travels along the $x$ axis with increasing speed. We are not sure if it is moving to the left or to the right. Which of the graphs in Fig. 2–37 could possibly represent the motion of the car?

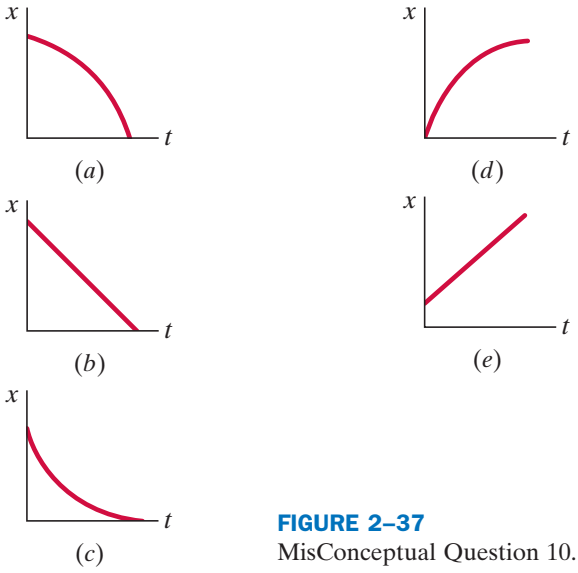

**FIGURE 2–37**
MisConceptual Question 10.

**11.** Two objects start at the same place at the same time and move along the same straight line (the $x$ axis). Figure 2–38 shows the position $x$ as a function of time $t$ for each object. At point $A$, what must be true about the motion of the objects? (More than one statement may be correct.)
(*a*) Both have the same instantaneous speed.
(*b*) Both have the same instantaneous velocity.
(*c*) Both are at the same position.
(*d*) Both have traveled the same total distance.
(*e*) With respect to the start, both have the same average velocity.

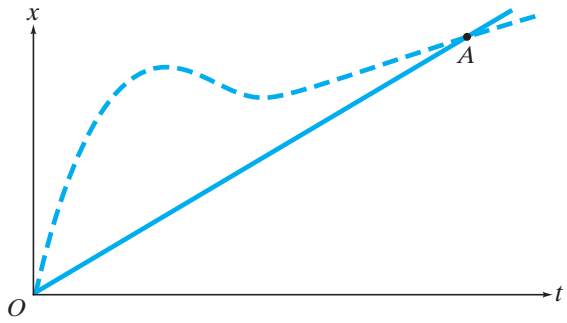

**FIGURE 2–38** MisConceptual Question 11.

# Problems

[*The Problems at the end of each Chapter are ranked* I, II, *or* III *according to estimated difficulty, with level* I *Problems being easiest. Level* III *are meant as challenges for the best students. The Problems are arranged by Section, meaning that the reader should have read up to and including that Section, but not only that Section—Problems often depend on earlier material. Next is a set of "General Problems" not arranged by Section and not ranked.*]

(Note: *In Problems, assume a number like* 6.4 *is accurate to* ±0.1; *and* 950 *is* ±10 *unless* 950 *is said to be "precisely" or "very nearly"* 950, *in which case assume* 950 ± 1. *See Section 1–3.*)

## 2–1 to 2–3 Speed and Velocity

**1.** (I) If you are driving 85 km/h along a straight road and you look to the side for 2.0 s, how far do you travel during this inattentive period?

**2.** (I) What must your car's average speed be in order to travel 235 km in 2.85 h?

**3.** (I) A particle at $t_1 = -2.0$ s is at $x_1 = 5.2$ cm and at $t_2 = 3.4$ s is at $x_2 = 8.5$ cm. What is its average velocity over this time interval? Can you calculate its average speed from these data? Why or why not?

**4.** (II) According to a rule-of-thumb, each five seconds between a lightning flash and the following thunder gives the distance to the flash in miles. (*a*) Assuming that the light from the flash arrives in essentially no time at all, estimate the speed of sound in m/s from this rule. (*b*) What would be the rule for kilometers?

**5.** (II) You are driving home from school steadily at 95 km/h for 210 km. It then begins to rain and you slow to 65 km/h. You arrive home after driving 4.5 h. (*a*) How far is your hometown from school? (*b*) What was your average speed?

**6.** (II) A horse trots away from its trainer in a straight line, moving 38 m away in 7.4 s. It then turns abruptly and gallops halfway back in 1.8 s. Calculate (*a*) its average speed and (*b*) its average velocity for the entire trip, using "away from the trainer" as the positive direction.

**7.** (II) A person jogs eight complete laps around a 400-m track in a total time of 14.5 min. Calculate (*a*) the average speed and (*b*) the average velocity, in m/s.

**8.** (II) Every year the Earth travels about $10^9$ km as it orbits the Sun. What is Earth's average speed in km/h?

**9.** (II) A car traveling 95 km/h is 310 m behind a truck traveling 75 km/h. How long will it take the car to reach the truck?

**10.** (II) Calculate (*a*) the average speed and (*b*) average velocity of a round trip: the outgoing 280 km is covered at 95 km/h, followed by a 1.0-h lunch break, and the return 280 km is covered at 55 km/h.

**11.** (II) Two locomotives approach each other on parallel tracks. Each has a speed of 155 km/h with respect to the ground. If they are initially 9.5 km apart, how long will it be before they reach each other? (See Fig. 2–39.)

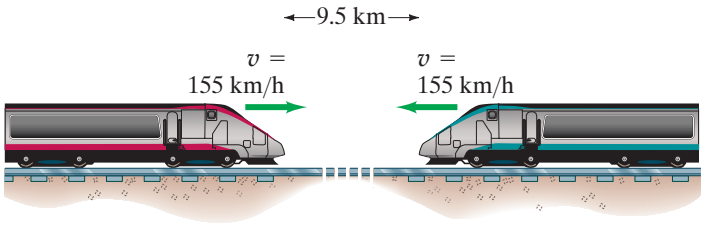

**FIGURE 2–39** Problem 11.

**12.** (II) Digital bits on a 12.0-cm diameter audio CD are encoded along an outward spiraling path that starts at radius $R_1 = 2.5\,\text{cm}$ and finishes at radius $R_2 = 5.8\,\text{cm}$. The distance between the centers of neighboring spiral-windings is $1.6\,\mu\text{m}$ $(= 1.6 \times 10^{-6}\,\text{m})$. (*a*) Determine the total length of the spiraling path. [*Hint*: Imagine "unwinding" the spiral into a straight path of width $1.6\,\mu\text{m}$, and note that the original spiral and the straight path both occupy the same area.] (*b*) The CD player adjusts the rotation of the CD so that the player's readout laser reads along the spiral path at a constant rate of about 1.2 m/s. Estimate the maximum playing time of such a CD.

**13.** (II) The position of a small object is given by $x = 27 + 10t - 2t^3$, where $t$ is in seconds and $x$ in meters. (*a*) Plot $x$ as a function of $t$ from $t = 0$ to $t = 3.0\,\text{s}$. (*b*) Find the average velocity of the object between 0 and 3.0 s. (*c*) At what time between 0 and 3.0 s is the instantaneous velocity zero?

**14.** (II) An airplane travels 1900 km at a speed of 720 km/h, and then encounters a tailwind that boosts its speed to 990 km/h for the next 2700 km. What was the total time for the trip? What was the average speed of the plane for this trip? [*Hint*: Does Eq. 2–12d apply?]

**15.** (II) Two ships need to arrive at a site in the middle of the ocean at the same time. They start out at the same time from positions equally distant from the arrival site. They travel at different velocities but both go in a straight line. The first ship travels at an average velocity of 20 km/h for the first 600 km, 40 km/h for the next 800 km, and 20 km/h for the final 600 km. The second ship can only sail at constant velocity. What is the magnitude of that velocity?

**16.** (II) The position of an object along a straight tunnel as a function of time is plotted in Fig. 2–40. What is its instantaneous velocity (*a*) at $t = 10.0\,\text{s}$ and (*b*) at $t = 30.0\,\text{s}$? What is its average velocity (*c*) between $t = 0$ and $t = 5.0\,\text{s}$, (*d*) between $t = 25.0\,\text{s}$ and $t = 30.0\,\text{s}$, and (*e*) between $t = 40.0\,\text{s}$ and $t = 50.0\,\text{s}$?

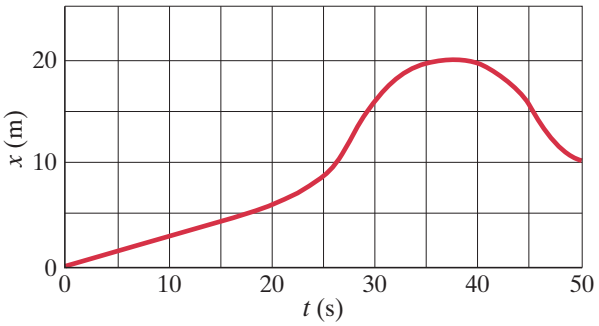

**FIGURE 2–40** Problems 16, 17, and 18.

**17.** (II) In Fig. 2–40, (*a*) during what time intervals, if any, is the velocity constant? (*b*) At what time is the velocity greatest? (*c*) At what time, if any, is the velocity zero? (*d*) Does the object move in one direction or in both directions during the time shown?

**18.** (III) Sketch the $v$ vs. $t$ graph for the object whose displacement as a function of time is given by Fig. 2–40.

**19.** (III) A bowling ball traveling with constant speed hits the pins at the end of a bowling lane 16.5 m long. The bowler hears the sound of the ball hitting the pins 2.75 s after the ball is released from his hands. What is the speed of the ball, assuming the speed of sound is 340 m/s?

**20.** (III) An automobile traveling 95 km/h overtakes a 1.50-km-long train traveling in the same direction on a track parallel to the road. If the train's speed is 75 km/h, how long does it take the car to pass it, and how far will the car have traveled in this time? See Fig. 2–41. What are the results if the car and train are traveling in opposite directions?

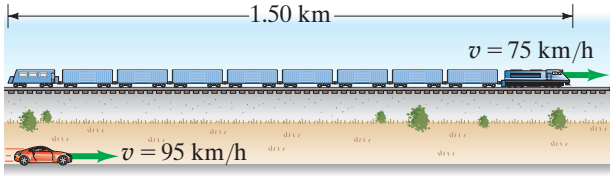

**FIGURE 2–41** Problem 20.

## 2–4 Acceleration

**21.** (I) A sprinter accelerates from rest to 9.00 m/s in 1.48 s. What is her acceleration in (*a*) $\text{m/s}^2$; (*b*) $\text{km/h}^2$?

**22.** (I) A bicyclist in the Tour de France crests a mountain pass as he moves at 15 km/h. At the bottom, 4.0 km farther, his speed is 65 km/h. Estimate his average acceleration $(\text{in m/s}^2)$ while riding down the mountain.

**23.** (II) A sports car moving at constant velocity travels 120 m in 5.0 s. If it then brakes and comes to a stop in 3.7 s, what is the magnitude of its acceleration (assumed constant) in $\text{m/s}^2$, and in $g$'s $(g = 9.80\,\text{m/s}^2)$?

**24.** (II) At highway speeds, a particular automobile is capable of an acceleration of about $1.8\,\text{m/s}^2$. At this rate, how long does it take to accelerate from 65 km/h to 120 km/h?

**25.** (II) A car moving in a straight line starts at $x = 0$ when $t_0 = 0$. It passes the point $x = 25.0\,\text{m}$ with a speed of 11.0 m/s at $t = 3.00\,\text{s}$. It passes the point $x = 385\,\text{m}$ with a speed of 45.0 m/s at $t = 20.0\,\text{s}$. Find (*a*) the average velocity, and (*b*) the average acceleration, between $t = 3.00\,\text{s}$ and $t = 20.0\,\text{s}$.

**26.** (II) A particle moves along the $x$ axis. Its position as a function of time is given by $x = 4.8t + 7.3t^2$, where $t$ is in seconds and $x$ is in meters. What is the acceleration as a function of time?

**27.** (II) The position of an object is given by $x = At + Bt^2$, where $x$ is in meters and $t$ is in seconds. (*a*) What are the units of $A$ and $B$? (*b*) What is the acceleration as a function of time? (*c*) What are the velocity and acceleration at $t = 6.0\,\text{s}$? (*d*) What is the velocity as a function of time if $x = At + Bt^{-3}$?

**28.** (II) The position of a race car, which starts from rest at $t = 0$ and moves in a straight line, is given as a function of time in the following Table. Estimate (*a*) its velocity and (*b*) its acceleration as a function of time. Display each in a Table and on a graph.

| $t$(s) | 0 | 0.25 | 0.50 | 0.75 | 1.00 | 1.50 | 2.00 | 2.50 |
|---|---|---|---|---|---|---|---|---|
| $x$(m) | 0 | 0.11 | 0.46 | 1.06 | 1.94 | 4.62 | 8.55 | 13.79 |

| $t$(s) | 3.00 | 3.50 | 4.00 | 4.50 | 5.00 | 5.50 | 6.00 |
|---|---|---|---|---|---|---|---|
| $x$(m) | 20.36 | 28.31 | 37.65 | 48.37 | 60.30 | 73.26 | 87.16 |

**29.** (II) A car traveling 25.0 m/s passes a second car which is at rest. When the cars are right next to each other, the first car slows down at a constant rate of $2.0\,\text{m/s}^2$ and the second car starts to accelerate at the same constant rate. When will the two cars be next to each other again?

**30.** (II) Figure 2–42 shows the velocity of a train as a function of time. (*a*) At what time was its velocity greatest? (*b*) During what periods, if any, was the velocity constant? (*c*) During what periods, if any, was the acceleration constant? (*d*) When was the magnitude of the acceleration greatest?

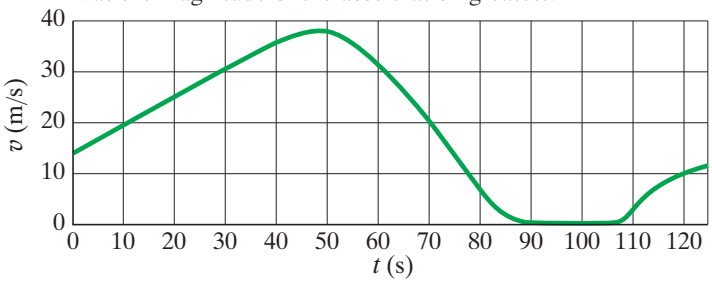

**FIGURE 2–42** Problem 30.

**31.** (II) A sports car accelerates approximately as shown in the velocity–time graph of Fig. 2–43. (The short flat spots in the curve represent manual shifting of the gears.) Estimate the car's average acceleration in (*a*) second gear and (*b*) fourth gear.

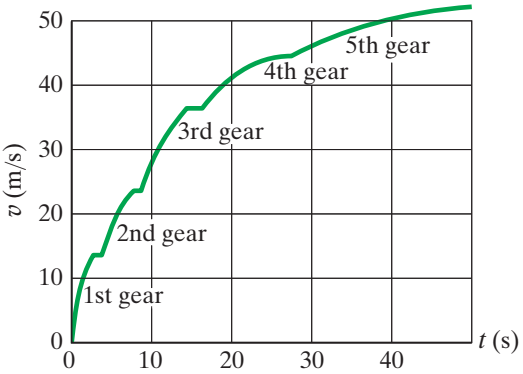

**FIGURE 2–43** Problem 31. The velocity of a car as a function of time, starting from a dead stop. The flat spots in the curve represent gear shifts.

**32.** (III) A fugitive tries to hop on a freight train traveling at a constant speed of 5.0 m/s. Just as an empty box car passes him, the fugitive starts from rest and accelerates at $a = 1.4\ \text{m/s}^2$ to his maximum speed of 6.0 m/s, which he then maintains. (*a*) How long does it take him to catch up to the empty box car? (*b*) What is the distance traveled to reach the box car?

## 2–5 to 2–6 Motion at Constant Acceleration

**33.** (I) A car slows down from 26 m/s to rest in a distance of 88 m. What was its acceleration, assumed constant?

**34.** (I) A car slows down from 28 m/s to rest in 6.3 s. What was its (constant) acceleration?

**35.** (I) A car accelerates from 13 m/s to 22 m/s in 6.5 s. What was its acceleration? How far did it travel in this time? Assume constant acceleration.

**36.** (II) A world-class sprinter can reach a top speed (of about 11.5 m/s) in the first 18.0 m of a race. What is the average acceleration of this sprinter and how long does it take her to reach that speed?

**37.** (II) A car slows down uniformly from a speed of 28.0 m/s to rest in 8.60 s. How far did it travel in that time?

**38.** (II) In coming to a stop, an old truck leaves skid marks 45 m long on the highway. Assuming a deceleration of $6.00\ \text{m/s}^2$, estimate the speed of the truck just before braking.

**39.** (II) A baseball pitcher throws a baseball with a speed of 43 m/s. Estimate the average acceleration of the ball during the throwing motion. In throwing the baseball, the pitcher accelerates it through a displacement of about 3.5 m, from behind the body to the point where it is released (Fig. 2–44).

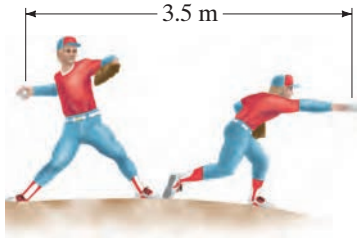

**FIGURE 2–44** Problem 39.

**40.** (II) A car traveling at 95 km/h strikes a tree. The front end of the car compresses and the driver comes to rest after traveling 0.80 m. What was the magnitude of the average acceleration of the driver during the collision? Express the answer in terms of "*g*'s," where $1.00\,g = 9.80\ \text{m/s}^2$.

**41.** (II) A car traveling 85 km/h slows down at a constant $0.50\ \text{m/s}^2$ just by "letting up on the gas." Calculate (*a*) the distance the car coasts before it stops, (*b*) the time it takes to stop, and (*c*) the distance it travels during the first and fifth seconds.

**42.** (II) Determine the stopping distances for an automobile going a constant initial speed of 95 km/h in the $+x$ direction, and human reaction time of 0.40 s: (*a*) for an acceleration $a = -2.5\ \text{m/s}^2$; (*b*) for $a = -5.5\ \text{m/s}^2$.

**43.** (II) A driver is traveling 18.0 m/s when she sees a red light ahead. Her car is capable of decelerating at a rate of $3.65\ \text{m/s}^2$. If it takes her 0.380 s to get the brakes on and she is 24.0 m from the intersection when she sees the light, will she be able to stop in time? How far from the beginning of the intersection will she be, and in which direction?

**44.** (II) Show that $\bar{v} = (v + v_0)/2$ (see Eq. 2–12d) is not valid when the acceleration $a = A + Bt$, where $A$ and $B$ are non-zero constants.

**45.** (II) An 85-m-long train begins uniform acceleration from rest. The front of the train has a speed of 18 m/s when it passes a railway worker who is standing 180 m from where the front of the train started. What will be the speed of the last car as it passes the worker? (See Fig. 2–45.)

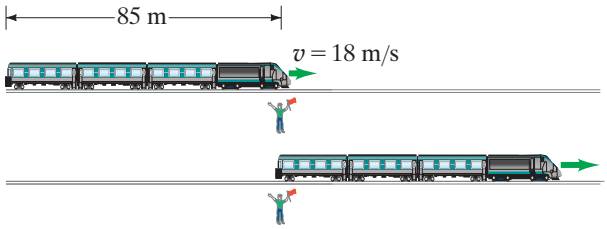

**FIGURE 2–45** Problem 45.

**46.** (II) A space vehicle accelerates uniformly from 85 m/s at $t = 0$ to 162 m/s at $t = 10.0$ s. How far did it move between $t = 2.0$ s and $t = 7.0$ s?

**47.** (II) A runner hopes to complete the 10,000-m run in less than 30.0 min. After running at constant speed for exactly 27.0 min, there are still 1200 m to go. The runner must then accelerate at $0.20\ \text{m/s}^2$ for how many seconds in order to achieve the desired time?

**48.** (III) Mary and Sally are in a foot race (Fig. 2–46). When Mary is 22 m from the finish line, she has a speed of 4.0 m/s and is 5.0 m behind Sally, who has a speed of 5.0 m/s. Sally thinks she has an easy win and so, during the remaining portion of the race, slows down at a constant rate of 0.40 m/s$^2$ to the finish line. What constant acceleration does Mary now need during the remaining portion of the race, if she wishes to cross the finish line side-by-side with Sally?

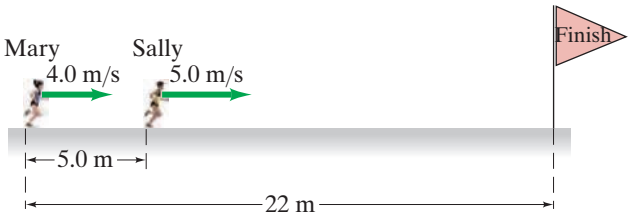

**FIGURE 2–46** Problem 48.

**49.** (III) An unmarked police car traveling a constant 95 km/h is passed by a speeder traveling 135 km/h. Precisely 1.00 s after the speeder passes, the police officer steps on the accelerator; if the police car's acceleration is 2.60 m/s$^2$, how much time passes before the police car overtakes the speeder (assumed moving at constant speed)?

**50.** (III) Assume in Problem 49 that the speeder's speed is not known. If the police car accelerates uniformly at 2.60 m/s$^2$ and overtakes the speeder after accelerating for 7.00 s, what was the speeder's speed?

**51.** (III) A runner completes a 400-meter race in 55.0 s. The 55.0 seconds is made up of a 0.15 s reaction time from the starting sound until the runner starts moving followed by 30.0 m of constant acceleration and then 370 m at constant speed. What are the values of the acceleration and the constant speed?

## 2–7 Freely Falling Objects (neglect air resistance)

**52.** (I) A stone is dropped from the top of a cliff. It is seen to hit the ground below after 3.25 s. How high is the cliff?

**53.** (I) Estimate (*a*) how long it took King Kong to fall straight down from the top of the Empire State Building (380 m high), and (*b*) his velocity just before "landing."

**54.** (I) If a car rolls gently $(v_0 = 0)$ off a vertical cliff, how long does it take it to reach 55 km/h?

**55.** (II) A ball player catches a ball 2.6 s after throwing it vertically upward. With what speed did he throw it, and what height did it reach?

**56.** (II) A baseball is hit almost straight up into the air with a speed of 22 m/s. Estimate (*a*) how high it goes, and (*b*) how long it is in the air. (*c*) What factors make this an estimate?

**57.** (II) A kangaroo jumps straight up to a vertical height of 1.45 m. How long was it in the air before returning to Earth?

**58.** (II) The best *rebounders* in *basketball* have a vertical leap (that is, the vertical movement of a fixed point on their body) of about 120 cm. (*a*) What is their initial "launch" speed off the ground? (*b*) How long are they in the air?

**59.** (II) A stone is thrown vertically upward with a speed of 18.0 m/s. (*a*) How fast is it moving when it is at a height of 11.0 m? (*b*) How much time is required to reach this height? (*c*) Why are there two answers to (*b*)?

**60.** (II) For an object falling freely from rest, show that the distance traveled *during* each successive second increases in the ratio of successive odd integers (1, 3, 5, etc.). (This was first shown by Galileo.) See Figs. 2–27 and 2–30.

**61.** (II) If there were no air resistance, how long would it take a free-falling skydiver to fall from a plane at 3800 m to an altitude of 450 m, where she will open her parachute? What would her speed be at 450 m? (In reality, air resistance will restrict her speed to perhaps 150 km/h.)

**62.** (II) Pelicans tuck their wings and free-fall straight down when diving for fish. Suppose a pelican starts its dive from a height of 16.0 m and cannot change its path once committed. If it takes a fish 0.20 s to perform evasive action, at what minimum height must it spot the pelican to escape? Assume the fish is at the surface of the water.

**63.** (II) A stone is thrown vertically upward with a speed of 15.5 m/s from the edge of a cliff 75.0 m high (Fig. 2–47). (*a*) How much later does it reach the bottom of the cliff? (*b*) What is its speed just before hitting? (*c*) What total distance did it travel?

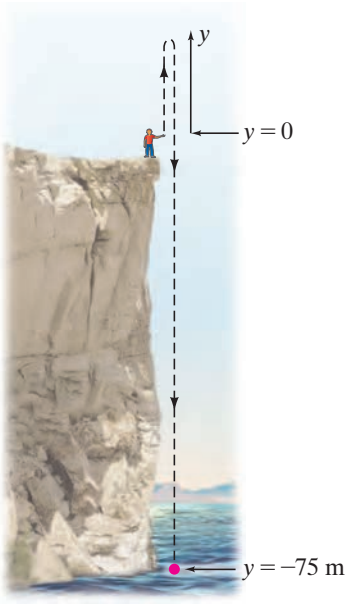

**FIGURE 2–47** Problem 63.

**64.** (II) A rocket rises vertically, from rest, with an acceleration of 3.2 m/s$^2$ until it runs out of fuel at an altitude of 725 m. After this point, its acceleration is that of gravity, downward. (*a*) What is the velocity of the rocket when it runs out of fuel? (*b*) How long does it take to reach this point? (*c*) What maximum altitude does the rocket reach? (*d*) How much time (total) does it take to reach maximum altitude? (*e*) With what velocity does it strike the Earth? (*f*) How long (total) is it in the air?

**65.** (II) Suppose you adjust your garden hose nozzle for a fast stream of water. You point the nozzle vertically upward at a height of 1.8 m above the ground (Fig. 2–48). When you quickly turn off the nozzle, you hear the water striking the ground next to you for another 2.5 s. What is the water speed as it leaves the nozzle?

**FIGURE 2–48** Problem 65.

66. (II) A helicopter is ascending vertically with a constant speed of 6.40 m/s. At a height of 105 m above the Earth, a package is dropped from the helicopter. How much time does it take for the package to reach the ground? [*Hint*: What is $v_0$ for the package?]

67. (II) Roger sees water balloons fall past his window. He notices that each balloon strikes the sidewalk 0.83 s after passing his window, 15 m above the sidewalk. (*a*) How fast are the balloons traveling when they pass Roger's window? (*b*) Assuming the balloons are being released from rest, from what height are they being released?

68. (II) A baseball is seen to pass upward by a window with a vertical speed of 13 m/s. If the ball was thrown by a person 18 m below on the street, (*a*) what was its initial speed, (*b*) what altitude does it reach, (*c*) when was it thrown, and (*d*) when does it reach the street again?

69. (III) A falling stone takes 0.28 s to travel past a window 2.2 m tall (Fig. 2–49). From what height above the top of the window did the stone fall?

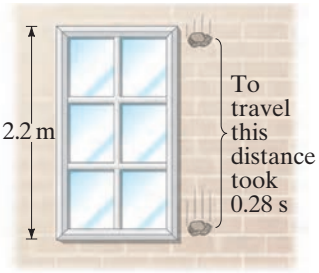

**FIGURE 2–49**
Problem 69.

70. (III) A toy rocket moving vertically upward passes by a 2.0-m-high window whose base is 8.0 m above the ground. The rocket takes 0.15 s to travel the 2.0 m height of the window. What was the launch speed of the rocket, and how high will it go? Assume the propellant is burned very quickly at blastoff.

71. (III) A ball is dropped from the top of a 55.0-m-high cliff. At the same time, a carefully aimed stone is thrown straight up from the bottom of the cliff with a speed of 24.0 m/s. The stone and ball collide part way up. How far above the base of the cliff does this happen?

### *2–8 Variable Acceleration; Calculus

*72. (II) Given $v(t) = 25 + 18t$, where $v$ is in m/s and $t$ is in s, use calculus to determine the total displacement from $t_1 = 1.3$ s to $t_2 = 3.6$ s.

*73. (III) The acceleration of a particle is given by $a = A\sqrt{t}$ where $A = 3.0\,\text{m/s}^{5/2}$. At $t = 0$, $v = 7.5$ m/s and $x = 0$. (*a*) What is the velocity as a function of time? (*b*) What is the displacement as a function of time? (*c*) What are the acceleration, velocity, and displacement at $t = 5.0$ s?

*74. (III) Air resistance acting on a falling body can be taken into account by the approximate relation for the acceleration:

$$a = \frac{dv}{dt} = g - kv,$$

where $k$ is a constant. (*a*) Derive a formula for the velocity of the body as a function of time assuming it starts from rest ($v = 0$ at $t = 0$). [*Hint*: Change variables by setting $u = g - kv$.] (*b*) Determine an expression for the terminal velocity, which is the maximum value the velocity reaches.

## General Problems

75. The acceleration due to gravity on the Moon is about one-sixth what it is on Earth. If an object is thrown vertically upward on the Moon, how many times higher will it go than it would on Earth, assuming the same initial velocity?

76. A person jumps out a fourth-story window 18.0 m above a firefighter's safety net. The survivor stretches the net 1.0 m before coming to rest, Fig. 2–50. (*a*) What was the average deceleration experienced by the survivor when she was slowed to rest by the net? (*b*) What would you do to make it "safer" (that is, to generate a smaller deceleration): would you stiffen or loosen the net? Explain.

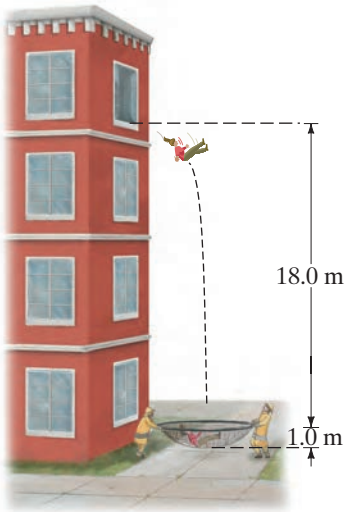

**FIGURE 2–50**
Problem 76.

77. A person who is properly restrained by an over-the-shoulder seat belt has a good chance of surviving a car collision if the deceleration does not exceed 30 "*g*'s" $(1.00\,g = 9.80\,\text{m/s}^2)$. Assuming uniform deceleration at 30 *g*'s, calculate the distance over which the front end of the car must be designed to collapse if a crash brings the car to rest from 95 km/h.

78. The position of a ball rolling in a straight line is given by $x = 2.0 - 3.6t + 1.7t^2$, where $x$ is in meters and $t$ in seconds. (*a*) What do the numbers 2.0, 3.6, and 1.7 refer to? (*b*) What are the units of each of these numbers? (*c*) Determine the position of the ball at $t = 1.0$ s, 2.0 s, and 3.0 s. (*d*) What is the average velocity over the interval $t = 1.0$ s to $t = 3.0$ s?

79. In a lecture demonstration, a 3.0-m-long vertical string with ten bolts tied to it at equal intervals is dropped from the ceiling of the lecture hall. The string falls on a tin plate, and the class hears the clink of each bolt as it hits the plate. (*a*) The sounds will not occur at equal time intervals. Why? (*b*) Will the time between clinks increase or decrease as the string falls? (*c*) How could the bolts be tied so that the clinks occur at equal intervals? (Assume the string is vertical with the bottom bolt touching the tin plate when the string is released.)

80. Two students are asked to find the height of a particular building using a barometer. Instead of using the barometer as an altitude-measuring device, they take it to the roof of the building and drop it off, timing its fall. One student reports a fall time of 2.0 s, and the other, 2.3 s. What % difference does the 0.3 s make for the estimates of the building's height?

**81.** Consider the street pattern shown in Fig. 2–51. Each intersection has a traffic signal, and the speed limit is 40 km/h. Suppose you are driving from the west at the speed limit. When you are 10.0 m from the first intersection, all the lights turn green. The lights are green for 13.0 s each. (*a*) Calculate the time needed to reach the third stoplight. Can you make it through all three lights without stopping? (*b*) Another car was stopped at the first light when all the lights turned green. It can accelerate at the rate of 2.00 m/s$^2$ to the speed limit. Can the second car make it through all three lights without stopping? By how many seconds would it make it, or not make it?

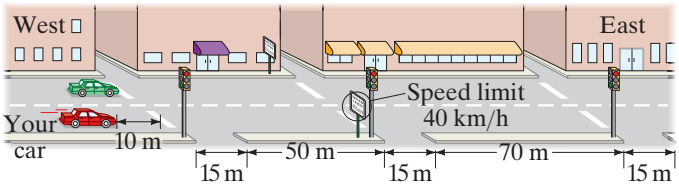

**FIGURE 2–51** Problem 81.

**82.** Suppose a car manufacturer tested its cars for front-end collisions by hauling them up on a crane and dropping them from a certain height. (*a*) Show that the speed just before a car hits the ground, after falling from rest a vertical distance $H$, is given by $\sqrt{2gH}$. What height corresponds to a collision at (*b*) 35 km/h? (*c*) 95 km/h?

**83.** A stone is dropped from the roof of a high building. A second stone is dropped 1.50 s later. How far apart are the stones when the second one has reached a speed of 12.0 m/s?

**84.** A person jumps off a diving board 4.0 m above the water's surface into a deep pool. The person's downward motion stops 1.8 m below the surface of the water. Estimate the average deceleration of the person while under the water.

**85.** A police car at rest is passed by a speeder traveling at a constant 140 km/h. The police officer takes off in hot pursuit and catches up to the speeder in 850 m, maintaining a constant acceleration. (*a*) Qualitatively plot the position vs. time graph for both cars from the police car's start to the catch-up point. Calculate (*b*) how long it took the police officer to overtake the speeder, (*c*) the required police car acceleration, and (*d*) the speed of the police car at the overtaking point. (*e*) This last result is unrealistic—so which assumptions do we have to reconsider?

**86.** Agent Bond is standing on a bridge, 15 m above the road below, and his pursuers are getting too close for comfort. He spots a flatbed truck approaching at 25 m/s, which he measures by knowing that the telephone poles the truck is passing are 25 m apart in this region. The roof of the truck is 3.5 m above the road, and Bond quickly calculates how many poles away the truck should be when he drops down from the bridge onto the truck, making his getaway. How many poles is it?

**87.** Two children are playing on two trampolines. The first child bounces up one-and-a-half times higher than the second child. The initial speed upwards of the second child is 4.0 m/s. (*a*) Find the maximum height the second child reaches. (*b*) What is the initial speed of the first child? (*c*) How long was the first child in the air?

**88.** In putting, the force with which a golfer strikes a ball is planned so that the ball will stop within some small distance of the cup, say 1.0 m long or short, in case the putt is missed. Accomplishing this from an uphill lie (that is, putting the ball downhill, see Fig. 2–52) is more difficult than from a downhill lie. To see why, assume that on a particular "green" the ball decelerates constantly at 1.8 m/s$^2$ going downhill, and constantly at 2.6 m/s$^2$ going uphill. Suppose we have an uphill lie 7.0 m from the cup. Calculate the allowable range of initial velocities we may impart to the ball so that it stops in the range 1.0 m short to 1.0 m long of the cup. Do the same for a downhill lie 7.0 m from the cup. What in your results suggests that the downhill putt is more difficult?

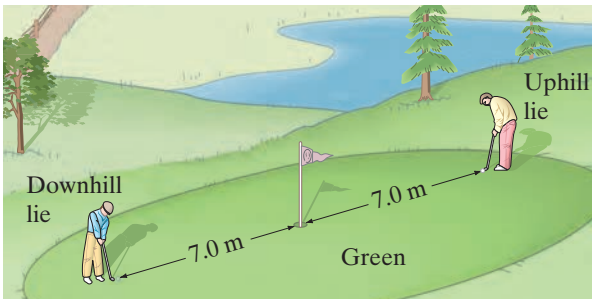

**FIGURE 2–52** Problem 88.

**89.** A person driving her car at 35 km/h approaches an intersection just as the traffic light turns yellow. She knows that the yellow light lasts only 2.0 s before turning to red, and she is 28 m away from the near side of the intersection (Fig. 2–53). Should she try to stop, or should she speed up to cross the intersection before the light turns red? The intersection is 15 m wide. Her car's maximum deceleration is −5.8 m/s$^2$, whereas it can accelerate from 45 km/h to 65 km/h in 6.0 s. Ignore the length of her car and her reaction time.

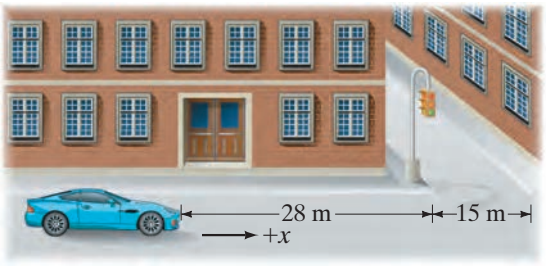

**FIGURE 2–53** Problem 89.

**90.** A car is behind a truck going 18 m/s on the highway. The car's driver looks for an opportunity to pass, guessing that his car can accelerate at 0.60 m/s$^2$ and that he has to cover the 20-m length of the truck, plus 10 m of extra space at the rear of the truck and 10 m more at the front of it. In the oncoming lane, he sees a car approaching, probably at the speed limit, 25 m/s (55 mph). He estimates that the car is about 500 m away. Should he attempt the pass? Give details.

**91.** A rock is dropped from a sea cliff and the sound of it striking the ocean is heard 4.1 s later. If the speed of sound is 340 m/s, how high is the cliff?

**92.** A conveyor belt is used to send burgers through a grilling machine. If the grilling machine is 1.2 m long and the burgers require 2.8 min to cook, how fast must the conveyor belt travel? If the burgers are spaced 25 cm apart, what is the rate of burger production (in burgers/min)?

**93.** A rock is thrown vertically upward with a speed of 15.0 m/s. Exactly 1.00 s later, a ball is thrown up vertically along the same path with a speed of 22.0 m/s. (*a*) At what time will they strike each other? (*b*) At what height will the collision occur? (*c*) Answer (*a*) and (*b*) assuming that the order is reversed: the ball is thrown 1.00 s before the rock.

**94.** Figure 2–54 is a position versus time graph for the motion of an object along the $x$ axis. Consider the time interval from A to B. (*a*) Is the object moving in the positive or negative $x$ direction? (*b*) Is the object speeding up or slowing down? (*c*) Is the acceleration of the object positive or negative? Now consider the time interval from D to E. (*d*) Is the object moving in the positive or negative $x$ direction? (*e*) Is the object speeding up or slowing down? (*f*) Is the acceleration of the object positive or negative? (*g*) Finally, answer these same three questions for the time interval from C to D.

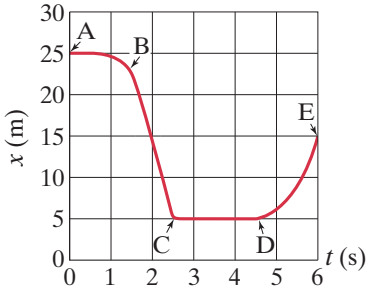

**FIGURE 2–54**
Problem 94.

**95.** In the design of a **rapid transit system**, it is necessary to balance the average speed of a train against the distance between station stops. The more stops there are, the slower the train's average speed. To get an idea of this problem, calculate the time it takes a train to make a 15.0-km trip in two situations: (*a*) the stations at which the trains must stop are 3.0 km apart (a total of 6 stations, including those at the ends); and (*b*) the stations are 5.0 km apart (4 stations total). Assume that at each station the train accelerates at a rate of 1.1 m/s$^2$ until it reaches 95 km/h, then stays at this speed until its brakes are applied for arrival at the next station, at which time it decelerates at $-2.0$ m/s$^2$. Assume it stops at each intermediate station for 22 s.

**96.** A race car driver must average 200.0 km/h over the course of a time trial lasting ten laps. If the first nine laps were done at an average speed of 196.0 km/h, what average speed must be maintained for the last lap?

**97.** A parachutist bails out of an airplane, and freely falls 75 m (ignore air friction). Then the parachute opens, and her acceleration is $-1.5$ m/s$^2$ (up). The parachutist reaches the ground with a speed of 1.5 m/s. (*a*) From how high did she bail out of the plane? (*b*) How much time did her fall take?

**98.** You stand at the top of a cliff while your friend stands on a beach below you. You drop a ball from rest and see that she catches it 1.4 s later. Your friend then throws the ball up to you, and it comes to rest just as it reaches your hand. What is the speed with which your friend threw the ball?

**99.** A robot used in a pharmacy picks up a medicine bottle at $t = 0$. It accelerates at 0.20 m/s$^2$ for 4.5 s, then travels without acceleration for 68 s and finally decelerates at $-0.40$ m/s$^2$ for 2.5 s to reach the counter where the pharmacist will take the medicine from the robot. From how far away did the robot fetch the medicine?

**100.** Bill can throw a ball vertically at a speed 1.5 times faster than Joe can. How many times higher will Bill's ball go than Joe's?

**101.** On an audio compact disc (CD), digital bits of information are encoded sequentially along a spiral path. Each bit occupies about 0.28 $\mu$m. A CD player's readout laser scans along the spiral's sequence of bits at a constant rate of about 1.2 m/s as the CD spins. (*a*) Determine the number $N$ of digital bits that a CD player reads every second. (*b*) The audio information is sent to each of the two loudspeakers 44,100 times per second. Each of these samplings requires 16 bits, and so you might expect the required bit rate for a CD player to be

$$N_0 = 2\left(44{,}100\,\frac{\text{samplings}}{\text{s}}\right)\left(16\,\frac{\text{bits}}{\text{sampling}}\right) = 1.4\times10^6\,\frac{\text{bits}}{\text{s}},$$

where the 2 is for the 2 loudspeakers (the 2 stereo channels). Note that $N_0$ is less than the number $N$ of bits actually read per second by a CD player. The excess number of bits $(= N - N_0)$ is needed for encoding and error correction. What percentage of the bits on a CD are dedicated to encoding and error correction?

**102.** Figure 2–55 shows the position vs. time graph for two bicycles, A and B. (*a*) Identify any instant at which the two bicycles have the same velocity. (*b*) Which bicycle has the larger acceleration? (*c*) At which instant(s) are the bicycles passing each other? Which bicycle is passing the other? (*d*) Which bicycle has the larger instantaneous velocity? (*e*) Which bicycle has the larger average velocity?

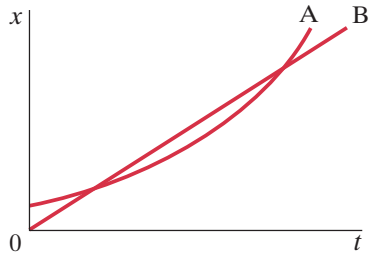

**FIGURE 2–55**
Problem 102.

**103.** You are traveling at a constant speed $v_M$, and there is a car in front of you traveling with a speed $v_A$. You realize that $v_M > v_A$, so you start slowing down with a constant acceleration $a$ when the distance between you and the other car is $x$. What relationship between $a$ and $x$ determines whether or not you run into the car in front of you?

## ANSWERS TO EXERCISES

**A:** (*a*) displacement $= -30$ cm; (*b*) total distance $= 50$ cm.
**B:** (*b*).
**C:** (*b*).
**D:** (*a*) +; (*b*) −; (*c*) −; (*d*) +.
**E:** (*c*).
**F:** (*b*).
**G:** (*e*).
**H:** (*c*).

This snowboarder flying through the air is an example of motion in two dimensions. In the absence of air resistance, the path would be a perfect parabola. The gold arrow represents the downward acceleration of gravity, $\vec{\mathbf{g}}$.

Galileo analyzed the motion of objects in two dimensions under the action of gravity near the Earth's surface (now called "projectile motion") by separating its horizontal and vertical components.

We will discuss how to manipulate vectors and how to add them. Besides analyzing projectile motion, we will also discuss unit vectors and vector kinematics, plus see how to work with relative velocity.

## CHAPTER-OPENING QUESTION—Guess now!

[*Don't worry about getting the right answer now—you will get another chance later in the Chapter. See also page 1 of Chapter 1 for more explanation.*]

A small heavy box of emergency supplies is dropped from a moving helicopter at point A as it flies at constant speed in a horizontal direction. Which path in the drawing below best describes the path of the box (neglecting wind and air resistance) as seen by a person standing on the ground?

In Chapter 2 we dealt with motion along a straight line. We now consider the motion of objects that move in paths in two (or three) dimensions. In particular, we discuss an important type of motion known as *projectile motion*: objects projected outward near the Earth's surface, such as struck baseballs and golf balls, kicked footballs, and other projectiles. Before beginning our discussion of motion in two dimensions, we will need to discuss vectors, and how to add them.

# 3–1 Vectors and Scalars

We mentioned in Chapter 2 that the term *velocity* refers not only to how fast an object is moving but also to its direction. A quantity such as velocity, which has *direction* as well as *magnitude*, is a **vector** quantity. Other quantities that are also vectors are displacement, force, and momentum. However, many quantities have no direction associated with them, such as mass, time, and temperature. They are specified completely by a number and units. Such quantities are called **scalar** quantities.

Drawing a diagram of a particular physical situation is always helpful in physics, and this is especially true when dealing with vectors. On a diagram, each vector is represented by an arrow. The arrow is always drawn so that it points in the direction of the vector quantity it represents. The *length* of the arrow is drawn proportional to the magnitude of the vector quantity. For example, in Fig. 3–1, green arrows have been drawn representing the velocity of a car at various places as it rounds a curve. The magnitude of the velocity at each point can be read off Fig. 3–1 by measuring the length of the corresponding arrow and using the scale shown (1 cm = 90 km/h).

When we write the symbol for a vector, we will always use boldface type, with a tiny arrow over the symbol. Thus for velocity we write $\vec{\mathbf{v}}$. If we are concerned only with the magnitude of the vector, we will write simply $v$, in italics, as we do for other symbols.

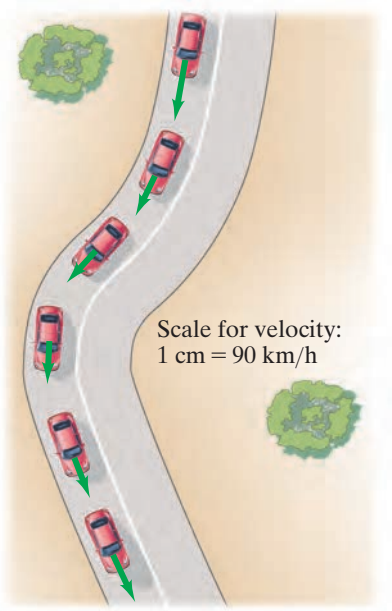

**FIGURE 3–1** Car traveling on a road, slowing down to round the curve. The green arrows represent the velocity vector at each position.

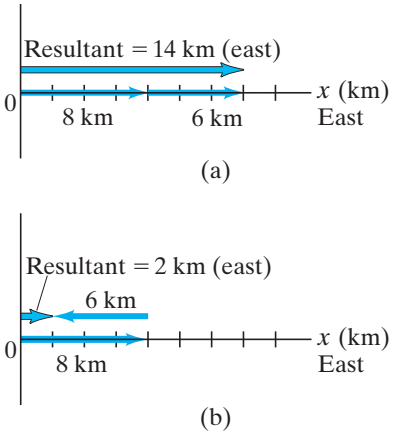

# 3–2 Addition of Vectors—Graphical Methods

Because vectors are quantities that have direction as well as magnitude, they must be added in a special way. In this Chapter, we will deal mainly with displacement vectors, for which we now use the symbol $\vec{\mathbf{D}}$, and velocity vectors, $\vec{\mathbf{v}}$. But the results apply for acceleration and other vectors we will encounter later.

We use simple arithmetic for adding scalars. Simple arithmetic can also be used for adding vectors if they are in the same direction. For example, if a person walks 8 km east one day, and 6 km east the next day, the person will be 8 km + 6 km = 14 km east of the point of origin. We say that the *net* or *resultant* displacement is 14 km to the east (Fig. 3–2a). If, on the other hand, the person walks 8 km east on the first day, and 6 km west (in the reverse direction) on the second day, then the person will end up 2 km from the origin (Fig. 3–2b), so the resultant displacement is 2 km to the east. In this case, the resultant displacement is obtained by subtraction: 8 km − 6 km = 2 km.

But simple arithmetic cannot be used if the two vectors are not along the same line. For example, suppose a person walks 10.0 km east and then walks 5.0 km north. These displacements can be represented on a graph in which the positive $y$ axis points north and the positive $x$ axis points east, Fig. 3–3. On this graph, we draw an arrow, labeled $\vec{\mathbf{D}}_1$, to represent the 10.0-km displacement to the east. Then we draw a second arrow, $\vec{\mathbf{D}}_2$, to represent the 5.0-km displacement to the north. Both vectors are drawn to scale, as shown in Fig. 3–3.

**FIGURE 3–2** Combining vectors in one dimension.

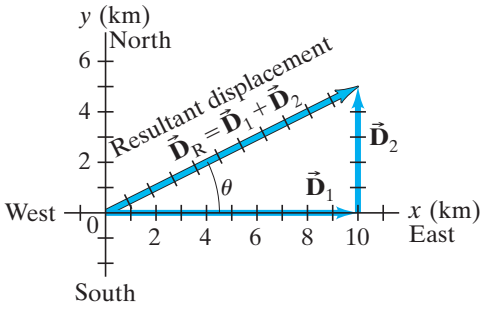

**FIGURE 3–3** A person walks 10.0 km east and then 5.0 km north. These two displacements are represented by the vectors $\vec{\mathbf{D}}_1$ and $\vec{\mathbf{D}}_2$, which are shown as arrows. Also shown is the resultant displacement vector, $\vec{\mathbf{D}}_R$, which is the vector sum of $\vec{\mathbf{D}}_1$ and $\vec{\mathbf{D}}_2$. Measurement on the graph with ruler and protractor shows that $\vec{\mathbf{D}}_R$ has a magnitude of 11.2 km and points at an angle $\theta = 27°$ north of east.

After taking this walk, the person is now 10.0 km east and 5.0 km north of the point of origin. The **resultant displacement** is represented by the arrow labeled $\vec{\mathbf{D}}_R$ in Fig. 3–3. (The subscript R stands for resultant.) Using a ruler and a protractor, you can measure on this diagram (Fig. 3–3 on previous page) that the person is 11.2 km from the origin at an angle $\theta = 27°$ north of east. In other words, the resultant displacement vector has a magnitude of 11.2 km and makes an angle $\theta = 27°$ with the positive $x$ axis. The magnitude (length) of $\vec{\mathbf{D}}_R$ can also be obtained using the theorem of Pythagoras in this case, because $D_1$, $D_2$, and $D_R$ form a right triangle with $D_R$ as the hypotenuse. Thus

$$D_R = \sqrt{D_1^2 + D_2^2} = \sqrt{(10.0\,\text{km})^2 + (5.0\,\text{km})^2}$$
$$= \sqrt{125\,\text{km}^2} = 11.2\,\text{km}.$$

You can use the Pythagorean theorem only when the vectors are *perpendicular* to each other.

The resultant displacement vector, $\vec{\mathbf{D}}_R$, is the sum of the vectors $\vec{\mathbf{D}}_1$ and $\vec{\mathbf{D}}_2$. That is,

$$\vec{\mathbf{D}}_R = \vec{\mathbf{D}}_1 + \vec{\mathbf{D}}_2.$$

This is a *vector* equation. An important feature of adding two vectors that are not along the same line is that the magnitude of the resultant vector is not equal to the sum of the magnitudes of the two separate vectors, but is smaller than their sum. That is,

$$D_R \leq (D_1 + D_2),$$

where the equals sign applies only if the two vectors point in the same direction. In our example (Fig. 3–3), $D_R = 11.2$ km, whereas $D_1 + D_2$ equals 15 km, which is the total distance traveled. Note also that we cannot set $\vec{\mathbf{D}}_R$ equal to 11.2 km, because we have a vector equation and 11.2 km is only a part of the resultant vector, its magnitude. We could write something like this, though: $\vec{\mathbf{D}}_R = \vec{\mathbf{D}}_1 + \vec{\mathbf{D}}_2 = (11.2\,\text{km}, 27°\ \text{N of E})$.

Figure 3–3 illustrates the general rules for graphically adding two vectors together, no matter what angles they make, to get their sum. The rules are as follows:

1. On a diagram, draw one of the vectors—call it $\vec{\mathbf{D}}_1$—to scale.
2. Next draw the second vector, $\vec{\mathbf{D}}_2$, to scale, placing its tail at the tip of the first vector and being sure its direction is correct.
3. The arrow drawn from the tail of the first vector to the tip of the second vector represents the *sum*, or **resultant**, of the two vectors.

The length of the resultant vector represents its magnitude. Note that vectors can be moved parallel to themselves on paper (maintaining the same length and angle) to accomplish these manipulations. The length of the resultant can be measured with a ruler and compared to the scale. Angles can be measured with a protractor. This method is known as the **tail-to-tip method of adding vectors**.

The resultant is not affected by the order in which the vectors are added. For example, a displacement of 5.0 km north, to which is added a displacement of 10.0 km east, yields a resultant of 11.2 km and angle $\theta = 27°$ (see Fig. 3–4), the same as when they were added in reverse order (Fig. 3–3). Thus we can write, using $\vec{\mathbf{V}}$ to represent any type of vector,

$$\vec{\mathbf{V}}_1 + \vec{\mathbf{V}}_2 = \vec{\mathbf{V}}_2 + \vec{\mathbf{V}}_1, \qquad \text{[commutative property]} \quad \textbf{(3–1a)}$$

which is known as the *commutative* property of vector addition.

The tail-to-tip method of adding vectors can be extended to three or more vectors. The resultant is drawn from the tail of the first vector to the tip of the last

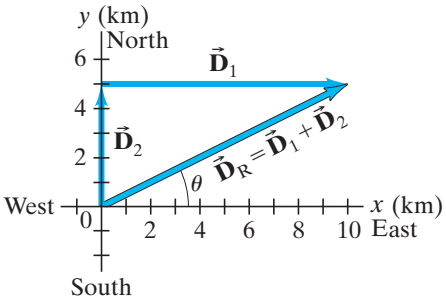

**FIGURE 3–4** If the vectors are added in reverse order, the resultant is the same. (Compare to Fig. 3–3.)

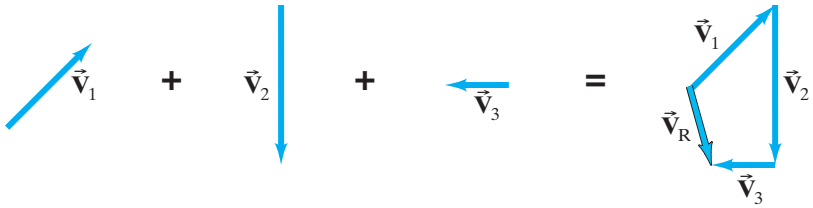

**FIGURE 3–5** The resultant of three vectors: $\vec{V}_R = \vec{V}_1 + \vec{V}_2 + \vec{V}_3$.

one added. An example is shown in Fig. 3–5; the three vectors could represent displacements (northeast, south, west) or perhaps three forces. Check for yourself that you get the same resultant no matter in which order you add the three vectors; that is,

$$(\vec{V}_1 + \vec{V}_2) + \vec{V}_3 = \vec{V}_1 + (\vec{V}_2 + \vec{V}_3), \quad \text{[associative property]} \quad \textbf{(3–1b)}$$

which is known as the *associative* property of vector addition.

A second way to add two vectors is the **parallelogram method**. It is fully equivalent to the tail-to-tip method. In this method, the two vectors are drawn starting from a common origin, and a parallelogram is constructed using these two vectors as adjacent sides as shown in Fig. 3–6b. The resultant is the diagonal drawn from the common origin. In Fig. 3–6a, the tail-to-tip method is shown, and we can see that both methods yield the same result.

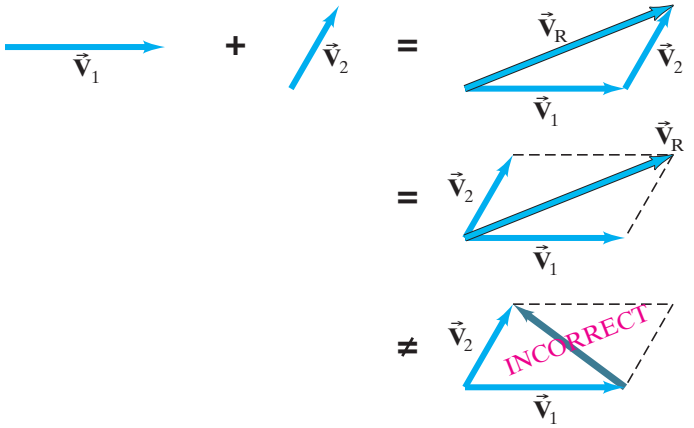

**FIGURE 3–6** Vector addition by two different methods, (a) and (b). Part (c) is incorrect.

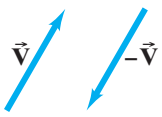
It is a common error to draw the sum vector as the diagonal running between the tips of the two vectors, as in Fig. 3–6c. *This is incorrect*: it does not represent the sum of the two vectors. (In fact, it represents their difference, $\vec{V}_2 - \vec{V}_1$, as we will see in the next Section.)

**CAUTION**

*Be sure to use the correct diagonal on the parallelogram to get the resultant*

**CONCEPTUAL EXAMPLE 3–1** **Range of vector lengths.** Suppose two vectors each have length 3.0 units. What is the range of possible lengths for the vector representing the sum of the two?



**RESPONSE** The sum can take on any value from 6.0 $(= 3.0 + 3.0)$ where the vectors point in the same direction, to 0 $(= 3.0 - 3.0)$ when the vectors are antiparallel. Magnitudes between 0 and 6.0 occur when the two vectors are at an angle other than 0° and 180°.

**EXERCISE A** If the two vectors of Example 3–1 are perpendicular to each other, what is the resultant vector length?

## 3–3 Subtraction of Vectors, and Multiplication of a Vector by a Scalar

Given a vector $\vec{V}$, we define the *negative* of this vector $(-\vec{V})$ to be a vector with the same magnitude as $\vec{V}$ but opposite in direction, Fig. 3–7. Note, however, that no vector is ever negative in the sense of its magnitude: the magnitude of every vector is positive. Rather, a minus sign tells us about its direction.

**FIGURE 3–7** The negative of a vector is a vector having the same length but opposite direction.

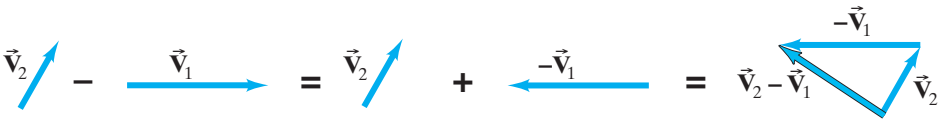


**FIGURE 3–8** Subtracting two vectors: $\vec{\mathbf{V}}_2 - \vec{\mathbf{V}}_1$.

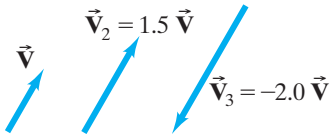

We can now define the subtraction of one vector from another: the difference between two vectors $\vec{\mathbf{V}}_2 - \vec{\mathbf{V}}_1$ is defined as

$$\vec{\mathbf{V}}_2 - \vec{\mathbf{V}}_1 = \vec{\mathbf{V}}_2 + (-\vec{\mathbf{V}}_1).$$

That is, the difference between two vectors is equal to the sum of the first plus the negative of the second. Thus our rules for addition of vectors can be applied as shown in Fig. 3–8 using the tail-to-tip method.

A vector $\vec{\mathbf{V}}$ can be multiplied by a scalar $c$. We define their product so that $c\vec{\mathbf{V}}$ has the same direction as $\vec{\mathbf{V}}$ and has magnitude $cV$. That is, multiplication of a vector by a positive scalar $c$ changes the magnitude of the vector by a factor $c$ but doesn't alter the direction. If $c$ is a negative scalar, the magnitude of the product $c\vec{\mathbf{V}}$ is still $|c|V$ (where $|c|$ means the magnitude of $c$), but the direction is precisely opposite to that of $\vec{\mathbf{V}}$. See Fig. 3–9.

**FIGURE 3–9** Multiplying a vector $\vec{\mathbf{V}}$ by a scalar $c$ gives a vector whose magnitude is $c$ times greater and in the same direction as $\vec{\mathbf{V}}$ (or opposite direction if $c$ is negative).

**EXERCISE B** What does the "incorrect" vector in Fig. 3–6c represent? (*a*) $\vec{\mathbf{V}}_2 - \vec{\mathbf{V}}_1$, (*b*) $\vec{\mathbf{V}}_1 - \vec{\mathbf{V}}_2$, (*c*) something else (specify).

## 3–4 Adding Vectors by Components

Adding vectors graphically using a ruler and protractor is often not sufficiently accurate and is not useful for vectors in three dimensions. We discuss now a more powerful and precise method for adding vectors. But do not forget graphical methods—they are useful for visualizing, for checking your math, and thus for getting the correct result.

Consider first a vector $\vec{\mathbf{V}}$ that lies in a particular plane, and we have chosen an $x$ and a $y$ axis on this plane. Then $\vec{\mathbf{V}}$ can be expressed as the sum of two other vectors, called the **components** of the original vector, which are usually chosen to be along the $x$ and $y$ axes. The process of finding the components is known as **resolving the vector into its components**. An example is shown in Fig. 3–10; the vector $\vec{\mathbf{V}}$ could be a displacement vector that points at an angle $\theta = 30°$ north of east, where we have chosen the positive $x$ axis to be to the east and the positive $y$ axis north. This vector $\vec{\mathbf{V}}$ is resolved into its $x$ and $y$ components by drawing dashed lines out from the tip (A) of the vector (lines AB and AC), making them perpendicular to the $x$ and $y$ axes. Then the lines 0B and 0C represent the $x$ and $y$ components of $\vec{\mathbf{V}}$, respectively, as shown in Fig. 3–10b. These *vector components* are written $\vec{\mathbf{V}}_x$ and $\vec{\mathbf{V}}_y$. In this book we usually show vector components as arrows, like vectors, but dashed. The *scalar components*, $V_x$ and $V_y$, are the magnitudes of the vector components, with units, accompanied by a positive or negative sign depending on whether they point along the positive or negative $x$ or $y$ axis. As can be seen in Fig. 3–10, $\vec{\mathbf{V}}_x + \vec{\mathbf{V}}_y = \vec{\mathbf{V}}$ by the parallelogram method of adding vectors.

Space is made up of three dimensions, and sometimes it is necessary to resolve a vector into components along three mutually perpendicular directions. In rectangular coordinates the components are $\vec{\mathbf{V}}_x$, $\vec{\mathbf{V}}_y$, and $\vec{\mathbf{V}}_z$.

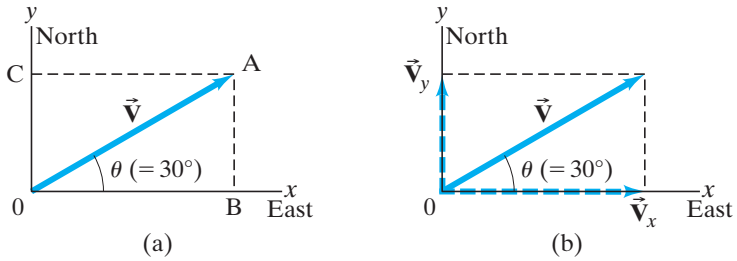

**FIGURE 3–10** Resolving a vector $\vec{\mathbf{V}}$ into its components along a chosen set of $x$ and $y$ axes. The components, once found, themselves represent the vector. That is, the components contain as much information as the vector itself.

The use of trigonometric functions for finding the components of a vector is illustrated in Fig. 3–11, where a vector and its two components are thought of as making up a right triangle. (See also Appendix A for other details on trigonometric functions and identities.) We then see that the sine, cosine, and tangent are as given in Fig. 3–11, where $\theta$ is the angle $\vec{\mathbf{V}}$ makes with the $+x$ axis, measured positive counterclockwise. If we multiply the definition of $\sin\theta = V_y/V$ by $V$ on both sides, we get

$$V_y = V\sin\theta. \tag{3–2a}$$

Similarly, from the definition of $\cos\theta$, we obtain

$$V_x = V\cos\theta. \tag{3–2b}$$

Keep in mind that $\theta$ is chosen (by convention) to be the angle that the vector makes with the positive $x$ axis, measured positive counterclockwise.

The components of a given vector will be different for different choices of coordinate axes. It is therefore crucial to specify the choice of coordinate system when giving the components.

There are two ways to specify a vector in a given coordinate system:

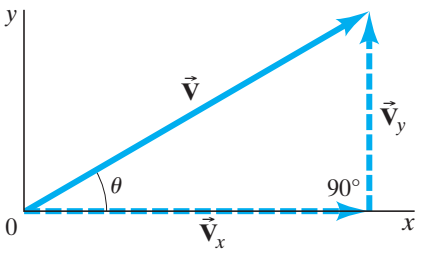
1. We can give its components, $V_x$ and $V_y$.
2. We can give its magnitude $V$ and the angle $\theta$ it makes with the positive $x$ axis.

We can shift from one description to the other using Eqs. 3–2, and, for the reverse, by using the theorem of Pythagoras[†] and the definition of tangent:

$$V = \sqrt{V_x^2 + V_y^2} \tag{3–3a}$$

$$\tan\theta = \frac{V_y}{V_x} \tag{3–3b}$$

as can be seen in Fig. 3–11.



We can now discuss how to add vectors using components. The first step is to resolve each vector into its components, Eqs. 3–2. Next we can see, using Fig. 3–12, that the addition of any two vectors $\vec{\mathbf{V}}_1$ and $\vec{\mathbf{V}}_2$ to give a resultant $\vec{\mathbf{V}}_R = \vec{\mathbf{V}}_1 + \vec{\mathbf{V}}_2$, implies that

$$\begin{aligned} V_{Rx} &= V_{1x} + V_{2x} \\ V_{Ry} &= V_{1y} + V_{2y}. \end{aligned} \tag{3–4}$$

That is, the sum of the $x$ components equals the $x$ component of the resultant vector, and the sum of the $y$ components equals the $y$ component of the resultant vector, as can be verified by a careful examination of Fig. 3–12. Note that we do *not* add $x$ components to $y$ components.

If the magnitude and direction of the resultant vector are desired, they can be obtained using Eqs. 3–3.

[†]In three dimensions, the theorem of Pythagoras becomes $V = \sqrt{V_x^2 + V_y^2 + V_z^2}$, where $V_z$ is the component along the third, or $z$, axis.

$$\sin\theta = \frac{V_y}{V}$$
$$\cos\theta = \frac{V_x}{V}$$
$$\tan\theta = \frac{V_y}{V_x}$$
$$V^2 = V_x^2 + V_y^2$$

**FIGURE 3–11** Finding the components of a vector using trigonometric functions. The equations are valid only if $\theta$ is the angle $\vec{\mathbf{V}}$ makes with the positive $x$ axis.

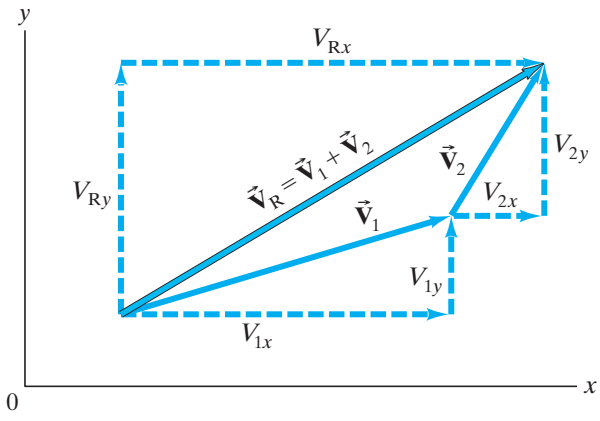


**FIGURE 3–12** The components of $\vec{\mathbf{V}}_R = \vec{\mathbf{V}}_1 + \vec{\mathbf{V}}_2$ are
$V_{Rx} = V_{1x} + V_{2x}$
$V_{Ry} = V_{1y} + V_{2y}$.

The components of a given vector depend on the choice of coordinate axes. You can often reduce the work involved in adding vectors by a good choice of axes—for example, by choosing one of the axes to be in the same direction as one of the vectors. Then that vector will have only one nonzero component.

**EXAMPLE 3–2** **Mail carrier's displacement.** A rural mail carrier leaves the post office and drives 22.0 km in a northerly direction. She then drives in a direction 60.0° south of east for 47.0 km (Fig. 3–13a). What is her displacement from the post office?

**APPROACH** We choose the positive $x$ axis to be east and the positive $y$ axis to be north, since those are the compass directions used on most maps. The origin of the $xy$ coordinate system is at the post office. We resolve each vector into its $x$ and $y$ components. We add the $x$ components together, and then the $y$ components together, giving us the $x$ and $y$ components of the resultant.

**SOLUTION** Resolve each displacement vector into its components, as shown in Fig. 3–13b. Since $\vec{\mathbf{D}}_1$ has magnitude 22.0 km and points north, it has only a $y$ component:

$$D_{1x} = 0, \qquad D_{1y} = 22.0\,\text{km}.$$

$\vec{\mathbf{D}}_2$ has both $x$ and $y$ components:

$$D_{2x} = +(47.0\,\text{km})(\cos 60°) = +(47.0\,\text{km})(0.500) = +23.5\,\text{km}$$
$$D_{2y} = -(47.0\,\text{km})(\sin 60°) = -(47.0\,\text{km})(0.866) = -40.7\,\text{km}.$$

Notice that $D_{2y}$ is negative because this vector component points along the negative $y$ axis. The resultant vector, $\vec{\mathbf{D}}_\text{R}$, has components:

$$D_{\text{R}x} = D_{1x} + D_{2x} = 0\,\text{km} + 23.5\,\text{km} = +23.5\,\text{km}$$
$$D_{\text{R}y} = D_{1y} + D_{2y} = 22.0\,\text{km} + (-40.7\,\text{km}) = -18.7\,\text{km}.$$

This specifies the resultant vector completely:

$$D_{\text{R}x} = 23.5\,\text{km}, \qquad D_{\text{R}y} = -18.7\,\text{km}.$$

We can also specify the resultant vector by giving its magnitude and angle using Eqs. 3–3:

$$D_\text{R} = \sqrt{D_{\text{R}x}^2 + D_{\text{R}y}^2} = \sqrt{(23.5\,\text{km})^2 + (-18.7\,\text{km})^2} = 30.0\,\text{km}$$

$$\tan\theta = \frac{D_{\text{R}y}}{D_{\text{R}x}} = \frac{-18.7\,\text{km}}{23.5\,\text{km}} = -0.796.$$

A calculator with a key labeled INV TAN, or ARC TAN, or $\text{TAN}^{-1}$ gives $\theta = \tan^{-1}(-0.796) = -38.5°$. The negative sign means $\theta = 38.5°$ below the $x$ axis, Fig. 3–13c. So, the resultant displacement is 30.0 km directed at 38.5° in a southeasterly direction.

**NOTE** Always be attentive about the quadrant in which the resultant vector lies. An electronic calculator does not fully give this information, but a good diagram does.

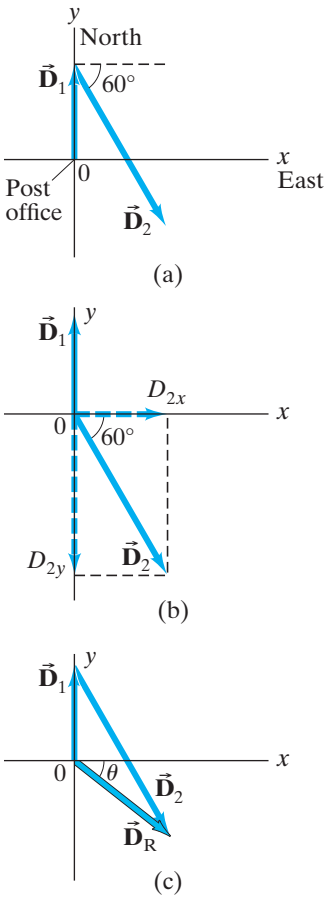

**FIGURE 3–13** Example 3–2. (a) The two displacement vectors, $\vec{\mathbf{D}}_1$ and $\vec{\mathbf{D}}_2$. (b) $\vec{\mathbf{D}}_2$ is resolved into its components. (c) $\vec{\mathbf{D}}_1$ and $\vec{\mathbf{D}}_2$ are added graphically to obtain the resultant $\vec{\mathbf{D}}_\text{R}$. The component method of adding the vectors is explained in the Example.

**PROBLEM SOLVING**
*Identify the correct quadrant by drawing a careful diagram*

As we saw in Example 3–2, any component that points along the negative $x$ or $y$ axis gets a minus sign. The signs of trigonometric functions depend on which "quadrant" the angle falls in: for example, the tangent is positive in the first and third quadrants (from 0° to 90°, and 180° to 270°), but negative in the second and fourth quadrants; see Appendix A–9, Fig. A–6. The best way to keep track of angles, and to check any vector result, is always to draw a vector diagram, like Fig. 3–13. A vector diagram gives you something tangible to look at when analyzing a problem, and provides a check on the results.

The following Problem Solving Strategy should not be considered a prescription. Rather it is a summary of things to do to get you thinking and involved in the problem at hand.

PROBLEM SOLVING

## Adding Vectors

Here is a brief summary of how to add two or more vectors using components:

1. **Draw a diagram**, adding the vectors graphically by either the parallelogram or tail-to-tip method.
2. **Choose** $x$ and $y$ **axes**. Choose them in a way, if possible, that will make your work easier. (For example, choose one axis along the direction of one of the vectors, which then will have only one component.)
3. **Resolve** each vector into its $x$ and $y$ **components**, showing each component along its appropriate ($x$ or $y$) axis as a (dashed) arrow.
4. **Calculate each component** (when not given) using sines and cosines. If $\theta_1$ is the angle that vector $\vec{\mathbf{V}}_1$ makes with the positive $x$ axis, then:

$$V_{1x} = V_1 \cos\theta_1, \qquad V_{1y} = V_1 \sin\theta_1.$$

Pay careful attention to **signs**: any component that points along the negative $x$ or $y$ axis gets a minus sign.

5. **Add** the $x$ **components** together to get the $x$ component of the resultant. Similarly for $y$:

$$V_{Rx} = V_{1x} + V_{2x} + \text{any others}$$
$$V_{Ry} = V_{1y} + V_{2y} + \text{any others}.$$

This is the answer: the components of the resultant vector. Check signs to see if they fit the quadrant shown in your diagram (point 1 above).

6. If you want to know the **magnitude and direction** of the resultant vector, use Eqs. 3–3:

$$V_R = \sqrt{V_{Rx}^2 + V_{Ry}^2}, \qquad \tan\theta = \frac{V_{Ry}}{V_{Rx}}.$$

The vector diagram you already drew helps to obtain the correct position (quadrant) of the angle $\theta$.

**EXAMPLE 3–3** **Three short trips.** An airplane trip involves three legs, with two stopovers, as shown in Fig. 3–14a. The first leg is due east for 620 km; the second leg is southeast (45°) for 440 km; and the third leg is at 53° south of west, for 550 km, as shown. What is the plane's total displacement?

**APPROACH** We follow the steps in the Problem Solving Strategy above.

**SOLUTION**

1. **Draw a diagram** such as Fig. 3–14a, where $\vec{\mathbf{D}}_1$, $\vec{\mathbf{D}}_2$, and $\vec{\mathbf{D}}_3$ represent the three legs of the trip, and $\vec{\mathbf{D}}_R$ is the plane's total displacement.
2. **Choose axes**: Axes are also shown in Fig. 3–14a: $x$ is east, $y$ north.
3. **Resolve components**: It is imperative to draw a good diagram. The components are drawn in Fig. 3–14b. Instead of drawing all the vectors starting from a common origin, as we did in Fig. 3–13b, here we draw them "tail-to-tip" style, which is just as valid and may make it easier to see.
4. **Calculate the components**:

$$\vec{\mathbf{D}}_1: D_{1x} = +D_1\cos 0° = D_1 = 620\text{ km}$$
$$D_{1y} = +D_1\sin 0° = 0\text{ km}$$
$$\vec{\mathbf{D}}_2: D_{2x} = +D_2\cos 45° = +(440\text{ km})(0.707) = +311\text{ km}$$
$$D_{2y} = -D_2\sin 45° = -(440\text{ km})(0.707) = -311\text{ km}$$
$$\vec{\mathbf{D}}_3: D_{3x} = -D_3\cos 53° = -(550\text{ km})(0.602) = -331\text{ km}$$
$$D_{3y} = -D_3\sin 53° = -(550\text{ km})(0.799) = -439\text{ km}.$$

We have given a minus sign to each component that in Fig. 3–14b points in the $-x$ or $-y$ direction. The components are shown in the Table in the margin.

5. **Add the components**: We add the $x$ components together, and we add the $y$ components together to obtain the $x$ and $y$ components of the resultant:

$$D_{Rx} = D_{1x} + D_{2x} + D_{3x} = 620\text{ km} + 311\text{ km} - 331\text{ km} = 600\text{ km}$$
$$D_{Ry} = D_{1y} + D_{2y} + D_{3y} = 0\text{ km} - 311\text{ km} - 439\text{ km} = -750\text{ km}.$$

The $x$ and $y$ components of the resultant are 600 km and −750 km, and point respectively to the east and south. This is one way to give the answer.

6. **Magnitude and direction**: We can also give the answer as

$$D_R = \sqrt{D_{Rx}^2 + D_{Ry}^2} = \sqrt{(600)^2 + (-750)^2}\,\text{km} = 960\text{ km}$$
$$\tan\theta = \frac{D_{Ry}}{D_{Rx}} = \frac{-750\text{ km}}{600\text{ km}} = -1.25, \qquad \text{so } \theta = -51°.$$

Thus, the total displacement has magnitude 960 km and points 51° below the $x$ axis (south of east), as was shown in our original sketch, Fig. 3–14a.

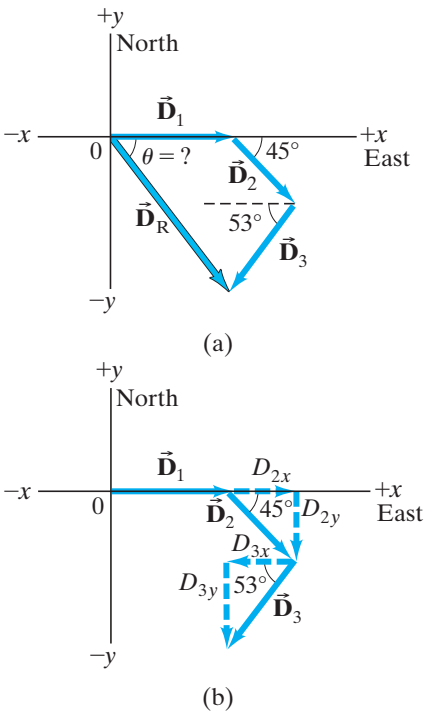

**FIGURE 3–14** Example 3–3.

| Vector | Components $x$ (km) | $y$ (km) |
|---|---|---|
| $\vec{\mathbf{D}}_1$ | 620 | 0 |
| $\vec{\mathbf{D}}_2$ | 311 | −311 |
| $\vec{\mathbf{D}}_3$ | −331 | −439 |
| $\vec{\mathbf{D}}_R$ | 600 | −750 |

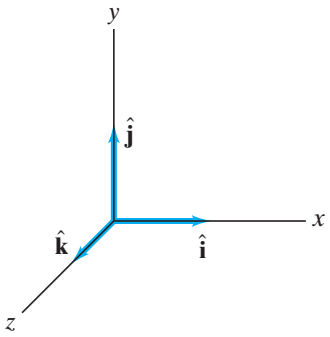

**FIGURE 3–15** Unit vectors $\hat{\mathbf{i}}$, $\hat{\mathbf{j}}$, and $\hat{\mathbf{k}}$ along the $x$, $y$, and $z$ axes.

# 3–5 Unit Vectors

Vectors can be conveniently written in terms of *unit vectors*. A **unit vector** is defined to have a magnitude exactly equal to one (1). (The word "unit" comes from the Latin, unus, meaning "one".) It is useful to define unit vectors that point along coordinate axes, and in an $x$, $y$, $z$ rectangular coordinate system these unit vectors are called $\hat{\mathbf{i}}$, $\hat{\mathbf{j}}$, and $\hat{\mathbf{k}}$. They point, respectively, along the positive $x$, $y$, and $z$ axes as shown in Fig. 3–15. Like other vectors, $\hat{\mathbf{i}}$, $\hat{\mathbf{j}}$, and $\hat{\mathbf{k}}$ do not have to be placed at the origin, but can be placed elsewhere as long as the direction and unit length remain unchanged. It is common to write unit vectors with a "hat": $\hat{\mathbf{i}}$, $\hat{\mathbf{j}}$, $\hat{\mathbf{k}}$ (and we will do so in this book) as a reminder that each has magnitude of exactly one unit.

Because of the definition of multiplication of a vector by a scalar (Section 3–3), the components of a vector $\vec{\mathbf{V}}$ can be written $\vec{\mathbf{V}}_x = V_x\hat{\mathbf{i}}$, $\vec{\mathbf{V}}_y = V_y\hat{\mathbf{j}}$, and $\vec{\mathbf{V}}_z = V_z\hat{\mathbf{k}}$. Hence any vector $\vec{\mathbf{V}}$ can be written in terms of its components as

$$\vec{\mathbf{V}} = V_x\hat{\mathbf{i}} + V_y\hat{\mathbf{j}} + V_z\hat{\mathbf{k}}. \qquad \textbf{(3–5)}$$

Unit vectors are helpful when adding vectors analytically by components. For example, Eq. 3–4 can be seen to be true by using unit vector notation for each vector (which we write for the two-dimensional case, with the extension to three dimensions being straightforward):

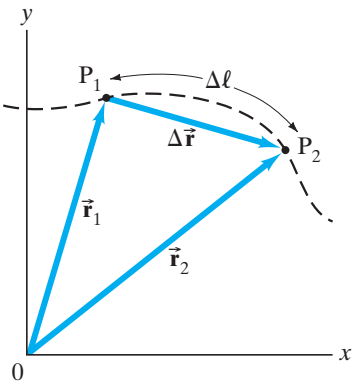
$$\begin{aligned}\vec{\mathbf{V}}_R = (V_{Rx})\hat{\mathbf{i}} + (V_{Ry})\hat{\mathbf{j}} &= \vec{\mathbf{V}}_1 + \vec{\mathbf{V}}_2 \\ &= (V_{1x}\hat{\mathbf{i}} + V_{1y}\hat{\mathbf{j}}) + (V_{2x}\hat{\mathbf{i}} + V_{2y}\hat{\mathbf{j}}) \\ &= (V_{1x} + V_{2x})\hat{\mathbf{i}} + (V_{1y} + V_{2y})\hat{\mathbf{j}}.\end{aligned}$$

Comparing the first line to the third line, we get Eqs. 3–4.

**EXAMPLE 3–4** **Using unit vectors.** Write the vectors of Example 3–2 in unit vector notation, and perform the addition.

**APPROACH** We use the components we found in Example 3–2, $D_{1x} = 0$, $D_{1y} = 22.0\,\text{km}$, and $D_{2x} = 23.5\,\text{km}$, $D_{2y} = -40.7\,\text{km}$, and we now write them in the form of Eq. 3–5.

**SOLUTION** We have



$$\begin{aligned}\vec{\mathbf{D}}_1 &= 0\hat{\mathbf{i}} + 22.0\,\text{km}\,\hat{\mathbf{j}} \\ \vec{\mathbf{D}}_2 &= 23.5\,\text{km}\,\hat{\mathbf{i}} - 40.7\,\text{km}\,\hat{\mathbf{j}}.\end{aligned}$$

Then the resultant displacement is

$$\begin{aligned}\vec{\mathbf{D}}_R = \vec{\mathbf{D}}_1 + \vec{\mathbf{D}}_2 &= (0 + 23.5)\,\text{km}\,\hat{\mathbf{i}} + (22.0 - 40.7)\,\text{km}\,\hat{\mathbf{j}} \\ &= 23.5\,\text{km}\,\hat{\mathbf{i}} - 18.7\,\text{km}\,\hat{\mathbf{j}}.\end{aligned}$$

The components of the resultant displacement, $\vec{\mathbf{D}}_R$, are $D_x = 23.5\,\text{km}$ and $D_y = -18.7\,\text{km}$. The magnitude of $\vec{\mathbf{D}}_R$ is $D_R = \sqrt{(23.5\,\text{km})^2 + (18.7\,\text{km})^2} = 30.0\,\text{km}$, just as in Example 3–2.

**FIGURE 3–16** Path of a particle in the $xy$ plane. At time $t_1$ the particle is at point $P_1$ given by the position vector $\vec{\mathbf{r}}_1$; at $t_2$ the particle is at point $P_2$ given by the position vector $\vec{\mathbf{r}}_2$. The displacement vector for the time interval $t_2 - t_1$ is $\Delta\vec{\mathbf{r}} = \vec{\mathbf{r}}_2 - \vec{\mathbf{r}}_1$. The actual distance traveled along the path between $P_1$ and $P_2$ is $\Delta\ell$.

# 3–6 Vector Kinematics

We can now extend our definitions of velocity and acceleration in a formal way to two- and three-dimensional motion. Suppose a particle follows a path in the $xy$ plane as shown in Fig. 3–16. At time $t_1$, the particle is at point $P_1$, and at time $t_2$, it is at point $P_2$. The vector $\vec{\mathbf{r}}_1$ is the position vector of the particle at time $t_1$ (it represents the displacement of the particle from the origin of the coordinate system). And $\vec{\mathbf{r}}_2$ is the position vector at time $t_2$.

In one dimension, we defined displacement as the *change in position* of the particle. In the more general case of two or three dimensions, the **displacement vector** is defined as the vector representing change in position. We call it $\Delta\vec{\mathbf{r}}$,[†] where

$$\Delta\vec{\mathbf{r}} = \vec{\mathbf{r}}_2 - \vec{\mathbf{r}}_1.$$

This represents the displacement during the time interval $\Delta t = t_2 - t_1$.

[†]We used $\vec{\mathbf{D}}$ for the displacement vector earlier in the Chapter for illustrating vector addition. The new notation here, $\Delta\vec{\mathbf{r}}$, emphasizes that it is the difference between two position vectors.

In unit vector notation, we can write

$$\vec{\mathbf{r}}_1 = x_1\hat{\mathbf{i}} + y_1\hat{\mathbf{j}} + z_1\hat{\mathbf{k}}, \tag{3–6a}$$

where $x_1$, $y_1$, and $z_1$ are the coordinates of point $P_1$. Similarly,

$$\vec{\mathbf{r}}_2 = x_2\hat{\mathbf{i}} + y_2\hat{\mathbf{j}} + z_2\hat{\mathbf{k}}.$$

Hence

$$\Delta\vec{\mathbf{r}} = (x_2 - x_1)\hat{\mathbf{i}} + (y_2 - y_1)\hat{\mathbf{j}} + (z_2 - z_1)\hat{\mathbf{k}}. \tag{3–6b}$$

If the motion is along the $x$ axis only, then $y_2 - y_1 = 0$, $z_2 - z_1 = 0$, and the magnitude of the displacement is $\Delta r = x_2 - x_1$, which is consistent with our earlier one-dimensional equation (Section 2–1). Even in one dimension, displacement is a vector, as are velocity and acceleration.

The **average velocity vector** over the time interval $\Delta t = t_2 - t_1$ is defined as

$$\text{average velocity} = \frac{\Delta\vec{\mathbf{r}}}{\Delta t}. \tag{3–7}$$

Now let us consider shorter and shorter time intervals—that is, we let $\Delta t$ approach zero so that the distance between points $P_2$ and $P_1$ also approaches zero, Fig. 3–17a. We define the **instantaneous velocity vector** as the limit of the average velocity as $\Delta t$ approaches zero:

$$\vec{\mathbf{v}} = \lim_{\Delta t \to 0} \frac{\Delta\vec{\mathbf{r}}}{\Delta t} = \frac{d\vec{\mathbf{r}}}{dt}. \tag{3–8}$$

The direction of $\vec{\mathbf{v}}$ at any moment is along the line tangent to the path at that moment (Fig. 3–17b).

Note that the magnitude of the average velocity in Fig. 3–16 is not equal to the average speed, which is the actual distance traveled along the path, $\Delta\ell$, divided by $\Delta t$. In some special cases, the average speed and average velocity are equal in magnitude (such as motion along a straight line in one direction), but in general they are not. However, in the limit $\Delta t \to 0$, $\Delta r$ always approaches $\Delta\ell$, so the instantaneous speed *always* equals the magnitude of the instantaneous velocity at any time.

The instantaneous velocity (Eq. 3–8) is equal to the derivative of the position vector with respect to time. Equation 3–8 can be written in terms of components starting with Eq. 3–6a as:

$$\vec{\mathbf{v}} = \frac{d\vec{\mathbf{r}}}{dt} = \frac{dx}{dt}\hat{\mathbf{i}} + \frac{dy}{dt}\hat{\mathbf{j}} + \frac{dz}{dt}\hat{\mathbf{k}} = v_x\hat{\mathbf{i}} + v_y\hat{\mathbf{j}} + v_z\hat{\mathbf{k}}, \tag{3–9}$$

where $v_x = dx/dt$, $v_y = dy/dt$, $v_z = dz/dt$ are the $x$, $y$, and $z$ components of the velocity. Note that $d\hat{\mathbf{i}}/dt = d\hat{\mathbf{j}}/dt = d\hat{\mathbf{k}}/dt = 0$ since these unit vectors are constant in both magnitude and direction.

Acceleration in two or three dimensions is treated in a similar way. The **average acceleration vector**, over a time interval $\Delta t = t_2 - t_1$ is defined as

$$\text{average acceleration} = \frac{\Delta\vec{\mathbf{v}}}{\Delta t} = \frac{\vec{\mathbf{v}}_2 - \vec{\mathbf{v}}_1}{t_2 - t_1}, \tag{3–10}$$

where $\Delta\vec{\mathbf{v}}$ is the change in the instantaneous velocity vector during that time interval: $\Delta\vec{\mathbf{v}} = \vec{\mathbf{v}}_2 - \vec{\mathbf{v}}_1$. Note that $\vec{\mathbf{v}}_2$ in many cases, such as in Fig. 3–18a, may not be in the same direction as $\vec{\mathbf{v}}_1$. Hence the average acceleration vector may be in a different direction from either $\vec{\mathbf{v}}_1$ or $\vec{\mathbf{v}}_2$ (Fig. 3–18b). Furthermore, $\vec{\mathbf{v}}_2$ and $\vec{\mathbf{v}}_1$ may have the same magnitude but different directions, and the difference of two such vectors will not be zero. Hence acceleration can result from either a change in the magnitude of the velocity, or from a change in direction of the velocity, or from a change in both.

The **instantaneous acceleration vector** is defined as the limit of the average acceleration vector as the time interval $\Delta t$ is allowed to approach zero:

$$\vec{\mathbf{a}} = \lim_{\Delta t \to 0} \frac{\Delta\vec{\mathbf{v}}}{\Delta t} = \frac{d\vec{\mathbf{v}}}{dt}, \tag{3–11}$$

and is thus the derivative of $\vec{\mathbf{v}}$ with respect to $t$.

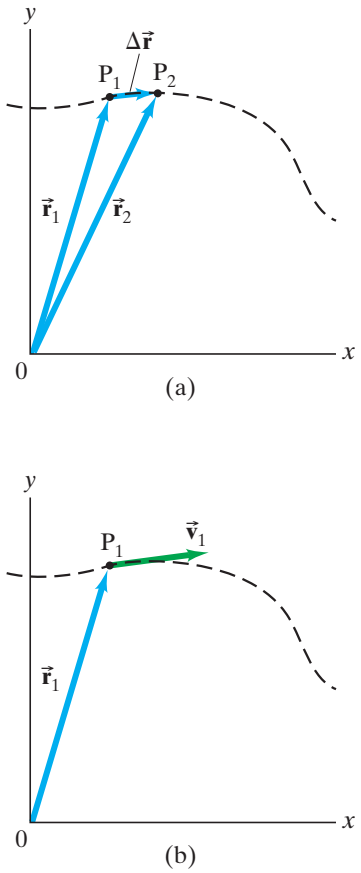


**FIGURE 3–17** (a) As we take $\Delta t$ and $\Delta\vec{\mathbf{r}}$ smaller and smaller [compare to Fig. 3–16] we see that the direction of $\Delta\vec{\mathbf{r}}$ and of the instantaneous velocity ($\Delta\vec{\mathbf{r}}/\Delta t$, where $\Delta t \to 0$) is (b) tangent to the curve at $P_1$.

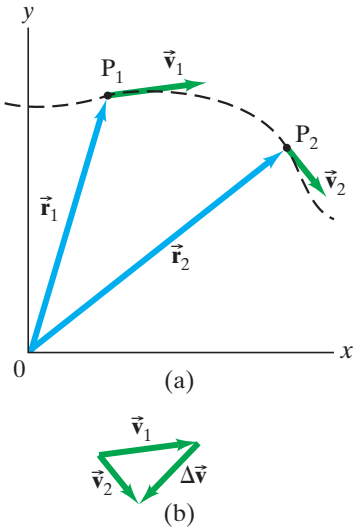

**FIGURE 3–18** (a) Velocity vectors $\vec{\mathbf{v}}_1$ and $\vec{\mathbf{v}}_2$ at instants $t_1$ and $t_2$ for a particle at points $P_1$ and $P_2$, as in Fig. 3–16. (b) The direction of the average acceleration is in the direction of $\Delta\vec{\mathbf{v}} = \vec{\mathbf{v}}_2 - \vec{\mathbf{v}}_1$.

We can write $\vec{\mathbf{a}}$ using components:

$$\vec{\mathbf{a}} = \frac{d\vec{\mathbf{v}}}{dt} = \frac{dv_x}{dt}\hat{\mathbf{i}} + \frac{dv_y}{dt}\hat{\mathbf{j}} + \frac{dv_z}{dt}\hat{\mathbf{k}}$$
$$= a_x\hat{\mathbf{i}} + a_y\hat{\mathbf{j}} + a_z\hat{\mathbf{k}}, \qquad \textbf{(3–12a)}$$

where $a_x = dv_x/dt$, etc. Because $v_x = dx/dt$, then $a_x = dv_x/dt = d^2x/dt^2$, as we saw in Section 2–4. Thus we can also write the acceleration as

$$\vec{\mathbf{a}} = \frac{d^2x}{dt^2}\hat{\mathbf{i}} + \frac{d^2y}{dt^2}\hat{\mathbf{j}} + \frac{d^2z}{dt^2}\hat{\mathbf{k}}. \qquad \textbf{(3–12b)}$$

The instantaneous acceleration will be nonzero not only when the magnitude of the velocity changes, but also if its direction changes. For example, a person riding in a car traveling at constant speed around a curve, or a child riding on a merry-go-round, will both experience an acceleration because of a change in the direction of the velocity, even though the speed may be constant. (More on this in Chapter 5.)

In general, we will use the terms "velocity" and "acceleration" to mean the instantaneous values. If we want to discuss average values, we will use the word "average."

**EXAMPLE 3–5** **Position given as a function of time.** The position of a particle as a function of time is given by

$$\vec{\mathbf{r}} = \left[(5.0\,\text{m/s})t + (6.0\,\text{m/s}^2)t^2\right]\hat{\mathbf{i}} + \left[(7.0\,\text{m}) - (3.0\,\text{m/s}^3)t^3\right]\hat{\mathbf{j}},$$

where $r$ is in meters and $t$ is in seconds. (*a*) What is the particle's displacement between $t_1 = 2.0\,\text{s}$ and $t_2 = 3.0\,\text{s}$? (*b*) Determine the particle's instantaneous velocity and acceleration as a function of time. (*c*) Evaluate $\vec{\mathbf{v}}$ and $\vec{\mathbf{a}}$ at $t = 3.0\,\text{s}$.

**APPROACH** For (*a*), we find $\Delta\vec{\mathbf{r}} = \vec{\mathbf{r}}_2 - \vec{\mathbf{r}}_1$, inserting $t_1 = 2.0\,\text{s}$ for finding $\vec{\mathbf{r}}_1$, and $t_2 = 3.0\,\text{s}$ for $\vec{\mathbf{r}}_2$. For (*b*), we take derivatives (Eqs. 3–9 and 3–12), and for (*c*) we substitute $t = 3.0\,\text{s}$ into our results in (*b*).

**SOLUTION** (*a*) We insert $t_1 = 2.0\,\text{s}$ into the given equation for $\vec{\mathbf{r}}$:

$$\vec{\mathbf{r}}_1 = \left[(5.0\,\text{m/s})(2.0\,\text{s}) + (6.0\,\text{m/s}^2)(2.0\,\text{s})^2\right]\hat{\mathbf{i}} + \left[(7.0\,\text{m}) - (3.0\,\text{m/s}^3)(2.0\,\text{s})^3\right]\hat{\mathbf{j}}$$
$$= (34\,\text{m})\hat{\mathbf{i}} - (17\,\text{m})\hat{\mathbf{j}}.$$

Similarly, at $t_2 = 3.0\,\text{s}$,

$$\vec{\mathbf{r}}_2 = (15\,\text{m} + 54\,\text{m})\hat{\mathbf{i}} + (7.0\,\text{m} - 81\,\text{m})\hat{\mathbf{j}} = (69\,\text{m})\hat{\mathbf{i}} - (74\,\text{m})\hat{\mathbf{j}}.$$

Thus

$$\Delta\vec{\mathbf{r}} = \vec{\mathbf{r}}_2 - \vec{\mathbf{r}}_1 = (69\,\text{m} - 34\,\text{m})\hat{\mathbf{i}} + (-74\,\text{m} + 17\,\text{m})\hat{\mathbf{j}} = (35\,\text{m})\hat{\mathbf{i}} - (57\,\text{m})\hat{\mathbf{j}}.$$

That is, $\Delta x = 35\,\text{m}$, and $\Delta y = -57\,\text{m}$.

(*b*) To find velocity, we take the derivative of the given $\vec{\mathbf{r}}$ with respect to time, noting (Appendix B–2) that $d(t^2)/dt = 2t$, and $d(t^3)/dt = 3t^2$:

$$\vec{\mathbf{v}} = \frac{d\vec{\mathbf{r}}}{dt} = \left[5.0\,\text{m/s} + (12\,\text{m/s}^2)t\right]\hat{\mathbf{i}} + \left[0 - (9.0\,\text{m/s}^3)t^2\right]\hat{\mathbf{j}}.$$

The acceleration is (keeping only two significant figures):

$$\vec{\mathbf{a}} = \frac{d\vec{\mathbf{v}}}{dt} = (12\,\text{m/s}^2)\hat{\mathbf{i}} - (18\,\text{m/s}^3)t\,\hat{\mathbf{j}}.$$

Thus $a_x = 12\,\text{m/s}^2$ is constant; but $a_y = -(18\,\text{m/s}^3)t$ depends linearly on time, increasing in magnitude with time in the negative $y$ direction.

(*c*) We substitute $t = 3.0\,\text{s}$ into the equations we just derived for $\vec{\mathbf{v}}$ and $\vec{\mathbf{a}}$:

$$\vec{\mathbf{v}} = (5.0\,\text{m/s} + 36\,\text{m/s})\hat{\mathbf{i}} - (81\,\text{m/s})\hat{\mathbf{j}} = (41\,\text{m/s})\hat{\mathbf{i}} - (81\,\text{m/s})\hat{\mathbf{j}}$$
$$\vec{\mathbf{a}} = (12\,\text{m/s}^2)\hat{\mathbf{i}} - (54\,\text{m/s}^2)\hat{\mathbf{j}}.$$

Their magnitudes at $t = 3.0\,\text{s}$ are $v = \sqrt{(41\,\text{m/s})^2 + (81\,\text{m/s})^2} = 91\,\text{m/s}$, and $a = \sqrt{(12\,\text{m/s}^2)^2 + (54\,\text{m/s}^2)^2} = 55\,\text{m/s}^2$.

### Constant Acceleration

In Chapter 2 we studied the important case of one-dimensional motion for which the acceleration is constant. In two or three dimensions, if the acceleration vector, $\vec{\mathbf{a}}$, is constant in magnitude and direction, then $a_x$ = constant, $a_y$ = constant, $a_z$ = constant. The average acceleration in this case is equal to the instantaneous acceleration at any moment. The equations we derived in Chapter 2 for one dimension, Eqs. 2–12a, b, and c, apply separately to each perpendicular component of two- or three-dimensional motion.

In two dimensions we let $\vec{\mathbf{v}}_0 = v_{x0}\hat{\mathbf{i}} + v_{y0}\hat{\mathbf{j}}$ be the initial velocity, and we apply Eqs. 3–6a, 3–9, and 3–12b for the position vector $\vec{\mathbf{r}}$, velocity $\vec{\mathbf{v}}$, and acceleration $\vec{\mathbf{a}}$. We can then write Eqs. 2–12a, b, and c for two dimensions as shown in Table 3–1.

**TABLE 3–1 Kinematic Equations for Constant Acceleration in 2 Dimensions**

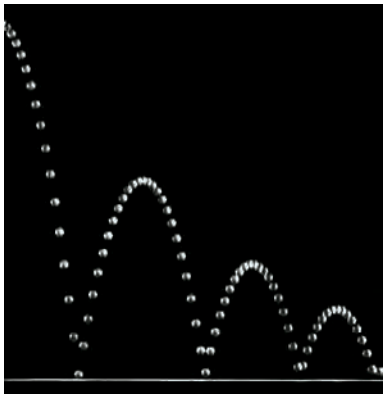
| *x* component (horizontal) | | *y* component (vertical) |
|---|---|---|
| $v_x = v_{x0} + a_x t$ | (Eq. 2–12a) | $v_y = v_{y0} + a_y t$ |
| $x = x_0 + v_{x0}t + \frac{1}{2}a_x t^2$ | (Eq. 2–12b) | $y = y_0 + v_{y0}t + \frac{1}{2}a_y t^2$ |
| $v_x^2 = v_{x0}^2 + 2a_x(x - x_0)$ | (Eq. 2–12c) | $v_y^2 = v_{y0}^2 + 2a_y(y - y_0)$ |

The first two of the equations in Table 3–1 can be written more formally in vector notation.

$$\vec{\mathbf{v}} = \vec{\mathbf{v}}_0 + \vec{\mathbf{a}}t \qquad [\vec{\mathbf{a}} = \text{constant}] \quad \textbf{(3–13a)}$$

$$\vec{\mathbf{r}} = \vec{\mathbf{r}}_0 + \vec{\mathbf{v}}_0 t + \tfrac{1}{2}\vec{\mathbf{a}}t^2. \qquad [\vec{\mathbf{a}} = \text{constant}] \quad \textbf{(3–13b)}$$

Here, $\vec{\mathbf{r}}$ is the position vector at any time, and $\vec{\mathbf{r}}_0$ is the position vector at $t = 0$. These equations are the vector equivalent of Eqs. 2–12a and b. In practical situations, we usually use the component form given in Table 3–1.



## 3–7 Projectile Motion

In Chapter 2, we studied one-dimensional motion of an object in terms of displacement, velocity, and acceleration, including purely vertical motion of a falling object undergoing acceleration due to gravity. Now we examine the more general translational motion of objects moving through the air in two dimensions near the Earth's surface, such as a golf ball, a thrown or batted baseball, kicked footballs, and speeding bullets. These are all examples of **projectile motion** (see Fig. 3–19), which we can describe as taking place in two dimensions if there is no wind.

Although air resistance is often important, in many cases its effect can be ignored, and we will ignore it in the following analysis. We will not be concerned now with the process by which the object is thrown or projected. We consider only its motion *after* it has been projected, and *before* it lands or is caught—that is, we analyze our projected object only when it is moving freely through the air under the action of gravity alone. Then the acceleration of the object is that due to gravity, which acts downward with magnitude $g = 9.80\,\text{m/s}^2$, and we assume it is constant.[†]

Galileo was the first to describe projectile motion accurately. He showed that it could be understood by analyzing the horizontal and vertical components of the motion separately. For convenience, we assume that the motion begins at time $t = 0$ at the origin of an $xy$ coordinate system (so $x_0 = y_0 = 0$).

[†]This restricts us to objects whose distance traveled and maximum height above the Earth are small compared to the Earth's radius (6400 km).

(a)

(b)

**FIGURE 3–19** Photographs of (a) a bouncing ball and (b) a thrown basketball, each showing the characteristic "parabolic" path of projectile motion.

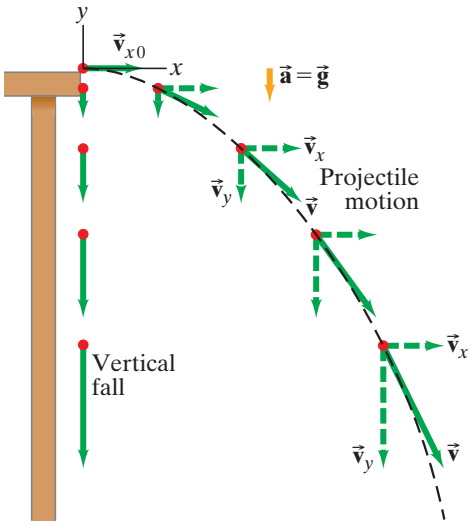


**FIGURE 3–20** Projectile motion of a small ball projected horizontally with initial velocity $\vec{\mathbf{v}} = \vec{\mathbf{v}}_{x0}$. The dashed black line represents the path of the object. The velocity vector $\vec{\mathbf{v}}$ is in the direction of motion at each point, and thus is tangent to the path. The velocity vectors are green arrows, and velocity components are dashed. (A vertically falling object starting from rest at the same place and time is shown at the left for comparison; $v_y$ is the same at each instant for the falling object and the projectile.)

Let us look at a (tiny) ball rolling off the end of a horizontal table with an initial velocity in the horizontal ($x$) direction, $\vec{\mathbf{v}}_{x0}$. See Fig. 3–20, where an object falling vertically is also shown for comparison. The velocity vector $\vec{\mathbf{v}}$ at each instant points in the direction of the ball's motion at that instant and is thus always tangent to the path. Like Galileo, we treat the horizontal and vertical components of the velocity and acceleration separately, and we apply the kinematic equations (Eqs. 2–12) to the $x$ and $y$ components of the motion.

First we examine the vertical ($y$) component of the motion. At the instant the ball leaves the table's top ($t = 0$), it has only an $x$ component of velocity. Once the ball leaves the table (at $t = 0$), it experiences a vertically downward acceleration $g$, the acceleration due to gravity. Thus $v_y$ is initially zero ($v_{y0} = 0$) but increases continually in the downward direction (until the ball hits the ground). Let us take $y$ to be positive upward. Then the acceleration due to gravity is in the $-y$ direction, so $a_y = -g$. From Eq. 2–12a (using $y$ in place of $x$) we can write $v_y = v_{y0} + a_y t = -gt$ since we set $v_{y0} = 0$. The vertical displacement is given by Eq. 2–12b written in terms of $y$: $y = y_0 + v_{y0} + \frac{1}{2}a_y t^2$. Given $y_0 = 0$, $v_{y0} = 0$, and $a_y = -g$, then $y = -\frac{1}{2}gt^2$.

In the horizontal direction, the acceleration is zero (ignoring air resistance). With $a_x = 0$, the horizontal component of velocity, $v_x$, remains constant, equal to its initial value, $v_{x0}$, and thus has the same magnitude at each point on the path. The horizontal displacement (with $a_x = 0$) is given by $x = v_{x0}t + \frac{1}{2}a_x t^2 = v_{x0}t$.

The two vector components, $\vec{\mathbf{v}}_x$ and $\vec{\mathbf{v}}_y$, can be added vectorially at any instant to obtain the velocity $\vec{\mathbf{v}}$ at that time (each point on the path), as shown in Fig. 3–20.

One result of this analysis, which Galileo himself predicted, is that *an object projected horizontally will reach the ground in the same time as an object dropped vertically*. The vertical motions are the same in both cases, as shown in Fig. 3–20. Figure 3–21 is a multiple-exposure photograph of an experiment that confirms this.

If an object is projected at an upward angle, as in Fig. 3–22, the analysis is similar, but now there is an initial vertical component of velocity, $v_{y0}$. Because of the downward acceleration of gravity, the upward component of velocity $v_y$ gradually decreases with time until the object reaches the highest point on its path, at which point $v_y = 0$. The object then moves downward (Fig. 3–22) and $v_y$ increases in the downward direction (becoming more negative). As before, $v_x$ remains constant.

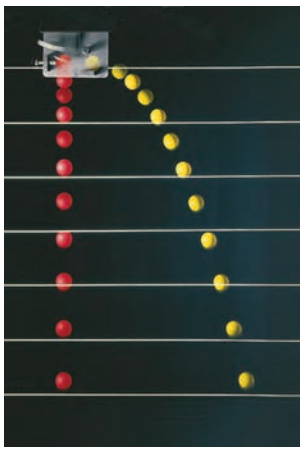

**FIGURE 3–21** Multiple-exposure photograph showing positions of two balls at equal time intervals. One ball was dropped from rest at the same time the other was projected horizontally outward. The vertical position of each ball is seen to be the same at each instant.

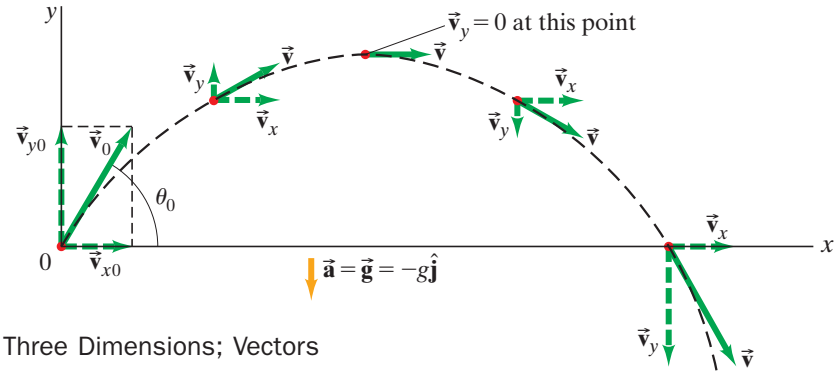

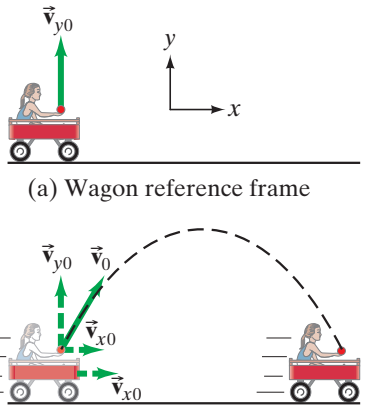

**FIGURE 3–22** Path of a projectile fired with initial velocity $\vec{\mathbf{v}}_0$ at angle $\theta_0$ to the horizontal. Path is shown dashed in black, the velocity vectors are green arrows, and velocity components are dashed. The acceleration $\vec{\mathbf{a}} = d\vec{\mathbf{v}}/dt$ is downward. That is, $\vec{\mathbf{a}} = \vec{\mathbf{g}} = -g\hat{\mathbf{j}}$ where $\hat{\mathbf{j}}$ is the unit vector in the positive $y$ direction. Not shown is where the projectile hits the ground (at that point projectile motion ceases).

**CONCEPTUAL EXAMPLE 3–6** **Where does the apple land?** A child sits upright in a wagon that moves to the right at constant speed, Fig. 3–23. The child extends her hand and throws an apple straight up (from her own point of view, Fig. 3–23a), as the wagon moves forward at constant speed. Neglecting air resistance, will the apple land (*a*) behind the wagon, (*b*) in the wagon, or (*c*) in front of the wagon?

**RESPONSE** The child throws the apple straight up in her own reference frame with initial velocity $\vec{\mathbf{v}}_{y0}$ (Fig. 3–23a). But when viewed by someone on the ground, the apple also has an initial horizontal component of velocity equal to the velocity of the wagon, $\vec{\mathbf{v}}_{x0}$. Thus, to a person on the ground, the apple follows the path of a projectile as shown in Fig. 3–23b. The apple experiences no horizontal acceleration, so $\vec{\mathbf{v}}_{x0}$ stays constant, equal to the speed of the wagon. As the apple follows its arc, the wagon will be directly under the apple at all times because they have the same horizontal velocity. When the apple comes down, it will drop right into the outstretched hand of the child. The answer is (*b*).

(a) Wagon reference frame

(b) Ground reference frame

**FIGURE 3–23** Example 3–6.

**EXERCISE C** Return to the Chapter-Opening Question, page 54, and answer it again now. Try to explain why you may have answered differently the first time. Describe the role of the helicopter in this example of projectile motion.

# 3–8 Solving Problems Involving Projectile Motion

We can simplify Eqs. 2–12 (Table 3–1) for the case of projectile motion because we can set $a_x = 0$. See Table 3–2, which assumes $y$ is positive upward, so $a_y = -g = -9.80\,\text{m/s}^2$. If $\theta$ is chosen relative to the $+x$ axis, as in Fig. 3–22, then

$$v_{x0} = v_0 \cos\theta_0, \quad \text{and} \quad v_{y0} = v_0 \sin\theta_0.$$

In doing Problems involving projectile motion, we must consider a time interval for which our chosen object is in the air, influenced only by gravity. We do not consider the throwing (or projecting) process, nor the time after the object lands or is caught, because then other influences act on the object, and we can no longer set $\vec{\mathbf{a}} = \vec{\mathbf{g}}$.

**PROBLEM SOLVING**
*Choice of time interval*

**TABLE 3–2 Kinematic Equations for Projectile Motion**
($y$ positive upward; $a_x = 0$, $a_y = -g = -9.80\,\text{m/s}^2$)

| Horizontal Motion ($a_x = 0$, $v_x$ = constant) | | Vertical Motion† ($a_y = -g$ = constant) |
|---|---|---|
| $v_x = v_{x0}$ | (Eq. 2–12a) | $v_y = v_{y0} - gt$ |

PROBLEM SOLVING

## Projectile Motion

Our approach to solving Problems in Section 2–6 also applies here. Solving projectile motion Problems can require creativity, and cannot be done just by following rules. You must avoid just plugging numbers into equations that seem to "work."

1. As always, **read** carefully; **choose** the **object** (or objects) you are going to analyze.
2. **Draw** a careful **diagram** showing what is happening.
3. **Choose** an origin and an $xy$ **coordinate system**.
4. Decide on the **time interval**, which for projectile motion can only include motion under the effect of gravity alone, not throwing or landing. The time interval must be the same for the $x$ and $y$ analyses. The $x$ and $y$ motions are connected by the common time, $t$.
5. **Examine** the horizontal ($x$) and vertical ($y$) **motions** separately. If you are given the initial velocity, you may want to resolve it into its $x$ and $y$ components.
6. List the **known** and **unknown** quantities, choosing $a_x = 0$ and $a_y = -g$ or $+g$, where $g = 9.80\,\text{m/s}^2$, depending on choice of $y$ positive up or down. Recall: $v_x$ never changes throughout the trajectory, and $v_y = 0$ at the highest point of any trajectory that returns downward. The velocity just before landing is generally not zero.
7. Think for a minute before jumping into the equations. **Apply** the **relevant equations** (Table 3–2), combining them if necessary. You may need to combine components of a vector to get magnitude and direction (Eqs. 3–3).

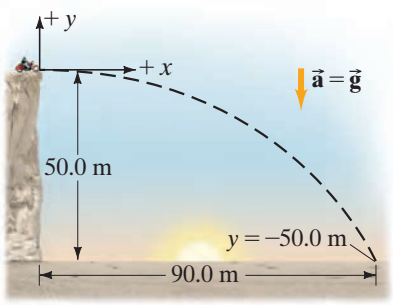

**FIGURE 3–24** Example 3–7.

**EXAMPLE 3–7** **Driving off a cliff.** A movie stunt driver on a motorcycle speeds horizontally off a 50.0-m-high cliff. How fast must the motorcycle leave the clifftop to land on level ground below, 90.0 m from the base of the cliff where the cameras are? Ignore air resistance.

**APPROACH** We explicitly follow the steps of the Problem Solving Strategy on the previous page.

**SOLUTION**

1. and **2. Read, choose the object, and draw a diagram**. Our object is the motorcycle and driver, taken as a single unit. The diagram is shown in Fig. 3–24.
3. **Choose a coordinate system**. We choose the $y$ direction to be positive upward, with the top of the cliff as $y_0 = 0$. The $x$ direction is horizontal with $x_0 = 0$ at the point where the motorcycle leaves the cliff.
4. **Choose a time interval**. We choose our time interval to begin ($t = 0$) just as the motorcycle leaves the clifftop at position $x_0 = 0$, $y_0 = 0$. Our time interval ends just before the motorcycle touches the ground below.
5. **Examine *x* and *y* motions**. In the horizontal ($x$) direction, the acceleration $a_x = 0$, so the velocity is constant. The value of $x$ when the motorcycle reaches the ground is $x = +90.0\,\text{m}$. In the vertical direction, the acceleration is the acceleration due to gravity, $a_y = -g = -9.80\,\text{m/s}^2$. The value of $y$ when the motorcycle reaches the ground is $y = -50.0\,\text{m}$. The initial velocity is horizontal and is our unknown, $v_{x0}$; the initial vertical velocity is zero, $v_{y0} = 0$.
6. **List knowns and unknowns**. See the Table in the margin. Note that in addition to not knowing the initial horizontal velocity $v_{x0}$ (which stays constant until landing), we also do not know the time $t$ when the motorcycle reaches the ground.
7. **Apply relevant equations**. The motorcycle maintains constant $v_x$ as long as it is in the air. The time it stays in the air is determined by the $y$ motion—when it reaches the ground. So we first find the time using the $y$ motion, and then use this time value in the $x$ equations. To find out how long it takes the motorcycle to reach the ground below, we use Eq. 2–12b (Table 3–2) for the vertical ($y$) direction with $y_0 = 0$ and $v_{y0} = 0$:

$$\begin{aligned} y &= y_0 + v_{y0}t + \tfrac{1}{2}a_y t^2 \\ &= 0 + 0 + \tfrac{1}{2}(-g)t^2 \end{aligned}$$

or

$$y = -\tfrac{1}{2}gt^2.$$

We solve for $t$ and set $y = -50.0\,\text{m}$:

$$t = \sqrt{\frac{2y}{-g}} = \sqrt{\frac{2(-50.0\,\text{m})}{-9.80\,\text{m/s}^2}} = 3.19\,\text{s}.$$

To calculate the needed initial velocity, $v_{x0}$, we again use Eq. 2–12b, but this time for the horizontal ($x$) direction, with $a_x = 0$ and $x_0 = 0$:

$$\begin{aligned} x &= x_0 + v_{x0}t + \tfrac{1}{2}a_x t^2 \\ &= 0 + v_{x0}t + 0 \end{aligned}$$

or

$$x = v_{x0}t.$$

So the motorcycle needs to leave the clifftop with a speed

$$v_{x0} = \frac{x}{t} = \frac{90.0\,\text{m}}{3.19\,\text{s}} = 28.2\,\text{m/s},$$

which is about 100 km/h (roughly 60 mi/h).

| Known | Unknown |
|---|---|
| $x_0 = y_0 = 0$ | $v_{x0}$ |
| $x = 90.0\,\text{m}$ | $t$ |
| $y = -50.0\,\text{m}$ | |
| $a_x = 0$ | |
| $a_y = -g = -9.80\,\text{m/s}^2$ | |
| $v_{y0} = 0$ | |

**NOTE** In the time interval of the projectile motion, the only acceleration is $g$ in the negative $y$ direction. The acceleration in the $x$ direction is zero.

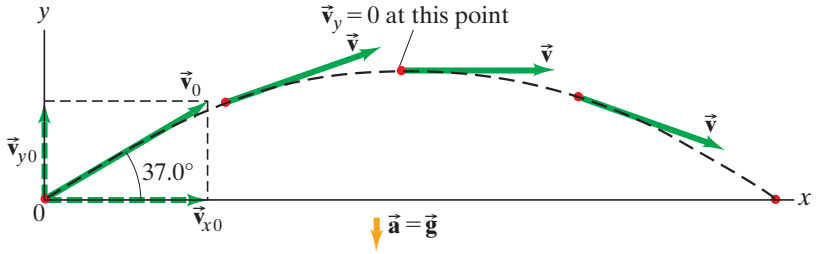

**FIGURE 3–25** Example 3–8.

**EXAMPLE 3–8** **A kicked football.** A football is kicked at an angle $\theta_0 = 37.0°$ with a velocity of 20.0 m/s, as shown in Fig. 3–25. Calculate (*a*) the maximum height, (*b*) the time of travel before the football hits the ground, and (*c*) how far away it hits the ground. Assume the ball leaves the foot at ground level, and ignore air resistance, wind, and rotation of the ball.

PHYSICS APPLIED
*Sports*

**APPROACH** This may seem difficult at first because there are so many questions. But we can deal with them one at a time. We take the $y$ direction as positive upward, and treat the $x$ and $y$ motions separately. The total time in the air is again determined by the $y$ motion. The $x$ motion occurs at constant velocity. The $y$ component of velocity varies, being positive (upward) initially, decreasing to zero at the highest point, and then becoming negative as the football falls.

**SOLUTION** We resolve the initial velocity into its components (Fig. 3–25):

$$v_{x0} = v_0 \cos 37.0° = (20.0\,\text{m/s})(0.799) = 16.0\,\text{m/s}$$
$$v_{y0} = v_0 \sin 37.0° = (20.0\,\text{m/s})(0.602) = 12.0\,\text{m/s}.$$

(*a*) To find the maximum height, we consider a time interval that begins just after the football loses contact with the foot until the ball reaches its maximum height. During this time interval, the acceleration is $g$ downward. At the maximum height, the velocity is horizontal (Fig. 3–25), so $v_y = 0$; and this occurs at a time given by $v_y = v_{y0} - gt$ with $v_y = 0$ (see Eq. 2–12a in Table 3–2). Thus

$$t = \frac{v_{y0}}{g} = \frac{(12.0\,\text{m/s})}{(9.80\,\text{m/s}^2)} = 1.224\,\text{s} \approx 1.22\,\text{s}.$$

From Eq. 2–12b, with $y_0 = 0$, we can solve for $y$ at this time $t = v_{y0}/g$:

$$y = v_{y0}t - \tfrac{1}{2}gt^2 = \frac{v_{y0}^2}{g} - \frac{1}{2}\frac{v_{y0}^2}{g} = \frac{v_{y0}^2}{2g} = \frac{(12.0\,\text{m/s})^2}{2(9.80\,\text{m/s}^2)} = 7.35\,\text{m}.$$

The maximum height is 7.35 m. [Solving Eq. 2–12c for $y$ gives the same result.]

(*b*) To find the time it takes for the ball to return to the ground, we consider a different time interval, starting at the moment the ball leaves the foot ($t = 0$, $y_0 = 0$) and ending just before the ball touches the ground ($y = 0$ again). We can use Eq. 2–12b with $y_0 = 0$ and also set $y = 0$ (ground level):

$$y = y_0 + v_{y0}t - \tfrac{1}{2}gt^2$$
$$0 = 0 + v_{y0}t - \tfrac{1}{2}gt^2.$$

This equation can be easily factored:

$$t(\tfrac{1}{2}gt - v_{y0}) = 0.$$

There are two solutions, $t = 0$ (which corresponds to the initial point, $y_0$), and

$$t = \frac{2v_{y0}}{g} = \frac{2(12.0\,\text{m/s})}{(9.80\,\text{m/s}^2)} = 2.45\,\text{s},$$

which is the total travel time of the football.

(*c*) The total distance traveled in the $x$ direction is found by applying Eq. 2–12b with $x_0 = 0$, $a_x = 0$, $v_{x0} = 16.0\,\text{m/s}$, and $t = 2.45\,\text{s}$:

$$x = v_{x0}t = (16.0\,\text{m/s})(2.45\,\text{s}) = 39.2\,\text{m}.$$

**NOTE** In (*b*) the time needed for the whole trip, $t = 2v_{y0}/g = 2.45\,\text{s}$, is double the time to reach the highest point, calculated in (*a*). That is, the time to go up equals the time to come back down to the same level (ignoring air resistance).

**EXERCISE D** In Example 3–8, what is (*a*) the velocity vector at the maximum height, and (*b*) the acceleration vector at maximum height?

In Example 3–8 we treated the football as if it were a particle, ignoring its rotation. We also ignored air resistance. Because air resistance is significant on a football, our results are only estimates (mainly overestimates). We also ignored any wind. If there happened to be a cross-wind, we would need a third axis for such 3-dimensional motion.

**EXERCISE E** Two balls are thrown in the air at different angles, but each reaches the same height. Which ball remains in the air longer: the one thrown at the steeper angle or the one thrown at a shallower angle?

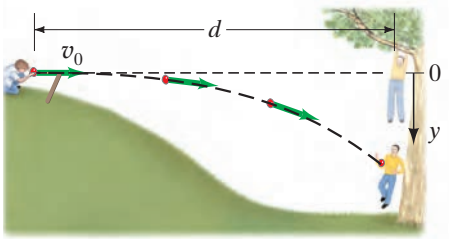

**FIGURE 3–26** Example 3–9.

**CONCEPTUAL EXAMPLE 3–9** **The wrong strategy.** A boy on a small hill aims his water-balloon slingshot horizontally, straight at a second boy hanging from a tree branch a distance *d* away, Fig. 3–26. At the instant the water balloon is released, the second boy lets go and falls from the tree, hoping to avoid being hit. Show that he made the wrong move. (He hadn't studied physics yet.) Ignore air resistance.

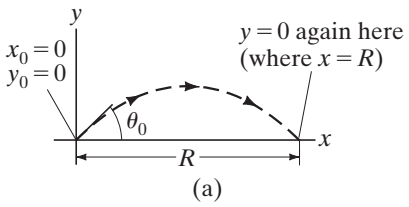
**RESPONSE** Both the water balloon and the boy in the tree start falling at the same instant, and in a time $t$ they each fall the same vertical distance $y = \frac{1}{2}gt^2$, much like Fig. 3–21. In the time it takes the water balloon to travel the horizontal distance $d$, the balloon will have the same $y$ position as the falling boy. Splat. If the boy had stayed in the tree, he would have avoided the humiliation.

## Level Horizontal Range

The total distance the football traveled in Example 3–8 is called the horizontal **range** $R$. We now derive a formula for the range, which applies to a projectile that lands at the same level it started ($= y_0$): that is, $y(\text{final}) = y_0$ (see Fig. 3–27a). Looking back at Example 3–8 part (*c*), we see that $x = R = v_{x0}t$ where (from part *b*) $t = 2v_{y0}/g$. Thus

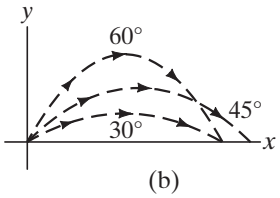
$$R = v_{x0}t = v_{x0}\left(\frac{2v_{y0}}{g}\right) = \frac{2v_{x0}v_{y0}}{g} = \frac{2v_0^2 \sin\theta_0 \cos\theta_0}{g}, \quad [y = y_0]$$

where $v_{x0} = v_0 \cos\theta_0$ and $v_{y0} = v_0 \sin\theta_0$. This can be rewritten, using the trigonometric identity $2\sin\theta\cos\theta = \sin 2\theta$ (Appendix A or inside the rear cover):



$$R = \frac{v_0^2 \sin 2\theta_0}{g}. \qquad [\text{only if } y(\text{final}) = y_0]$$

Note that the *maximum* range, for a given initial velocity $v_0$, is obtained when $\sin 2\theta$ takes on its maximum value of 1.0, which occurs for $2\theta_0 = 90°$; so



$$\theta_0 = 45° \text{ for maximum range, and } R_{\max} = v_0^2/g.$$

The maximum range increases by the square of $v_0$, so doubling the initial velocity of a projectile increases its maximum range by a factor of 4.

When air resistance is important, the range is less for a given $v_0$, and the maximum range is obtained at an angle smaller than 45°.

(a)

(b)

**FIGURE 3–27** (a) The range $R$ of a projectile. (b) There are generally two angles $\theta_0$ that will give the same range. If one angle is $\theta_{01}$, the other is $\theta_{02} = 90° - \theta_{01}$. Also see Example 3–10.

**EXAMPLE 3–10** **Range of a cannon ball.** Suppose one of Napoleon's cannons had a muzzle speed, $v_0$, of 60.0 m/s. At what angle should it have been aimed (ignore air resistance) to strike a target 320 m away?

**APPROACH** We use the equation just derived for the range, $R = v_0^2 \sin 2\theta_0/g$, with $R = 320$ m.

**SOLUTION** We solve for $\sin 2\theta_0$ in the range formula:

$$\sin 2\theta_0 = \frac{Rg}{v_0^2} = \frac{(320\text{ m})(9.80\text{ m/s}^2)}{(60.0\text{ m/s})^2} = 0.871.$$

We want to solve for an angle $\theta_0$ that is between 0° and 90°, which means $2\theta_0$ in this equation can be as large as 180°. Then $\sin^{-1}(0.871) = 2\theta_0 = 60.6°$ is a solution,

so the cannon should be aimed at $\theta_0 = 30.3°$. But $2\theta_0 = 180° - 60.6° = 119.4°$ is also a solution (see Appendix A–9), so $\theta_0$ can also be $\theta_0 = 59.7°$. In general we have two solutions (see Fig. 3–27b), which in the present case are given by

$$\theta_0 = 30.3° \quad \text{or} \quad 59.7°.$$

Either angle gives the same range. Only when $\sin 2\theta_0 = 1$ (so $\theta_0 = 45°$) is there a single solution (that is, both solutions are the same).

The level range formula applies only if takeoff and landing are at the same height $(y = y_0)$. Example 3–11 below considers a case where they are not equal heights $(y \neq y_0)$.

**EXAMPLE 3–11** **A punt.** Suppose the football in Example 3–8 was punted and left the punter's foot at a height of 1.00 m above the ground. How far did the football travel before hitting the ground? Set $x_0 = 0$, $y_0 = 0$.

**PHYSICS APPLIED**
*Sports*

**PROBLEM SOLVING**
*Do not use any formula unless you are sure its range of validity fits the problem; the range formula does not apply here because $y \neq y_0$*

**APPROACH** The $x$ and $y$ motions are again treated separately. But we cannot use the range formula as in Example 3–10 because the range formula is valid only if $y(\text{final}) = y_0$, which is not the case here. Now we have $y_0 = 0$, and the football hits the ground where $y = -1.00$ m (see Fig. 3–28). We choose our time interval to start when the ball leaves his foot $(t = 0,\ y_0 = 0,\ x_0 = 0)$ and end just before the ball hits the ground $(y = -1.00\text{ m})$. We can get $x$ from Eq. 2–12b, $x = v_{x0}t$, and we saw that $v_{x0} = 16.0$ m/s in Example 3–8. But first we must find $t$, the time at which the ball hits the ground, which we obtain from the $y$ motion.

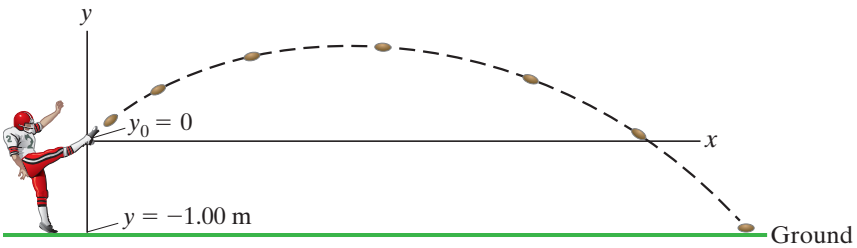


**FIGURE 3–28** Example 3–11: the football leaves the punter's foot at $y = 0$, and reaches the ground where $y = -1.00$ m.

**SOLUTION** To find $t$ with $y = -1.00$ m and $v_{y0} = 12.0$ m/s (see Example 3–8), we use the equation

$$y = y_0 + v_{y0}t - \tfrac{1}{2}gt^2,$$

and obtain

$$-1.00\text{ m} = 0 + (12.0\text{ m/s})t - (4.90\text{ m/s}^2)t^2.$$

We rearrange this equation into standard form $(ax^2 + bx + c = 0)$ so we can use the quadratic formula:

$$(4.90\text{ m/s}^2)t^2 - (12.0\text{ m/s})t - (1.00\text{ m}) = 0.$$

The quadratic formula (Appendix A–1) gives

$$t = \frac{12.0\text{ m/s} \pm \sqrt{(-12.0\text{ m/s})^2 - 4(4.90\text{ m/s}^2)(-1.00\text{ m})}}{2(4.90\text{ m/s}^2)}$$
$$= 2.53\text{ s} \quad \text{or} \quad -0.081\text{ s}.$$

The second solution would correspond to a time prior to our chosen time interval that begins at the kick $(t = 0)$, so it doesn't apply. With $t = 2.53$ s for the time at which the ball touches the ground, the horizontal distance the ball traveled is (using $v_{x0} = 16.0$ m/s from Example 3–8):

$$x = v_{x0}t = (16.0\text{ m/s})(2.53\text{ s}) = 40.5\text{ m}.$$

Our assumption in Example 3–8 that the ball leaves the foot at ground level gives a result (39.2 m) that is an underestimate of about 1.3 m in the distance our punt traveled. (But Example 3–8 would apply for a kickoff or field goal in American football.)

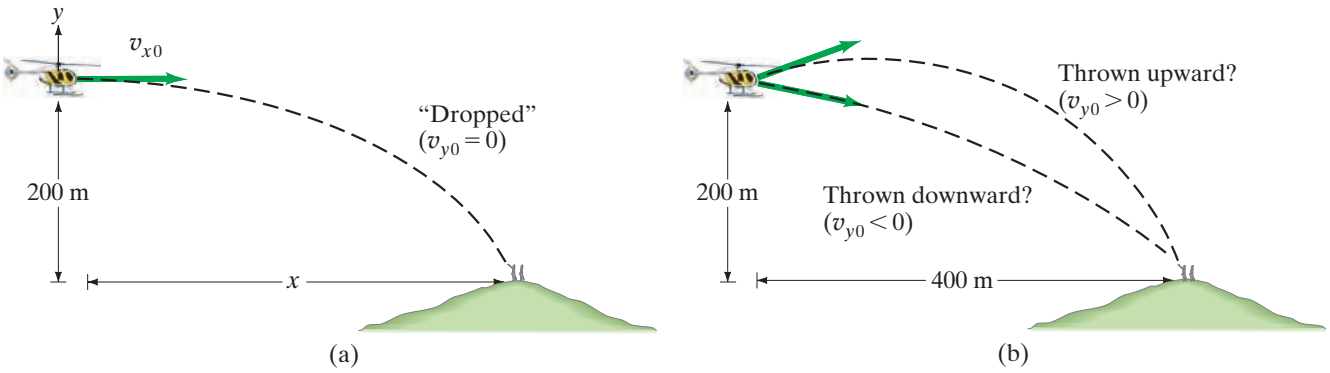

**FIGURE 3–29** Example 3–12.

PHYSICS APPLIED
*Reaching a target from a moving helicopter*

**EXAMPLE 3–12** **Rescue helicopter drops supplies.** A rescue helicopter wants to drop a package of supplies to isolated mountain climbers on a rocky ridge 200 m below. If the helicopter is traveling horizontally with a speed of 70 m/s (250 km/h), (*a*) how far in advance of the recipients (horizontal distance) must the package be dropped (Fig. 3–29a)? (*b*) Suppose, instead, that the helicopter releases the package a horizontal distance of 400 m in advance of the mountain climbers. What vertical velocity should the package be given (up or down) so that it arrives precisely at the climbers' position (Fig. 3–29b)? (*c*) With what speed does the package land in the latter case?

**APPROACH** We choose the origin of our $xy$ coordinate system at the initial position of the helicopter, taking $+y$ upward, and use the kinematic equations (Table 3–2).

**SOLUTION** (*a*) We can find the time to reach the climbers using the vertical distance of 200 m. The package is "dropped" so initially it has the velocity of the helicopter, $v_{x0} = 70\ \text{m/s}$, $v_{y0} = 0$. Then, since $y = -\frac{1}{2}gt^2$, we have

$$t = \sqrt{\frac{-2y}{g}} = \sqrt{\frac{-2(-200\ \text{m})}{9.80\ \text{m/s}^2}} = 6.39\ \text{s}.$$

The horizontal motion of the falling package is at constant speed of 70 m/s. So

$$x = v_{x0}t = (70\ \text{m/s})(6.39\ \text{s}) = 447\ \text{m} \approx 450\ \text{m},$$

assuming the given numbers were good to two significant figures.

(*b*) We are given $x = 400\ \text{m}$, $v_{x0} = 70\ \text{m/s}$, $y = -200\ \text{m}$, and we want to find $v_{y0}$ (see Fig. 3–29b). Like most problems, this one can be approached in various ways. Instead of searching for a formula or two, let's try to reason it out in a simple way, based on what we did in part (*a*). If we know $t$, perhaps we can get $v_{y0}$. Since the horizontal motion of the package is at constant speed (once it is released we don't care what the helicopter does), we have $x = v_{x0}t$, so

$$t = \frac{x}{v_{x0}} = \frac{400\ \text{m}}{70\ \text{m/s}} = 5.71\ \text{s}.$$

Now let's try to use the vertical motion to get $v_{y0}$: $y = y_0 + v_{y0}t - \frac{1}{2}gt^2$. Since $y_0 = 0$ and $y = -200\ \text{m}$, we can solve for $v_{y0}$:

$$v_{y0} = \frac{y + \frac{1}{2}gt^2}{t} = \frac{-200\ \text{m} + \frac{1}{2}(9.80\ \text{m/s}^2)(5.71\ \text{s})^2}{5.71\ \text{s}} = -7.0\ \text{m/s}.$$

Thus, in order to arrive at precisely the mountain climbers' position, the package must be thrown *downward* from the helicopter with a speed of 7.0 m/s.

(*c*) We want to know $v$ of the package at $t = 5.71\ \text{s}$. The components are:

$$v_x = v_{x0} = 70\ \text{m/s}$$
$$v_y = v_{y0} - gt = -7.0\ \text{m/s} - (9.80\ \text{m/s}^2)(5.71\ \text{s}) = -63\ \text{m/s}.$$

So $v = \sqrt{(70\ \text{m/s})^2 + (-63\ \text{m/s})^2} = 94\ \text{m/s}$. (Better not to release the package from such an altitude, or use a parachute.)

### Projectile Motion Is Parabolic

We now show that the path followed by any projectile is a *parabola*, if we can ignore air resistance and can assume that only gravity is acting with $\vec{\mathbf{g}}$ constant. To do so, we need to find $y$ as a function of $x$ by eliminating $t$ between the two equations for horizontal and vertical motion (Eq. 2–12b in Table 3–2), and for simplicity we set $x_0 = y_0 = 0$:

$$x = v_{x0}t$$
$$y = v_{y0}t - \tfrac{1}{2}gt^2.$$

From the first equation, we have $t = x/v_{x0}$, and we substitute this into the second equation to obtain

$$y = \left(\frac{v_{y0}}{v_{x0}}\right)x - \left(\frac{g}{2v_{x0}^2}\right)x^2. \qquad \textbf{(3–14)}$$

We see that $y$ as a function of $x$ has the form

$$y = Ax - Bx^2,$$

where $A$ and $B$ are constants for any specific projectile motion. This is the well-known equation for a parabola. See Figs. 3–19 and 3–30.

The idea that projectile motion is parabolic was at the forefront of physics research in Galileo's day. Today we discuss it in Chapter 3 of introductory physics!

(a)

(b)

**FIGURE 3–30** Examples of projectile motion: (a) a boy leaping, (b) glowing lava from the volcano Stromboli.

## 3–9 Relative Velocity

We now consider how observations made in different frames of reference are related to each other. For example, consider two trains approaching one another, each with a speed of 80 km/h with respect to the Earth. Observers on the Earth beside the train tracks will measure 80 km/h for the speed of each of the trains. Observers on either one of the trains (different frames of reference) will measure a speed of 160 km/h for the other train approaching them.

Similarly, when one car traveling 90 km/h passes a second car traveling in the same direction at 75 km/h, the first car has a speed relative to the second car of 90 km/h − 75 km/h = 15 km/h.

When the velocities are along the same line, simple addition or subtraction is sufficient to obtain the **relative velocity**. But if they are not along the same line, we must make use of vector addition. We emphasize, as mentioned in Section 2–1, that when specifying a velocity, it is important to specify what the reference frame is.

When determining relative velocity, it is easy to make a mistake by adding or subtracting the wrong velocities. It is important, therefore, to draw a diagram and use a careful labeling process. Each velocity is labeled by *two subscripts: the first refers to the object, the second to the reference frame in which it has this velocity*. For example, suppose a boat heads directly across a river, as shown in Fig. 3–31. We let $\vec{\mathbf{v}}_{BW}$ be the velocity of the **B**oat with respect to the **W**ater. (This is also what the boat's velocity would be relative to the shore if the water were still.) Similarly, $\vec{\mathbf{v}}_{BS}$ is the velocity of the **B**oat with respect to the **S**hore, and $\vec{\mathbf{v}}_{WS}$ is the velocity of the **W**ater with respect to the **S**hore (this is the river current). Note that $\vec{\mathbf{v}}_{BW}$ is what the boat's motor produces (against the water), whereas $\vec{\mathbf{v}}_{BS}$ is equal to $\vec{\mathbf{v}}_{BW}$ plus the effect of the current, $\vec{\mathbf{v}}_{WS}$. Therefore, the velocity of the boat relative to the shore is (see vector diagram, Fig. 3–31)

$$\vec{\mathbf{v}}_{BS} = \vec{\mathbf{v}}_{BW} + \vec{\mathbf{v}}_{WS}. \qquad \textbf{(3–15)}$$

By writing the subscripts using this convention, we see that the inner subscripts (the two W's) on the right-hand side of Eq. 3–15 are the same; also, the outer subscripts on the right of Eq. 3–15 (the B and the S) are the same as the two subscripts for the sum vector on the left, $\vec{\mathbf{v}}_{BS}$.

**FIGURE 3–31** A boat heads north directly across a river which flows west. Velocity vectors are shown as green arrows:
$\vec{\mathbf{v}}_{BS}$ = velocity of **B**oat with respect to the **S**hore,
$\vec{\mathbf{v}}_{BW}$ = velocity of **B**oat with respect to the **W**ater,
$\vec{\mathbf{v}}_{WS}$ = velocity of **W**ater with respect to the **S**hore (river current).
As it crosses the river, the boat is dragged downstream by the current $(\vec{\mathbf{v}}_{WS})$.

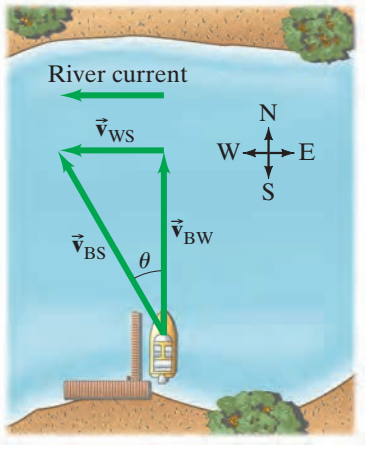

**FIGURE 3–32** Derivation of relative velocity equation (Eq. 3–15), in this case for a person walking along the corridor in a train. We are looking down on the train and two reference frames are shown: $xy$ on the Earth and $x'y'$ fixed on the train. We have:

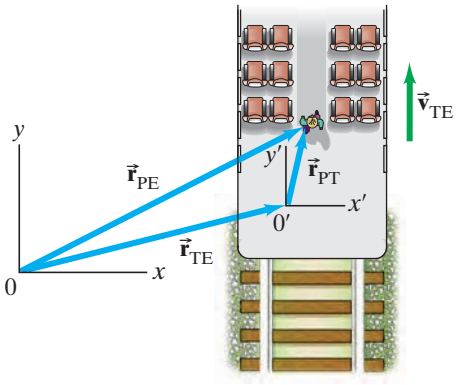
$\vec{\mathbf{r}}_{PT}$ = position vector of person (P) relative to train (T),

$\vec{\mathbf{r}}_{PE}$ = position vector of person (P) relative to Earth (E),

$\vec{\mathbf{r}}_{TE}$ = position vector of train's coordinate system (T) relative to Earth (E).

From the diagram we see that

$$\vec{\mathbf{r}}_{PE} = \vec{\mathbf{r}}_{PT} + \vec{\mathbf{r}}_{TE}.$$



We take the derivative with respect to time to obtain

$$\frac{d}{dt}(\vec{\mathbf{r}}_{PE}) = \frac{d}{dt}(\vec{\mathbf{r}}_{PT}) + \frac{d}{dt}(\vec{\mathbf{r}}_{TE}),$$

or, since $d\vec{\mathbf{r}}/dt = \vec{\mathbf{v}}$,

$$\vec{\mathbf{v}}_{PE} = \vec{\mathbf{v}}_{PT} + \vec{\mathbf{v}}_{TE}.$$

This is the equivalent of Eq. 3–15 for the present situation (check the subscripts!).

By following this convention (first subscript for the object, second for the reference frame), you can write down the correct equation relating velocities in different reference frames.†

Figure 3–32 gives a derivation of Eq. 3–15, $\vec{\mathbf{v}}_{BS} = \vec{\mathbf{v}}_{BW} + \vec{\mathbf{v}}_{WS}$, but using different subscripts.

Equation 3–15 is valid in general and can be extended to three or more velocities. For example, if a fisherman on a boat walks with a velocity $\vec{\mathbf{v}}_{FB}$ relative to the boat, his velocity relative to the shore is $\vec{\mathbf{v}}_{FS} = \vec{\mathbf{v}}_{FB} + \vec{\mathbf{v}}_{BW} + \vec{\mathbf{v}}_{WS}$. The equations involving relative velocity will be correct when adjacent inner subscripts are identical and when the outermost ones correspond exactly to the two on the velocity on the left of the equation. But this works only with plus signs (on the right), not minus signs.

It is often useful to remember that for any two objects or reference frames, A and B, the velocity of A relative to B has the same magnitude, but opposite direction, as the velocity of B relative to A:

$$\vec{\mathbf{v}}_{BA} = -\vec{\mathbf{v}}_{AB}. \qquad \textbf{(3–16)}$$

For example, if a train is traveling 100 km/h relative to the Earth in a certain direction, objects on the Earth (such as trees) appear to an observer on the train to be traveling 100 km/h in the opposite direction.

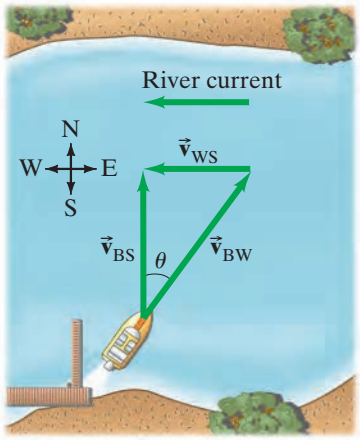


**FIGURE 3–33** Example 3–13. A boat, in order to go directly across a moving river current, must head upstream.

**EXAMPLE 3–13** **Heading upstream.** A boat's speed in still water is $v_{BW} = 1.85$ m/s. If the boat is to travel north directly across a river whose westward current has speed $v_{WS} = 1.20$ m/s, at what upstream angle must the boat head? See Fig. 3–33.

**APPROACH** If the boat heads straight across the river, the current will drag the boat downstream (westward). To overcome the river's current, the boat must have an upstream (eastward) component of velocity as well as a cross-stream (northward) component. Figure 3–33 has been drawn with $\vec{\mathbf{v}}_{BS}$, the velocity of the **B**oat relative to the **S**hore, pointing directly across the river because this is where the boat is supposed to go. Note that $\vec{\mathbf{v}}_{BS} = \vec{\mathbf{v}}_{BW} + \vec{\mathbf{v}}_{WS}$.

**SOLUTION** Vector $\vec{\mathbf{v}}_{BW}$ points upstream at angle $\theta$ as shown. From the diagram,

$$\sin\theta = \frac{v_{WS}}{v_{BW}} = \frac{1.20\text{ m/s}}{1.85\text{ m/s}} = 0.6486.$$

Thus $\theta = 40.4°$, so the boat must head upstream at a 40.4° angle.

†We thus can see, for example, that the equation $\vec{\mathbf{v}}_{BW} = \vec{\mathbf{v}}_{BS} + \vec{\mathbf{v}}_{WS}$ is wrong: the inner subscripts are not the same, and the outer ones on the right do not correspond to the subscripts on the left.

**EXAMPLE 3–14** **Heading across the river.** The same boat ($v_{BW} = 1.85\,\text{m/s}$) now heads directly across the river whose current is still 1.20 m/s. (*a*) What is the velocity (magnitude and direction) of the boat relative to the shore? (*b*) If the river is 110 m wide, how long will it take to cross and how far downstream will the boat be then?

**APPROACH** The boat now heads directly across the river and is pulled downstream by the current, as shown in Fig. 3–34. The boat's velocity with respect to the shore, $\vec{\mathbf{v}}_{BS}$, is the sum of the boat's velocity with respect to the water, $\vec{\mathbf{v}}_{BW}$, plus the velocity of the water with respect to the shore, $\vec{\mathbf{v}}_{WS}$ (= the river's current). Just as before,

$$\vec{\mathbf{v}}_{BS} = \vec{\mathbf{v}}_{BW} + \vec{\mathbf{v}}_{WS}.$$

**SOLUTION** (*a*) Since $\vec{\mathbf{v}}_{BW}$ is perpendicular to $\vec{\mathbf{v}}_{WS}$, we can get $v_{BS}$ using the theorem of Pythagoras:

$$v_{BS} = \sqrt{v_{BW}^2 + v_{WS}^2} = \sqrt{(1.85\,\text{m/s})^2 + (1.20\,\text{m/s})^2} = 2.21\,\text{m/s}.$$

We can obtain the angle (note how $\theta$ is defined in Fig. 3–34) from:

$$\tan\theta = v_{WS}/v_{BW} = (1.20\,\text{m/s})/(1.85\,\text{m/s}) = 0.6486.$$

A calculator with a key such as INV TAN or ARC TAN or $\text{TAN}^{-1}$ gives $\theta = \tan^{-1}(0.6486) = 33.0°$. Note that this angle is not equal to the angle calculated in Example 3–13.

(*b*) To find the travel time for the boat to cross the river, recall the river's width $D = 110\,\text{m}$, and use the velocity component that points directly across the river, $v_{BW} = D/t$. Solving for $t$, we get $t = 110\,\text{m}/(1.85\,\text{m/s}) = 59.5\,\text{s}$. Also, the boat will have been carried downstream, in this time, a distance

$$d = v_{WS}t = (1.20\,\text{m/s})(59.5\,\text{s}) = 71.4\,\text{m} \approx 71\,\text{m}.$$

**NOTE** There is no acceleration in this Example, so the motion involves only constant velocities (of the boat or of the river).

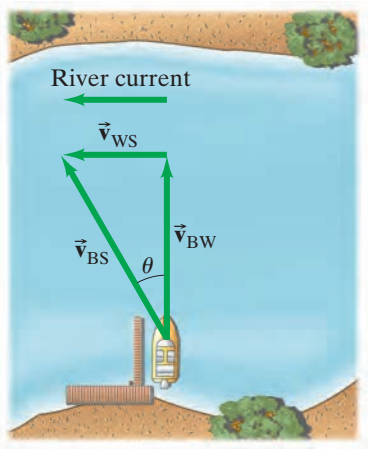

**FIGURE 3–34** Example 3–14. A boat heading directly across a river whose current moves at 1.20 m/s.

**EXAMPLE 3–15** **Car velocities at 90°.** Two cars approach a street corner at right angles to each other with the same speed of 40.0 km/h (= 11.11 m/s) relative to the ground, as shown in Fig. 3–35a. What is the relative velocity of car 1 as seen by car 2?

**APPROACH** Figure 3–35a shows the situation in a reference frame fixed to the Earth. But we want to view the situation from a reference frame in which car 2 is at rest, and this is shown in Fig. 3–35b. In this reference frame (the world as seen by the driver of car 2), the Earth moves toward car 2 with velocity $\vec{\mathbf{v}}_{E2}$ (speed of 40.0 km/h), which is of course equal and opposite to $\vec{\mathbf{v}}_{2E}$, the velocity of car 2 with respect to the Earth (Eq. 3–16):

$$\vec{\mathbf{v}}_{2E} = -\vec{\mathbf{v}}_{E2}.$$

Then the velocity of car 1 as seen by car 2 is (see Eq. 3–15)

$$\vec{\mathbf{v}}_{12} = \vec{\mathbf{v}}_{1E} + \vec{\mathbf{v}}_{E2}.$$

**SOLUTION** Because $\vec{\mathbf{v}}_{E2} = -\vec{\mathbf{v}}_{2E}$, then

$$\vec{\mathbf{v}}_{12} = \vec{\mathbf{v}}_{1E} - \vec{\mathbf{v}}_{2E}.$$

That is, the velocity of car 1 as seen by car 2 is the difference of their velocities, $\vec{\mathbf{v}}_{1E} - \vec{\mathbf{v}}_{2E}$, both measured relative to the Earth; see Fig. 3–35c. Since the magnitudes of $\vec{\mathbf{v}}_{1E}$, $\vec{\mathbf{v}}_{2E}$, and $\vec{\mathbf{v}}_{E2}$ are equal (40.0 km/h = 11.11 m/s), we see (Fig. 3–35b) that $\vec{\mathbf{v}}_{12}$ points at a 45° angle toward car 2; the speed is

$$v_{12} = \sqrt{(11.11\,\text{m/s})^2 + (11.11\,\text{m/s})^2} = 15.7\,\text{m/s}\ (= 56.6\,\text{km/h}).$$

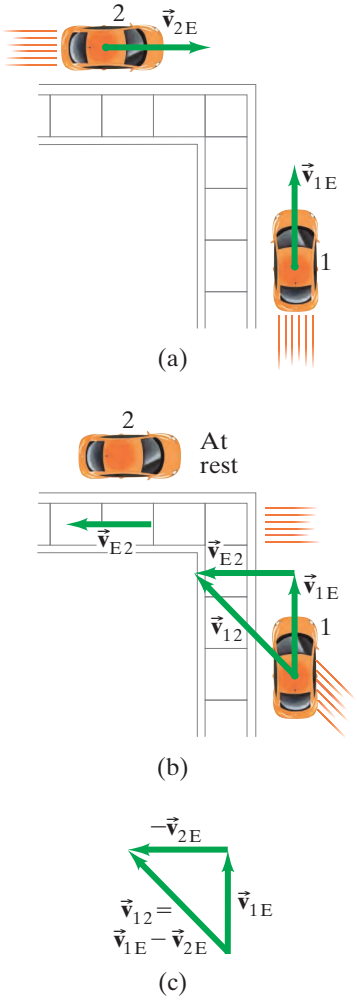

**FIGURE 3–35** Example 3–15.

# Summary

A quantity such as velocity, that has both a magnitude and a direction, is called a **vector**. A quantity such as mass, that has only a magnitude, is called a **scalar**. On diagrams, vectors are represented by arrows.

Addition of vectors can be done graphically by placing the tail of each successive arrow at the tip of the previous one. The sum, or **resultant vector**, is the arrow drawn from the tail of the first vector to the tip of the last vector. Two vectors can also be added using the *parallelogram* method.

Vectors can be added more accurately by adding their **components** along chosen axes with the aid of trigonometric functions. A vector of magnitude $V$ making an angle $\theta$ with the $+x$ axis has components

$$V_x = V\cos\theta, \qquad V_y = V\sin\theta. \tag{3–2}$$

Given the components, we can find a vector's magnitude and direction from

$$V = \sqrt{V_x^2 + V_y^2}, \qquad \tan\theta = \frac{V_y}{V_x}. \tag{3–3}$$

It is often helpful to express a vector in terms of its components along chosen axes using **unit vectors**, which are vectors of unit length along the chosen coordinate axes; for Cartesian coordinates the unit vectors along the $x$, $y$, and $z$ axes are called $\hat{\mathbf{i}}$, $\hat{\mathbf{j}}$, and $\hat{\mathbf{k}}$.

The general definitions for the **instantaneous velocity**, $\vec{\mathbf{v}}$, and **acceleration**, $\vec{\mathbf{a}}$, of a particle (in one, two, or three dimensions) are

$$\vec{\mathbf{v}} = \frac{d\vec{\mathbf{r}}}{dt} \tag{3–8}$$

$$\vec{\mathbf{a}} = \frac{d\vec{\mathbf{v}}}{dt}, \tag{3–11}$$

where $\vec{\mathbf{r}}$ is the position vector of the particle. The kinematic equations for motion with constant acceleration can be written for each of the $x$, $y$, and $z$ components of the motion and have the same form as for one-dimensional motion (Eqs. 2–12). Or they can be written in the more general vector form:

$$\begin{aligned}\vec{\mathbf{v}} &= \vec{\mathbf{v}}_0 + \vec{\mathbf{a}}t \\ \vec{\mathbf{r}} &= \vec{\mathbf{r}}_0 + \vec{\mathbf{v}}_0 t + \tfrac{1}{2}\vec{\mathbf{a}}t^2.\end{aligned} \tag{3–13}$$

**Projectile motion** is the motion of an object in the air near the Earth's surface under the effect of gravity alone. It can be analyzed as two separate motions if air resistance can be ignored. The horizontal component of motion is at constant velocity, whereas the vertical component is at constant acceleration, $\vec{\mathbf{g}}$, just as for an object falling vertically under the action of gravity.

The velocity of an object relative to one frame of reference can be found by vector addition if its velocity relative to a second frame of reference, and the **relative velocity** of the two reference frames, are known.

# Questions

1. One car travels due east at 40 km/h, and a second car travels north at 40 km/h. Are their velocities equal? Explain.
2. Can you conclude that a car is not accelerating if its speedometer indicates a steady 60 km/h? Explain.
3. Give several examples of an object's motion in which a great distance is traveled but the displacement is zero.
4. Can the displacement vector for a particle moving in two dimensions be longer than the length of path traveled by the particle over the same time interval? Can it be less? Discuss.
5. During baseball practice, a player hits a very high fly ball and then runs in a straight line and catches it. Which had the greater displacement, the player or the ball? Explain.
6. If $\vec{\mathbf{V}} = \vec{\mathbf{V}}_1 + \vec{\mathbf{V}}_2$, is $V$ necessarily greater than $V_1$ and/or $V_2$? Discuss.
7. Two vectors have lengths $V_1 = 4.5$ km and $V_2 = 5.0$ km. What are the maximum and minimum magnitudes of their vector sum?
8. Can two vectors, of unequal magnitude, add up to give the zero vector? Can *three* unequal vectors? Under what conditions?
9. Can the magnitude of a vector ever (*a*) equal, or (*b*) be less than, one of its components?
10. Does the odometer of a car measure a scalar or a vector quantity? What about the speedometer?
11. How could you determine the speed a slingshot imparts to a rock, using only a meter stick, a rock, and the slingshot?
12. In archery, should the arrow be aimed directly at the target? How should your angle of aim depend on the distance to the target?
13. Where in Fig. 3–22 is (*a*) $\vec{\mathbf{v}} = 0$, (*b*) $v_y = 0$, (*c*) $v_x = 0$?
14. It was reported in World War I that a pilot flying at an altitude of 2 km caught in his bare hands a bullet fired at the plane! Using the fact that a bullet slows down considerably due to air resistance, explain how this incident occurred.
15. You are on the street trying to hit a friend in his dorm window with a water balloon. He has a similar idea and is aiming at you with *his* water balloon. You aim straight at each other and throw at the same instant. Do the water balloons hit each other? Explain why or why not.
16. A projectile is launched at an upward angle of 30° to the horizontal with a speed of 30 m/s. How does the horizontal component of its velocity 1.0 s after launch compare with its horizontal component of velocity 2.0 s after launch, ignoring air resistance? Explain.
17. A projectile has the least speed at what point in its path?
18. Two cannonballs, A and B, are fired from the ground with identical initial speeds, but with $\theta_A$ larger than $\theta_B$. (*a*) Which cannonball reaches a higher elevation? (*b*) Which stays longer in the air? (*c*) Which travels farther? Explain.
19. A person sitting in an enclosed train car, moving at constant velocity, throws a ball straight up into the air in her reference frame. (*a*) Where does the ball land? What is your answer if the car (*b*) accelerates, (*c*) decelerates, (*d*) rounds a curve, (*e*) moves with constant velocity but is open to the air?
20. If you are riding on a train that speeds past another train moving in the same direction on an adjacent track, it appears that the other train is moving backward. Why?
21. Two rowers, who can row at the same speed in still water, set off across a river at the same time. One heads straight across and is pulled downstream somewhat by the current. The other one heads upstream at an angle so as to arrive at a point opposite the starting point. Which rower reaches the opposite side first? Explain.
22. If you stand motionless under an umbrella in a rainstorm where the drops fall vertically, you remain relatively dry. However, if you start running, the rain begins to hit your legs even if they remain under the umbrella. Why?

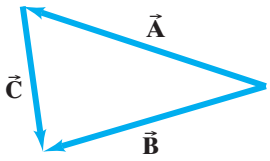
# MisConceptual Questions

**1.** You are adding vectors of length 20 and 40 units. Which of the following choices is a possible resultant magnitude?
(*a*) 0. (*b*) 18. (*c*) 37. (*d*) 64. (*e*) 100.

**2.** The magnitude of a component of a vector must be
(*a*) less than or equal to the magnitude of the vector.
(*b*) equal to the magnitude of the vector.
(*c*) greater than or equal to the magnitude of the vector.
(*d*) less than, equal to, or greater than the magnitude of the vector.

**3.** You are in the middle of a large field. You walk in a straight line for 100 m, then turn left and walk 100 m more in a straight line before stopping. When you stop, you are 100 m from your starting point. By how many degrees did you turn?
(*a*) 90°. (*b*) 120°. (*c*) 30°. (*d*) 180°.
(*e*) This is impossible. You cannot walk 200 m and be only 100 m away from where you started.

**4.** Which of the following equations correctly expresses the relation between vectors $\vec{\mathbf{A}}$, $\vec{\mathbf{B}}$, and $\vec{\mathbf{C}}$, shown in Fig. 3–36?
(*a*) $\vec{\mathbf{A}} = \vec{\mathbf{B}} + \vec{\mathbf{C}}$.
(*b*) $\vec{\mathbf{B}} = \vec{\mathbf{A}} + \vec{\mathbf{C}}$.
(*c*) $\vec{\mathbf{C}} = \vec{\mathbf{A}} + \vec{\mathbf{B}}$.
(*d*) $\vec{\mathbf{A}} + \vec{\mathbf{B}} + \vec{\mathbf{C}} = 0$.



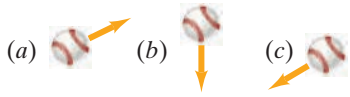


**FIGURE 3–36**
MisConceptual Question 4.

**5.** A car is driven at a constant speed of 10.0 m/s around a circle of radius 20.0 m. As it goes $\frac{1}{4}$ of the way around,
(*a*) the magnitude of the average velocity is 0.
(*b*) the magnitude of the average velocity is 10 m/s.
(*c*) the magnitude of the average velocity is between 0 and 10 m/s.
(*d*) the magnitude of the average velocity is greater than 10 m/s.

**6.** A bullet fired horizontally from a rifle begins to fall
(*a*) as soon as it leaves the barrel.
(*b*) after air friction reduces its speed.
(*c*) not at all if air resistance is ignored.

**7.** A baseball player hits a ball that soars high into the air. After the ball has left the bat, and while it is traveling upward (at point P in Fig. 3–37), what is the direction of acceleration? Ignore air resistance.

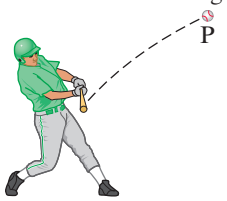

**FIGURE 3–37**
MisConceptual Question 7.

**8.** One ball is dropped vertically from a window. At the same instant, a second ball is thrown horizontally from the same window. Which ball has the greater speed at ground level?
(*a*) The dropped ball.
(*b*) The thrown ball.
(*c*) Neither—they both have the same speed on impact.
(*d*) It depends on how hard the ball was thrown.

**9.** Two balls having different speeds roll off the edge of a horizontal table at the same time. Which hits the floor sooner?
(*a*) The faster one.
(*b*) The slower one.
(*c*) Both the same.

**10.** You are riding in an enclosed train car moving at 90 km/h. If you throw a baseball straight up, where will the baseball land?
(*a*) In front of you.
(*b*) Behind you.
(*c*) In your hand.
(*d*) Can't decide from the given information.

**11.** Which of the three kicks in Fig. 3–38 is in the air for the longest time? They all reach the same maximum height *h*. Ignore air resistance.
(*a*), (*b*), (*c*), or
(*d*) all the same time.

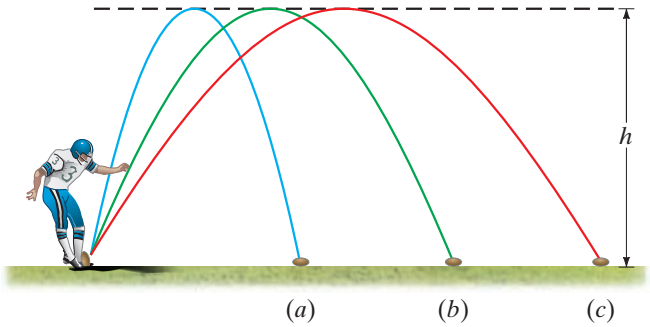

**FIGURE 3–38** MisConceptual Question 11.

**12.** A baseball is hit high and far. Which of the following statements is true? At the highest point,
(*a*) the magnitude of the acceleration is zero.
(*b*) the magnitude of the velocity is zero.
(*c*) the magnitude of the velocity is the slowest.
(*d*) more than one of the above is true.
(*e*) none of the above are true.

**13.** A hunter is aiming horizontally at a monkey who is sitting in a tree. The monkey is so terrified when it sees the gun that it falls off the tree. At that very instant, the hunter pulls the trigger. What will happen?
(*a*) The bullet will miss the monkey because the monkey falls down while the bullet speeds straight forward.
(*b*) The bullet will hit the monkey because both the monkey and the bullet are falling downward at the same rate due to gravity.
(*c*) The bullet will miss the monkey because although both the monkey and the bullet are falling downward due to gravity, the monkey is falling faster.
(*d*) It depends on how far the hunter is from the monkey.

**14.** Which statements are *not* valid for a projectile? Take up as positive and ignore air resistance.
(*a*) The projectile has the same *x* velocity at any point on its path.
(*b*) The acceleration of the projectile is positive and decreasing when the projectile is moving upwards, zero at the top, and increasingly negative as the projectile descends.
(*c*) The acceleration of the projectile has a constant negative value.
(*d*) The *y* component of the velocity of the projectile is zero at the highest point of the projectile's path.
(*e*) The velocity at the highest point is zero.

**15.** A car travels 10 m/s east. Another car travels 10 m/s north. The relative speed of the first car with respect to the second is
(*a*) less than 20 m/s.
(*b*) exactly 20 m/s.
(*c*) more than 20 m/s.

# Problems

## 3–2 to 3–5 Vector Addition; Unit Vectors

1. (I) A car is driven 245 km west and then 118 km southwest (45.0°). What is the displacement of the car from the point of origin (magnitude and direction)? Draw a diagram.
2. (I) A delivery truck travels 21 blocks north, 16 blocks east, and 26 blocks south. What is its final displacement from the origin? Assume the blocks are equal length.
3. (I) If $V_x = 9.40$ units and $V_y = -6.80$ units, determine the magnitude and direction of $\vec{\mathbf{V}}$.
4. (II) Graphically determine the resultant of the following three vector displacements: (1) 24 m, 36° north of east; (2) 18 m, 37° east of north; and (3) 26 m, 33° west of south.
5. (II) $\vec{\mathbf{V}}$ is a vector 21.8 units in magnitude and points at an angle of 23.4° above the negative $x$ axis. (*a*) Sketch this vector. (*b*) Calculate $V_x$ and $V_y$. (*c*) Use $V_x$ and $V_y$ to obtain (again) the magnitude and direction of $\vec{\mathbf{V}}$. [*Note*: Part (*c*) is a good way to check if you've resolved your vector correctly.]
6. (II) Vector $\vec{\mathbf{V}}_1$ is 6.2 units long and points along the negative $x$ axis. Vector $\vec{\mathbf{V}}_2$ is 8.1 units long and points at +55° to the positive $x$ axis. (*a*) What are the $x$ and $y$ components of each vector? (*b*) Determine the sum $\vec{\mathbf{V}}_1 + \vec{\mathbf{V}}_2$ (magnitude and angle).
7. (II) Figure 3–39 shows two vectors, $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$, whose magnitudes are $A = 6.8$ units and $B = 5.5$ units. Determine $\vec{\mathbf{C}}$ if (*a*) $\vec{\mathbf{C}} = \vec{\mathbf{A}} + \vec{\mathbf{B}}$, (*b*) $\vec{\mathbf{C}} = \vec{\mathbf{A}} - \vec{\mathbf{B}}$, (*c*) $\vec{\mathbf{C}} = \vec{\mathbf{B}} - \vec{\mathbf{A}}$. Give the magnitude and direction for each.

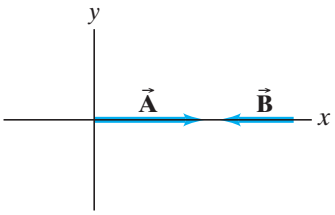

**FIGURE 3–39** Problem 7.

8. (II) An airplane is traveling 815 km/h in a direction 41.5° west of north (Fig. 3–40). (*a*) Find the components of the velocity vector in the northerly and westerly directions. (*b*) How far north and how far west has the plane traveled after 1.75 h?

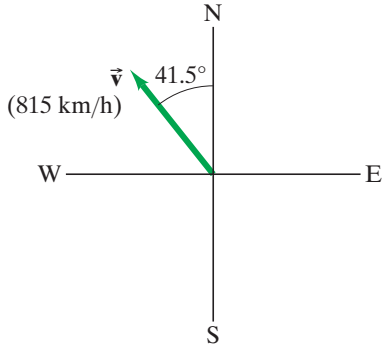

**FIGURE 3–40** Problem 8.

9. (II) The summit of a mountain, 2450 m above base camp, is measured on a map to be 4580 m horizontally from the camp in a direction 38.4° west of north. What are the components of the displacement vector from camp to summit? What is its magnitude? Choose the $x$ axis east, $y$ axis north, and $z$ axis up.
10. (II) Three vectors are shown in Fig. 3–41. Their magnitudes are given in arbitrary units. Determine the sum of the three vectors. Give the resultant in terms of (*a*) components, (*b*) magnitude and angle with the $+x$ axis.

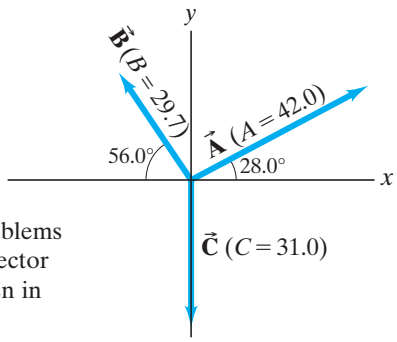

**FIGURE 3–41** Problems 10, 11, 12, and 13. Vector magnitudes are given in arbitrary units.

11. (II) (*a*) Given the vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ shown in Fig. 3–41, determine $\vec{\mathbf{B}} - \vec{\mathbf{A}}$. (*b*) Determine $\vec{\mathbf{A}} - \vec{\mathbf{B}}$ without using your answer in (*a*). (*c*) Compare your results and see if they are opposite.
12. (II) Determine the vector $\vec{\mathbf{A}} - \vec{\mathbf{C}}$, given the vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{C}}$ in Fig. 3–41.
13. (II) For the vectors shown in Fig. 3–41, determine (*a*) $\vec{\mathbf{B}} - 3\vec{\mathbf{A}}$, (*b*) $2\vec{\mathbf{A}} - 3\vec{\mathbf{B}} + 2\vec{\mathbf{C}}$, and (*c*) $\vec{\mathbf{C}} - \vec{\mathbf{A}} - \vec{\mathbf{B}}$.
14. (II) Let $\vec{\mathbf{V}}_1 = -6.0\,\hat{\mathbf{i}} + 8.0\,\hat{\mathbf{j}}$ and $\vec{\mathbf{V}}_2 = -4.5\,\hat{\mathbf{i}} - 5.0\,\hat{\mathbf{j}}$. Determine the magnitude and direction of (*a*) $\vec{\mathbf{V}}_1$, (*b*) $\vec{\mathbf{V}}_2$, (*c*) $\vec{\mathbf{V}}_1 + \vec{\mathbf{V}}_2$, and (*d*) $\vec{\mathbf{V}}_1 - \vec{\mathbf{V}}_2$.
15. (II) (*a*) Determine the magnitude and direction of the sum of the three vectors $\vec{\mathbf{V}}_1 = 4.0\,\hat{\mathbf{i}} - 8.0\,\hat{\mathbf{j}}$, $\vec{\mathbf{V}}_2 = \hat{\mathbf{i}} + \hat{\mathbf{j}}$, and $\vec{\mathbf{V}}_3 = -2.0\,\hat{\mathbf{i}} + 4.0\,\hat{\mathbf{j}}$. (*b*) Determine $\vec{\mathbf{V}}_1 - \vec{\mathbf{V}}_2 + \vec{\mathbf{V}}_3$.
16. (II) Suppose a vector $\vec{\mathbf{V}}$ makes an angle $\phi$ with respect to the $y$ axis. What could be the $x$ and $y$ components of the vector $\vec{\mathbf{V}}$?
17. (II) Two vectors, $\vec{\mathbf{V}}_1$ and $\vec{\mathbf{V}}_2$, add to a resultant $\vec{\mathbf{V}}_R = \vec{\mathbf{V}}_1 + \vec{\mathbf{V}}_2$. Describe $\vec{\mathbf{V}}_1$ and $\vec{\mathbf{V}}_2$ if (*a*) $V_R = V_1 + V_2$, (*b*) $V_R^2 = V_1^2 + V_2^2$, (*c*) $V_1 + V_2 = V_1 - V_2$.
18. (III) You are given a vector in the $xy$ plane that has a magnitude of 95.0 units and a $y$ component of −60.0 units. (*a*) What are the two possibilities for its $x$ component? (*b*) Assuming the $x$ component is known to be positive, specify the vector which, if you add it to the original one, would give a resultant vector that is 80.0 units long and points entirely in the $-x$ direction.

## 3–6 Vector Kinematics

19. (I) The position of a particular particle as a function of time is given by $\vec{\mathbf{r}} = (9.60t\,\hat{\mathbf{i}} + 6.45\,\hat{\mathbf{j}} - 1.50t^2\,\hat{\mathbf{k}})$ m. Determine the particle's velocity and acceleration as a function of time.
20. (I) What was the average velocity of the particle in Problem 19 between $t = 1.00$ s and $t = 3.00$ s? What is the magnitude of the instantaneous velocity at $t = 2.00$ s?
21. (II) A car is moving with speed 16.0 m/s due south at one moment and 25.7 m/s due east 8.00 s later. Over this time interval, determine the magnitude and direction of (*a*) its average velocity, (*b*) its average acceleration. (*c*) What is its average speed? [*Hint*: Can you determine all these from the information given?]

22. (II) At $t = 0$, a particle starts from rest at $x = 0$, $y = 0$, and moves in the $xy$ plane with an acceleration $\vec{\mathbf{a}} = (4.0\,\hat{\mathbf{i}} + 3.0\,\hat{\mathbf{j}})\,\text{m/s}^2$. Determine (*a*) the $x$ and $y$ components of velocity, (*b*) the speed of the particle, and (*c*) the position of the particle, all as a function of time. (*d*) Evaluate all the above at $t = 2.0\,\text{s}$.

23. (II) (*a*) A skier is accelerating down a 30.0° hill at $1.80\,\text{m/s}^2$ (Fig. 3–42). What is the vertical component of her acceleration? (*b*) How long will it take her to reach the bottom of the hill, assuming she starts from rest and accelerates uniformly, if the elevation change is 125 m?

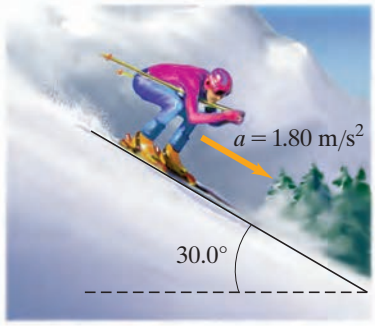

**FIGURE 3–42** Problem 23.

24. (II) A hiker follows a winding trail for 5.5 hours while climbing a mountain. The distance along the trail is 11.5 km and the summit is 850 m above and 8.0 km due north of the starting point. What are the average speed and the magnitude and direction of the average velocity vector?

25. (II) An ant walks on a piece of graph paper straight along the $x$ axis a distance of 10.0 cm in 2.40 s. It then turns left 40.0° and walks in a straight line another 10.0 cm in 1.80 s. Finally, it turns another 70.0° to the left and walks another 10.0 cm in 1.55 s. Determine (*a*) the $x$ and $y$ components of the ant's average velocity, and (*b*) its magnitude and direction.

26. (II) Suppose the position of an object is given by $\vec{\mathbf{r}} = (3.0t^2\,\hat{\mathbf{i}} - 6.0t^3\,\hat{\mathbf{j}})\,\text{m}$. (*a*) Determine its velocity $\vec{\mathbf{v}}$ and acceleration $\vec{\mathbf{a}}$, as a function of time. (*b*) Determine $\vec{\mathbf{r}}$ and $\vec{\mathbf{v}}$ at time $t = 3.5\,\text{s}$.

27. (II) A particle's position as a function of time $t$ is given by $\vec{\mathbf{r}} = (5.0t + 6.0t^2)\,\text{m}\,\hat{\mathbf{i}} + (7.0 - 3.0t^3)\,\text{m}\,\hat{\mathbf{j}}$. At $t = 5.0\,\text{s}$, find the magnitude and direction of the particle's displacement vector $\Delta\vec{\mathbf{r}}$ relative to the point $\vec{\mathbf{r}}_0 = (2.0\,\hat{\mathbf{i}} + 7.0\,\hat{\mathbf{j}})\,\text{m}$.

28. (II) On mountainous downhill roads, an escape lane is sometimes placed to the side of the road for trucks whose brakes might fail. Assuming a constant upward slope of 26°, calculate the horizontal and vertical components of the acceleration of a truck that slowed from 110 km/h to rest in 7.0 s. See Fig. 3–43.

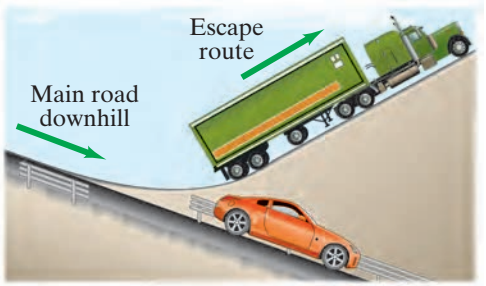

**FIGURE 3–43** Problem 28.

29. (II) A light plane is headed due south with a speed relative to still air of 185 km/h. After 1.25 h, the pilot notices that they have covered only 135 km and their direction is not south but 15.0° east of south. What is the wind velocity?

30. (III) An object, which is at the origin at time $t = 0$, has initial velocity $\vec{\mathbf{v}}_0 = (-14.0\,\hat{\mathbf{i}} - 7.0\,\hat{\mathbf{j}})\,\text{m/s}$ and constant acceleration $\vec{\mathbf{a}} = (6.0\,\hat{\mathbf{i}} + 3.0\,\hat{\mathbf{j}})\,\text{m/s}^2$. Find the position $\vec{\mathbf{r}}$ where the object comes to rest (momentarily).

31. (III) A particle starts from the origin at $t = 0$ with an initial velocity of 5.0 m/s along the positive $x$ axis. If the acceleration is $(-3.0\,\hat{\mathbf{i}} + 4.5\,\hat{\mathbf{j}})\,\text{m/s}^2$, determine the velocity and position of the particle at the moment it reaches its maximum $x$ coordinate.

### 3–7 and 3–8 Projectile Motion (neglect air resistance)

32. (I) A tiger leaps horizontally from a 7.5-m-high rock with a speed of 3.0 m/s. How far from the base of the rock will she land?

33. (I) A diver running 2.5 m/s dives out horizontally from the edge of a vertical cliff and 3.5 s later reaches the water below. How high was the cliff and how far from its base did the diver hit the water?

34. (II) A ball is thrown horizontally from the roof of a building 7.5 m tall and lands 9.5 m from the base. What was the ball's initial speed?

35. (II) A ball thrown horizontally at 10.8 m/s from the roof of a building lands 21.0 m from the base of the building. How high is the building?

36. (II) A football is kicked at ground level with a speed of 18.0 m/s at an angle of 31.0° to the horizontal. How much later does it hit the ground?

37. (II) A fire hose held near the ground shoots water at a speed of 6.5 m/s. At what angle(s) should the nozzle point in order that the water land 2.5 m away (Fig. 3–44)? Why are there two different angles? Sketch the two trajectories.

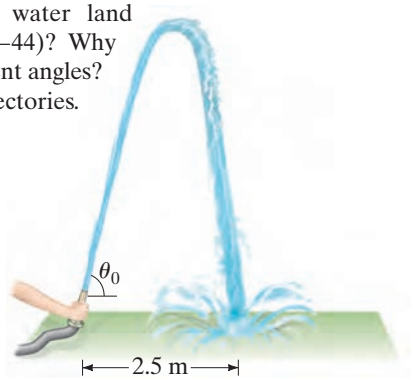

**FIGURE 3–44** Problem 37.

38. (II) You buy a plastic dart gun, and being a clever physics student you decide to do a quick calculation to find its maximum horizontal range. You shoot the gun straight up, and it takes 3.4 s for the dart to land back at the barrel. What is the maximum horizontal range of your gun?

39. (II) A projectile is fired with an initial speed of 38.8 m/s at an angle of 42.2° above the horizontal on a long flat firing range. Determine (*a*) the maximum height reached by the projectile, (*b*) the total time in the air, (*c*) the total horizontal distance covered (that is, the range), and (*d*) the speed of the projectile 1.50 s after firing.

40. (II) A diver leaves the end of a diving board that is 2.0 m above the surface of the water. Her dive takes her 1.2 m above the board, and then into the water a horizontal distance of 2.2 m from the end of the board. At what speed and angle did she leave the board?

41. (II) The maximum range of a projectile is found to be 95 m. If the projectile strikes the ground a distance of 68 m away, what was the angle of launch?

**42.** (II) A projectile is shot from the edge of a cliff 125 m above ground level with an initial speed of 62.0 m/s at an angle of 35.0° with the horizontal, as shown in Fig. 3–45. (*a*) Determine the time taken by the projectile to hit point P at ground level. (*b*) Determine the distance $X$ of point P from the base of the vertical cliff. At the instant just before the projectile hits point P, find (*c*) the horizontal and the vertical components of its velocity, (*d*) the magnitude of the velocity, and (*e*) the angle made by the velocity vector with the horizontal. (*f*) Find the maximum height above the cliff top reached by the projectile.

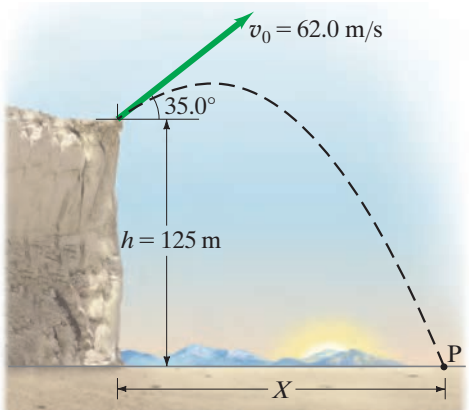

**FIGURE 3–45** Problem 42.

**43.** (II) An athlete performing a long jump leaves the ground at a 27.0° angle and lands 7.80 m away. (*a*) What was the takeoff speed? (*b*) If this speed were increased by just 5.0%, how much longer would the jump be?

**44.** (II) In Example 3–11 we chose the $x$ axis to the right and $y$ axis up. Redo this problem by defining the $x$ axis to the left and $y$ axis down, and show that the conclusion remains the same—the football lands on the ground 40.5 m to the right of where it departed the punter's foot.

**45.** (II) A stunt driver wants to make his car jump over 8 cars parked side by side below a horizontal ramp (Fig. 3–46). (*a*) With what minimum speed must he drive off the horizontal ramp? The vertical height of the ramp is 1.5 m above the car roofs and the horizontal distance he must clear is 22 m. (*b*) If the ramp is now tilted upward, so that "takeoff angle" is 9.0° above the horizontal, what is the new minimum speed?

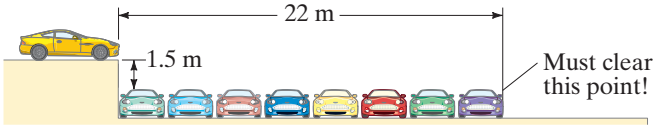

**FIGURE 3–46** Problem 45.

**46.** (II) A baseball is hit with a speed of 27.0 m/s at an angle of 45.0°. It lands on the flat roof of a 12.5-m-tall nearby building. If the ball was hit when it was 1.2 m above the ground, what horizontal distance does it travel before it lands on the building?

**47.** (II) A rescue plane wants to drop supplies to isolated mountain climbers on a rocky ridge 265 m below. If the plane is traveling horizontally with a speed of 125 km/h, how far in advance of the recipients (horizontal distance) must the goods be dropped?

**48.** (II) Show that the time required for a projectile to reach its highest point is equal to the time for it to return to its original height if air resistance is negligible.

**49.** (II) Exactly 3.0 s after a projectile is fired into the air from the ground, it is observed to have a velocity $\vec{\mathbf{v}} = (7.8\,\hat{\mathbf{i}} + 5.2\,\hat{\mathbf{j}})$ m/s, where the $x$ axis is horizontal and the $y$ axis is positive upward. Determine (*a*) the horizontal range of the projectile, (*b*) its maximum height above the ground, and (*c*) its speed and angle of motion just before it strikes the ground.

**50.** (II) At what projection angle will the range of a projectile equal its maximum height?

**51.** (II) A ball is thrown horizontally from the top of a cliff with initial speed $v_0$ (at $t = 0$). At any moment, its direction of motion makes an angle $\theta$ to the horizontal (Fig. 3–47). Derive a formula for $\theta$ as a function of time, $t$, as the ball follows a projectile's path.

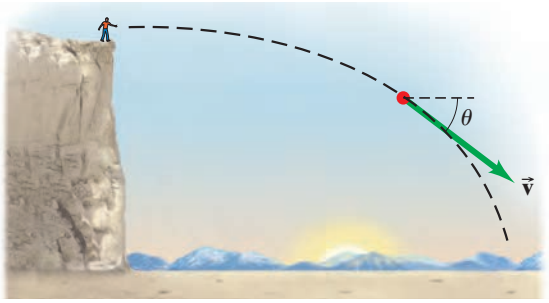

**FIGURE 3–47** Problem 51.

**52.** (II) Romeo is throwing pebbles gently up to Juliet's window, and he wants the pebbles to hit the window with only a horizontal component of velocity. He is standing at the edge of a rose garden 8.0 m below her window and 8.5 m from the base of the wall (Fig. 3–48). How fast are the pebbles going when they hit her window?

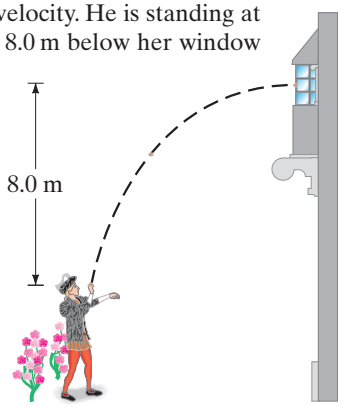

**FIGURE 3–48** Problem 52.

**53.** (II) (*a*) A long jumper leaves the ground at 45° above the horizontal and lands 8.0 m away. What is her "takeoff" speed $v_0$? (*b*) Now she is out on a hike and comes to the left bank of a river. There is no bridge and the right bank is 10.0 m away horizontally and 2.5 m vertically below. If she jumps from the edge of the left bank at 45° with the speed calculated in (*a*), how long, or short, of the opposite bank will she land (Fig. 3–49)?

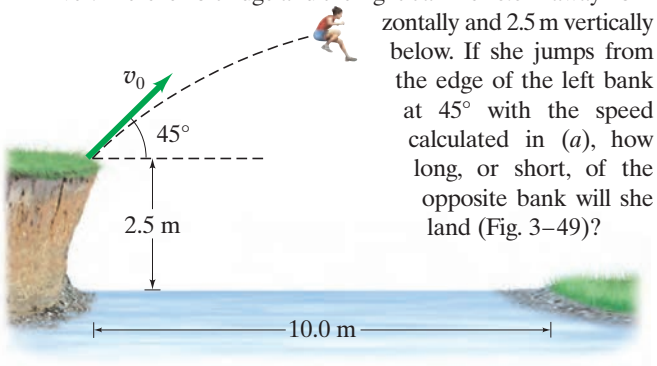

**FIGURE 3–49** Problem 53.

54. (II) Show that the speed with which a projectile leaves the ground is equal to its speed just before it strikes the ground at the end of its journey, assuming the firing level equals the landing level.

55. (II) If a ball is kicked from ground level at 15.0 m/s, there are two launch angles that will make the ball land 20.0 m away. (*a*) What are the two angles? (*b*) What maximum height does the ball reach in each case? (*c*) How long is the ball in the air for each case? Ignore air resistance.

56. (II) At serve, a tennis player aims to hit the ball horizontally. What minimum speed is required for the ball to clear the 0.90-m-high net about 15.0 m from the server if the ball is "launched" from a height of 2.30 m? Where will the ball land if it just clears the net (and will it be "good" in the sense that it lands within 7.0 m of the net)? How long will it be in the air? See Fig. 3–50.

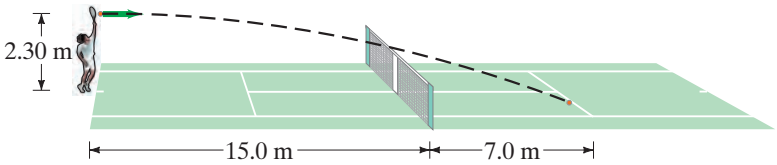

**FIGURE 3–50** Problem 56.

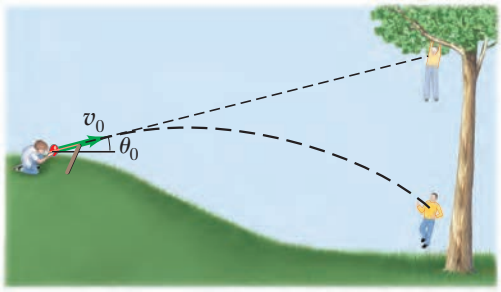
57. (II) An Olympic long jumper is capable of jumping 8.0 m. Assuming his horizontal speed is 9.1 m/s as he leaves the ground, how long is he in the air and how high does he go? Assume that he lands standing upright—that is, the same way he left the ground.

58. (III) Revisit Example 3–9, and assume that the boy with the slingshot is *below* the boy in the tree (Fig. 3–51) and so aims *upward*, directly at the boy in the tree. Show that again the boy in the tree makes the wrong move by letting go at the moment the water balloon is shot.



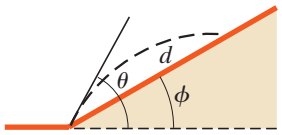


**FIGURE 3–51** Problem 58.

59. (III) Suppose the kick in Example 3–8 is attempted 36.0 m from the goalposts, whose crossbar is 3.05 m above the ground. If the football is directed perfectly between the goalposts, will it pass over the bar and be a field goal? Show why or why not. If not, from what horizontal distance must this kick be made if it is to score?

60. (III) A person stands at the base of a hill that is a straight incline making an angle $\phi$ with the horizontal (Fig. 3–52). For a given initial speed $v_0$, at what angle $\theta$ (to the horizontal) should objects be thrown so that the distance $d$ they land up the hill is as large as possible?

**FIGURE 3–52** Problem 60. Given $\phi$ and $v_0$, determine $\theta$ to make $d$ maximum.

61. (III) Derive a formula for the horizontal range $R$ of a projectile when it lands at a height $h$ above its initial point. (For $h < 0$, it lands a distance $-h$ below the starting point.) Assume it is projected at an angle $\theta_0$ with initial speed $v_0$.

## 3–9 Relative Velocity

62. (I) A person going for a morning jog on the deck of a cruise ship is running toward the bow (front) of the ship at 2.5 m/s while the ship is moving ahead at 8.8 m/s. What is the velocity of the jogger relative to the water? Later, the jogger is moving toward the stern (rear) of the ship. What is the jogger's velocity relative to the water now?

63. (I) Huck Finn walks at a speed of 0.70 m/s across his raft (that is, he walks perpendicular to the raft's motion relative to the shore). The heavy raft is traveling down the Mississippi River at a speed of 1.50 m/s relative to the river bank (Fig. 3–53). What is Huck's velocity (speed and direction) relative to the river bank?

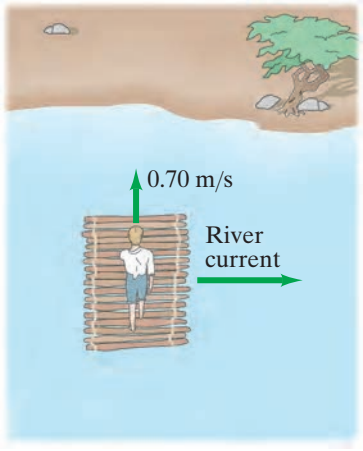

**FIGURE 3–53** Problem 63.

64. (II) Determine the speed of the boat with respect to the shore in Example 3–13.

65. (II) A motorboat whose speed in still water is 4.30 m/s must aim upstream at an angle of 23.5° (with respect to a line perpendicular to the shore) in order to travel directly across the stream. (*a*) What is the speed of the current? (*b*) What is the resultant speed of the boat with respect to the shore? (See Fig. 3–33.)

66. (II) A passenger on a boat moving at 1.70 m/s on a still lake walks up a flight of stairs at a speed of 0.60 m/s, Fig. 3–54. The stairs are angled at 45° pointing in the direction of motion as shown. Write the vector velocity of the passenger relative to the water.

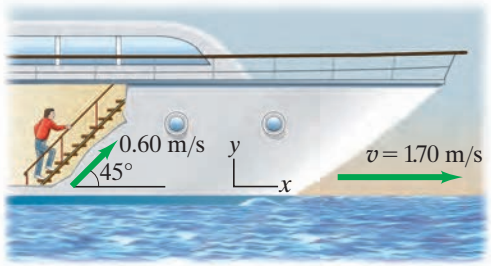

**FIGURE 3–54** Problem 66.

67. (II) An airplane is heading due south at a speed of 688 km/h. If a wind begins blowing from the southwest at a speed of 85.0 km/h (average), calculate (*a*) the velocity (magnitude and direction) of the plane, relative to the ground, and (*b*) how far from its intended position it will be after 11.0 min if the pilot takes no corrective action. [*Hint*: First draw a diagram.]

68. (II) In what direction should the pilot aim the plane in Problem 67 so that it will fly due south?

**69.** (II) Raindrops make an angle $\theta$ with the vertical when viewed through a moving train window (Fig. 3–55). If the speed of the train is $v_T$, what is the speed of the raindrops in the reference frame of the Earth in which they are assumed to fall vertically?

**FIGURE 3–55**
Problem 69.

**70.** (II) A boat, whose speed in still water is 2.80 m/s, must cross a 265-m-wide river and arrive at a point 118 m upstream from where it starts (Fig. 3–56). To do so, the pilot must head the boat at a 45.0° upstream angle. What is the speed of the river's current?

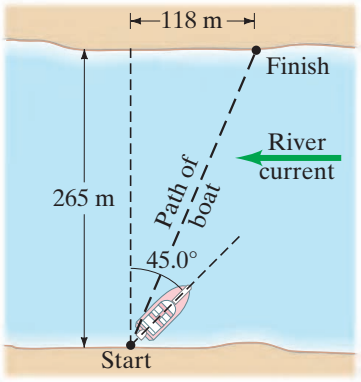

**FIGURE 3–56**
Problem 70.

**71.** (II) A swimmer is capable of swimming 0.60 m/s in still water. (*a*) If she aims her body directly across a 55-m-wide river whose current is 0.50 m/s, how far downstream (from a point opposite her starting point) will she land? (*b*) How long will it take her to reach the other side?

**72.** (II) (*a*) At what upstream angle must the swimmer in Problem 71 aim, if she is to arrive at a point directly across the stream? (*b*) How long will it take her?

**73.** (II) Two cars approach a street corner at right angles to each other (Fig. 3–57). Car 1 travels at a speed relative to Earth $v_{1E} = 35$ km/h, and car 2 at $v_{2E} = 55$ km/h. What is the relative velocity of car 1 as seen by car 2? What is the velocity of car 2 relative to car 1?

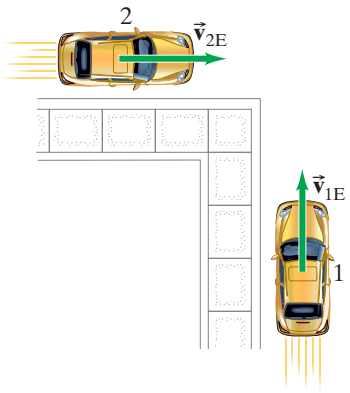

**FIGURE 3–57** Problem 73.

**74.** (III) An airplane, whose air speed is 560 km/h, is supposed to fly in a straight path 38.0° N of E. But a steady 82 km/h wind is blowing from the north. In what direction should the plane head? [*Hint*: Use the law of sines, Appendix A–9.]

**75.** (III) Point B is located across the river from point A and at a 42.0° angle upstream from A. A boat travels from point A to point B, sailing at 18.0 km/h relative to the water. The current in the river flows at 5.60 km/h. The river is 1.45 km wide. (*a*) At what angle should the boat head? (*b*) What will be the boat's speed relative to the ground? (*c*) How much time does the trip from point A to point B take?

# General Problems

**76.** A plumber steps out of his truck, walks 55 m east and 38 m south, and then takes an elevator 12 m into the subbasement of a building where a bad leak is occurring. What is the displacement of the plumber relative to his truck? Give your answer in components. Also give the magnitude and angles, with respect to the $x$ axis, in the vertical and horizontal planes. Assume $x$ is east, $y$ is north, and $z$ is up.

**77.** *Apollo* astronauts took a "nine iron" to the Moon and hit a golf ball about 180 m. Assuming that the swing, launch angle, and so on, were the same as on Earth where the same astronaut could hit it only 32 m, estimate the acceleration due to gravity on the surface of the Moon. (We neglect air resistance in both cases, but on the Moon there is none.)

**78.** A car moving at 95 km/h passes a 1.40-km-long train traveling in the same direction on a track that is parallel to the road. If the speed of the train is 75 km/h, how long does it take the car to pass the train, and how far will the car have traveled in this time? What are the results if the car and train are instead traveling in opposite directions?

**79.** When Babe Ruth hit a homer over the 8.0-m-high right-field fence 98 m from home plate, roughly what was the minimum speed of the *baseball* when it left the bat? Assume the ball was hit 1.0 m above the ground and its path initially made a 36° angle with the ground.

**80.** A child runs down a 12° hill and then suddenly jumps upward at a 15° angle above horizontal and lands 1.3 m down the hill as measured along the hill. What was the child's initial speed at the jump?

**81.** Here is something to try at a sporting event. Show that the maximum height $h$ attained by an object projected into the air, such as a baseball, football, or soccer ball, is approximately given by

$$h \approx 1.2t^2 \text{ m},$$

where $t$ is the total time of flight for the object in seconds. Assume that the object returns to the same level as that from which it was launched, as in Fig. 3–58. For example, if you count seconds and find that a baseball was in the air for $t = 5.0$ s, the maximum height attained was $h = 1.2 \times (5.0)^2 = 30$ m. The fun of this relation is that $h$ can be determined without knowledge of the launch speed $v_0$ or launch angle $\theta_0$. Why is that exactly? See Section 3–8.

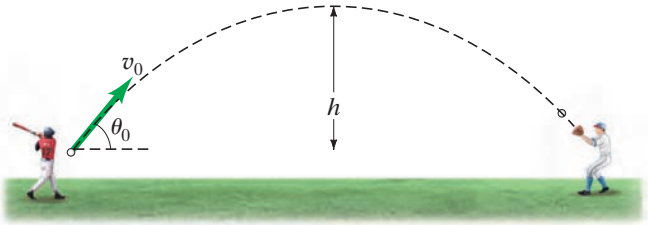

**FIGURE 3–58** Problem 81.

**82.** The cliff divers of Acapulco push off horizontally from rock platforms about 35 m above the water, but they must clear rocky outcrops at water level that extend out into the water 5.0 m from the base of the cliff directly under their launch point. See Fig. 3–59. What minimum pushoff speed is necessary to clear the rocks? How long are they in the air?

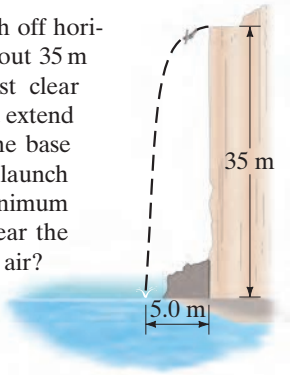

**FIGURE 3–59**
Problem 82.

**83.** A grasshopper hops along a level road. On each hop, the grasshopper launches itself at angle $\theta_0 = 45°$ and achieves a range $R = 0.80$ m. What is the average horizontal speed of the grasshopper as it hops along the road? Assume that the time spent on the ground between hops is negligible.

**84.** Spymaster Andrea, flying a constant 208 km/h horizontally in a low-flying helicopter, wants to drop secret documents into her contact's open car which is traveling 135 km/h on a level highway 78.0 m below. At what angle (with the horizontal) should the car be in her sights when the packet is released (Fig. 3–60)?

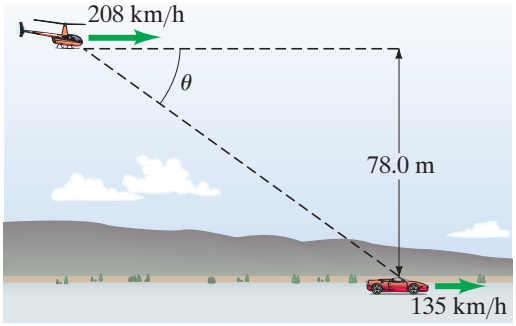

**FIGURE 3–60** Problem 84.

**85.** A basketball leaves a player's hands at a height of 2.10 m above the floor. The basket is 3.05 m above the floor. The player likes to shoot the ball at a 38.0° angle. If the shot is made from a horizontal distance of 11.00 m and must be accurate to $\pm 0.22$ m (horizontally), what is the range of initial speeds allowed to make the basket?

**86.** Extreme-sports enthusiasts have been known to jump off the top of El Capitan, a sheer granite cliff of height 910 m in Yosemite National Park. Assume a jumper runs horizontally off the top of El Capitan with speed 4.0 m/s and enjoys a free fall until she is 150 m above the valley floor, at which point she opens her parachute (Fig. 3–61). (*a*) How long is the jumper in free fall? Ignore air resistance. (*b*) It is important to be as far away from the cliff as possible before opening the parachute. How far from the cliff is this jumper when she opens her chute?

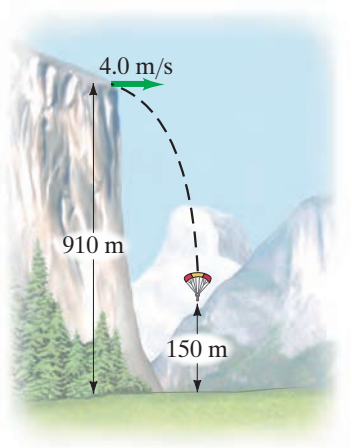

**FIGURE 3–61**
Problem 86.

**87.** If a baseball pitch leaves the pitcher's hand horizontally at a velocity of 130 km/h, by what % will the pull of gravity change the magnitude of the velocity when the ball reaches the batter, 18 m away? For this estimate, ignore air resistance and spin on the ball.

**88.** A projectile is launched from ground level to the top of a cliff which is 195 m away and 135 m high (see Fig. 3–62). If the projectile lands on top of the cliff 6.6 s after it is fired, find the initial velocity of the projectile (magnitude and direction). Neglect air resistance.

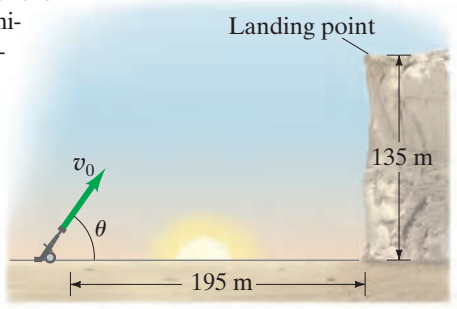

**FIGURE 3–62**
Problem 88.

**89.** A diver leaves the end of a 3.5-m-high diving board and strikes the water 1.3 s later, 3.0 m beyond the end of the board. Considering the diver as a particle, determine: (*a*) her initial velocity, $\vec{\mathbf{v}}_0$; (*b*) the maximum height reached; and (*c*) the velocity $\vec{\mathbf{v}}_f$ with which she enters the water.

**90.** A basketball is shot from an initial height of 2.40 m (Fig. 3–63) with an initial speed $v_0 = 12$ m/s directed at an angle $\theta_0 = 35°$ above the horizontal. (*a*) How far from the basket was the player if he made a basket? (*b*) At what angle to the horizontal did the ball enter the basket?

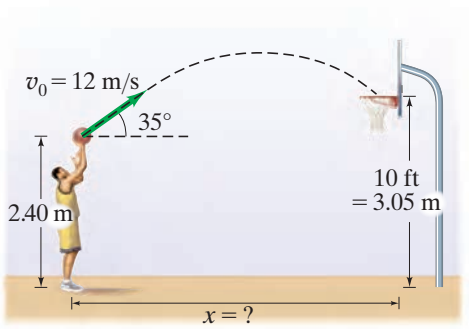

**FIGURE 3–63**
Problem 90.

**91.** A hunter aims directly at a target (on the same level) 38.0 m away. (*a*) If the arrow leaves the bow at a speed of 21.3 m/s, by how much will it miss the target? (*b*) At what angle should the bow be aimed so the target will be hit?

**92.** A person in the passenger basket of a hot-air balloon throws a ball horizontally outward from the basket with speed 12.0 m/s (Fig. 3–64). What initial velocity (magnitude and direction) does the ball have relative to a person standing on the ground (*a*) if the hot-air balloon is rising at 3.0 m/s relative to the ground during this throw, and (*b*) if the hot-air balloon is descending at 3.0 m/s relative to the ground?

**FIGURE 3–64**
Problem 92.

**93.** A rock is kicked horizontally at 15 m/s from a hill with a 45° slope (Fig. 3–65). How long does it take for the rock to hit the ground?

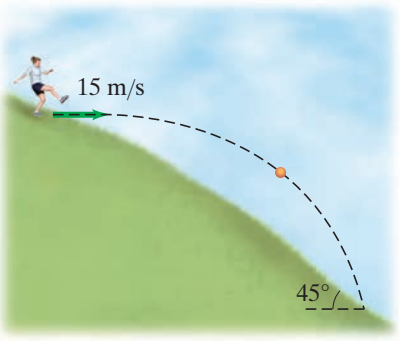

**FIGURE 3–65** Problem 93.

**94.** A batter hits a fly ball which leaves the bat 0.90 m above the ground at an angle of 64° with an initial speed of 28 m/s heading toward centerfield. Ignore air resistance. (*a*) How far from home plate would the ball land if not caught? (*b*) The ball is caught by the centerfielder who, starting at a distance of 105 m from home plate just as the ball was hit, runs straight toward home plate at a constant speed and makes the catch at ground level. Find his speed.

**95.** A ball is shot from the top of a building with an initial velocity of 24 m/s at an angle $\theta = 42°$ above the horizontal. (*a*) What are the horizontal and vertical components of the initial velocity? (*b*) If a nearby building is the same height and 65 m away, how far below the top of the building will the ball strike the nearby building?

**96.** The speed of a boat in still water is $v$. The boat is to make a round trip in a river whose current travels at speed $u$. Derive a formula for the time needed to make a round trip of total distance $D$ if the boat makes the round trip by moving (*a*) upstream and back downstream, and (*b*) directly across the river and back. We must assume $u < v$; why?

**97.** At $t = 0$ a batter hits a baseball with an initial speed of 28 m/s at a 55° angle to the horizontal. An outfielder is 85 m from the batter at $t = 0$ and, as seen from home plate, the line of sight to the outfielder makes a horizontal angle of 22° with the plane in which the ball moves (see Fig. 3–66). What speed and direction must the fielder take to catch the ball at the same height from which it was struck? Give the angle with respect to the outfielder's line of sight to home plate.

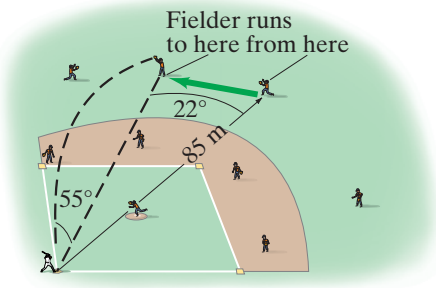

**FIGURE 3–66**
Problem 97.

**98.** A child, who is 45 m from the bank of a river, is being carried helplessly downstream by the river's swift current of 1.0 m/s. As the child passes a lifeguard on the river's bank, the lifeguard starts swimming in a straight line (Fig. 3–67) until she reaches the child at a point downstream. If the lifeguard can swim at a speed of 2.0 m/s relative to the water, how long does it take her to reach the child? How far downstream does the lifeguard intercept the child?

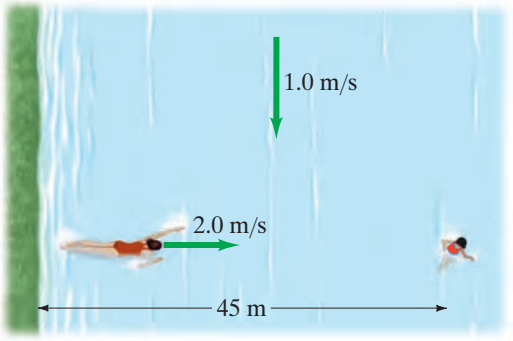

**FIGURE 3–67** Problem 98.

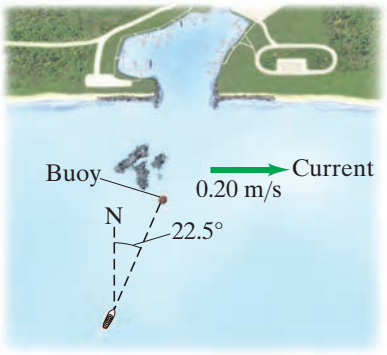
**99.** A particle has a velocity of $\vec{\mathbf{v}} = (-3.0\,\hat{\mathbf{i}} + 4.5t\,\hat{\mathbf{j}})$ m/s. The particle starts at $\vec{\mathbf{r}} = (2.5\,\hat{\mathbf{i}} - 3.1\,\hat{\mathbf{j}})$ m at $t = 0$. Give the position and acceleration as a function of time. What is the shape of the resulting path?

**100.** In hot pursuit, Agent Logan of the FBI must get directly across a 1300-m-wide river in minimum time. The river's current is 0.80 m/s, he can row a boat at 1.60 m/s, and he can run 3.00 m/s. Describe the path he should take (rowing plus running along the shore) for the minimum crossing time, and determine the minimum time.

**101.** You are driving south on a highway at 12 m/s (approximately 25 mi/h) in a snowstorm. When you last stopped, you noticed that the snow was coming down vertically, but it is passing the windows of the moving car at an angle of 9.0° to the horizontal. Estimate the speed of the vertically falling snowflakes relative to the ground. [*Hint*: Construct a relative velocity diagram similar to Fig. 3–33 or 3–34. Be careful about which angle is the angle given.]

**102.** A boat is traveling where there is a current of 0.20 m/s east (Fig. 3–68). To avoid some offshore rocks, the boat must clear a buoy that is NNE (22.5°) and 2.8 km away. The boat's speed through still water is 2.1 m/s. If the boat wants to pass the right side of the buoy by 0.15 km, at what angle should the boat head?



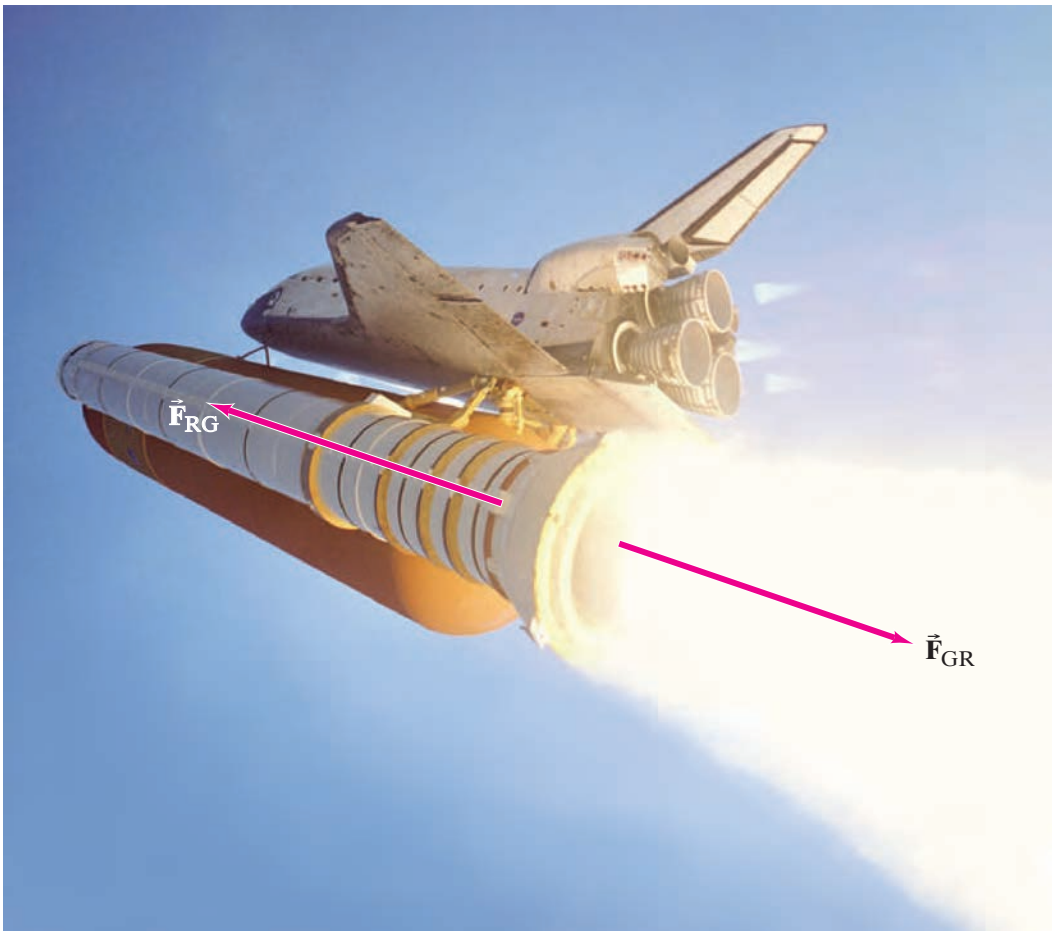


**FIGURE 3–68** Problem 102.

## ANSWERS TO EXERCISES

**A:** $3.0\sqrt{2} \approx 4.2$ units.
**B:** (*a*).
**C:** (*d*). Helicopter provides the initial velocity of the box.
**D:** (*a*) $v = v_{x0} = 16.0$ m/s, horizontal; (*b*) 9.80 m/s$^2$ down.
**E:** Both balls reach the same height, so are in the air for the same length of time.

A space shuttle is carried out into space by powerful rockets. They are accelerating, increasing in speed rapidly. To do so, a force must be exerted on them according to Newton's second law, $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$. What exerts this force? The **r**ocket engines exert a force on the **g**ases they push out (expel) from the rear of the rockets (labeled $\vec{\mathbf{F}}_{GR}$). According to Newton's third law, these ejected gases exert an equal and opposite force on the rockets in the forward direction. This "reaction" force exerted *on* the **r**ockets *by* the **g**ases, labeled $\vec{\mathbf{F}}_{RG}$, is the *net* force on the rockets and accelerates the rockets. (Any other forces, such as gravity, are assumed small in comparison.)

CHAPTER 4

# Dynamics: Newton's Laws of Motion

## CHAPTER-OPENING QUESTIONS—Guess now!

**1.** A 150-kg football player collides head-on with a 75-kg running back. During the collision, the heavier player exerts a force of magnitude $F_A$ on the smaller player. If the smaller player exerts a force $F_B$ back on the heavier player, which response is most accurate?

**(a)** $F_B = F_A$.
**(b)** $F_B < F_A$.
**(c)** $F_B > F_A$.
**(d)** $F_B = 0$.
**(e)** We need more information.

**2.** A line by the poet T. S. Eliot (from *Murder in the Cathedral*) has the women of Canterbury say "the earth presses up against our feet." What force is this?

**(a)** Gravity.
**(b)** The normal force.
**(c)** A friction force.
**(d)** Centrifugal force.
**(e)** No force—they are being poetic.

4–8 Problem Solving—A General Approach

We have discussed how motion is *described* in terms of velocity and acceleration. Now we deal with the question of *why* objects move as they do: What makes an object at rest begin to move? What causes an object to accelerate or decelerate? What is involved when an object moves in a curved path? We can answer in each case that a force is required. In this Chapter,[†] we will investigate the connection between force and motion, which is the subject called **dynamics**.

## 4–1 Force

Intuitively, we experience **force** as any kind of a push or a pull on an object. When you push a stalled car or a grocery cart (Fig. 4–1), you are exerting a force on it. When a motor lifts an elevator, or a hammer hits a nail, or the wind blows the leaves of a tree, a force is being exerted. We often call these *contact forces* because the force is exerted when one object comes in contact with another object. On the other hand, we say that an object falls because of the *force of gravity* (which is not a contact force).

**FIGURE 4–1** A force exerted on a grocery cart—in this case exerted by a person.

If an object is at rest, to start it moving requires force—that is, a force is needed to accelerate an object from zero velocity to a nonzero velocity. For an object already moving, if you want to change its velocity—either in direction or in magnitude—a force is required. In other words, to accelerate an object, a force is always required. In Section 4–4 we discuss the precise relation between acceleration and net force, which is Newton's second law.

One way to measure the magnitude (or strength) of a force is to use a spring scale (Fig. 4–2). Normally, such a spring scale is used to find the weight of an object; by weight we mean the force of gravity acting on the object (Section 4–6). The spring scale, once calibrated, can be used to measure other kinds of forces as well, such as the pulling force shown in Fig. 4–2.

A force exerted in a different direction has a different effect. Force has direction as well as magnitude, and is indeed a vector that follows the rules of vector addition discussed in Chapter 3. We can represent any force on a diagram by an arrow, just as we did with velocity. The direction of the arrow is the direction of the push or pull, and its length is drawn proportional to the magnitude of the force. Force vectors in this book are drawn as red in color, velocity is green.

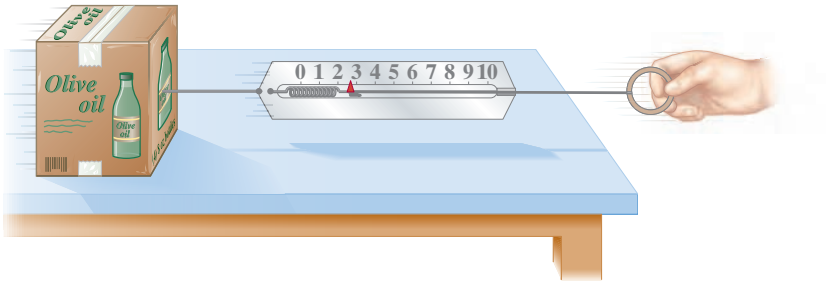

**FIGURE 4–2** A spring scale used to measure a force.

## 4–2 Newton's First Law of Motion

What is the relationship between force and motion? The ancient Greeks, including Aristotle (384–322 B.C.), believed that a force was required to keep an object moving along a horizontal plane. To Aristotle, the natural state of an object was at rest, and a force was thought necessary to keep an object in motion. Aristotle also argued that the greater the force on the object, the greater its speed.

Some 2000 years later, in the early 1600s, Galileo disagreed. Galileo maintained that it is just as natural for an object to be in motion with a constant velocity as it is for it to be at rest. See Section 1–1, page 2.

[†]We treat everyday objects in motion here. When velocities are extremely high, close to the speed of light $(3.0 \times 10^8 \text{ m/s})$, we use the theory of relativity (Chapter 36), and in the submicroscopic world of atoms and molecules we use quantum theory (Chapter 37 *ff*).

To understand Galileo's idea, consider the following observations involving motion along a horizontal plane. To push an object with a rough surface along a tabletop at constant speed requires a certain amount of force. To push an equally heavy object with a very smooth surface across the table at the same speed will require less force. If a layer of oil or other lubricant is placed between the surface of the object and the table, then almost no force is required to keep the object moving. Notice that in each successive step, less force is required. As the next step, we imagine there is no friction at all, that the object does not rub against the table—or there is a perfect lubricant between the object and the table—and theorize that once started, the object would move across the table at constant speed with *no* force applied. A steel ball bearing rolling on a hard horizontal surface approaches this situation. So does a puck on an air table, in which a thin layer of air reduces friction almost to zero.

It was Galileo's genius to imagine such an idealized world—in this case, one where there is no friction—and to see that it could lead to a more accurate and richer understanding of the real world. This idealization led him to his remarkable conclusion that if no force is applied to a moving object, it will continue to move with constant speed in a straight line. An object slows down only if a force is exerted on it. Galileo thus interpreted friction as a force akin to ordinary pushes and pulls.

To push an object across a table at constant speed requires a force from your hand that can balance the force of friction (Fig. 4–3). When the object moves at constant speed, your pushing force is equal in magnitude to the friction force; but these two forces are in opposite directions, so the *net* force on the object (the vector sum of the two forces) is zero. This is consistent with Galileo's viewpoint: the object moves with constant velocity when no *net* force is exerted on it.

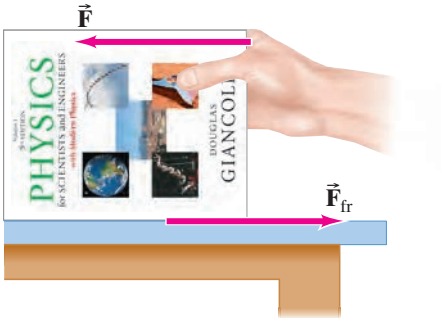

**FIGURE 4–3** $\vec{\mathbf{F}}$ represents the force applied by the person and $\vec{\mathbf{F}}_{\text{fr}}$ represents the force of friction.

Upon this foundation laid by Galileo, Isaac Newton (Fig. 4–4) built his great theory of motion. Newton's analysis of motion is summarized in his famous "three laws of motion." In his great work, the *Principia* (published in 1687), Newton readily acknowledged his debt to Galileo. In fact, **Newton's first law of motion** is close to Galileo's conclusions. It states that

*NEWTON'S FIRST LAW OF MOTION*

> **Every object continues in its state of rest, or of uniform velocity in a straight line, as long as no net force acts on it.**

The tendency of an object to maintain its state of rest or of uniform velocity in a straight line is called **inertia**. Newton's first law is thus often called the **law of inertia**.

**CONCEPTUAL EXAMPLE 4–1** **Newton's first law.** A school bus comes to a sudden stop, and all of the backpacks on the floor start to slide forward. What force causes them to do that?

**RESPONSE** It isn't "force" that does it. By Newton's first law, the backpacks continue their state of motion, maintaining their velocity. The backpacks slow down if a force is applied, such as friction with the floor.

**FIGURE 4–4**
Isaac Newton (1642–1727). Besides developing mechanics, including his three great laws of motion and the law of universal gravitation, he also tried to understand the nature of light.

## Inertial Reference Frames

Newton's first law does not hold in every reference frame. For example, if your reference frame is an accelerating car, an object such as a cup resting on the dashboard may begin to move toward you (it stayed at rest as long as the car's velocity remained constant). The cup accelerated toward you, but neither you nor anything else exerted a force on it in that direction. Similarly, in the reference frame of the decelerating bus in Example 4–1, there was no force pushing the backpacks forward. In accelerating reference frames, Newton's first law does not hold. Physics is easier in reference frames in which Newton's first law *does* hold, and they are called **inertial reference frames** (the law of inertia is valid in them). For most purposes, we usually make the approximation that a reference frame fixed on the Earth is an inertial frame. This is not precisely true, due to the Earth's rotation, but usually it is close enough.

Any reference frame that moves with constant velocity (say, a car or an airplane) relative to an inertial frame is also an inertial reference frame. Reference frames where the law of inertia does *not* hold, such as the accelerating reference frames discussed above, are called **noninertial** reference frames. How can we be sure a reference frame is inertial or not? By checking to see if Newton's first law holds. Thus Newton's first law serves as the definition of inertial reference frames.

## 4–3 Mass

Newton's second law, which we come to in the next Section, makes use of the concept of mass. Newton used the term *mass* as a synonym for "quantity of matter." This intuitive notion of the mass of an object is not very precise because the concept "quantity of matter" is not very well defined. More precisely, we can say that **mass** is a *measure of the inertia* of an object. The more mass an object has, the greater the force needed to give it a particular acceleration. It is harder to start it moving from rest, or to stop it when it is moving, or to change its velocity sideways out of a straight-line path. A truck has much more inertia than a baseball moving at the same speed, and a much greater force is needed to change the truck's velocity at the same rate as the ball's. The truck therefore has much more mass.

To quantify the concept of mass, we must define a standard. In SI units, the unit of mass is the **kilogram** (kg) as we discussed in Chapter 1, Section 1–4.

⚠ **CAUTION**
*Distinguish mass from weight*

The terms *mass* and *weight* are often confused with one another, but it is important to distinguish between them. Mass is a property of an object itself (a measure of an object's inertia, or its "quantity of matter"). Weight, on the other hand, is a force, the pull of gravity acting on an object. To see the difference, suppose we take an object to the Moon. The object will weigh only about one-sixth as much as it did on Earth, since the force of gravity is weaker. But its mass will be the same. It will have the same amount of matter as on Earth, and will have just as much inertia. It will be just as hard to start it moving on the Moon as on Earth. (More on weight in Section 4–6.)

## 4–4 Newton's Second Law of Motion

Newton's first law states that if no net force is acting on an object at rest, the object remains at rest; or if the object is moving, it continues moving with constant speed in a straight line. But what happens if a net force *is* exerted on an object? Newton perceived that the object's velocity will change (Fig. 4–5). A net force exerted on an object may make its velocity increase. Or, if the net force is in a direction opposite to the motion, that force will reduce the object's velocity. If the net force acts sideways on a moving object, the *direction* of the object's velocity changes. That change in the *direction* of the velocity is also an acceleration. So a sideways net force on an object also causes acceleration. In general, we can say that *a net force causes acceleration*.

**FIGURE 4–5** The bobsled accelerates because the team exerts a force.

What precisely is the relationship between acceleration and force? Everyday experience can suggest an answer. Consider the force required to push a cart when friction is small enough to ignore. (If there is friction, consider the *net* force, which is the force you exert minus the force of friction.) If you push the cart horizontally with a gentle but constant force for a certain period of time, you will make the cart accelerate from rest up to some speed, say 3 km/h. If you push with twice the force, the cart will reach 3 km/h in half the time. The acceleration will be twice as great. If you triple the force, the acceleration is tripled, and so on. Thus, the acceleration of an object is directly proportional to the net applied force. But the acceleration depends on the mass of the object as well. If you push an empty grocery cart with the same force as you push one that is filled with groceries, you will find that the full cart has a smaller acceleration. The greater the mass, the less the acceleration for the same net force. The mathematical relation, as Newton argued, is that the

acceleration of an object is inversely proportional to its mass. These relationships are found to hold in general and can be summarized as follows:

**The acceleration of an object is directly proportional to the net force acting on it, and is inversely proportional to the object's mass. The direction of the acceleration is in the direction of the net force acting on the object.**

*NEWTON'S SECOND LAW OF MOTION*

This is **Newton's second law of motion**.

Newton's second law can be written as an equation:

$$\vec{\mathbf{a}} = \frac{\Sigma\vec{\mathbf{F}}}{m},$$

where $\vec{\mathbf{a}}$ stands for acceleration, $m$ for the mass, and $\Sigma\vec{\mathbf{F}}$ for the *net force* on the object. The symbol $\Sigma$ (Greek "sigma") stands for "sum of"; $\vec{\mathbf{F}}$ stands for force, so $\Sigma\vec{\mathbf{F}}$ means the *vector sum of all forces* acting on the object, which we define as the **net force**.

We rearrange this equation to obtain the familiar statement of Newton's second law:

$$\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}. \qquad \textbf{(4–1a)}$$

*NEWTON'S SECOND LAW OF MOTION*

Newton's second law relates the description of motion (acceleration) to the cause of motion (force). It is one of the most fundamental relationships in physics. From Newton's second law we can make a more precise definition of **force** as *an action capable of accelerating an object*.

Every force $\vec{\mathbf{F}}$ is a vector, with magnitude and direction. Equation 4–1a is a vector equation valid in any inertial reference frame. It can be written in component form in rectangular coordinates as

$$\Sigma F_x = ma_x, \qquad \Sigma F_y = ma_y, \qquad \Sigma F_z = ma_z, \qquad \textbf{(4–1b)}$$

where

$$\vec{\mathbf{F}} = F_x\hat{\mathbf{i}} + F_y\hat{\mathbf{j}} + F_z\hat{\mathbf{k}}.$$

The component of acceleration in each direction is affected only by the component of the net force in that direction. (See Section 3–5 for unit vectors $\hat{\mathbf{i}}$, $\hat{\mathbf{j}}$, $\hat{\mathbf{k}}$.)

If the motion is all along a line (one-dimensional), we can leave out the subscripts and simply write $\Sigma F = ma$. Again, $a$ is the acceleration of an object of mass $m$, and $\Sigma F$ includes all the forces acting on that object, and *only* forces acting on that object. Sometimes the net force $\Sigma F$ is written as $F_{\text{net}}$, so $F_{\text{net}} = ma$.

In SI units, with the mass in kilograms, the unit of force is called the **newton** (N). One newton is the force required to impart an acceleration of $1\ \text{m/s}^2$ to a mass of 1 kg. Thus $1\ \text{N} = 1\ \text{kg}\cdot\text{m/s}^2$.

In cgs units, the unit of mass is the **gram** (g), which is $\frac{1}{1000}$ of a kilogram.[†] The unit of force is the **dyne**, which is defined as the net force needed to impart an acceleration of $1\ \text{cm/s}^2$ to a mass of 1 g. Thus $1\ \text{dyne} = 1\ \text{g}\cdot\text{cm/s}^2$. Because $1\ \text{g} = 10^{-3}\ \text{kg}$ and $1\ \text{cm} = 10^{-2}\ \text{m}$, then $1\ \text{dyne} = 10^{-5}\ \text{N}$.

In the British system, which we rarely use, the unit of force is the **pound** (abbreviated lb), where $1\ \text{lb} = 4.44822\ \text{N} \approx 4.45\ \text{N}$. The unit of mass is the **slug**, which is defined as that mass which will undergo an acceleration of $1\ \text{ft/s}^2$ when a force of 1 lb is applied to it. Thus $1\ \text{lb} = 1\ \text{slug}\cdot\text{ft/s}^2$. Table 4–1 summarizes the units in the different systems.

**TABLE 4–1**
**Units for Mass and Force**

| System | Mass | Force |
|---|---|---|
| SI | kilogram (kg) | newton (N) $(= \text{kg}\cdot\text{m/s}^2)$ |
| cgs | gram (g) | dyne $(= \text{g}\cdot\text{cm/s}^2)$ |
| British | slug | pound (lb) |

Conversion factors: $1\ \text{dyne} = 10^{-5}\ \text{N}$; $1\ \text{lb} \approx 4.45\ \text{N}$; $1\ \text{slug} \approx 14.6\ \text{kg}$.

**PROBLEM SOLVING**
*Use a consistent set of units*

It is very important that only one set of units be used in a given calculation or problem, with the SI being what we almost always use. If the force is given in, say, newtons, and the mass in grams, then before attempting to solve for the acceleration in SI units, we must change the mass to kilograms. For example, if the force is given as 2.0 N along the $x$ axis and the mass is 500 g, we change the latter to 0.50 kg, and the acceleration will then automatically come out in $\text{m/s}^2$ when Newton's second law is used:

$$a_x = \frac{\Sigma F_x}{m} = \frac{2.0\ \text{N}}{0.50\ \text{kg}} = \frac{2.0\ \text{kg}\cdot\text{m/s}^2}{0.50\ \text{kg}} = 4.0\ \text{m/s}^2,$$

where we set $1\ \text{N} = 1\ \text{kg}\cdot\text{m/s}^2$.

[†]Be careful not to confuse g for gram with $g$ for the acceleration due to gravity. The latter is always italicized (or boldface when shown as a vector).

**EXAMPLE 4–2** **ESTIMATE** **Force to accelerate a fast car.** Estimate the net force needed to accelerate (*a*) a 1000-kg car at $\frac{1}{2}g$; (*b*) a 200-gram apple at the same rate.

**APPROACH** We use Newton's second law to find the net force needed for each object; we are given the mass and the acceleration. This is an estimate (the $\frac{1}{2}$ is not said to be precise) so we round off to one significant figure.

**SOLUTION** (*a*) The car's acceleration is $a = \frac{1}{2}g = \frac{1}{2}(9.8\,\text{m/s}^2) \approx 5\,\text{m/s}^2$. We use Newton's second law to get the net force needed to achieve this acceleration:

$$\Sigma F = ma \approx (1000\,\text{kg})(5\,\text{m/s}^2) = 5000\,\text{N}.$$

(If you are used to British units, to get an idea of what a 5000-N force is, you can divide by 4.45 N/lb and get a force of about 1000 lb.)

(*b*) For the apple, $m = 200\,\text{g} = 0.2\,\text{kg}$, so

$$\Sigma F = ma \approx (0.2\,\text{kg})(5\,\text{m/s}^2) = 1\,\text{N}.$$

**EXAMPLE 4–3** **Force to stop a car.** What average net force is required to bring a 1500-kg car to rest from a speed of 100 km/h within a distance of 55 m?

**APPROACH** We use Newton's second law, $\Sigma F = ma$, to determine the force, but first we need to calculate the acceleration *a*. We assume the acceleration is constant so that we can use the kinematic equations, Eqs. 2–12, to calculate it.

**FIGURE 4–6** Example 4–3.

**SOLUTION** We assume the motion is along the $+x$ axis (Fig. 4–6). We are given the initial velocity $v_0 = 100\,\text{km/h} = 27.8\,\text{m/s}$ (Section 1–5), the final velocity $v = 0$, and the distance traveled $x - x_0 = 55\,\text{m}$. From Eq. 2–12c, we have

$$v^2 = v_0^2 + 2a(x - x_0),$$

so

$$a = \frac{v^2 - v_0^2}{2(x - x_0)} = \frac{0 - (27.8\,\text{m/s})^2}{2(55\,\text{m})} = -7.0\,\text{m/s}^2.$$

The net force required is then

$$\Sigma F = ma = (1500\,\text{kg})(-7.0\,\text{m/s}^2) = -1.1 \times 10^4\,\text{N},$$

or 11,000 N. The force must be exerted in the direction *opposite* to the initial velocity, which is what the negative sign means.

**NOTE** If the acceleration is not precisely constant, then we are determining an "average" acceleration and we obtain an "average" net force.

Newton's second law, like the first law, is valid only in inertial reference frames (Section 4–2). In the noninertial reference frame of a car that begins accelerating, a cup on the dashboard starts sliding—it accelerates—even though the net force on it is zero. Thus $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$ does not work in such an accelerating reference frame $(\Sigma\vec{\mathbf{F}} = 0$, but $\vec{\mathbf{a}} \neq 0$ in this noninertial frame$)$.

**EXERCISE A** Suppose you watch a cup slide on the (smooth) dashboard of an accelerating car as we just discussed, but this time from an inertial reference frame outside the car, on the street. From your inertial frame, Newton's laws are valid. What force pushes the cup off the dashboard?

## *Precise Definition of Mass

As mentioned in Section 4–3, we can quantify the concept of mass using its definition as a measure of inertia. How to do this is evident from Eq. 4–1a, where we see that the acceleration of an object is inversely proportional to its mass.

If the same net force $\Sigma F$ acts to accelerate each of two masses, $m_1$ and $m_2$, then the ratio of their masses can be defined as the inverse ratio of their accelerations:

$$\frac{m_2}{m_1} = \frac{a_1}{a_2}.$$

If one of the masses is known (it could be the standard kilogram) and the two accelerations are precisely measured, then the unknown mass is obtained from this definition. For example, if $m_1 = 1.00\,\text{kg}$, and for a particular force $a_1 = 3.00\,\text{m/s}^2$ and $a_2 = 2.00\,\text{m/s}^2$, then $m_2 = 1.50\,\text{kg}$.

## 4–5 Newton's Third Law of Motion

Newton's second law of motion describes quantitatively how forces affect motion. But where do forces come from? Observations suggest that a force exerted on any object is always exerted *by another object*. A horse pulls a wagon, a person pushes a grocery cart, a hammer pushes on a nail, a magnet attracts a paper clip. In each of these examples, a force is exerted *on* one object, and that force is exerted *by* another object. The force exerted *on* the nail is exerted *by* the hammer.

But Newton realized that things are not so one-sided. True, the hammer exerts a force on the nail (Fig. 4–7). But the nail evidently exerts a force back on the hammer as well, for the hammer's speed is rapidly reduced to zero upon contact. Only a strong force could cause such a rapid deceleration of the hammer. Thus, said Newton, the two objects must be treated on an equal basis. The hammer exerts a force on the nail, and the nail exerts a force back on the hammer. This is the essence of **Newton's third law of motion**:

**Whenever one object exerts a force on a second object, the second object exerts an equal force in the opposite direction on the first.**

This law is sometimes stated as "to every action there is an equal and opposite reaction." But to avoid confusion, it is very important to remember that the "action" force and the "reaction" force are acting on *different* objects.

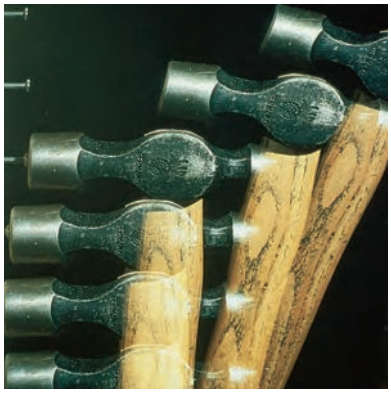

**FIGURE 4–7** A hammer striking a nail. The hammer exerts a force on the nail and the nail exerts a force back on the hammer. The latter force decelerates the hammer and brings it to rest.

*NEWTON'S THIRD LAW OF MOTION*

**CAUTION**

*Action and reaction forces act on different objects*

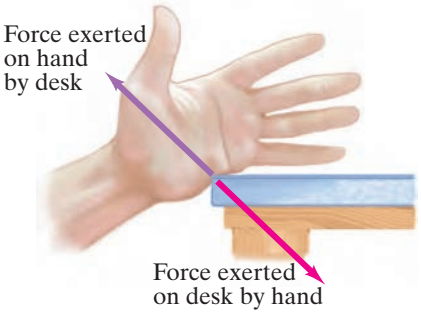

**FIGURE 4–8** If your hand pushes against the edge of a desk (the force vector is shown in red), the desk pushes back against your hand (this force vector is shown in a different color, violet, to remind us that this force acts on a different object).

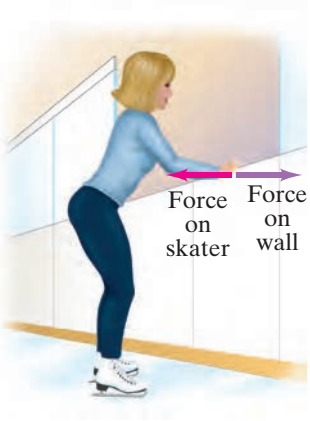
As evidence for the validity of Newton's third law, look at your hand when you push against the edge of a desk, Fig. 4–8. Your hand's shape is distorted, clear evidence that a force is being exerted on it. You can *see* the edge of the desk pressing into your hand. You can even *feel* the desk exerting a force on your hand; it hurts! The harder you push against the desk, the harder the desk pushes back on your hand. (You only feel forces exerted *on* you; when you exert a force on another object, what you feel is that object pushing back on you.)

The force the desk exerts on your hand has the same magnitude as the force your hand exerts on the desk. This is true not only if the desk is at rest but is true even if the desk is accelerating due to the force your hand exerts.

As another demonstration of Newton's third law, consider the ice skater in Fig. 4–9. There is very little friction between her skates and the ice, so she will move freely if a force is exerted on her. She pushes against the wall; and then *she* starts moving backward. The force she exerts on the wall cannot make *her* start moving, because that force acts on the wall. Something had to exert a force *on her* to start her moving, and that force could only have been exerted by the wall. The wall pushes on her with a force, by Newton's third law, equal and opposite to the force she exerts on the wall.

**FIGURE 4–9** An example of Newton's third law: when an ice skater pushes against the wall, the wall pushes back and this force causes her to accelerate away.



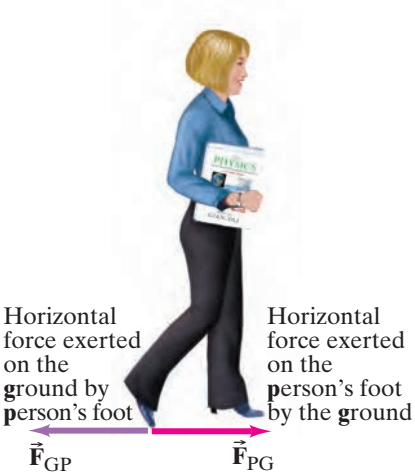


**FIGURE 4–10** Another example of Newton's third law: the launch of a rocket. The rocket engine pushes the gases downward, and the gases exert an equal and opposite force upward on the rocket, accelerating it upward. (A rocket does *not* accelerate as a result of its expelled gases pushing against the ground.)

**FIGURE 4–11** We can walk forward because, when one foot pushes backward against the ground, the ground pushes forward on that foot (Newton's third law). The two forces shown *act on different objects*.

**⚠ CAUTION**

*Distinguish **on** what object a force is exerted, and **by** what object*

*NEWTON'S THIRD LAW OF MOTION*

When a person throws a package out of a small boat (initially at rest), the boat starts moving in the opposite direction. The person exerts a force on the package. The package exerts an equal and opposite force back on the person, and this force propels the person (and the boat) backward slightly.

Rocket propulsion also is explained using Newton's third law (Fig. 4–10). A common misconception is that rockets accelerate because the gases rushing out the back of the engine push against the ground or the atmosphere. Not true. What happens, instead, is that a rocket exerts a strong force on the gases, expelling them; and the gases exert an equal and opposite force *on the rocket*. It is this latter force that propels the rocket forward—the force exerted *on* the rocket *by* the gases (see Chapter-Opening Photo, page 85). Thus, a space vehicle is maneuvered in empty space by firing its rockets in the direction opposite to that in which it needs to accelerate. When the rocket pushes on the gases in one direction, the gases push back on the rocket in the opposite direction. Jet aircraft too accelerate because the gases they thrust out backwards exert a forward force on the engines (Newton's third law).

Consider how we walk. A person begins walking by pushing with the foot backward against the ground. The ground then exerts an equal and opposite force forward on the person (Fig. 4–11), and it is this force, *on* the person, that moves the person forward. (If you doubt this, try walking normally where there is no friction, such as on very smooth slippery ice.) In a similar way, a bird flies forward by exerting a backward force on the air, but it is the air pushing forward (Newton's third law) on the bird's wings that propels the bird forward.

**CONCEPTUAL EXAMPLE 4–4** **What exerts the force to move a car?**

What makes a car go forward?

**RESPONSE** A common answer is that the engine makes the car move forward. But it is not so simple. The engine makes the wheels and tires go around. But if the tires are on slick ice or wet mud, they just spin. Friction is needed. On firm ground, the tires push backward against the ground because of friction between the tires and the ground. By Newton's third law, the ground pushes on the tires in the opposite direction, accelerating the car forward.

We tend to associate forces with active objects such as humans, animals, engines, or a moving object like a hammer. It is often difficult to see how an inanimate object at rest, such as a wall or a desk (Fig. 4–8), or the wall of an ice rink (Fig. 4–9), can exert a force. The explanation is that every material, no matter how hard, is elastic (springy) at least to some degree. A stretched rubber band can exert a force on a wad of paper and accelerate it to fly across the room. Other materials may not stretch as readily as rubber, but they do stretch or compress when a force is applied to them. And just as a stretched rubber band exerts a force, so does a stretched (or compressed) wall, desk, or car fender.

From the examples discussed above, we can see how important it is to remember *on* what object a given force is exerted and *by* what object that force is exerted. A force influences the motion of an object only when it is applied *on* that object. A force exerted *by* an object does not influence that same object; it only influences the other object *on* which it is exerted. Thus, to avoid confusion, the two prepositions *on* and *by* must always be used—and used with care.

One way to keep clear which force acts on which object is to use double subscripts. For example, the force exerted *on* the **P**erson *by* the **G**round as the person walks in Fig. 4–11 can be labeled $\vec{\mathbf{F}}_{PG}$. And the force exerted on the ground by the person is $\vec{\mathbf{F}}_{GP}$. By Newton's third law

$$\vec{\mathbf{F}}_{GP} = -\vec{\mathbf{F}}_{PG}. \qquad (4\text{–}2)$$

$\vec{\mathbf{F}}_{GP}$ and $\vec{\mathbf{F}}_{PG}$ have the same magnitude (Newton's third law), and the minus sign reminds us that these two forces are in opposite directions.

Note carefully that the two forces shown in Fig. 4–11 act on different objects—to emphasize this we used slightly different colors for the vector arrows representing these forces. These two forces would never appear together in a sum of forces in Newton's second law, $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$. Why not? Because they act on different objects: $\vec{\mathbf{a}}$ is the acceleration of one particular object, and $\Sigma\vec{\mathbf{F}}$ must include *only* the forces on that *one* object.

**⚠ CAUTION**

*The 2 forces in Newton's third law act on different bodies. Only one can be included in $\Sigma F = ma$ for an object*

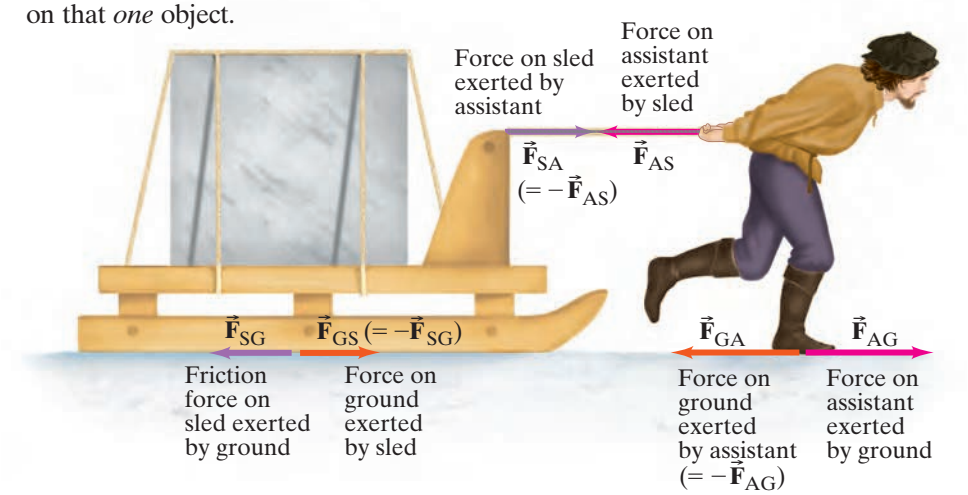

**FIGURE 4–12** Example 4–5, showing only horizontal forces. Michelangelo has selected a fine block of marble for his next sculpture. Shown here is his assistant pulling it on a sled away from the quarry. Forces on the assistant are shown as red (magenta) arrows. Forces on the sled are purple arrows. Forces acting on the ground are orange arrows. Action–reaction forces that are equal and opposite are labeled by the same subscripts but reversed (such as $\vec{\mathbf{F}}_{GA}$ and $\vec{\mathbf{F}}_{AG}$) and are of different colors because they act on different objects.

**CONCEPTUAL EXAMPLE 4–5** **Third law clarification.** Michelangelo's assistant has been assigned the task of moving a block of marble using a sled (Fig. 4–12). He says to his boss, "When I exert a forward force on the sled, the sled exerts an equal and opposite force backward. So how can I ever start it moving? No matter how hard I pull, the backward reaction force always equals my forward force, so the net force must be zero. I'll never be able to move this load." Is he correct?

**RESPONSE** No. Although it is true that the action and reaction forces are equal in magnitude, the assistant has forgotten that they are exerted on different objects. The forward ("action") force is exerted by the assistant on the sled (Fig. 4–12), whereas the backward "reaction" force is exerted by the sled on the assistant. To determine if the *assistant* moves or not, we must consider only the forces *on the assistant* and then apply $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$, where $\Sigma\vec{\mathbf{F}}$ is the net force *on the assistant*, $\vec{\mathbf{a}}$ is the acceleration of the assistant, and $m$ is the assistant's mass. There are two forces on the assistant that affect his forward motion; they are shown as bright red (magenta) arrows in Figs. 4–12 and 4–13: they are (1) the horizontal force $\vec{\mathbf{F}}_{AG}$ exerted on the assistant by the ground (the harder he pushes backward against the ground, the harder the ground pushes forward on him—Newton's third law), and (2) the force $\vec{\mathbf{F}}_{AS}$ exerted on the assistant by the sled, pulling backward on him; see Fig. 4–13. If he pushes hard enough on the ground, the force on him exerted by the ground, $\vec{\mathbf{F}}_{AG}$, will be larger than the sled pulling back, $\vec{\mathbf{F}}_{AS}$, and the assistant accelerates forward (Newton's second law). The sled, on the other hand, accelerates forward when the force on *it* exerted by the assistant is greater than the frictional force exerted backward on it by the ground (that is, when $\vec{\mathbf{F}}_{SA}$ has greater magnitude than $\vec{\mathbf{F}}_{SG}$ in Fig. 4–12).

**PROBLEM SOLVING**

*A study of Newton's second and third laws*

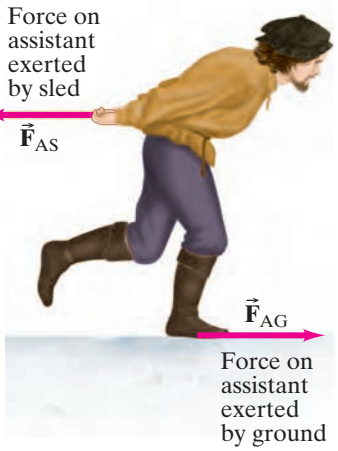

**FIGURE 4–13** Example 4–5. The horizontal forces on the assistant.

Using double subscripts to clarify Newton's third law can become cumbersome, and we won't usually use them in this way. We will usually use a single subscript referring to what exerts the force on the object being discussed. Nevertheless, if there is any confusion in your mind about a given force, go ahead and use two subscripts to identify *on* what object and *by* what object the force is exerted.

**EXERCISE B** A tennis ball collides head-on with a more massive baseball. (i) Which ball experiences the greater force of impact? (ii) Which experiences the greater acceleration during the impact? (iii) Which of Newton's laws are useful to obtain the correct answers?

**EXERCISE C** If you push on a heavy desk, does it always push back on you? (*a*) No. (*b*) Yes. (*c*) Not unless someone else also pushes on it. (*d*) Yes, if it is out in space. (*e*) A desk never pushes.

**EXERCISE D** Return to the first Chapter-Opening Question, page 85, and answer it again now. Try to explain why you may have answered differently the first time.

## 4–6 Weight—the Force of Gravity; and the Normal Force

As we saw in Chapter 2, Galileo claimed that all objects dropped near the surface of the Earth would fall with the same acceleration, $\vec{\mathbf{g}}$, if air resistance was negligible. The force that causes this acceleration is called the *force of gravity* or *gravitational force*. What exerts the gravitational force on an object? It is the Earth, as we will discuss in Chapter 5, and the force acts vertically[†] downward, toward the center of the Earth. Let us apply Newton's second law to an object of mass $m$ falling freely due to gravity. For the acceleration, $\vec{\mathbf{a}}$, we use the downward acceleration due to gravity, $\vec{\mathbf{g}}$. Thus, the **gravitational force** on an object, $\vec{\mathbf{F}}_G$, can be written as

$$\vec{\mathbf{F}}_G = m\vec{\mathbf{g}}. \qquad \textbf{(4–3)}$$

The direction of this force is down toward the center of the Earth. The magnitude of the force of gravity on an object, $mg$, is commonly called the object's **weight**.

In SI units, $g = 9.80\,\text{m/s}^2 = 9.80\,\text{N/kg}$,[‡] so the weight of a 1.00-kg mass on Earth is $1.00\,\text{kg} \times 9.80\,\text{m/s}^2 = 9.80\,\text{N}$. We will mainly be concerned with the weight of objects on Earth, but we note that on the Moon, on other planets, or in space, the weight of a given mass will be different than it is on Earth. For example, on the Moon the acceleration due to gravity is about one-sixth what it is on Earth, and a 1.0-kg mass weighs only 1.6 N. Although we will not use British units, we note that for practical purposes on the Earth, a mass of 1.0 kg weighs about 2.2 lb. (On the Moon, 1 kg weighs only about 0.4 lb.)

The force of gravity acts on an object when it is falling. When an object is at rest on the Earth, the gravitational force on it does not disappear, as we know if we weigh it on a spring scale. The same force, given by Eq. 4–3, continues to act. Why, then, doesn't the object move? From Newton's second law, the net force on an object that remains at rest is zero. There must be another force on the object to balance the gravitational force. For an object resting on a table, the table exerts this upward force; see Fig. 4–14a. The table is compressed slightly beneath the object, and due to its elasticity, it pushes up on the object as shown. The force exerted by the table is often called a **contact force**, since it occurs when two objects are in contact. (The force of your hand pushing on a cart is also a contact force.) When a contact force acts *perpendicular* to the common surface of contact, it is referred to as the **normal force** ("normal" means perpendicular); hence it is labeled $\vec{\mathbf{F}}_N$ in Fig. 4–14a.

The two forces shown in Fig. 4–14a are both acting on the statue, which remains at rest, so the vector sum of these two forces must be zero (Newton's second law). Hence $\vec{\mathbf{F}}_G$ and $\vec{\mathbf{F}}_N$ must be of equal magnitude and in opposite directions. But they are *not* the equal and opposite forces spoken of in Newton's third law. The action and reaction forces of Newton's third law act on *different objects*, whereas the two forces shown in Fig. 4–14a act on the *same* object. For each of the forces shown in Fig. 4–14a, we can ask, "What is the reaction force?" The upward force $\vec{\mathbf{F}}_N$ on the statue is exerted by the table. The reaction to this force is a force exerted by the statue downward on the table. It is shown in Fig. 4–14b, where it is labeled $\vec{\mathbf{F}}'_N$. This force, $\vec{\mathbf{F}}'_N$, exerted on the table by the statue, is the reaction force to $\vec{\mathbf{F}}_N$ in accord with Newton's third law. What about the other force on the statue, the force of gravity $\vec{\mathbf{F}}_G$ exerted by the Earth? Can you guess what the reaction is to this force? We will see in Chapter 5 that the reaction force is also a gravitational force, exerted on the Earth by the statue.

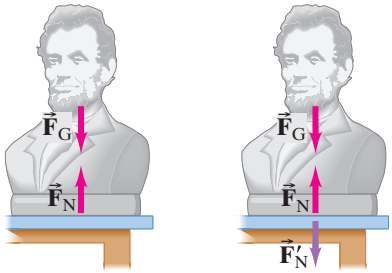

**FIGURE 4–14** (a) The net force on an object at rest is zero according to Newton's second law. Therefore the downward force of gravity $(\vec{\mathbf{F}}_G)$ on an object at rest must be balanced by an upward force (the normal force $\vec{\mathbf{F}}_N$) exerted by the table in this case. (b) $\vec{\mathbf{F}}'_N$ is the force exerted on the table by the statue and is the reaction force to $\vec{\mathbf{F}}_N$ by Newton's third law. ($\vec{\mathbf{F}}'_N$ is shown in a different color to remind us it acts on a different object.) The reaction force to $\vec{\mathbf{F}}_G$ is not shown.

**⚠ CAUTION**

*Weight and normal force are* **not** *action–reaction pairs*

[†]The concept of "vertical" is tied to gravity. The best definition of *vertical* is that it is the direction in which objects fall. A surface that is "horizontal," on the other hand, is a surface on which a round object won't start rolling: gravity has no effect. Horizontal is perpendicular to vertical.

[‡]Since $1\,\text{N} = 1\,\text{kg}\cdot\text{m/s}^2$ (Section 4–4), then $1\,\text{m/s}^2 = 1\,\text{N/kg}$.

**EXERCISE E** Return to the second Chapter-Opening Question, page 85, and answer it again now. Try to explain why you may have answered differently the first time.

**EXAMPLE 4–6 Weight, normal force, and a box.** A friend has given you a special gift, a box of mass 10.0 kg with a mystery surprise inside. The box is resting on the smooth (frictionless) horizontal surface of a table (Fig. 4–15a). (*a*) Determine the weight of the box and the normal force exerted on it by the table. (*b*) Now your friend pushes down on the box with a force of 40.0 N, as in Fig. 4–15b. Again determine the normal force exerted on the box by the table. (*c*) If your friend instead pulls upward on the box with a force of 40.0 N (Fig. 4–15c), what now is the normal force exerted on the box by the table?

**APPROACH** The box is at rest on the table, so the net force on the box in each case is zero (Newton's first or second law). The weight of the box has magnitude $mg$ in all three cases.

**SOLUTION** (*a*) The weight of the box is $mg = (10.0\,\text{kg})(9.80\,\text{m/s}^2) = 98.0\,\text{N}$, and this force acts downward. The only other force on the box is the normal force $\vec{\mathbf{F}}_\text{N}$ exerted upward on it by the table, as shown in Fig. 4–15a. We choose the upward direction as the positive $y$ direction; then the net force $\Sigma F_y$ on the box is $\Sigma F_y = F_\text{N} - mg$; the minus sign means $mg$ acts in the negative $y$ direction ($m$ and $g$ are magnitudes). The box is at rest, so the net force on it must be zero (Newton's second law, $\Sigma F_y = ma_y$, and $a_y = 0$). Thus

$$\begin{aligned} \Sigma F_y &= ma_y \\ F_\text{N} - mg &= 0, \end{aligned}$$

so we have

$$F_\text{N} = mg.$$

The normal force on the box, exerted by the table, is 98.0 N upward, and has magnitude equal to the box's weight.

(*b*) Your friend is pushing down on the box with a force of 40.0 N. So instead of only two forces acting on the box, now there are three forces acting on the box, as shown in Fig. 4–15b. The weight of the box is still $mg = 98.0\,\text{N}$. The net force is $\Sigma F_y = F_\text{N} - mg - 40.0\,\text{N}$, and is equal to zero because the box remains at rest ($a = 0$). Newton's second law gives

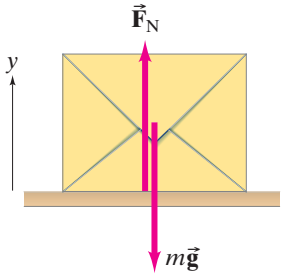
$$\Sigma F_y = F_\text{N} - mg - 40.0\,\text{N} = 0.$$

We solve this equation for the normal force:

$$F_\text{N} = mg + 40.0\,\text{N} = 98.0\,\text{N} + 40.0\,\text{N} = 138.0\,\text{N},$$

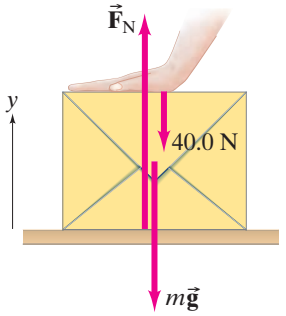
which is greater than in (*a*). The table pushes back with more force when a person pushes down on the box. The normal force is not always equal to the weight!

(*c*) The box's weight is still 98.0 N and acts downward. The force exerted by your friend and the normal force both act upward (positive direction), as shown in Fig. 4–15c. The box doesn't move since your friend's upward force is less than the weight. The net force, again set to zero in Newton's second law because $a = 0$, is



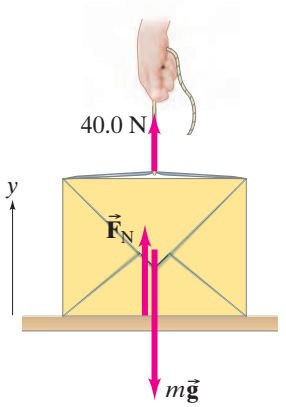
$$\Sigma F_y = F_\text{N} - mg + 40.0\,\text{N} = 0,$$

so



$$F_\text{N} = mg - 40.0\,\text{N} = 98.0\,\text{N} - 40.0\,\text{N} = 58.0\,\text{N}.$$

The table does not push against the full weight of the box because of the upward force exerted by your friend.



**NOTE** The weight of the box ($= mg$) does not change as a result of your friend's push or pull. Only the normal force is affected.

(a) $\Sigma F_y = F_\text{N} - mg = 0$

(b) $\Sigma F_y = F_\text{N} - mg - 40.0\,\text{N} = 0$

(c) $\Sigma F_y = F_\text{N} - mg + 40.0\,\text{N} = 0$

**FIGURE 4–15** Example 4–6. (a) A 10-kg gift box is at rest on a table. (b) A person pushes down on the box with a force of 40.0 N. (c) A person pulls upward on the box with a force of 40.0 N. The forces are all assumed to act along a line; they are shown slightly displaced in order to be distinguishable. Only forces acting on the box are shown.

**CAUTION**

*The normal force $F_\text{N}$ is not always equal to the weight*

**CAUTION**

*The normal force, $\vec{\mathbf{F}}_N$, is not necessarily vertical*

Recall that the normal force is elastic in origin (the table in Fig. 4–15 sags slightly under the weight of the box). The normal force in Example 4–6 is vertical, perpendicular to the horizontal table. The normal force is not always vertical, however. When you push against a wall, for example, the normal force with which the wall pushes back on you is horizontal (see Fig. 4–9). If an object is on a plane inclined at an angle to the horizontal, such as a skier or car on a hill, the normal force acts perpendicular to the plane and so is not vertical.

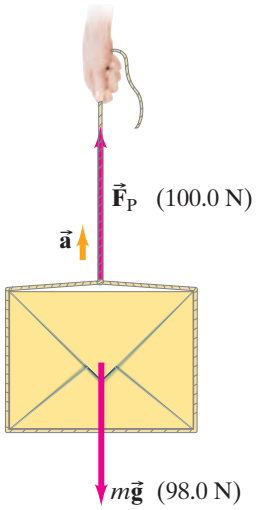


**FIGURE 4–16** Example 4–7. The box accelerates upward because $F_P > mg$.

**EXAMPLE 4–7** **Accelerating the box.** What happens when a person pulls upward on the box in Example 4–6*c* with a force equal to, or greater than, the box's weight? For example, let $F_P = 100.0\,\text{N}$ (Fig. 4–16) rather than the 40.0 N shown in Fig. 4–15c.

**APPROACH** We can start just as in Example 4–6, but be ready for a surprise.

**SOLUTION** The net force on the box is

$$\begin{aligned}\Sigma F_y &= F_N - mg + F_P \\ &= F_N - 98.0\,\text{N} + 100.0\,\text{N},\end{aligned}$$

and if we set this equal to zero (thinking the acceleration might be zero), we would get $F_N = -2.0\,\text{N}$. This is nonsense, since the negative sign implies $F_N$ points downward, and the table surely cannot *pull* down on the box (unless there's glue on the table). The least $F_N$ can be is zero, which it will be in this case, $F_N = 0$. What really happens here is that the box leaves the table and accelerates upward ($a \neq 0$, see gold vector in Fig. 4–16) because the net force is not zero. The net force (setting the normal force $F_N = 0$) is

$$\begin{aligned}\Sigma F_y &= F_P - mg = 100.0\,\text{N} - 98.0\,\text{N} \\ &= 2.0\,\text{N}\end{aligned}$$

upward. See Fig. 4–16. We apply Newton's second law and see that the box moves upward with an acceleration

$$a_y = \frac{\Sigma F_y}{m} = \frac{2.0\,\text{N}}{10.0\,\text{kg}} = 0.20\,\text{m/s}^2.$$

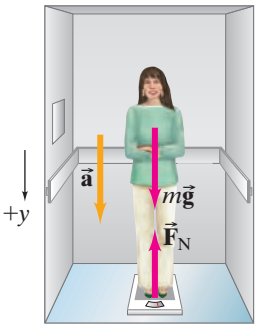
**EXAMPLE 4–8** **Apparent weight loss.** A 65-kg woman descends in an elevator that briefly accelerates at $0.20\,g$ downward. She stands on a scale that reads in kg. (*a*) During this acceleration, what is her weight and what does the scale read? (*b*) What does the scale read when the elevator descends at a constant speed of 2.0 m/s?

**APPROACH** Figure 4–17 shows all the forces that act on the woman (and *only* those that act on her). The direction of the acceleration is downward, so we choose the positive direction as down (this is the opposite choice from Examples 4–6 and 4–7).

**SOLUTION** (*a*) From Newton's second law,

$$\begin{aligned}\Sigma F &= ma \\ mg - F_N &= m(0.20\,g).\end{aligned}$$

We solve for $F_N$:



$$\begin{aligned}F_N &= mg - 0.20\,mg \\ &= 0.80\,mg,\end{aligned}$$

and it acts upward. The normal force $\vec{\mathbf{F}}_N$ is the force the scale exerts on the person, and it is equal and opposite to the force she exerts on the scale: $F'_N = 0.80\,mg$ downward. Her weight (force of gravity on her) is still $mg = (65\,\text{kg})(9.8\,\text{m/s}^2) = 640\,\text{N}$. But the scale, needing to exert a force of only $0.80\,mg$, will give a reading of $0.80\,m = 52\,\text{kg}$.

(*b*) Now there is no acceleration, $a = 0$, so by Newton's second law, $mg - F_N = 0$ and $F_N = mg$. The scale reads her true mass of 65 kg.

**NOTE** The scale in (*a*) gives a reading of 52 kg (as an "apparent mass"), but her mass doesn't change as a result of the acceleration: it stays at 65 kg.

**FIGURE 4–17** Example 4–8. The acceleration vector is shown in gold to distinguish it from the red force vectors.

# 4–7 Solving Problems with Newton's Laws: Free-Body Diagrams

Newton's second law tells us that the acceleration of an object is proportional to the *net force* acting on the object. The **net force**, as mentioned earlier, is the *vector sum* of all forces acting on the object. Indeed, extensive experiments have shown that forces do add together as vectors precisely according to the rules we developed in Chapter 3. For example, in Fig. 4–18, two forces of equal magnitude (100 N each) are shown acting on an object at right angles to each other. Intuitively, or from *symmetry*, we can see that the object will start moving at a 45° angle and thus the net force acts at a 45° angle. This is just what the rules of vector addition give. From the theorem of Pythagoras, the magnitude of the resultant force is $F_R = \sqrt{(100\,\text{N})^2 + (100\,\text{N})^2} = 141\,\text{N}$.

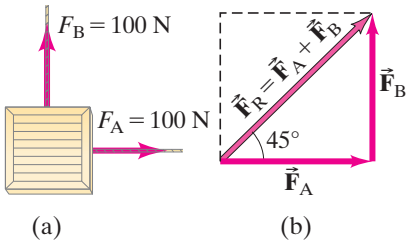


**FIGURE 4–18** (a) Two horizontal forces, $\vec{F}_A$ and $\vec{F}_B$, exerted by workers A and B, act on a crate (we are looking down from above). (b) The sum, or resultant, of $\vec{F}_A$ and $\vec{F}_B$ is $\vec{F}_R$.

**EXAMPLE 4–9** **Adding force vectors.** Calculate the sum of the two forces exerted on the boat by workers A and B in Fig. 4–19a.

**APPROACH** We add force vectors like any other vectors as described in Chapter 3. The first step is to choose an $xy$ coordinate system (see Fig. 4–19a), and then resolve vectors into their components.

**SOLUTION** The two force vectors are shown resolved into components in Fig. 4–19b. We add the forces using the method of components. The components of $\vec{F}_A$ are

$$F_{Ax} = F_A \cos 45.0° = (40.0\,\text{N})(0.707) = 28.3\,\text{N},$$
$$F_{Ay} = F_A \sin 45.0° = (40.0\,\text{N})(0.707) = 28.3\,\text{N}.$$

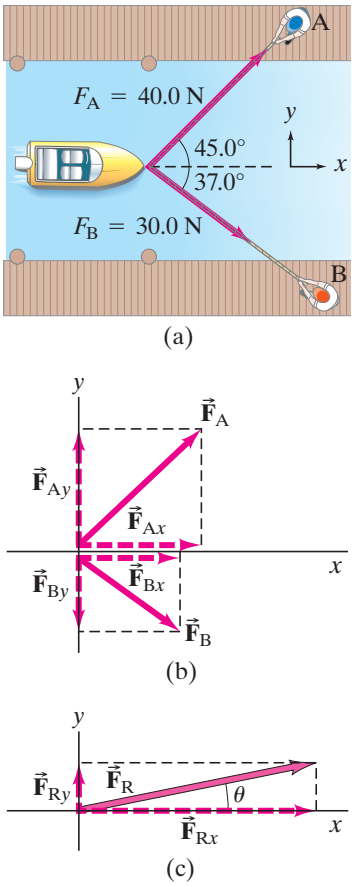
The components of $\vec{F}_B$ are

$$F_{Bx} = +F_B \cos 37.0° = +(30.0\,\text{N})(0.799) = +24.0\,\text{N},$$
$$F_{By} = -F_B \sin 37.0° = -(30.0\,\text{N})(0.602) = -18.1\,\text{N}.$$

$F_{By}$ is negative because it points along the negative $y$ axis. The components of the resultant force are (see Fig. 4–19c)

$$F_{Rx} = F_{Ax} + F_{Bx} = 28.3\,\text{N} + 24.0\,\text{N} = 52.3\,\text{N},$$
$$F_{Ry} = F_{Ay} + F_{By} = 28.3\,\text{N} - 18.1\,\text{N} = 10.2\,\text{N}.$$

To find the magnitude of the resultant force, we use the Pythagorean theorem,



$$F_R = \sqrt{F_{Rx}^2 + F_{Ry}^2} = \sqrt{(52.3)^2 + (10.2)^2}\,\text{N} = 53.3\,\text{N}.$$

The only remaining question is the angle $\theta$ that the net force $\vec{F}_R$ makes with the $x$ axis, Fig. 4–19c. We use:

$$\tan\theta = \frac{F_{Ry}}{F_{Rx}} = \frac{10.2\,\text{N}}{52.3\,\text{N}} = 0.195,$$

and $\tan^{-1}(0.195) = 11.0°$. The net force on the boat has magnitude 53.3 N and acts at an 11.0° angle to the $x$ axis.

**FIGURE 4–19** Example 4–9: Two force vectors act on a boat.

When solving problems involving Newton's laws and force, it is very important to draw a diagram showing all the forces acting *on* each object involved. Such a diagram is called a **free-body diagram**, or **force diagram**: choose one object, and draw an arrow to represent each force acting on it. Include *every* force acting on that object. Do not show forces that the chosen object exerts on *other* objects. To help you identify each and every force that is exerted on your chosen object, ask yourself what other objects could exert a force on it. If your problem involves more than one object, a separate free-body diagram is needed for each object. For now, the likely forces that could be acting are *gravity* and *contact forces* (one object pushing or pulling another, normal force, friction). Later we will consider other types of force such as buoyancy, fluid pressure, and electric and magnetic forces.

**PROBLEM SOLVING**
*Free-body diagram*

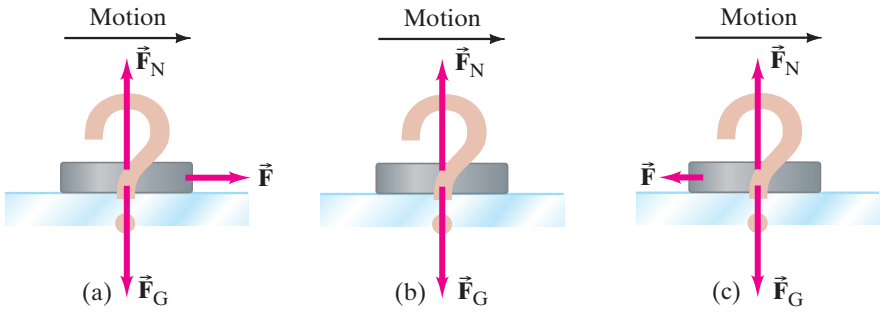


**FIGURE 4–20** Example 4–10. Which is the correct free-body diagram for a hockey puck sliding across frictionless ice?

**CONCEPTUAL EXAMPLE 4–10** **The hockey puck.** A hockey puck is sliding at constant velocity across a flat horizontal ice surface that is assumed to be frictionless. Which of the sketches in Fig. 4–20 is the correct free-body diagram for this puck? What would your answer be if the puck slowed down?

**RESPONSE** Did you choose (*a*)? If so, can you answer the question: what exerts the horizontal force labeled $\vec{\mathbf{F}}$ on the puck? If you say that it is the force needed to maintain the motion, ask yourself: what exerts this force? Remember that another object must exert any force—and there simply isn't any possibility here. Therefore, (*a*) is wrong. Besides, the force $\vec{\mathbf{F}}$ in Fig. 4–20a would give rise to an acceleration by Newton's second law. It is (*b*) that is correct. No net force acts on the puck, and the puck slides at constant velocity across the ice.

In the real world, where even smooth ice exerts at least a tiny friction force, (*c*) is the correct answer. The tiny friction force is in the direction opposite to the motion, and the puck's velocity decreases, even if very slowly.

PROBLEM SOLVING

## Newton's Laws; Free-Body Diagrams

**1. Draw a sketch** of the situation, after carefully reading the problem at least twice.

**2.** Consider only one object (at a time), and draw a **free-body diagram** for that object, showing *all* the forces acting *on* that object. Include any unknown forces that you have to solve for. Do not show any forces that the chosen object exerts on other objects.

Draw the arrow for each force vector reasonably accurately for direction and magnitude. Label each force acting on the object, including forces you must solve for, according to its source (gravity, person, friction, and so on).

If several objects are involved, draw a free-body diagram for each object *separately*. For each object, show all the forces acting *on that object* (and *only* forces acting on that object). For each (and every) force, you must be clear about: *on* what object that force acts, and *by* what object that force is exerted. Only forces acting *on* a given object can be included in $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$ for that object.

**3.** Newton's second law involves vectors, and it is usually important to **resolve vectors** into components. **Choose** $x$ and $y$ **axes** in a way that simplifies the calculation. For example, it often saves work if you choose one coordinate axis to be in the direction of the acceleration (if known).

**4.** For each object, **apply Newton's second law** to the $x$ and $y$ components separately. That is, the $x$ component of the net force on that object is related to the $x$ component of that object's acceleration: $\Sigma F_x = ma_x$, and similarly for the $y$ direction.

**5. Solve** the equation or equations for the unknown(s). Put in numerical values only at the end, and keep track of units.

This Problem Solving Strategy should not be considered a prescription. Rather it is a summary of things to do that will start you thinking and getting involved in the problem at hand.

**CAUTION**
*Treating an object as a particle*

When we are concerned only about *translational motion*, all the forces on a given object can be drawn as acting at the center of the object, thus treating the object as a **point particle**. However, for problems involving rotation or statics, the place *where* each force acts is also important, as we shall see in Chapters 10, 11, and 12.

In the Examples in this Section, we assume that all surfaces are very smooth so that friction can be ignored. (Friction, and Examples using it, are discussed in Chapter 5.)

**EXAMPLE 4–11** **Pulling the mystery box.** Suppose a friend asks to examine the 10.0-kg box you were given (Example 4–6, Fig. 4–15), hoping to guess what is inside; and you respond, "Sure, pull the box over to you." She then pulls the box by the attached cord, as shown in Fig. 4–21a, along the smooth surface of the table. The magnitude of the force exerted by the person is $F_P = 40.0\,N$, and it is exerted at a 30.0° angle as shown. Calculate (*a*) the acceleration of the box, and (*b*) the magnitude of the upward force $F_N$ exerted by the table on the box. Assume that friction can be neglected.

**APPROACH** We follow the Problem Solving Strategy on the previous page.

**SOLUTION**

1. **Draw a sketch**: The situation is shown in Fig. 4–21a; it shows the box and the force applied by the person, $F_P$.
2. **Free-body diagram**: Figure 4–21b shows the free-body diagram of the box. To draw it correctly, we show *all* the forces acting on the box and *only* the forces acting on the box. They are: the force of gravity $m\vec{\mathbf{g}}$; the normal force exerted by the table $\vec{\mathbf{F}}_N$; and the force exerted by the person $\vec{\mathbf{F}}_P$. We are interested only in translational motion, so we can show the three forces acting at a point, Fig. 4–21c.
3. **Choose axes and resolve vectors**: We expect the motion to be horizontal, so we choose the $x$ axis horizontal and the $y$ axis vertical. The pull of 40.0 N has components
$$F_{Px} = (40.0\,N)(\cos 30.0°) = (40.0\,N)(0.866) = 34.6\,N,$$
$$F_{Py} = (40.0\,N)(\sin 30.0°) = (40.0\,N)(0.500) = 20.0\,N.$$
In the horizontal ($x$) direction, $\vec{\mathbf{F}}_N$ and $m\vec{\mathbf{g}}$ have zero components. Thus the horizontal component of the net force is $F_{Px}$.
4. (*a*) **Apply Newton's second law** to determine the $x$ component of the acceleration:
$$F_{Px} = ma_x.$$
5. (*a*) **Solve**:
$$a_x = F_{Px}/m = 34.6\,N/10.0\,kg = 3.46\,m/s^2.$$
The acceleration of the box is 3.46 m/s$^2$ to the right.

(*b*) Next we want to find $F_N$.

4′. (*b*) **Apply Newton's second law** to the vertical ($y$) direction, with upward as positive:
$$\Sigma F_y = ma_y$$
$$F_N - mg + F_{Py} = ma_y.$$

5′. (*b*) **Solve**: We have $mg = (10.0\,kg)(9.80\,m/s^2) = 98.0\,N$ and, from step 3 above, $F_{Py} = 20.0\,N$. Furthermore, since $F_{Py} < mg$, the box does not move vertically, so $a_y = 0$. Thus
$$F_N - 98.0\,N + 20.0\,N = 0,$$
so $F_N = 78.0\,N$.

**NOTE** $F_N$ is less than $mg$: the table does not push against the full weight of the box because part of the pull exerted by the person is in the upward direction.

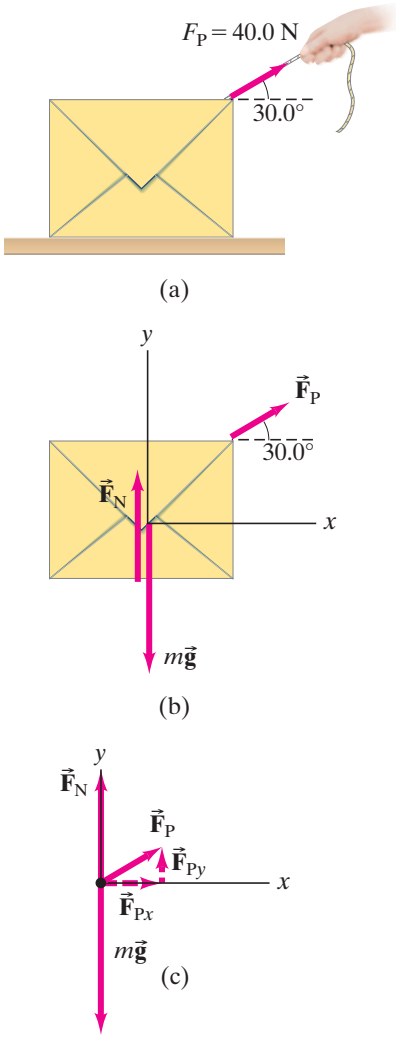

**FIGURE 4–21** (a) Pulling the box, Example 4–11; (b) is the free-body diagram for the box, and (c) is the free-body diagram considering all the forces to act at a point (translational motion only, which is what we have here).

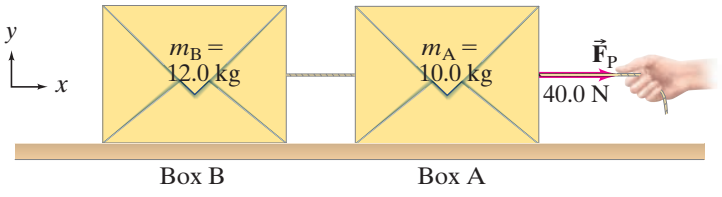
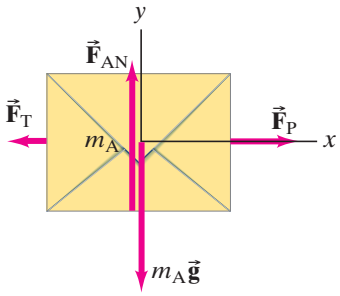


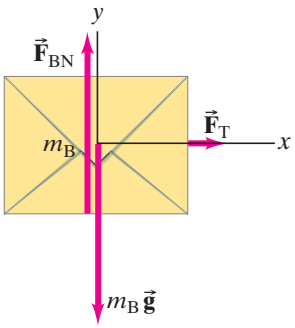
**EXERCISE F** If the force $\vec{\mathbf{F}}_P$ (Fig. 4–21) exerted by the person is doubled in magnitude, what now will be the normal force?

**EXERCISE G** A 10.0-kg box is dragged on a horizontal frictionless surface by a horizontal force of 10.0 N. If the applied force is doubled, the normal force on the box will (*a*) increase; (*b*) remain the same; (*c*) decrease.



## Tension in a Flexible Cord

When a flexible cord pulls on an object, the cord is said to be under **tension**, and the force it exerts on the object is the tension $F_T$. If the cord has negligible mass, the force exerted at one end is transmitted undiminished to each adjacent piece of cord along the entire length to the other end. Why? Because $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}} = 0$ for the cord if the cord's mass $m$ is zero (or negligible) no matter what $\vec{\mathbf{a}}$ is. Hence the forces pulling on the cord at its two ends must add up to zero ($F_T$ and $-F_T$). Note that flexible cords and strings can only pull. They can't push because they bend.



**PROBLEM SOLVING**
*Cords can pull but can't push; tension exists throughout a taut cord*

(a)

(b)

(c)

**FIGURE 4–22** Example 4–12. (a) Two boxes, A and B, are connected by a cord. A person pulls horizontally on box A with force $F_P = 40.0\,\text{N}$. (b) Free-body diagram for box A. (c) Free-body diagram for box B.

Our next Example involves two boxes connected by a cord. We can refer to this group of objects as a system. A **system** is any group of one or more objects we choose to consider and study.

**EXAMPLE 4–12** **Two boxes connected by a cord.** Two boxes, A and B, are connected by a lightweight cord and are resting on a smooth (frictionless) table. The boxes have masses of 12.0 kg and 10.0 kg. A horizontal force $F_P$ of 40.0 N is applied to the 10.0-kg box by a person pulling on a cord, as shown in Fig. 4–22a. Find (*a*) the acceleration of each box, and (*b*) the tension in the cord connecting the boxes.

**APPROACH** We streamline our approach by not listing each step. We have two boxes so we draw a free-body diagram for each. To draw them correctly, we must consider the forces on *each* box by itself, so that Newton's second law can be applied to each. The person exerts a force $F_P$ on box A. Box A exerts a force $F_T$ on the connecting cord, and the cord exerts an opposite but equal magnitude force $F_T$ back on box A (Newton's third law). The two horizontal forces on box A are shown in Fig. 4–22b, along with the force of gravity $m_A\vec{\mathbf{g}}$ downward and the normal force $\vec{\mathbf{F}}_{AN}$ exerted upward by the table. The cord is light, so we neglect its mass. The tension at each end of the cord is thus the same. Hence the cord exerts a force $F_T$ on the second box. Figure 4–22c shows the forces on box B, which are $\vec{\mathbf{F}}_T$, $m_B\vec{\mathbf{g}}$, and the normal force $\vec{\mathbf{F}}_{BN}$. There will be only horizontal motion. We take the positive $x$ axis to the right.

**SOLUTION** (*a*) We apply $\Sigma F_x = ma_x$ to box A:

$$\Sigma F_x = F_P - F_T = m_A a_A. \qquad \text{[box A]}$$

For box B, the only horizontal force is $F_T$, so

$$\Sigma F_x = F_T = m_B a_B. \qquad \text{[box B]}$$

The boxes are connected, and if the cord remains taut and doesn't stretch, then the two boxes will have the same acceleration $a$. Thus $a_A = a_B = a$. We now have 2 unknowns, $F_T$ and $a$, and the two equations above to solve for them. We are given $m_A = 10.0\,\text{kg}$ and $m_B = 12.0\,\text{kg}$. We can add the two equations above to eliminate an unknown $(F_T)$ and obtain

$$(m_A + m_B)\,a = F_P - F_T + F_T = F_P$$

or

$$a = \frac{F_P}{m_A + m_B} = \frac{40.0\,\text{N}}{22.0\,\text{kg}} = 1.82\,\text{m/s}^2.$$

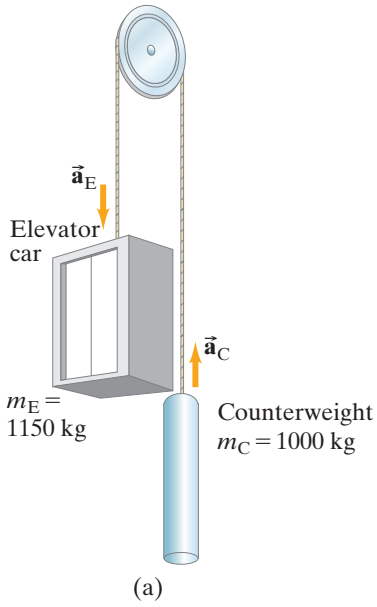
This is what we sought.

(*b*) From the equation for box B above $(F_T = m_B a_B)$, the tension in the cord is

$$F_T = m_B a = (12.0\,\text{kg})(1.82\,\text{m/s}^2) = 21.8\,\text{N}.$$

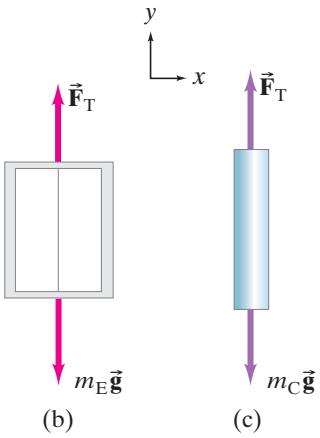
Thus, $F_T < F_P\ (= 40.0\,\text{N})$, as we expect, since $F_T$ acts to accelerate only $m_B$.

***Alternate Solution to (a)*** We would have obtained the same result had we considered a single system, of mass $m_A + m_B$, acted on by a net horizontal force equal to $F_P$. (The tension forces $F_T$ would then be considered internal to the system as a whole, and summed together would make zero contribution to the net force on the *whole* system.)



**NOTE** It might be tempting to say that the force the person exerts, $F_P$, acts not only on box A but also on box B. It doesn't. $F_P$ acts only on box A. It affects box B via the tension in the cord, $F_T$, which acts on box B and accelerates it. (You could look at it this way: $F_T < F_P$ because $F_P$ accelerates *both* boxes whereas $F_T$ only accelerates box B.)

**⚠ CAUTION**



*For any object, use only the forces on that object in calculating $\Sigma F = ma$*

**EXAMPLE 4–13** **Elevator and counterweight (Atwood machine).** A system of two objects suspended over a pulley by a flexible cable, as shown in Fig. 4–23a, is sometimes referred to as an *Atwood machine*. Consider the real-life application of an elevator $(m_E)$ and its counterweight $(m_C)$. To minimize the work done by the motor to raise and lower the elevator safely, $m_E$ and $m_C$ are made similar in mass. We leave the motor out of the system for this calculation, and assume that the cable's mass is negligible and that the mass of the pulley, as well as any friction, is small and ignorable. These assumptions ensure that the tension $F_T$ in the cable has the same magnitude on both sides of the pulley. Let the mass of the counterweight be $m_C = 1000\,\text{kg}$. Assume the mass of the empty elevator is 850 kg, and its mass when carrying four passengers is $m_E = 1150\,\text{kg}$. For the latter case $(m_E = 1150\,\text{kg})$, calculate (*a*) the acceleration of the elevator and (*b*) the tension in the cable.

**PHYSICS APPLIED**
*Elevator (as Atwood machine)*

(a)

(b) (c)

**FIGURE 4–23** Example 4–13. (a) Atwood machine in the form of an elevator–counterweight system. (b) and (c) Free-body diagrams for the two objects.

**APPROACH** Again we have two objects, and we will need to apply Newton's second law to each of them separately. Each mass has two forces acting on it: gravity downward and the cable tension pulling upward, $\vec{\mathbf{F}}_T$. Figures 4–23b and c show the free-body diagrams for the elevator $(m_E)$ and for the counterweight $(m_C)$. The elevator, being the heavier, will accelerate downward, whereas the counterweight will accelerate upward. The magnitudes of their accelerations will be equal (we assume the cable is massless and doesn't stretch). For the counterweight, $m_C g = (1000\,\text{kg})(9.80\,\text{m/s}^2) = 9800\,\text{N}$, so $F_T$ must be greater than 9800 N (in order that $m_C$ will accelerate upward). For the elevator, $m_E g = (1150\,\text{kg})(9.80\,\text{m/s}^2) = 11{,}300\,\text{N}$, which must have greater magnitude than $F_T$ so that $m_E$ accelerates downward. Thus our calculation must give $F_T$ between 9800 N and 11,300 N.

**SOLUTION** (*a*) To find $F_T$ as well as the acceleration $a$, we apply Newton's second law, $\Sigma F = ma$, to each object. We take upward as the positive $y$ direction for both objects. With this choice of axes, $a_C = a$ because $m_C$ accelerates upward, and $a_E = -a$ because $m_E$ accelerates downward. Thus

$$F_T - m_E g = m_E a_E = -m_E a$$
$$F_T - m_C g = m_C a_C = +m_C a.$$

We can subtract the first equation from the second to get

$$(m_E - m_C)g = (m_E + m_C)a,$$

where $a$ is now the only unknown. We solve this for $a$:

$$a = \frac{m_E - m_C}{m_E + m_C}g = \frac{1150\,\text{kg} - 1000\,\text{kg}}{1150\,\text{kg} + 1000\,\text{kg}}g = 0.070\,g = 0.68\,\text{m/s}^2.$$

The elevator $(m_E)$ accelerates downward (and the counterweight $m_C$ upward) at $a = 0.070\,g = 0.68\,\text{m/s}^2$.

(*b*) The tension in the cable $F_T$ can be obtained from either of the two $\Sigma F = ma$ equations at the start of our solution, setting $a = 0.070\,g = 0.68\,\text{m/s}^2$:

$$F_T = m_E g - m_E a = m_E(g - a)$$
$$= 1150\,\text{kg}\,(9.80\,\text{m/s}^2 - 0.68\,\text{m/s}^2) = 10{,}500\,\text{N},$$

or

$$F_T = m_C g + m_C a = m_C(g + a)$$
$$= 1000\,\text{kg}\,(9.80\,\text{m/s}^2 + 0.68\,\text{m/s}^2) = 10{,}500\,\text{N},$$

which are consistent. As predicted, our result lies between 9800 N and 11,300 N.

**NOTE** We can check our equation for the acceleration $a$ in this Example by noting that if the masses were equal $(m_E = m_C)$, then our equation above for $a$ would give $a = 0$, as we should expect. Also, if one of the masses is zero (say, $m_C = 0$), then the other mass $(m_E \neq 0)$ would be predicted by our equation to accelerate at $a = g$, again as expected.

**PROBLEM SOLVING**
*Check your result by seeing if it works in situations where the answer is easily guessed*

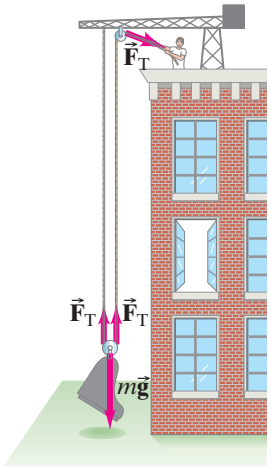


**FIGURE 4–24** Example 4–14.

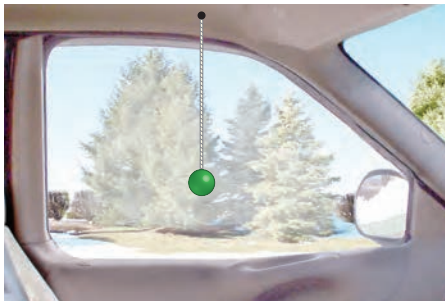
**CONCEPTUAL EXAMPLE 4–14** **The advantage of a pulley.** A mover is trying to lift a piano (slowly) up to a second-story apartment (Fig. 4–24). He is using a rope looped over two pulleys as shown. What force must he exert on the rope to slowly lift the piano's 1600-N weight?

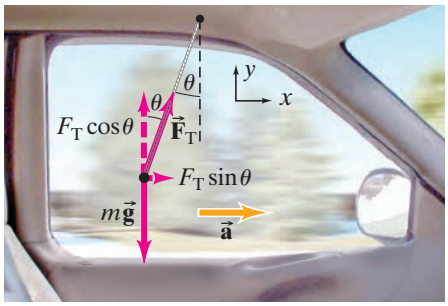
**RESPONSE** The magnitude of the tension force $F_T$ within the rope is the same at any point along the rope if we assume we can ignore the mass of the rope and pulleys. First notice the forces acting on the lower pulley at the piano. The weight of the piano $(= mg)$ pulls down on the pulley. The tension in the rope, looped through this pulley, pulls up *twice*, once on each side of the pulley. Let us apply Newton's second law to the pulley–piano combination (of mass $m$), choosing the upward direction as positive:

$$2F_T - mg = ma.$$



To move the piano with constant speed (set $a = 0$ in this equation) thus requires a tension in the rope, and hence a pull on the rope, of $F_T = mg/2$. The piano mover can exert a force equal to half the piano's weight.

**NOTE** We say the pulley has given a **mechanical advantage** of 2, since without the pulley the mover would have to exert twice the force.



**PHYSICS APPLIED**
*Accelerometer*

**EXAMPLE 4–15** **Accelerometer.** A small mass $m$ hangs from a thin string and can swing like a pendulum. You attach it above the window of your car as shown in Fig. 4–25a. When the car is at rest, the string hangs vertically. What angle $\theta$ does the string make $(a)$ when the car accelerates at a constant $a = 1.20\,\text{m/s}^2$, and $(b)$ when the car moves at constant velocity, $v = 90\,\text{km/h}$?

**FIGURE 4–25** Example 4–15.

(a)

(b)

**APPROACH** The free-body diagram of Fig. 4–25b shows the pendulum at some angle $\theta$ relative to the vertical, and the forces on it: $m\vec{g}$ downward, and the tension $\vec{F}_T$ in the cord (including its components). These forces do not add up to zero if $\theta \neq 0$; and since we have an acceleration $a$, we expect $\theta \neq 0$.

**SOLUTION** $(a)$ The acceleration $a = 1.20\,\text{m/s}^2$ is horizontal $(= a_x)$, and the only horizontal force is the $x$ component of $\vec{F}_T$: $F_T \sin\theta$ (Fig. 4–25b). Then from Newton's second law,

$$ma = F_T \sin\theta.$$

The vertical component of Newton's second law gives, since $a_y = 0$,

$$0 = F_T \cos\theta - mg.$$

So

$$mg = F_T \cos\theta.$$

Dividing the two equations involving $F_T$, we obtain

$$\tan\theta = \frac{F_T \sin\theta}{F_T \cos\theta} = \frac{ma}{mg} = \frac{a}{g}$$

or

$$\tan\theta = \frac{1.20\,\text{m/s}^2}{9.80\,\text{m/s}^2} = 0.122,$$

so

$$\theta = 7.0°.$$

$(b)$ The velocity is constant, so $a = 0$ and therefore $\tan\theta = 0$. Hence the pendulum hangs vertically $(\theta = 0°)$.

**NOTE** This simple device is an **accelerometer**—it can be used to determine acceleration, by measuring the angle $\theta$.

## Inclines

Now we consider what happens when an object slides down an incline, such as a hill or ramp. Such problems are interesting because gravity is the accelerating force, yet the acceleration is not vertical. Solving problems is usually easier if we choose the $xy$ coordinate system so the $x$ axis points along the incline (the direction of motion) and the $y$ axis is perpendicular to the incline, as shown in Fig. 4–26a. Note also that the normal force is not vertical, but is perpendicular to the sloping surface of the plane, along the $y$ axis in Fig. 4–26b.

**PROBLEM SOLVING**
*Good choice of coordinate system simplifies the calculation*

**EXAMPLE 4–16** **Box slides down an incline.** A box of mass $m$ is placed on a smooth (frictionless) incline that makes an angle $\theta$ with the horizontal, as shown in Fig. 4–26. (*a*) Determine the normal force on the box. (*b*) Determine the box's acceleration. (*c*) Evaluate for a mass $m = 10\,\text{kg}$ and an incline of $\theta = 30°$.

**APPROACH** We expect the motion to be along the incline, so we choose the $x$ axis along the slope, positive down the slope (the direction of motion). The $y$ axis is perpendicular to the incline, positive upwards. The free-body diagram is shown in Fig. 4–26b. The forces on the box are its weight $m\vec{\mathbf{g}}$ vertically downward, which is shown resolved into its components parallel and perpendicular to the incline, and the normal force $\vec{\mathbf{F}}_\text{N}$ along the $+y$ axis. The components of $m\vec{\mathbf{g}}$ along the $x$ and $y$ axes are found using the definitions of sine ("side opposite") and cosine ("side adjacent"): $(mg)_x = mg\sin\theta$, and $(mg)_y = mg\cos\theta$. (The angle $\theta$ of the plane equals the angle between $m\vec{\mathbf{g}}$ and its $y$ component because the left sides of the two angles are perpendicular to each other and so are the right sides—see Appendix A–6, Fig. A–2.)

**SOLUTION** (*a*) There is no motion in the $y$ direction, so $a_y = 0$. Applying Newton's second law we have

$$\begin{aligned} F_y &= ma_y \\ F_\text{N} - mg\cos\theta &= 0, \end{aligned}$$

where $F_\text{N}$ and the $y$ component of gravity $(mg\cos\theta)$ are all the forces acting on the box in the $y$ direction. Thus the normal force is given by

$$F_\text{N} = mg\cos\theta.$$

Note carefully that unless $\theta = 0°$, $F_\text{N}$ has magnitude less than the weight $mg$.
(*b*) In the $x$ direction the only force acting is the $x$ component of $m\vec{\mathbf{g}}$, which is $mg\sin\theta$. The acceleration $a$ is in the $x$ direction so

$$\begin{aligned} F_x &= ma_x \\ mg\sin\theta &= ma, \end{aligned}$$

and we see that the acceleration down the plane is

$$a = g\sin\theta.$$

Thus the acceleration along an incline is always less than $g$, except at $\theta = 90°$, for which $\sin\theta = 1$ and $a = g$. This makes sense since $\theta = 90°$ is pure vertical fall. For $\theta = 0°$, $a = 0$, which makes sense because $\theta = 0°$ means the plane is horizontal so gravity causes no acceleration. Note too that the *acceleration does not depend on the mass* ($m$).
(*c*) For $\theta = 30°$, $\cos\theta = 0.866$ and $\sin\theta = 0.500$, so

$$F_\text{N} = 0.866\,mg = 85\,\text{N},$$

and

$$a = 0.500\,g = 4.9\,\text{m/s}^2.$$

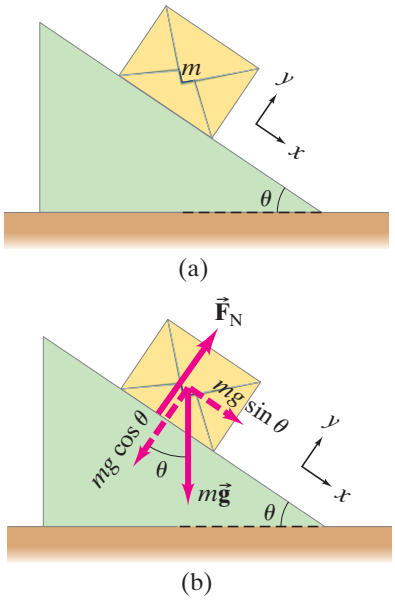


**FIGURE 4–26** Example 4–16. (a) Box sliding on inclined plane. (b) Free-body diagram of box.

**EXERCISE H** Is the normal force always perpendicular to an inclined plane? Is it always vertical?

We will discuss more Examples of motion on an incline in the next Chapter, where friction will be included.

## 4–8 Problem Solving—A General Approach

A basic part of a physics course is solving problems effectively. The approach discussed here, though emphasizing Newton's laws, can be applied generally for other topics discussed throughout this book.

PROBLEM SOLVING

### In General

**1. Read** and reread written problems carefully. A common error is to skip a word or two when reading, which can completely change the meaning of a problem.

**2. Draw** an accurate picture or diagram of the situation. (This is probably the most overlooked, yet most crucial, part of solving a problem.) Use arrows to represent vectors such as velocity or force, and label the vectors with appropriate symbols. When dealing with forces and applying Newton's laws, make sure to include all forces on a given object, including unknown ones, and make clear what forces act on what object (otherwise you may make an error in determining the *net force* on a particular object).

**3.** A separate **free-body diagram** needs to be drawn for each object involved, and it must show *all* the forces acting on a given object (and only on that object). Do not show forces that act on other objects.

**4.** Choose a convenient $xy$ **coordinate system** (one that makes your calculations easier, such as one axis in the direction of the acceleration). Vectors are to be resolved into components along the coordinate axes. When using Newton's second law, apply $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$ separately to $x$ and $y$ components, remembering that $x$ direction forces are related to $a_x$, and similarly for $y$. If more than one object is involved, you can choose different (convenient) coordinate systems for each.

**5.** List the knowns and the unknowns (what you are trying to determine), and decide what you need in order to find the unknowns. For problems in the present Chapter, we use Newton's laws. More generally, it may help to see if one or more **relationships** (or **equations**) relate the unknowns to the knowns. But be sure each relationship is applicable in the given case. It is very important to know the limitations of each formula or relationship—when it is valid and when not. In this book, the more general equations have been given numbers, but even these can have a limited range of validity (often stated in brackets to the right of the equation).

**6.** Try to solve the problem approximately, to see if it is doable (to check if enough information has been given) and reasonable. Use your intuition, and make **rough calculations**—see "Order of Magnitude Estimating" in Section 1–6. A rough calculation, or a reasonable guess about what the range of final answers might be, is very useful. And a rough calculation can be checked against the final answer to catch errors in calculation, such as in a decimal point or the powers of 10.

**7. Solve** the problem, which may include algebraic manipulation of equations and/or numerical calculations. Recall the mathematical rule that you need as many independent equations as you have unknowns; if you have three unknowns, for example, then you need three independent equations. It is usually best to work out the algebra symbolically before putting in the numbers. Why? Because (*a*) you can then solve a whole class of similar problems with different numerical values; (*b*) you can check your result for cases already understood (say, $\theta = 0^\circ$ or $90^\circ$); (*c*) there may be cancellations or other simplifications; (*d*) there is usually less chance for numerical error; and (*e*) you may gain better insight into the problem.

**8.** Be sure to keep track of **units**, for they can serve as a check (they must balance on both sides of any equation).

**9.** Again consider if your answer is **reasonable**. The use of dimensional analysis, described in Section 1–7, can also serve as a check for many problems.

# Summary

**Newton's three laws of motion** are the basic classical laws describing motion.

**Newton's first law** (the **law of inertia**) states that if the net force on an object is zero, an object originally at rest remains at rest, and an object in motion remains in motion in a straight line with constant velocity.

**Newton's second law** states that the acceleration of an object is directly proportional to the net force acting on it, and inversely proportional to its mass:

$$\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}. \qquad \textbf{(4–1a)}$$

Newton's second law is one of the most important and fundamental laws in classical physics.

**Newton's third law** states that whenever one object exerts a force on a second object, the second object always exerts a force on the first object which is equal in magnitude but opposite in direction:

$$\vec{\mathbf{F}}_{AB} = -\vec{\mathbf{F}}_{BA}, \qquad \textbf{(4–2)}$$

where $\vec{\mathbf{F}}_{BA}$ is the force on object B exerted by object A. This is true even if objects are moving and accelerating, and/or have different masses.

The tendency of an object to resist a change in its motion is called **inertia**. **Mass** is a measure of the inertia of an object.

**Weight** refers to the **gravitational force** on an object, and is equal to the product of the object's mass $m$ and the acceleration of gravity $\vec{\mathbf{g}}$:

$$\vec{\mathbf{F}}_G = m\vec{\mathbf{g}}. \qquad \textbf{(4–3)}$$

**Force**, which is a vector, can be considered as a push or pull; or, from Newton's second law, force can be defined as an action capable of giving rise to acceleration. The **net force** on an object is the vector sum of all forces acting on that object.

For solving problems involving the forces on one or more objects, it is essential to draw a **free-body diagram** for *each* object, showing all the forces acting on only that object. Newton's second law can be applied to the vector components for each object.

# Questions

1. Why does a child in a wagon seem to fall backward when you give the wagon a sharp pull forward?
2. A box rests on a frictionless part of a truck bed. The truck driver starts the truck and accelerates forward. The box immediately starts to slide toward the rear of the truck bed. Discuss the motion of the box, in terms of Newton's laws, as seen (*a*) by Francesca standing on the ground beside the truck, and (*b*) by Phil who is riding on the truck (Fig. 4–27).

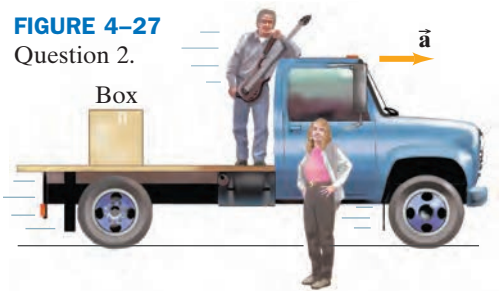

**FIGURE 4–27**
Question 2.

3. If an object is moving, is it possible for the net force acting on it to be zero? Explain.
4. If the acceleration of an object is zero, are no forces acting on it? Explain.
5. Only one force acts on an object. Can the object have zero acceleration? Can it have zero velocity? Explain.
6. When a golf ball is dropped to the pavement, it bounces back up. (*a*) Is a force needed to make it bounce back up? (*b*) If so, what exerts the force?
7. If you walk on a log floating on a lake, why does the log move in the opposite direction?
8. (*a*) Why do you push down harder on the pedals of a bicycle when first starting out than when moving at constant speed? (*b*) Why do you need to pedal at all when cycling at constant speed?
9. A stone hangs by a fine thread from the ceiling, and a section of the same thread dangles from the bottom of the stone (Fig. 4–28). If a person gives a sharp pull on the dangling thread, where is the thread likely to break: below the stone or above it? What if the person gives a slow and steady pull? Explain your answers.

**FIGURE 4–28**
Question 9.

10. The force of gravity on a 2-kg rock is twice as great as that on a 1-kg rock. Why then doesn't the heavier rock fall faster?
11. You pull a box with a constant force across a frictionless table using an attached rope held horizontally. If you now pull the rope with the same force at an angle to the horizontal (with the box remaining flat on the table), does the acceleration of the box increase, decrease, or remain the same? Explain.
12. When an object falls freely under the influence of gravity there is a net force $mg$ exerted on it by the Earth. Yet by Newton's third law the object exerts an equal and opposite force on the Earth. Does the Earth move? Explain.
13. Compare the effort (or force) needed to lift a 10-kg object when you are on the Moon with the force needed to lift it on Earth. Compare the force needed to throw a 2-kg object horizontally with a given speed on the Moon and on Earth.

14. According to Newton's third law, each team in a tug of war (Fig. 4–29) pulls with equal force on the other team. What, then, determines which team will win?

**FIGURE 4–29** Question 14. A tug of war. Describe the forces on each of the teams and on the rope.

15. When you stand still on the ground, how large a force does the ground exert on you? Why doesn't this force make you rise up into the air?
16. Whiplash sometimes results from an automobile accident when the victim's car is struck violently from the rear. Explain why the head of the victim seems to be thrown backward in this situation. Is it really?
17. Mary exerts an upward force of 40 N to hold a bag of groceries. Describe the "reaction" force (Newton's third law) by stating (*a*) its magnitude, (*b*) its direction, (*c*) *on* what object it is exerted, and (*d*) *by* what object it is exerted.
18. A father and his young daughter are ice skating. They face each other at rest and then push each other so they begin moving in opposite directions. Which one has the greater speed? Explain.
19. What would your bathroom scale read if you weighed yourself on an inclined plane? Assume the mechanism functions properly, even at an angle.
20. Which of the following objects weighs about 1 N: (*a*) an apple, (*b*) a mosquito, (*c*) this book, (*d*) you?
21. Why might your foot hurt if you kick a heavy desk or a wall?
22. When you are running and want to stop quickly, you must decelerate quickly. (*a*) What is the origin of the force that causes you to stop? (*b*) Estimate (using your own experience) the maximum rate of deceleration of a person running at top speed to come to rest.
23. Suppose that you are standing on top of a cardboard carton that just barely supports you. What would happen to it if you jumped up into the air? It would: (*a*) collapse; (*b*) be unaffected; (*c*) spring upward a bit; (*d*) move sideways. Explain your answer.

## MisConceptual Questions

1. A truck is traveling horizontally to the right (Fig. 4–30). When the truck starts to slow down, the crate on the frictionless truck bed starts to slide. In what direction could the net force be on the crate?
   (*a*) No direction. The net force is zero.
   (*b*) Straight down (gravity).
   (*c*) Straight up (the normal force).
   (*d*) Horizontal and to the right.
   (*e*) Horizontal and to the left.

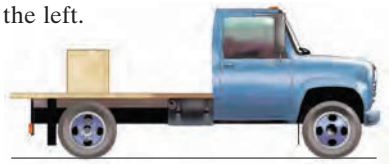

**FIGURE 4–30** MisConceptual Question 1.

2. George, in the foreground of Fig. 4–31, is able to move the large truck because
   (*a*) he is stronger than the truck.
   (*b*) he is heavier in some respects than the truck.
   (*c*) the truck offers no resistance because its brakes are off.
   (*d*) the ground exerts a greater friction force on George than it does on the truck.
   (*e*) he exerts a greater force on the truck than the truck exerts back on him.

**FIGURE 4–31** MisConceptual Question 2.

3. A bear sling, Fig. 4–32, is used in some national parks for placing backpackers' food out of the reach of bears. As the backpacker raises the pack by pulling down on the rope, the force $F$ needed:
   (*a*) decreases as the pack rises until the rope is straight across.
   (*b*) doesn't change.
   (*c*) increases until the rope is straight.
   (*d*) increases but the rope always sags where the pack hangs.

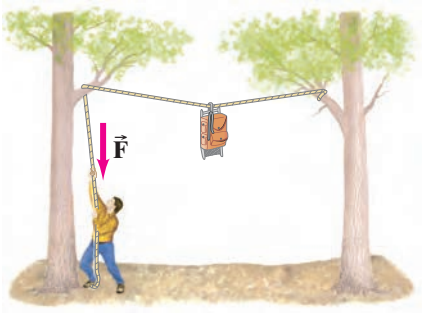

**FIGURE 4–32** MisConceptual Question 3.

4. What causes the boat in Fig. 4–33 to move forward?
   (*a*) The force the man exerts on the paddle.
   (*b*) The force the paddle exerts on the water.
   (*c*) The force the water exerts on the paddle.
   (*d*) The motion of the water itself.

**FIGURE 4–33** MisConceptual Question 4.

5. You are trying to push your stalled car. Although you apply a horizontal force of 400 N on the car, it doesn't budge, and neither do you. What other force(s) must also have a magnitude of 400 N?
(*a*) The force exerted by the car on you.
(*b*) The friction force exerted by the car on the road.
(*c*) The normal force exerted by the road on you.
(*d*) The friction force exerted by the road on you.

6. When a skier skis down a hill, the normal force exerted on the skier by the hill is
(*a*) equal to the weight of the skier.
(*b*) greater than the weight of the skier.
(*c*) less than the weight of the skier.

7. A golf ball is hit with a golf club. While the ball flies through the air, which forces act on the ball? Neglect air resistance.
(*a*) The force of the golf club acting on the ball.
(*b*) The force of gravity acting on the ball.
(*c*) The force of the ball moving forward through the air.
(*d*) All of the above.
(*e*) Both (*a*) and (*b*).

8. Suppose an object is accelerated by a force of 100 N. Suddenly a second force of 100 N in the opposite direction is exerted on the object, so that the forces cancel. The object
(*a*) quickly stops.
(*b*) decelerates gradually to rest.
(*c*) continues at the velocity it had before the second force was applied.
(*d*) is gradually brought to rest and then accelerates in the direction of the second force.

9. You are pushing a heavy box across a rough floor. When you are initially pushing the box and it is accelerating,
(*a*) you exert a force on the box, but the box does not exert a force on you.
(*b*) the box is so heavy it exerts a force on you, but you do not exert a force on the box.
(*c*) the force you exert on the box is greater than the force of the box pushing back on you.
(*d*) the force you exert on the box is equal to the force of the box pushing back on you.
(*e*) the force that the box exerts on you is greater than the force you exert on the box.

10. Two 5-newton boxes are attached to opposite ends of a spring scale and suspended from pulleys as shown in Fig. 4–34. What is the reading on the scale?
(*a*) 0 N.
(*b*) Between 0 and 5 N.
(*c*) 5 N.
(*d*) Between 5 and 10 N.
(*e*) 10 N.

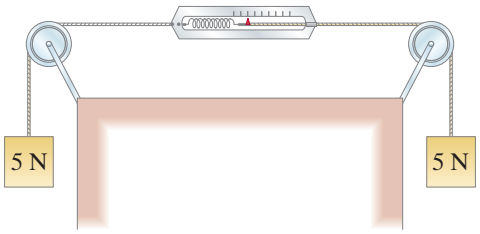

**FIGURE 4–34** MisConceptual Question 10.

11. Two tug of war opponents each pull with a force of 500 N on opposite ends of a rope. Assume the rope is massless. What is the tension in the rope?
(*a*) 0 N.
(*b*) 250 N.
(*c*) 500 N.
(*d*) 1000 N.
(*e*) Impossible to tell.

12. The normal force on an extreme skier descending a very steep slope (Fig. 4–35) can be zero if
(*a*) his speed is great enough.
(*b*) he leaves the slope (no longer touches the snow).
(*c*) the slope is greater than 75°.
(*d*) the slope is vertical (90°).

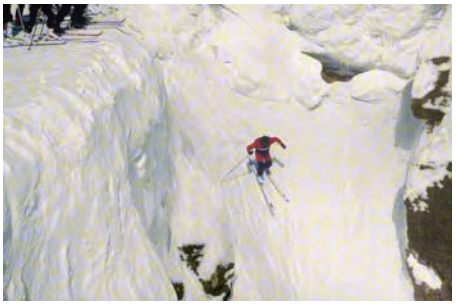

**FIGURE 4–35** MisConceptual Question 12.

13. To pull an old stump out of the ground, you and a friend tie two ropes to the stump. You pull on it with a force of 500 N to the north while your friend pulls with a force of 450 N to the northwest. The total force exerted by the two ropes is
(*a*) less than 950 N.
(*b*) exactly 950 N.
(*c*) more than 950 N.

# Problems

### 4–4 to 4–6 Newton's Laws, Gravitational Force, Normal Force [Assume no friction.]

1. (I) What net force is needed to accelerate a 45-kg sled at 1.4 $m/s^2$ on horizontal frictionless ice?

2. (I) What is the weight of a 74-kg astronaut (*a*) on Earth, (*b*) on the Moon ($g = 1.7\ m/s^2$), (*c*) on Mars ($g = 3.7\ m/s^2$), (*d*) in outer space traveling with constant velocity?

3. (I) How much tension must a rope withstand if it is used to accelerate a 1210-kg car horizontally along a frictionless surface at 1.35 $m/s^2$?

4. (I) A net force of 215 N accelerates a bike and rider at 2.30 $m/s^2$. What is the mass of the bike and rider together?

5. (II) What average force is required to stop a 950-kg car in 8.0 s if the car is traveling at 95 km/h?

6. (II) According to a simplified model of a *mammalian heart*, at each pulse approximately 20 g of blood is accelerated from 0.25 m/s to 0.35 m/s during a period of 0.10 s. What is the magnitude of the force exerted by the heart muscle?

7. (II) Superman must stop a 120-km/h train in 150 m to keep it from hitting a stalled car on the tracks. If the train's mass is $3.6 \times 10^5$ kg, how much force must he exert? Compare to the weight of the train (give as %). How much force does the train exert on Superman?

8. (II) A person has a reasonable chance of surviving an *automobile crash* if the deceleration is no more than 30 $g$'s. Calculate the force on a 65-kg person accelerating at this rate. What distance is traveled if brought to rest at this rate from 85 km/h?

9. (II) Estimate the average force exerted by a shot-putter on a 7.0-kg shot if the shot is moved through a distance of 2.8 m and is released with a speed of 13 m/s.

10. (II) A 0.140-kg baseball traveling 35.0 m/s strikes the catcher's mitt, which, in bringing the ball to rest, recoils backward 11.0 cm. What was the average force applied by the ball on the glove?

11. (II) A fisherman yanks a fish vertically out of the water with an acceleration of 2.5 $m/s^2$ using very light fishing line that has a breaking strength of 18 N ($\approx$ 4 lb). The fisherman unfortunately loses the fish as the line snaps. What can you say about the mass of the fish?

12. (II) How much tension must a cable withstand if it is used to accelerate a 1400-kg car vertically upward at 0.70 $m/s^2$?

13. (II) A 20.0-kg box rests on a table. (*a*) What is the weight of the box and the normal force acting on it? (*b*) A 10.0-kg box is placed on top of the 20.0-kg box, as shown in Fig. 4–36. Determine the normal force that the table exerts on the 20.0-kg box and the normal force that the 20.0-kg box exerts on the 10.0-kg box.

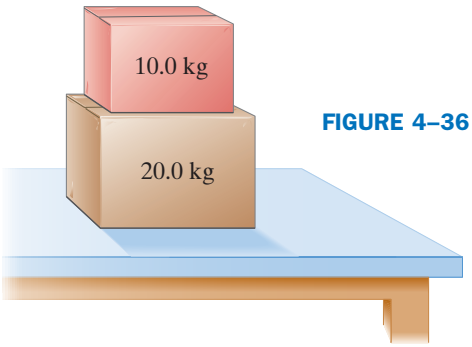

**FIGURE 4–36** Problem 13.

14. (II) A particular race car can cover a quarter-mile track (402 m) in 6.40 s starting from a standstill. Assuming the acceleration is constant, how many horizontal "$g$'s" does the driver experience? If the combined mass of the driver and race car is 535 kg, what horizontal force must the road exert on the tires? Ignore air resistance.

15. (II) A 14.0-kg bucket is lowered vertically by a rope in which there is 132 N of tension at a given instant. What is the acceleration of the bucket? Is it up or down?

16. (II) A 75-kg petty thief wants to escape from a third-story jail window. Unfortunately, a makeshift rope made of sheets tied together can support a mass of only 62 kg. How might the thief use this "rope" to escape? Give a quantitative answer.

17. (II) A woman stands on a bathroom scale in a motionless elevator. When the elevator begins to move, the scale briefly reads only 0.75 of her regular weight. Calculate the acceleration of the elevator, and find the direction of acceleration.

18. (II) Can cars "stop on a dime"? Calculate the acceleration of a 1400-kg car if it can stop from 35 km/h on a dime (diameter = 1.7 cm). How many $g$'s is this? What is the force felt by the 68-kg occupant of the car?

19. (II) The cable supporting a 2375-kg elevator has a maximum strength of 24,950 N. What maximum upward acceleration can it give the elevator without breaking?

20. (II) Using focused laser light, *optical tweezers* can apply a force of about 10 pN (piconewtons) to a 1.0-$\mu$m-diameter polystyrene bead, which has a density about equal to that of water: a volume of 1.0 $cm^3$ has a mass of about 1.0 g. Estimate the bead's acceleration in $g$'s.

21. (II) A *rocket* with a mass of $2.45 \times 10^6$ kg is launched by exerting a vertical force of $3.55 \times 10^7$ N on the gases it expels. Determine (*a*) the acceleration of the rocket, (*b*) its velocity after 8.0 s, and (*c*) how long it takes to reach an altitude of 9500 m. Assume $g$ remains constant, and ignore the mass of gas expelled (not realistic).

22. (II) (*a*) What is the acceleration of two falling *sky divers* (total mass = 148 kg including parachute) when the upward force of air resistance is equal to one-fourth of their weight? (*b*) After opening the parachute, the divers descend leisurely to the ground at constant speed. What now is the force of air resistance on the sky divers and their parachute?

23. (II) An elevator (mass 4850 kg, with people) is to be designed so that the maximum acceleration is 0.0640 $g$. What are the maximum and minimum forces the motor should exert on the supporting cable?

24. (II) An exceptional standing jump would raise a person 0.80 m off the ground. To do this, what force must a 68-kg person exert against the ground? Assume the person crouches a distance of 0.20 m prior to jumping, and thus the upward force has this distance to act over before he leaves the ground.

25. (II) High-speed *elevators* function under two limitations: (1) the maximum magnitude of vertical acceleration that a typical human body can experience without discomfort is about 1.2 $m/s^2$, and (2) the typical maximum speed attainable is about 9.0 m/s. You board an elevator on a skyscraper's ground floor and are transported 180 m above the ground level in three steps: acceleration of magnitude 1.2 $m/s^2$ from rest to 9.0 m/s, followed by constant upward velocity of 9.0 m/s, then deceleration of magnitude 1.2 $m/s^2$ from 9.0 m/s to rest. (*a*) Determine the elapsed time for each of these 3 stages. (*b*) Determine the change in the magnitude of the normal force, expressed as a % of your normal weight during each stage. (*c*) What fraction of the total transport time does the normal force not equal the person's weight?

26. (III) The 100-m dash can be run by the best sprinters in 10.0 s. A 66-kg sprinter accelerates uniformly for the first 45 m to reach top speed, which he maintains for the remaining 55 m. (*a*) What is the average horizontal component of force exerted on his feet by the ground during acceleration? (*b*) What is the speed of the sprinter over the last 55 m of the race (that is, his top speed)?

27. (III) A person jumps from the roof of a house 2.8 m high. When he strikes the ground below, he bends his knees so that his torso decelerates over an approximate distance of 0.70 m. If the mass of his torso (excluding legs) is 42 kg, find (*a*) his velocity just before his feet strike the ground, and (*b*) the average force exerted on his torso by his legs during deceleration.

## 4–7 Newton's Laws and Vectors [Ignore friction.]

**28.** (I) A box weighing 66.0 N rests on a table. A rope tied to the box runs vertically upward over a pulley and a weight is hung from the other end (Fig. 4–37). Determine the force that the table exerts on the box if the weight hanging on the other side of the pulley weighs (*a*) 30.0 N, (*b*) 60.0 N, and (*c*) 90.0 N.

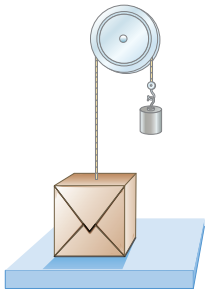

**FIGURE 4–37**
Problem 28.

**29.** (I) Draw the free-body diagram for a basketball player (*a*) just before leaving the ground on a jump, and (*b*) while in the air. See Fig. 4–38.

**FIGURE 4–38**
Problem 29.

**30.** (I) A 650-N force acts in a northwesterly direction. A second 650-N force must be exerted in what direction so that the resultant of the two forces points westward? Illustrate your answer with a vector diagram.

**31.** (I) Sketch the free-body diagram of a baseball (*a*) at the moment it is hit by the bat, and again (*b*) after it has left the bat and is flying toward the outfield. Ignore air resistance.

**32.** (II) Arlene is to walk across a "high wire" strung horizontally between two buildings 10.0 m apart. The sag in the rope when she is at the midpoint is 10.0°, as shown in Fig. 4–39. If her mass is 50.0 kg, what is the tension in the rope at this point?

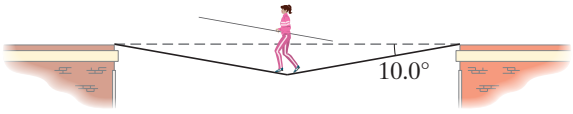

**FIGURE 4–39** Problem 32.

**33.** (II) A window washer pulls herself upward using the bucket–pulley apparatus shown in Fig. 4–40. (*a*) How hard must she pull downward to raise herself slowly at constant speed? (*b*) If she increases this force by 15%, what will her acceleration be? The mass of the person plus the bucket is 78 kg.

**FIGURE 4–40**
Problem 33.

**34.** (II) One 3.2-kg paint bucket is hanging by a massless cord from another 3.2-kg paint bucket, also hanging by a massless cord, as shown in Fig. 4–41. (*a*) If the buckets are at rest, what is the tension in each cord? (*b*) If the two buckets are pulled upward with an acceleration of 1.45 m/s$^2$ by the upper cord, calculate the tension in each cord.

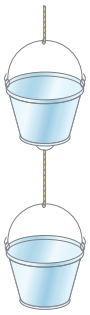

**FIGURE 4–41**
Problems 34 and 35.

**35.** (II) The cords accelerating the buckets in Problem 34b, Fig. 4–41, each have a weight of 2.0 N. Determine the tension in each cord at the three points of attachment.

**36.** (II) Two large snowcats are towing a housing unit north, as shown in Fig. 4–42. The sum of the forces $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_B$ exerted on the unit by the horizontal cables is north, parallel to the line L, and $F_A = 4200$ N. Determine $F_B$ and the magnitude of $\vec{\mathbf{F}}_A + \vec{\mathbf{F}}_B$.

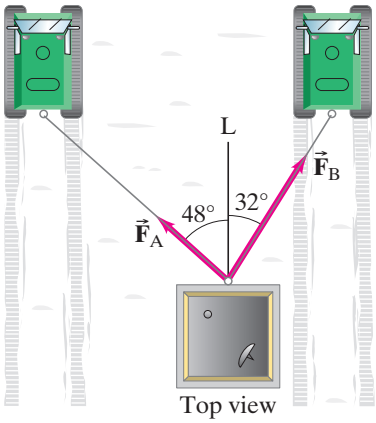

**FIGURE 4–42**
Problem 36.

**37.** (II) A train locomotive is pulling two cars of the same mass behind it, Fig. 4–43. Determine the ratio of the tension in the coupling (think of it as a cord) between the locomotive and the first car $(F_{T1})$ to that between the first car and the second car $(F_{T2})$, for any nonzero acceleration of the train.

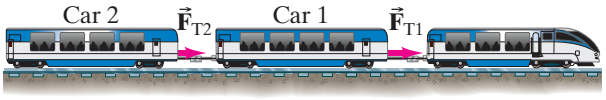

**FIGURE 4–43** Problem 37.

**38.** (II) The two forces $\vec{\mathbf{F}}_1$ and $\vec{\mathbf{F}}_2$ shown in Fig. 4–44a and b (looking down) act on an 18.5-kg object on a frictionless tabletop. If $F_1 = 10.4$ N and $F_2 = 16.2$ N, find the net force on the object and its acceleration for (a) and (b).

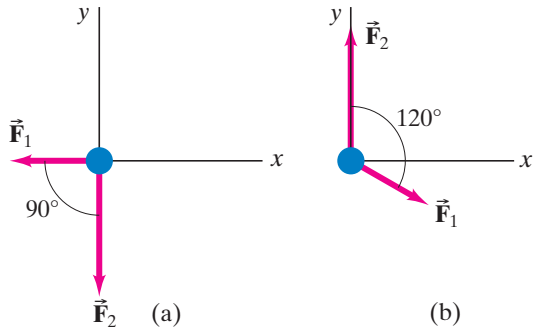

**FIGURE 4–44** Problem 38.

**39.** (II) A skateboarder, with an initial speed of 2.0 m/s, rolls virtually friction free down a straight incline of length 18 m in 3.3 s. At what angle $\theta$ is the incline oriented above the horizontal?

**40.** (II) At the instant a race began, a 65-kg sprinter exerted a force of 720 N on the starting block at a 22° angle with respect to the ground. (*a*) What was the horizontal acceleration of the sprinter? (*b*) If the force was exerted for 0.32 s, with what speed did the sprinter leave the starting block?

**41.** (II) A mass $m$ is at rest on a horizontal frictionless surface at $t = 0$. Then a constant force $F_0$ acts on it for a time $t_0$. Suddenly the force doubles to $2F_0$ and remains constant until $t = 2t_0$. Determine the total distance traveled from $t = 0$ to $t = 2t_0$.

**42.** (II) A 3.0-kg object has the following two forces acting on it:

$$\vec{\mathbf{F}}_1 = (16\hat{\mathbf{i}} + 12\hat{\mathbf{j}})\,\text{N}$$
$$\vec{\mathbf{F}}_2 = (-10\hat{\mathbf{i}} + 22\hat{\mathbf{j}})\,\text{N}$$

If the object is initially at rest, determine its velocity $\vec{\mathbf{v}}$ at $t = 4.0$ s.

**43.** (II) A 27-kg chandelier hangs from a ceiling on a vertical 3.4-m-long wire. (*a*) What horizontal force would be necessary to displace its position 0.15 m to one side? (*b*) What will be the tension in the wire?

**44.** (II) Redo Example 4–13 but (*a*) set up the equations so that the direction of the acceleration $\vec{\mathbf{a}}$ of each object is in the direction of motion of that object. (In Example 4–13, we took $\vec{\mathbf{a}}$ as positive upward for both masses.) (*b*) Solve the equations to obtain the same answers as in Example 4–13.

**45.** (II) The block shown in Fig. 4–45 has mass $m = 7.0$ kg and lies on a fixed smooth frictionless plane tilted at an angle $\theta = 22.0°$ to the horizontal. (*a*) Determine the acceleration of the block as it slides down the plane. (*b*) If the block starts from rest 12.0 m up the plane from its base, what will be the block's speed when it reaches the bottom of the incline?

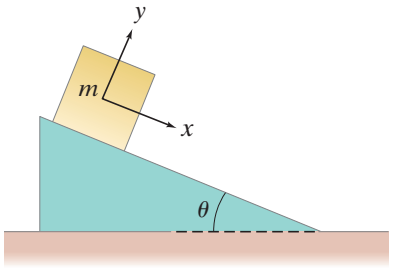

**FIGURE 4–45** Block on inclined plane. Problems 45 and 46.

**46.** (II) A block is given an initial speed of 5.2 m/s up the 22.0° plane shown in Fig. 4–45. (*a*) How far up the plane will it go? (*b*) How much time elapses before it returns to its starting point? Ignore friction.

**47.** (II) An object is hanging by a string from your rearview mirror. While you are accelerating at a constant rate from rest to 28 m/s in 5.0 s, what angle $\theta$ does the string make with the vertical? See Fig. 4–46.

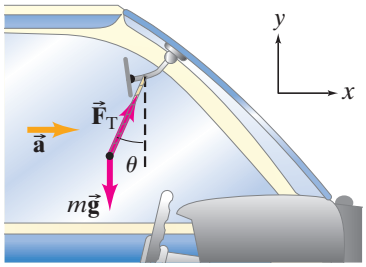

**FIGURE 4–46** Problem 47.

**48.** (II) A 2.0-kg purse is dropped from the top of the Leaning Tower of Pisa and falls 55 m before reaching the ground with a speed of 27 m/s. What was the average force of air resistance?

**49.** (II) Bob traverses a chasm by stringing a rope between a tree on one side of the chasm and a tree on the opposite side, 25 m away, Fig. 4–47. Assume the rope can provide a tension force of up to 31 kN before breaking, and use a "safety factor" of 10 (that is, the rope should only be required to undergo a tension force of 3.1 kN). (*a*) If Bob's mass is 72.0 kg, determine the distance $x$ that the rope must sag at a point halfway across if it is to be within its recommended safety range. (*b*) If the rope sags by only one-fourth the distance found in (*a*), determine the tension force in the rope. Will the rope break?

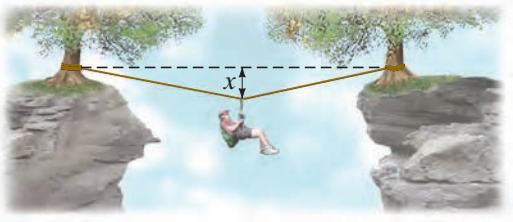

**FIGURE 4–47** Problem 49.

**50.** (II) As shown in Fig. 4–48, five balls (masses 2.00, 2.05, 2.10, 2.15, 2.20 kg) hang from a crossbar. Each mass is supported by "5-lb test" fishing line which will break when its tension force exceeds 22.2 N (= 5.00 lb). When this device is placed in an elevator, which accelerates upward, only the lines attached to the 2.05 and 2.00 kg masses do not break. Within what range is the elevator's acceleration?

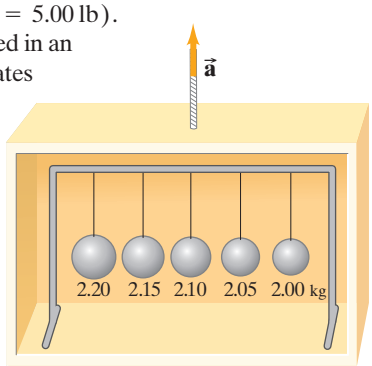

**FIGURE 4–48** Problem 50.

**51.** (II) A high-speed 14-car Italian train has a mass of 640 metric tons (640,000 kg). It can exert a maximum force of 400 kN horizontally against the tracks, whereas at maximum constant velocity (300 km/h), it exerts a force of about 150 kN. Calculate (*a*) its maximum acceleration, and (*b*) estimate the total force of friction and air resistance at top speed.

**52.** (II) A 450-kg piano is being unloaded from a truck by rolling it down a ramp inclined at 15°. There is negligible friction and the ramp is 4.0 m long. Two workers slow the rate at which the piano moves by pushing with a combined force of 1020 N parallel to the ramp. If the piano starts from rest, how fast is it moving at the bottom?

**53.** (II) Uphill escape ramps are sometimes provided to the side of steep downhill highways for trucks with overheated brakes. For a simple 11° upward ramp, what length would be needed to stop a runaway truck traveling 140 km/h? Note the large size of your calculated length. (If sand is used for the bed of the ramp, its length can be reduced by a factor of about 2.)

**54.** (II) A child on a sled reaches the bottom of a hill with a velocity of 10.0 m/s and travels 25.0 m along a horizontal straightaway to a stop. If the child and sled together have a mass of 60.0 kg, what is the average retarding force on the sled on the horizontal straightaway?

**55.** (II) Figure 4–49 shows a block (mass $m_A$) on a smooth horizontal surface, connected by a thin cord that passes over a pulley to a second block ($m_B$), which hangs vertically. (*a*) Draw a free-body diagram for each block, showing the force of gravity on each, the force (tension) exerted by the cord, and any normal force. (*b*) Apply Newton's second law to find formulas for the acceleration of the system and for the tension in the cord. Ignore friction and the masses of the pulley and cord.

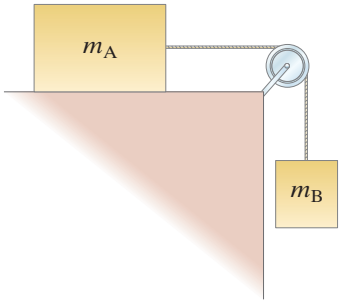

**FIGURE 4–49** Problems 55, 56, and 57. Mass $m_A$ rests on a smooth horizontal surface; $m_B$ hangs vertically.

**56.** (II) (*a*) If $m_A = 14.0\,\text{kg}$ and $m_B = 5.0\,\text{kg}$ in Fig. 4–49, determine the acceleration of each block. (*b*) If initially $m_A$ is at rest 1.250 m from the edge of the table, how long does it take to reach the edge of the table if the system is allowed to move freely? (*c*) If $m_B = 1.0\,\text{kg}$, how large must $m_A$ be if the acceleration of the system is to be kept at $\frac{1}{100}g$?

**57.** (III) Determine a formula for the acceleration of the system shown in Fig. 4–49 (see Problem 55) if the cord has a non-negligible mass $m_C$. Specify in terms of $\ell_A$ and $\ell_B$, the lengths of cord from the respective masses to the pulley. (The total cord length is $\ell = \ell_A + \ell_B$.)

**58.** (III) Suppose the pulley in Fig. 4–50 is suspended by a cord C. Determine the tension in this cord after the masses are released and before one hits the ground. Ignore the mass of the pulley and cords.

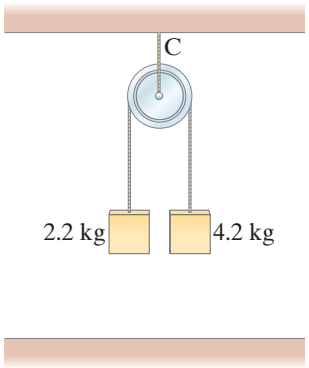

**FIGURE 4–50** Problem 58.

**59.** (III) Suppose two boxes on a frictionless table are connected by a heavy cord of mass 1.0 kg. Calculate the acceleration of each box and the tension at each end of the cord, using the free-body diagrams shown in Fig. 4–51. Assume $F_P = 40.0\,\text{N}$, and ignore sagging of the cord. Compare your results to Example 4–12 and Fig. 4–22.

**60.** (III) Three blocks on a frictionless horizontal surface are in contact with each other as shown in Fig. 4–52. A force $\vec{\mathbf{F}}$ is applied to block A (mass $m_A$). (*a*) Draw a free-body diagram for each block. Determine (*b*) the acceleration of the system (in terms of $m_A$, $m_B$, and $m_C$), (*c*) the net force on each block, and (*d*) the force of contact that each block exerts on its neighbor. (*e*) If $m_A = m_B = m_C = 10.0\,\text{kg}$ and $F = 96.0\,\text{N}$, give numerical answers to (*b*), (*c*), and (*d*). Explain how your answers make sense intuitively.

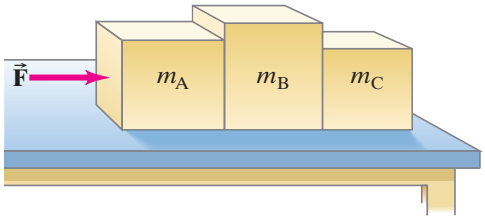

**FIGURE 4–52** Problem 60.

**61.** (III) A 2.5-kg block is placed on a frictionless table. The block is connected by massless ropes over massless pulleys to a 5.0-kg block on the right, and a 3.0-kg block on the left, as shown in Fig. 4–53. Find the acceleration of the block on the table.

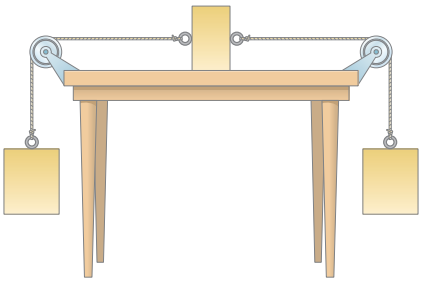

**FIGURE 4–53** Problem 61.

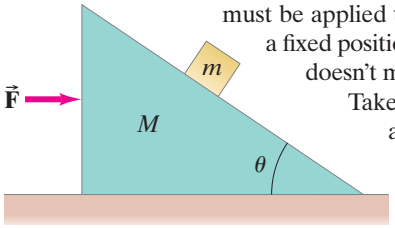
**62.** (III) A small block of mass $m$ rests on the sloping side of a triangular block of mass $M$ which itself rests on a horizontal table as shown in Fig. 4–54. Assuming all surfaces are frictionless, determine the magnitude of the force $\vec{\mathbf{F}}$ that must be applied to $M$ so that $m$ remains in a fixed position relative to $M$ (that is, $m$ doesn't move on the incline). [*Hint*: Take $x$ and $y$ axes horizontal and vertical.]



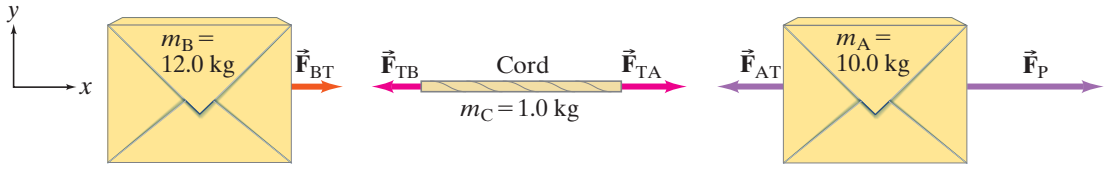


**FIGURE 4–54** Problem 62.

**FIGURE 4–51** Problem 59. Free-body diagrams for each of the objects of the system shown in Fig. 4–22a. Vertical forces, $\vec{\mathbf{F}}_N$ and $\vec{\mathbf{F}}_G$, are not shown.

(a) (b) (c)

**63.** (III) The double Atwood machine shown in Fig. 4–55 has frictionless, massless pulleys and cords. Determine (*a*) the acceleration of masses $m_A$, $m_B$, and $m_C$, and (*b*) the tensions $F_{TA}$ and $F_{TC}$ in the cords.

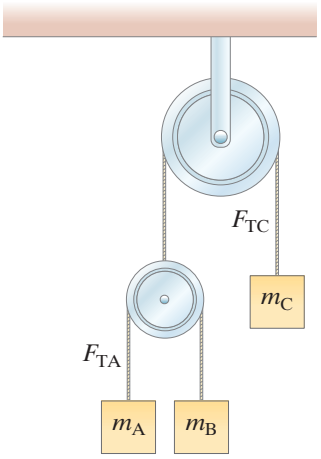

**FIGURE 4–55** Problem 63.

**64.** (III) Determine a formula for the magnitude of the force $\vec{\mathbf{F}}$ exerted on the large block $(m_C)$ in Fig. 4–56 so that the mass $m_A$ does not move relative to $m_C$. Ignore all friction. Assume $m_B$ does not make contact with $m_C$.

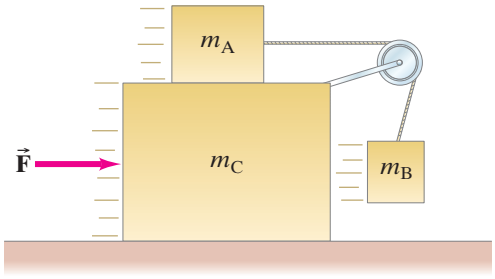

**FIGURE 4–56** Problem 64.

**65.** (III) The two masses shown in Fig. 4–57 are each initially 1.8 m above the ground, and the massless frictionless pulley is 4.8 m above the ground. What maximum height does the lighter object reach after the system is released? [*Hint*: First determine the acceleration of the lighter mass and then its velocity at the moment the heavier one hits the ground. This is its "launch" speed. Assume the mass doesn't hit the pulley or the ceiling. Ignore the mass of the cord.]

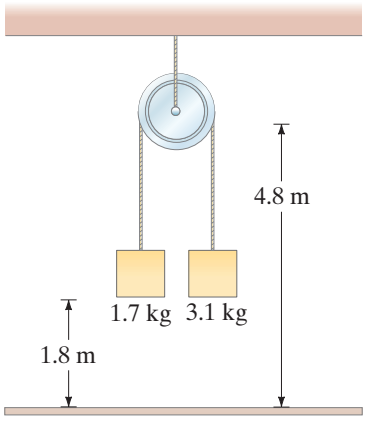

**FIGURE 4–57** Problem 65.

**66.** (III) A particle of mass $m$, initially at rest at $x = 0$, is accelerated by a force that increases in time as $F = Ct^2$. Determine its velocity $v$ and position $x$ as a function of time.

# General Problems

**67.** A crane's trolley at point P in Fig. 4–58 moves for a few seconds to the right with constant acceleration, and the 780-kg load hangs on a light cable at a 5.0° angle to the vertical as shown. What is the acceleration of the trolley and load?

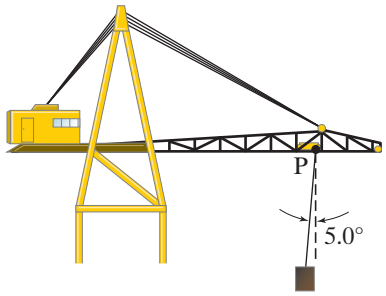

**FIGURE 4–58** Problem 67.

**68.** A 75.0-kg person stands on a scale in an elevator. What does the scale read (in N and in kg) when (*a*) the elevator is at rest, (*b*) the elevator is climbing at a constant speed of 2.0 m/s, (*c*) the elevator is descending at 2.0 m/s, (*d*) the elevator is accelerating upward at 2.0 m/s$^2$, (*e*) the elevator is accelerating downward at 2.0 m/s$^2$?

**69.** A *city planner* is working on the redesign of a hilly portion of a city. An important consideration is how steep the roads can be so that even low-powered cars can get up the hills without slowing down. A particular small car, with a mass of 920 kg, can accelerate on a level road from rest to 21 m/s (75 km/h) in 14.5 s. Using these data, calculate the maximum steepness of a hill.

**70.** If a bicyclist of mass 65 kg (including the *bicycle*) can coast down a 6.5° hill at a steady speed of 6.0 km/h because of air resistance, how much force must be applied to climb the hill at the same speed (and the same air resistance)?

**71.** Tom's *hang glider* supports his weight using the six ropes shown in Fig. 4–59. Each rope is designed to support an equal fraction of Tom's weight. Tom's mass is 78.0 kg. What is the tension in each of the support ropes?

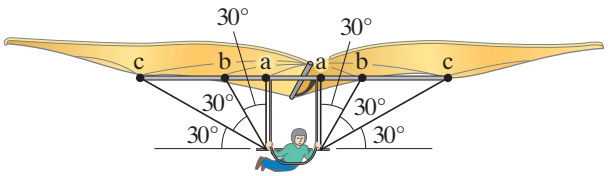

**FIGURE 4–59** Problem 71.

**72.** A wet bar of soap $(m = 150\,\text{g})$ slides freely down a ramp 3.0 m long inclined at 8.5°. How long does it take to reach the bottom? How would this change if the soap's mass were 250 g?

**73.** A parent pulls his child in a wagon across a floor. The child and wagon have a combined mass of 35 kg. The wagon handle is inclined at 55° to the horizontal, and the child and wagon (whose wheels are nearly frictionless) are accelerating at 0.42 m/s$^2$. With what force is the parent pulling on the wagon handle?

**74.** Two equal masses in contact on a frictionless surface are acted on by the forces $F_1$ and $F_2$ as shown in Fig. 4–60. Determine the magnitude of the contact force exerted on each mass by the other when (*a*) $F_2 = F_1$; (*b*) $F_2 = \frac{1}{2}F_1$; (*c*) $F_2 = 0$. Express your answer in terms of $m$ and $F_1$.

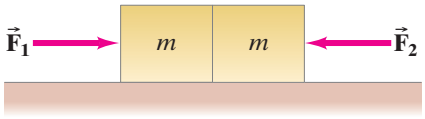

**FIGURE 4–60** Problem 74.

**75.** Andrea dangles her watch from a thin piece of string while the jetliner she is in accelerates for takeoff, which takes about 21 s. Estimate the takeoff speed of the aircraft if the string makes an angle of 24° with respect to the vertical, Fig. 4–61.

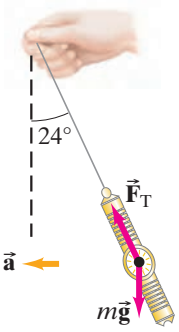

**FIGURE 4–61**
Problem 75.

**76.** A block (mass $m_A$) lying on a fixed frictionless inclined plane is connected to a mass $m_B$ by a cord passing over a pulley, as shown in Fig. 4–62. (*a*) Determine a formula for the acceleration of the system in terms of $m_A$, $m_B$, $\theta$, and $g$. (*b*) What conditions apply to masses $m_A$ and $m_B$ for the acceleration to be in one direction (say, $m_A$ down the plane), or in the opposite direction? Ignore the mass of the cord and pulley.

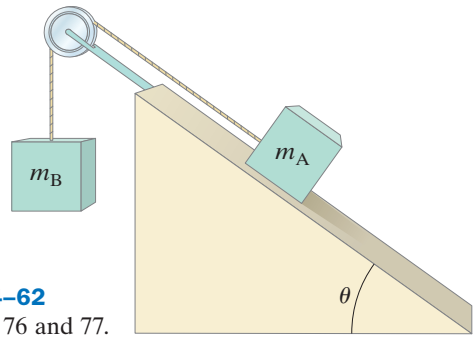

**FIGURE 4–62**
Problems 76 and 77.

**77.** (*a*) In Fig. 4–62, if $m_A = m_B = 1.00\,\text{kg}$ and $\theta = 38.0°$, what will be the acceleration of the system? (*b*) If $m_A = 1.00\,\text{kg}$ and the system remains at rest, what must the mass $m_B$ be? (*c*) Calculate the tension in the cord for (*a*) and (*b*).

**78.** The masses $m_A$ and $m_B$ slide on the smooth (frictionless) inclines fixed as shown in Fig. 4–63. (*a*) Determine a formula for the acceleration of the system in terms of $m_A$, $m_B$, $\theta_A$, $\theta_B$, and $g$. (*b*) If $\theta_A = 34°$, $\theta_B = 21°$, and $m_A = 5.0\,\text{kg}$, what value of $m_B$ would keep the system at rest? What would be the tension in the cord (negligible mass) in this case? (*c*) What ratio, $m_A/m_B$, would allow the masses to move at constant speed along their ramps in either direction?

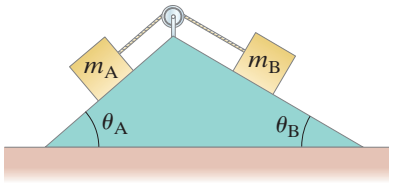

**FIGURE 4–63**
Problem 78.

**79.** (*a*) What minimum force $F$ is needed to lift a piano (mass $M$) using the pulley apparatus shown in Fig. 4–64? (*b*) Determine the tension in each section of rope: $F_{T1}$, $F_{T2}$, $F_{T3}$, and $F_{T4}$. Assume pulleys are massless and frictionless, and that ropes are massless.

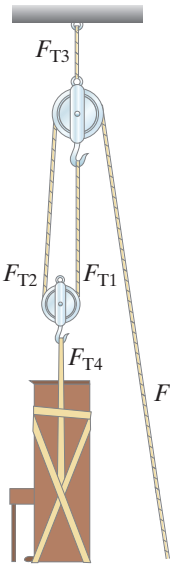

**FIGURE 4–64**
Problem 79.

**80.** In the *design of a supermarket*, there are to be several ramps connecting different parts of the store. Customers will have to push grocery carts up the ramps and it is desirable that this not be too difficult. The engineer has done a survey and found that almost no one complains if the force required is no more than 23 N. Ignoring friction, at what maximum angle $\theta$ should the ramps be built, assuming a full 25-kg cart?

**81.** A jet aircraft is accelerating at $3.8\,\text{m/s}^2$ as it climbs at an angle of 18° above the horizontal (Fig. 4–65). What is the total force that the cockpit seat exerts on the 75-kg pilot?

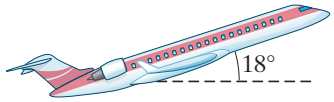

**FIGURE 4–65** Problem 81.

**82.** A 6750-kg helicopter accelerates upward at $0.80\,\text{m/s}^2$ while lifting a 1080-kg frame at a construction site, Fig. 4–66. (*a*) What is the lift force exerted by the air on the helicopter rotors? (*b*) What is the tension in the cable (ignore its mass) which connects the frame to the helicopter? (*c*) What force does the cable exert on the helicopter?

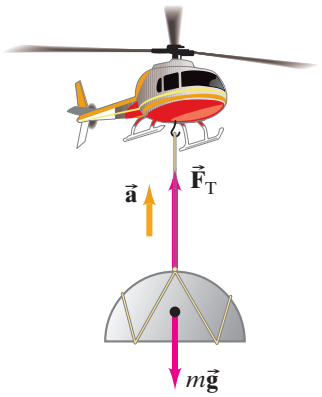

**FIGURE 4–66** Problem 82.

**83.** An elevator in a tall building is allowed to reach a maximum speed of 3.5 m/s going down. What must the tension be in the cable to stop this elevator over a distance of 2.6 m if the elevator has a mass of 1650 kg including occupants?

**84.** A fisherman in a boat is using a "10-lb test" fishing line. This means that the line can exert a force of 45 N without breaking (1 lb = 4.45 N). (*a*) How heavy a fish can the fisherman land if he pulls the fish up vertically at constant speed? (*b*) If he accelerates the fish upward at 2.0 m/s$^2$, what maximum weight fish can he land? (*c*) Is it possible to land a 15-lb trout on 10-lb test line? Why or why not?

**85.** A "doomsday" *asteroid* with a mass of $2.0 \times 10^{10}$ kg is hurtling through space. Unless the asteroid's speed is changed by about 0.20 cm/s, it will collide with Earth and cause tremendous damage. Researchers suggest that a small "space tug" sent to the asteroid's surface could exert a gentle constant force of 2.5 N. For how long must this force act?

**86.** Three mountain climbers who are roped together in a line are ascending an icefield inclined at 29° to the horizontal (Fig. 4–67). The last climber slips, pulling the second climber off his feet. The first climber is able to hold them both. If each climber has a mass of 75 kg, calculate the tension in each of the two sections of rope between the three climbers. Ignore friction between the ice and the fallen climbers.

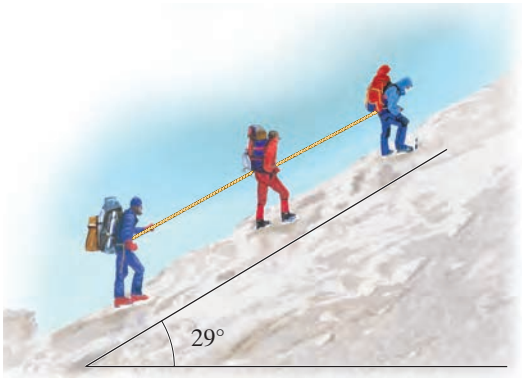

**FIGURE 4–67** Problem 86.

**87.** A *bicyclist* can coast down a 5.0° hill at a constant speed of 6.0 km/h. If the force of air resistance is proportional to the speed $v$ so that $F_{air} = cv$, calculate (*a*) the value of the constant $c$, and (*b*) the average force that must be applied (by the rider) in order to descend the hill at 18.0 km/h. The mass of the cyclist plus bicycle is 72.0 kg.

**88.** Consider the system shown in Fig. 4–68 with $m_A = 8.2$ kg and $m_B = 11.5$ kg. The angles $\theta_A = 59°$ and $\theta_B = 32°$. (*a*) In the absence of friction, what force $\vec{\mathbf{F}}$ would be required to pull the masses at a constant velocity up the fixed inclines? (*b*) The force $\vec{\mathbf{F}}$ is now removed. What are the magnitude and direction of the acceleration of the two blocks? (*c*) In the absence of $\vec{\mathbf{F}}$, what is the tension in the string?

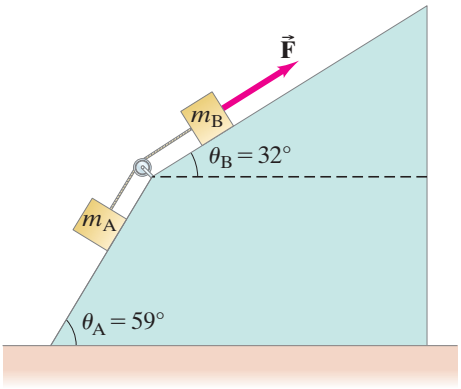

**FIGURE 4–68**
Problem 88.

**89.** A car starts rolling down a 1-in-4 hill (1-in-4 means that for each 4 m traveled along the sloping road, the elevation change is 1 m). How fast is it going when it reaches the bottom after traveling 55 m? Ignore friction.

**90.** An 18-kg child is riding in a child-restraint chair, securely fastened to the seat of a car (Fig. 4–69). Assume the car has speed 45 km/h when it hits a tree and is brought to rest in 0.20 s. Assuming constant deceleration during the collision, estimate the net horizontal force $F$ that the straps of the restraint chair exert on the child to hold her in the chair.

**FIGURE 4–69** Problem 90.

**91.** A 1.5-kg block rests on top of a 7.5-kg block (Fig. 4–70). The cord and pulley have negligible mass, and there is no significant friction anywhere. (*a*) What force $F$ must be applied to the bottom block so the top block accelerates to the right at 2.2 m/s$^2$? (*b*) What is the tension in the connecting cord?

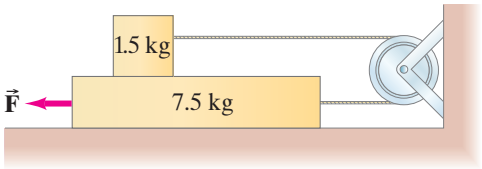

**FIGURE 4–70** Problem 91.

**92.** You are driving home in your 860-kg car at 15 m/s. At a point 45 m from the beginning of an intersection, you see a green traffic light change to yellow, which you expect will last 4.0 s, and the distance to the far side of the intersection is 65 m (Fig. 4–71). (*a*) If you choose to accelerate, your car's engine will furnish a forward force of 1200 N. Will you make it completely through the intersection before the light turns red? (*b*) If you decide to panic stop, your brakes will provide a force of 2300 N. Will you stop before entering the intersection? Assume your car is 4 m long.

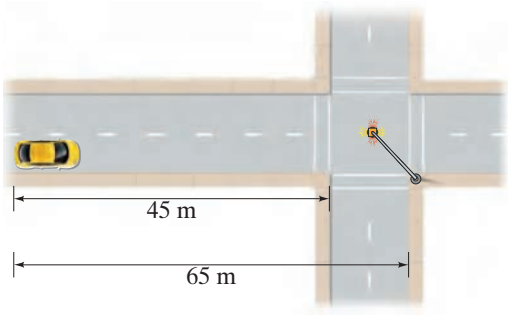

**FIGURE 4–71** Problem 92.

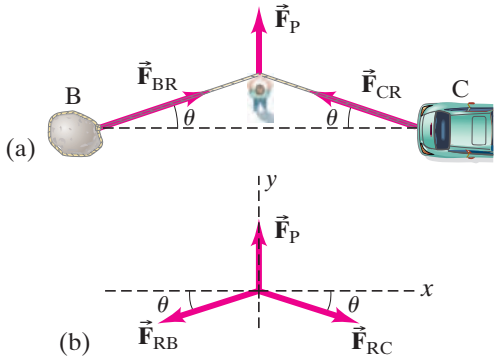
**93.** A person jumps from a height of 5.0 m into a swimming pool entering feet first with her hands at her sides. She maintains this position upon entering the water and experiences a constant upward force equal to 350% of her weight due to the water itself. How far down does she go?

**94.** Two rock climbers, Paul and Jeanne, use safety ropes of similar length. Jeanne's rope is more elastic, called a *dynamic rope* by climbers. Paul has a *static rope*, not recommended for safety reasons. (*a*) Jeanne (Fig. 4–72) falls freely about 2.0 m and then the rope stops her over a distance of 1.0 m. Estimate how large a force (assume constant) she will feel from the rope. (Express the result in multiples of her weight.) (*b*) In a similar fall, Paul's rope stretches by only 30 cm. How many times his weight will the rope pull on him? Which climber is more likely to be hurt?

**FIGURE 4–72**
Problem 94.

**95.** (*a*) Finding her car stuck in the mud, a bright graduate of a good physics course ties a strong rope to the back bumper of the car, and the other end to a boulder, as shown in Fig. 4–73a. She pushes at the midpoint of the rope with her maximum effort, which she estimates to be a force $F_P \approx 300$ N. The car just begins to budge with the rope at an angle $\theta$, which she estimates to be 5°. With what force is the rope pulling on the car? Neglect the mass of the rope. (*b*) What is the "mechanical advantage" of this technique (see Example 4–14)? (*c*) At what angle $\theta$ would this technique become counterproductive? [*Hint*: Consider the forces on a small segment of rope where $\vec{\mathbf{F}}_P$ acts, Fig. 4–73b.]



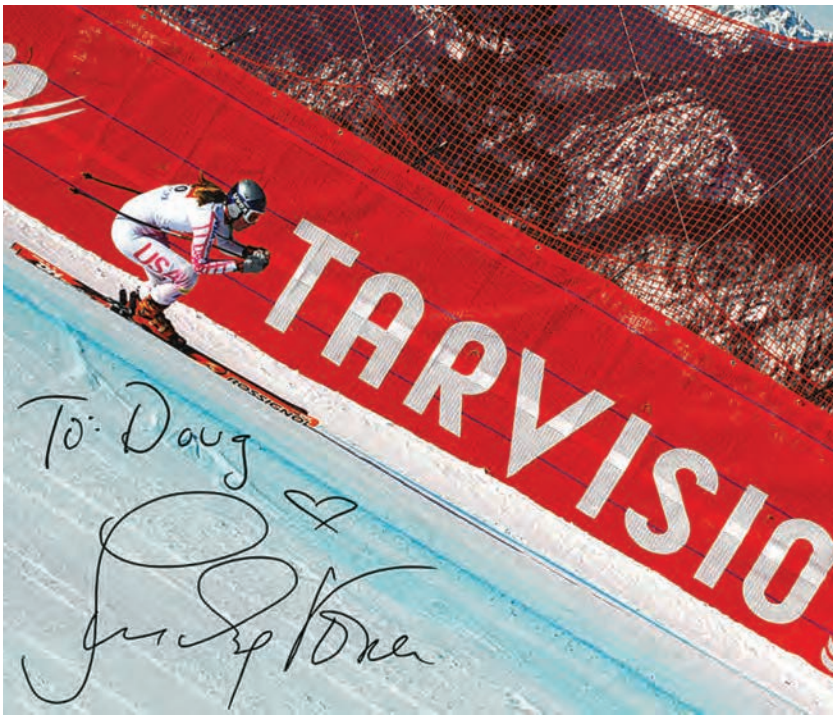


**FIGURE 4–73** Problem 95. (a) Getting a car out of the mud, showing the forces on the boulder, on the car, and exerted by the person. (b) The free-body diagram: forces on a small segment of rope.

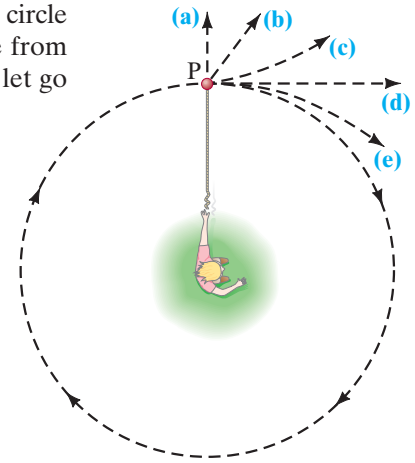
## ANSWERS TO EXERCISES

**A:** No force is needed. The car accelerates out from under the cup, which tends to remain at rest as seen from the reference frame of the street. Think of Newton's first law (see Example 4–1).
**B:** (i) The same; (ii) the tennis ball; (iii) Newton's third law for part (i), second law for part (ii).
**C:** (*b*).
**D:** (*a*).
**E:** (*b*).
**F:** 58.0 N.
**G:** (*b*).
**H:** Yes; no.

Newton's laws are fundamental in physics. These photos show two situations of using Newton's laws which involve some new elements in addition to those discussed in the previous Chapter. The downhill skier illustrates *friction* on an incline; she is also retarded by air resistance, a velocity-dependent force.

The people on the rotating amusement park ride below illustrate the dynamics of circular motion.

CHAPTER 5



# Using Newton's Laws: Friction, Circular Motion, Drag Forces

## CONTENTS

5–1 Using Newton's Laws with Friction
5–2 Uniform Circular Motion—Kinematics
5–3 Dynamics of Uniform Circular Motion
5–4 Highway Curves: Banked and Unbanked
5–5 Nonuniform Circular Motion
*5–6 Velocity-Dependent Forces: Drag and Terminal Velocity

**CHAPTER-OPENING QUESTION—Guess now!**

You revolve a ball around you in a horizontal circle at constant speed on a string, as shown here from above. Which path will the ball follow if you let go of the string when the ball is at point P?

This chapter continues our study of Newton's laws and emphasizes their fundamental importance in physics. We will see how to apply Newton's laws to understand important situations including friction, and in circular motion, as well as with drag forces which are velocity-dependent (an optional-advanced Section).

# 5–1 Using Newton's Laws with Friction

Until now we have mostly ignored friction, but it must be taken into account in most practical situations. Friction exists between two solid surfaces because even the smoothest looking surface is quite rough on a microscopic scale, Fig. 5–1. When we try to slide an object across a surface, these microscopic bumps impede the motion. Exactly what is happening at the microscopic level is not fully understood. One possibility is that the atoms on a bump of one surface may come so close to the atoms of the other surface that the atoms form a sort of "bond" or brief tiny weld between the two surfaces. Sliding an object across a surface is often jerky, perhaps due to the making and breaking of these bonds.

Even when a round object rolls across a surface, there is still some friction, called *rolling friction*, although it is generally much less than when an object slides across a surface.

We focus our attention now on sliding friction, which is usually called **kinetic friction** (*kinetic* is from the Greek for "moving"). When an object slides along a rough surface, the force of kinetic friction acts opposite to the direction of the object's velocity. The magnitude of the force of kinetic friction depends on the nature of the two sliding surfaces. For given surfaces, experiments show that the friction force is approximately proportional to the *normal force* between the two surfaces, which is the force that either object exerts on the other and is perpendicular to their common surface of contact (see Fig. 5–2). The force of friction in many cases depends very little on the total surface area of contact; that is, the friction force on a book is roughly the same whether it is being slid across a table on its wide face or on its spine, assuming the surfaces have similar smoothness. We consider a simple model of friction in which we make this assumption that the friction force is independent of area. Then we write the proportionality between the magnitudes of the friction force $F_{fr}$ and the normal force $F_N$ as an equation by inserting a constant of proportionality, $\mu_k$:

$$F_{fr} = \mu_k F_N. \qquad \text{[kinetic friction]}$$

This relation is not a fundamental law. It is an experimental relation between the magnitude of the friction force $F_{fr}$, which acts parallel to the two surfaces, and the magnitude of the normal force $F_N$, which acts perpendicular to the surfaces. It is *not* a vector equation since the two forces have different directions, perpendicular to one another. The term $\mu_k$ is called the *coefficient of kinetic friction*, and its value depends on the roughness of the two surfaces. Measured values for a variety of surfaces are given in Table 5–1. These are only approximate, however, since $\mu$ depends on whether the surfaces are wet or dry, on how much they have been sanded or rubbed, if any burrs remain, and other such factors. But $\mu_k$ (which has no units) is roughly independent of the sliding speed, as well as the area in contact.

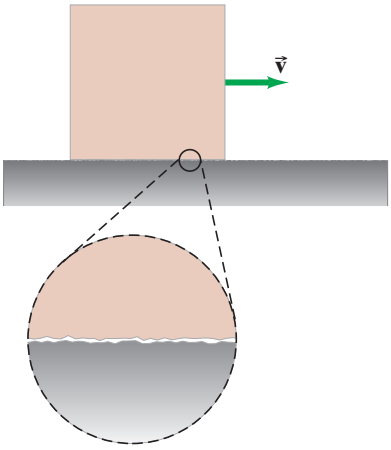


**FIGURE 5–1** An object moving to the right on a table or floor. The two surfaces in contact are rough, at least on a microscopic scale.

**FIGURE 5–2** When an object is pulled along a surface by an applied force $(\vec{\mathbf{F}}_A)$, the force of friction $\vec{\mathbf{F}}_{fr}$ opposes the motion. The magnitude of $\vec{\mathbf{F}}_{fr}$ is proportional to the magnitude of the normal force $(F_N)$.

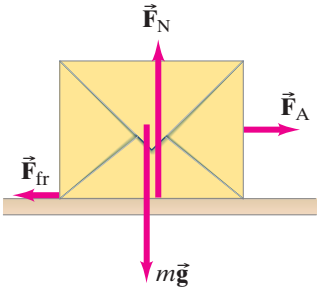

**TABLE 5–1 Coefficients of Friction†**

| Surfaces | Coefficient of Kinetic Friction, $\mu_k$ | Coefficient of Static Friction, $\mu_s$ |
|---|---|---|
| Wood on wood | 0.2 | 0.4 |
| Ice on ice | 0.03 | $\lesssim$0.1 |
| Metal on metal (lubricated) | 0.07 | 0.1 |
| Steel on steel (unlubricated) | 0.6 | 0.7 |
| Rubber on dry concrete | 0.8 | 0.8 |
| Rubber on wet concrete | 0.5 | 0.7 |
| Rubber on other solid surfaces | 1 | 1–4 |
| Teflon® on Teflon in air | 0.04 | 0.04 |
| Teflon on steel in air | 0.04 | 0.04 |
| Lubricated ball bearings | <0.01 | <0.01 |
| Synovial joints (in human limbs) | <0.01 | <0.01 |

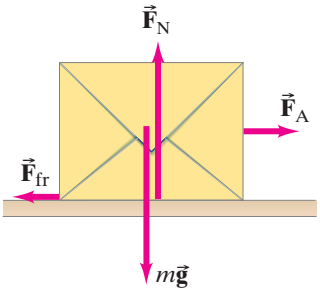
†Values are approximate and intended only as a guide.

What we have been discussing up to now is *kinetic friction*, when one object slides over another. There is also **static friction**, which refers to a force parallel to the two surfaces that can arise even when they are not moving. Suppose an object such as a desk is resting on a horizontal floor. If no horizontal force is exerted on the desk, there also is no friction force. But now suppose you try to push the desk, and it doesn't move. You are exerting a horizontal force, but the desk isn't moving, so there must be another force on the desk, in the opposite direction, keeping it from moving (the net force is zero on an object at rest). This is the force of *static friction* exerted by the floor on the desk. If you push with a greater force without moving the desk, the force of static friction in the opposite direction also has increased. If you push hard enough, the desk will eventually start to move, and kinetic friction takes over. At this point, you have exceeded the maximum force of static friction, which is given by $(F_{fr})_{max} = \mu_s F_N$, where $\mu_s$ is the *coefficient of static friction* (Table 5–1). Because the force of static friction can vary from zero to this maximum value, we write

$$F_{fr} \leq \mu_s F_N. \qquad \text{[static friction]}$$

You may have noticed that it is often easier to keep a heavy object sliding than it is to start it sliding in the first place. This is consistent with $\mu_s$ generally being greater than $\mu_k$ (see Table 5–1).

It seems that this simple relation for friction, $F_{fr} \leq \mu F_N$, was first established by the great "Renaissance man" Leonardo da Vinci (1452–1519).



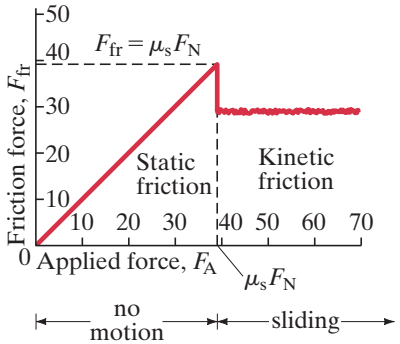


**FIGURE 5–2** Repeated for Example 5-1.

**FIGURE 5–3** Example 5–1. Magnitude of the force of friction as a function of the external force applied to an object initially at rest. As the applied force is increased in magnitude, the force of static friction increases in proportion until the applied force equals $\mu_s F_N$. If the applied force increases further, the object will begin to move, and the friction force drops to a roughly constant value characteristic of kinetic friction.

**EXAMPLE 5–1** **Friction: static and kinetic.** A 10.0-kg box rests on a horizontal floor. The coefficient of static friction is $\mu_s = 0.40$ and the coefficient of kinetic friction is $\mu_k = 0.30$. Determine the force of friction, $F_{fr}$, acting on the box if a horizontal external applied force $F_A$ is exerted on it of magnitude: (*a*) 0, (*b*) 10 N, (*c*) 20 N, (*d*) 38 N, and (*e*) 40 N.

**APPROACH** We don't know, right off, if we are dealing with static friction or kinetic friction, nor if the box remains at rest or accelerates. We need to draw a free-body diagram, and then determine in each case whether or not the box will move: the box starts moving if $F_A$ is greater than the maximum static friction force. The forces on the box are shown in Fig. 5–2: gravity $m\vec{\mathbf{g}}$; the normal force exerted upward by the floor $\vec{\mathbf{F}}_N$; the horizontal applied force $\vec{\mathbf{F}}_A$; and the friction force $\vec{\mathbf{F}}_{fr}$.

**SOLUTION** The free-body diagram of the box is shown in Fig. 5–2. In the vertical direction there is no motion, so Newton's second law in the vertical direction gives $\Sigma F_y = ma_y = 0$, which tells us $F_N - mg = 0$. Hence the normal force is

$$F_N = mg = (10.0\,\text{kg})(9.80\,\text{m/s}^2) = 98.0\,\text{N}.$$

(*a*) Because $F_A = 0$ in this first case, the box doesn't move, and $F_{fr} = 0$.

(*b*) The force of static friction will oppose any applied force up to a maximum of

$$\mu_s F_N = (0.40)(98.0\,\text{N}) = 39\,\text{N}.$$

When the applied force is $F_A = 10\,\text{N}$, the box will not move. Newton's second law gives $\Sigma F_x = F_A - F_{fr} = 0$, so $F_{fr} = 10\,\text{N}$.

(*c*) An applied force of 20 N is also not sufficient to move the box. Thus $F_{fr} = 20\,\text{N}$ to balance the applied force.

(*d*) The applied force of 38 N is still not quite large enough to move the box. So the friction force has now increased to 38 N to keep the box at rest.

(*e*) A force of 40 N will start the box moving since it exceeds the maximum force of static friction, $\mu_s F_N = (0.40)(98\,\text{N}) = 39\,\text{N}$. Instead of static friction, we now have kinetic friction, and its magnitude is

$$F_{fr} = \mu_k F_N = (0.30)(98.0\,\text{N}) = 29\,\text{N}.$$

There is now a net (horizontal) force on the box of magnitude $F = 40\,\text{N} - 29\,\text{N} = 11\,\text{N}$, so the box will accelerate at a rate

$$a_x = \frac{\Sigma F}{m} = \frac{11\,\text{N}}{10.0\,\text{kg}} = 1.1\,\text{m/s}^2$$

as long as the applied force is 40 N.

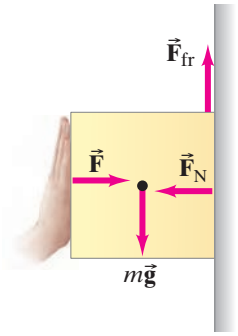
**NOTE** Figure 5–3 shows a graph that summarizes this Example.

Friction can be a hindrance. It slows down moving objects and causes heating and binding of moving parts in machinery. Friction can be reduced by using lubricants such as oil. More effective in reducing friction between two surfaces is to maintain a layer of air or other gas between them. Devices using this concept, which is not practical for most situations, include air tracks and air tables in which the layer of air is maintained by forcing air through many tiny holes. Another technique to maintain the air layer is to suspend objects in air using magnetic fields ("magnetic levitation").

On the other hand, friction can be helpful. Our ability to walk (see Fig. 4–11) depends on friction between the soles of our shoes (or feet) and the ground. Walking involves static friction, not kinetic friction. The movement of a car, and also its stability, depend on friction. When friction is low, such as on ice, safe walking or driving becomes difficult.

**CONCEPTUAL EXAMPLE 5–2** **A box against a wall.** You can hold a box against a rough wall (Fig. 5–4) and prevent it from slipping down by pressing hard horizontally. How does the application of a horizontal force keep an object from moving vertically?

**RESPONSE** This won't work well if the wall is slippery. You need friction. Even then, if you don't press hard enough, the box will slip. The horizontal force you apply produces a normal force on the box exerted by the wall (net force horizontally is zero since box doesn't move horizontally.) The force of gravity $mg$, acting downward on the box, can now be balanced by an upward static friction force whose maximum magnitude is proportional to the normal force. The harder you push, the greater $F_N$ is and the greater $F_{fr}$ can be. If you don't press hard enough, then $mg > \mu_s F_N$ and the box begins to slide down.



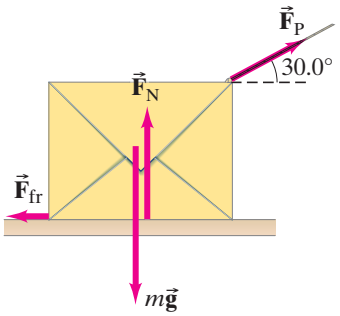


**FIGURE 5–4** Example 5–2.

**EXERCISE A** If $\mu_s = 0.40$ and $mg = 20\,\text{N}$, what minimum force $F$ will keep the box from falling: (*a*) 100 N; (*b*) 80 N; (*c*) 50 N; (*d*) 20 N; (*e*) 8 N?

**EXAMPLE 5–3** **Pulling against friction.** A 10.0-kg box is being pulled along a horizontal surface by a force $F_P$ of 40.0 N applied at a 30.0° angle above horizontal. This is like Example 4–11 except now there is friction, and we assume a coefficient of kinetic friction of 0.30. Calculate the acceleration.

**APPROACH** The free-body diagram is shown in Fig. 5–5. It is much like that in Fig. 4–21, but with one more force, that of friction.

**FIGURE 5–5** Example 5–3.

**SOLUTION** The calculation for the vertical ($y$) direction is just the same as in Example 4–11, $mg = (10.0\,\text{kg})(9.80\,\text{m/s}^2) = 98.0\,\text{N}$ and $F_{Py} = (40.0\,\text{N})(\sin 30.0°) = 20.0\,\text{N}$. With $y$ positive upward and $a_y = 0$, we have

$$F_N - mg + F_{Py} = ma_y$$
$$F_N - 98.0\,\text{N} + 20.0\,\text{N} = 0,$$

so the normal force is $F_N = 78.0\,\text{N}$. Now we apply Newton's second law for the horizontal ($x$) direction (positive to the right), and include the friction force:

$$F_{Px} - F_{fr} = ma_x.$$

The friction force is kinetic as long as $F_{fr} = \mu_k F_N$ is less than $F_{Px} = (40.0\,\text{N})\cos 30.0° = 34.6\,\text{N}$, which it is:

$$F_{fr} = \mu_k F_N = (0.30)(78.0\,\text{N}) = 23.4\,\text{N}.$$

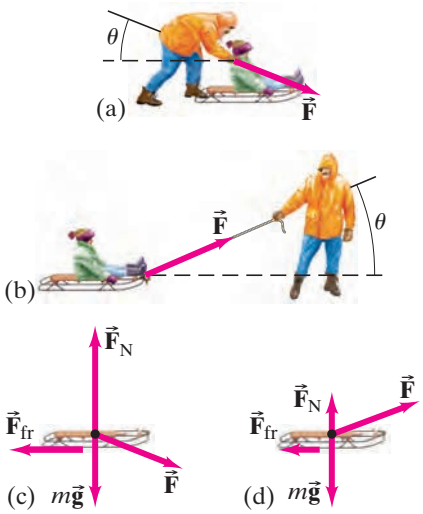
Hence the box does accelerate:

$$a_x = \frac{F_{Px} - F_{fr}}{m} = \frac{34.6\,\text{N} - 23.4\,\text{N}}{10.0\,\text{kg}} = 1.1\,\text{m/s}^2.$$

In the absence of friction, as we saw in Example 4–11, the acceleration would be much greater than this.

**NOTE** Our final answer has only two significant figures because our least significant input value $(\mu_k = 0.30)$ has two.

**EXERCISE B** If $\mu_k F_N$ were greater than $F_{Px}$, what would you conclude?



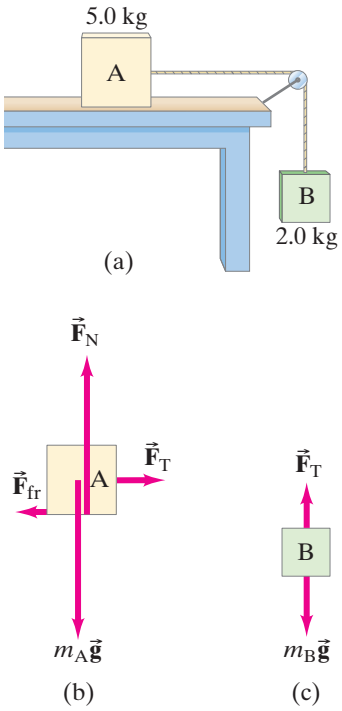


**FIGURE 5–6** Example 5–4.

**FIGURE 5–7** Example 5–5.

**CONCEPTUAL EXAMPLE 5–4** **To push or to pull a sled?** Your little sister wants a ride on her sled. If you are on flat snow, will you exert less force if you push her or pull her? See Figs. 5–6a and b. Assume the same angle $\theta$ in each case.

**RESPONSE** Let us draw free-body diagrams for the sled–sister combination, as shown in Figs. 5–6c and d. They show, for the two cases: the force exerted by you, $\vec{\mathbf{F}}$ (an unknown); by the snow, $\vec{\mathbf{F}}_N$ and $\vec{\mathbf{F}}_{fr}$; and gravity $m\vec{\mathbf{g}}$. (*a*) If you push her, and $\theta > 0$, there is a vertically downward component to your force. Hence the upward normal force exerted by the ground (Fig. 5–6c) will be larger than $mg$ (where $m$ is the mass of sister plus sled). (*b*) If you pull her, your force has a vertically upward component, so the normal force $F_N$ will be less than $mg$, Fig. 5–6d. Because the friction force is proportional to the normal force, $F_{fr}$ will be less if you pull her. So you can exert less force if you pull her.

**EXAMPLE 5–5** **Two boxes and a pulley.** In Fig. 5–7a, two boxes are connected by a cord running over a pulley. The coefficient of kinetic friction between box A and the table is 0.20. We ignore the mass of the cord and pulley and any friction in the pulley, which means we can assume that a force applied to one end of the cord will have the same magnitude at the other end. We wish to find the acceleration of the system, $a$, which will have the same magnitude for both boxes assuming the cord doesn't stretch. As box B moves down, box A moves to the right.

**APPROACH** The free-body diagrams for each box are shown in Figs. 5–7b and c. The forces on box A are the pulling force of the cord $F_T$, gravity $m_A g$, the normal force exerted by the table $F_N$, and a friction force exerted by the table $F_{fr}$. The forces on box B are gravity $m_B g$, and the cord pulling up, $F_T$.

**SOLUTION** Box A does not move vertically, so Newton's second law tells us the normal force just balances the weight,

$$F_N = m_A g = (5.0\,\text{kg})(9.8\,\text{m/s}^2) = 49\,\text{N}.$$

In the horizontal direction, there are two forces on box A (Fig. 5–7b): $F_T$, the tension in the cord (whose value we don't know), and the force of friction

$$F_{fr} = \mu_k F_N = (0.20)(49\,\text{N}) = 9.8\,\text{N}.$$

The horizontal acceleration of box A is what we wish to find; we use Newton's second law in the $x$ direction, $\Sigma F_{Ax} = m_A a_x$, which becomes (taking the positive direction to the right and setting $a_{Ax} = a$):

$$\Sigma F_{Ax} = F_T - F_{fr} = m_A a. \qquad \text{[box A]}$$

Next consider box B. The force of gravity $m_B g = (2.0\,\text{kg})(9.8\,\text{m/s}^2) = 19.6\,\text{N}$ pulls downward; and the cord pulls upward with a force $F_T$. So we can write Newton's second law for box B (taking the downward direction as positive):

$$\Sigma F_{By} = m_B g - F_T = m_B a. \qquad \text{[box B]}$$

[Notice that if $a \neq 0$, then $F_T$ is not equal to $m_B g$.]

We have two unknowns, $a$ and $F_T$, and we also have two equations. We solve the box A equation for $F_T$:

$$F_T = F_{fr} + m_A a,$$

and substitute this into the box B equation:

$$m_B g - F_{fr} - m_A a = m_B a.$$

Now we solve for $a$ and put in numerical values:

$$a = \frac{m_B g - F_{fr}}{m_A + m_B} = \frac{19.6\,\text{N} - 9.8\,\text{N}}{5.0\,\text{kg} + 2.0\,\text{kg}} = 1.4\,\text{m/s}^2,$$

which is the acceleration of box A to the right, and of box B down.

If we wish, we can calculate $F_T$ using the third equation up from here:

$$F_T = F_{fr} + m_A a = 9.8\,\text{N} + (5.0\,\text{kg})(1.4\,\text{m/s}^2) = 17\,\text{N}.$$

**NOTE** Box B is not in free fall. It does not fall at $a = g$ because an additional force, $F_T$, is acting upward on it.

In Chapter 4 we examined motion on ramps and inclines, and saw that it is usually an advantage to choose the $x$ axis along the plane, in the direction of acceleration. There we ignored friction, but now we take it into account.

**EXAMPLE 5–6** **The skier.** The skier in Fig. 5–8a descends a 30° slope. If the coefficient of kinetic friction is 0.10, what is her acceleration when she is in contact with the snow?

**APPROACH** We choose the $x$ axis along the slope, positive downslope in the direction of the skier's motion. The $y$ axis is perpendicular to the surface. The forces acting on the skier (Fig. 5–8b) are gravity, $\vec{\mathbf{F}}_G = m\vec{\mathbf{g}}$, which points vertically downward (*not* perpendicular to the slope), and the two forces exerted on her skis by the snow—the normal force perpendicular to the snowy slope (*not* vertical), and the friction force parallel to the surface. These three forces are shown acting at one point in Fig. 5–8b, which is our free-body diagram for the skier.

**SOLUTION** We have to resolve only one vector into components, the weight $\vec{\mathbf{F}}_G$, and its components are shown as dashed lines in Fig. 5–8c. To be general, we use $\theta$ rather than 30° for now. We use the definitions of sine ("side opposite") and cosine ("side adjacent") to obtain the components:

$$\begin{aligned} F_{Gx} &= mg\sin\theta, \\ F_{Gy} &= -mg\cos\theta \end{aligned}$$

where $F_{Gy}$ is in the negative $y$ direction. To calculate the skier's acceleration down the hill, $a_x$, we apply Newton's second law to the $x$ direction:

$$\begin{aligned} \Sigma F_x &= ma_x \\ mg\sin\theta - \mu_k F_N &= ma_x \end{aligned}$$

where the two forces are the $x$ component of the gravity force ($+x$ direction) and the friction force ($-x$ direction). We want to find the value of $a_x$, but we don't yet know $F_N$ in the last equation. Let's see if we can get $F_N$ from the $y$ component of Newton's second law:

$$\begin{aligned} \Sigma F_y &= ma_y \\ F_N - mg\cos\theta &= ma_y = 0 \end{aligned}$$

where we set $a_y = 0$ because there is no motion in the $y$ direction (perpendicular to the slope) when the skier is in contact with the slope. Thus we can solve for $F_N$:

$$F_N = mg\cos\theta$$

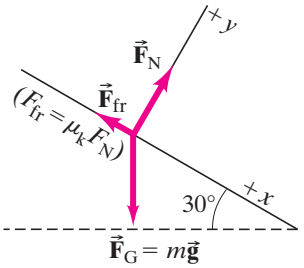
and we can substitute this into our equation above for $ma_x$:

$$mg\sin\theta - \mu_k(mg\cos\theta) = ma_x.$$

There is an $m$ in each term which can be canceled out. Thus (setting $\theta = 30°$ and $\mu_k = 0.10$):

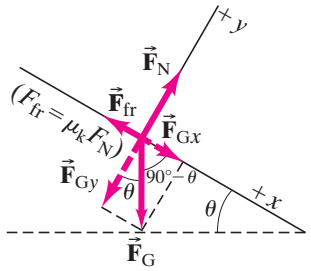
$$\begin{aligned} a_x &= g\sin 30° - \mu_k g\cos 30° \\ &= 0.50g - (0.10)(0.866)g = 0.41g. \end{aligned}$$

The skier's acceleration is 0.41 times the acceleration of gravity, which in numbers† is $a = (0.41)(9.8\,\text{m/s}^2) = 4.0\,\text{m/s}^2$.



**NOTE** The mass canceled out, so we have the useful conclusion that *the acceleration doesn't depend on the mass*. That such a cancellation sometimes occurs, and thus may give a useful conclusion as well as saving calculation, is a big advantage of working with the algebraic equations and putting in the numbers only at the end.

**NOTE** The friction force on high-speed alpine skiers is very small—it seems the heat produced under the skis by friction melts the snow so the skis float on tiny balls of water. Fast skiers are slowed more by air resistance, which they can reduce by going into a tuck to reduce their surface area. When going airborne (as over the top of a hill) they are slowed more (can't hold that tuck, especially when landing) than when in contact with the snow.



**PHYSICS APPLIED**
*Skiing*

(a)

(b)

(c)

**FIGURE 5–8** Example 5–6. A skier descending a slope; $\vec{\mathbf{F}}_G = m\vec{\mathbf{g}}$ is the force of gravity (weight) on the skier.

**PROBLEM SOLVING**
*It is often helpful to put in numbers only at the end*

**PHYSICS APPLIED**
*Skiers are faster on snow than when airborne*

†We used values rounded off to 2 significant figures to obtain $a = 4.0\,\text{m/s}^2$. If we kept all the extra digits in our calculator, we would find $a = 0.4134\,g \approx 4.1\,\text{m/s}^2$. This difference is within the expected precision (number of significant figures, Section 1–3).

**CAUTION**

*Directions of gravity and the normal force*

In problems involving a slope or "inclined plane," avoid making errors in the directions of the normal force and gravity. The normal force is *not* vertical: it is perpendicular to the slope or plane. And gravity is *not* perpendicular to the slope—gravity acts vertically downward toward the center of the Earth.

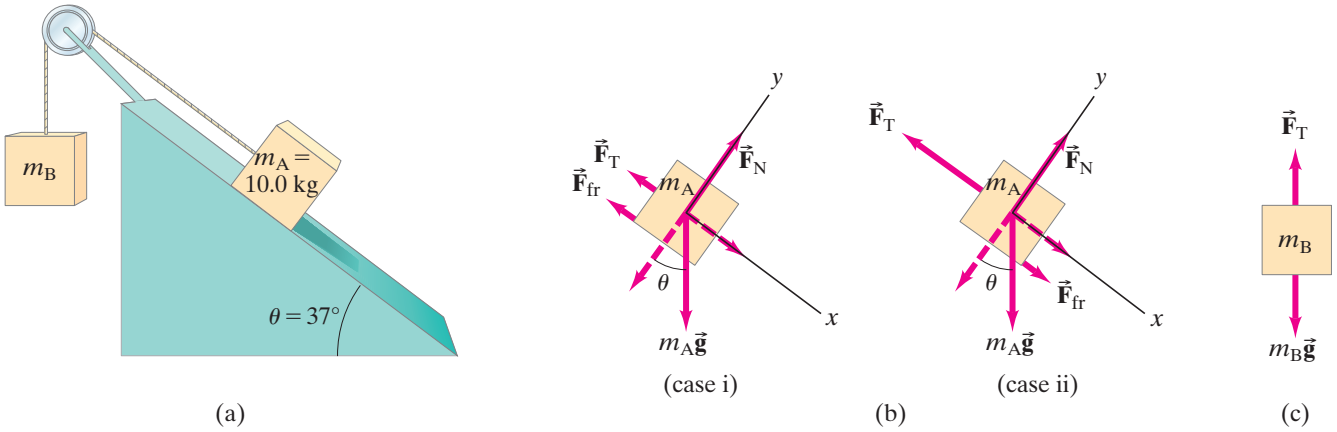


**FIGURE 5–9** Example 5–7. Note choice of $x$ and $y$ axes.

**EXAMPLE 5–7** **A ramp, a pulley, and two boxes.** A box of mass $m_A = 10.0\,\text{kg}$ rests on a surface inclined at $\theta = 37°$ to the horizontal. It is connected by a lightweight cord, which passes over a massless and frictionless pulley, to a second box of mass $m_B$, which hangs freely as shown in Fig. 5–9a. (*a*) If the coefficient of static friction is $\mu_s = 0.40$, determine what range of values for mass $m_B$ will keep the system at rest. (*b*) If the coefficient of kinetic friction is $\mu_k = 0.30$, and $m_B = 10.0\,\text{kg}$, determine the acceleration of the system.

**APPROACH** Figure 5–9b shows two free-body diagrams for box $m_A$ because the force of friction can be either up or down the slope, depending on which direction the box slides: (i) if $m_B = 0$ or is sufficiently small, $m_A$ would tend to slide down the incline, so $\vec{\mathbf{F}}_{fr}$ would be directed up the incline; (ii) if $m_B$ is large enough, $m_A$ will tend to be pulled up the plane, so $\vec{\mathbf{F}}_{fr}$ would point down the plane. The tension force exerted by the cord is labeled $\vec{\mathbf{F}}_T$.

**SOLUTION** (*a*) For both cases (i) and (ii), Newton's second law for the $y$ direction (perpendicular to the plane) is the same:

$$F_N - m_A g\cos\theta = m_A a_y = 0$$

since there is no $y$ motion. So

$$F_N = m_A g\cos\theta.$$

Now for the $x$ motion. We consider case (i) first for which $\Sigma F = ma$ gives

$$m_A g\sin\theta - F_T - F_{fr} = m_A a_x.$$

We want no acceleration, $a_x = 0$, and we solve for $F_T$ since $F_T$ is related to $m_B$ (whose value we are seeking) by $F_T = m_B g$ (see Fig. 5–9c). Thus

$$m_A g\sin\theta - F_{fr} = F_T = m_B g.$$

We solve this for $m_B$ and set $F_{fr}$ at its maximum value $\mu_s F_N = \mu_s m_A g\cos\theta$ to find the minimum value that $m_B$ can have to prevent motion $(a_x = 0)$:

$$\begin{aligned} m_B &= m_A\sin\theta - \mu_s m_A\cos\theta \\ &= (10.0\,\text{kg})(\sin 37° - 0.40\cos 37°) = 2.8\,\text{kg}. \end{aligned}$$

Thus if $m_B < 2.8\,\text{kg}$, then box A will slide down the incline.

Now for case (ii) in Fig. 5–9b, box A being tugged *up* the incline, but not actually quite accelerating. Newton's second law is

$$m_A g \sin\theta + F_{fr} - F_T = m_A a_x = 0.$$

Then the maximum value $m_B$ can have without causing acceleration is given by

$$F_T = m_B g = m_A g \sin\theta + \mu_s m_A g \cos\theta$$

or

$$\begin{aligned} m_B &= m_A \sin\theta + \mu_s m_A \cos\theta \\ &= (10.0\,\text{kg})(\sin 37° + 0.40 \cos 37°) = 9.2\,\text{kg}. \end{aligned}$$

Thus, to prevent motion, we have the condition

$$2.8\,\text{kg} < m_B < 9.2\,\text{kg}.$$

(*b*) If $m_B = 10.0\,\text{kg}$ and $\mu_k = 0.30$, then $m_B$ will fall and $m_A$ will slide up the plane (case ii). To find their acceleration $a$, we use $\Sigma F = ma$ for box A:

$$m_A a = F_T - m_A g \sin\theta - \mu_k F_N.$$

Since $m_B$ accelerates downward, Newton's second law for box B (Fig. 5–9c) tells us $m_B a = m_B g - F_T$, or $F_T = m_B g - m_B a$, and we substitute this into the equation above:

$$m_A a = m_B g - m_B a - m_A g \sin\theta - \mu_k F_N.$$

We solve for the acceleration $a$ and substitute $F_N = m_A g \cos\theta$, and then $m_A = m_B = 10.0\,\text{kg}$, to find

$$\begin{aligned} a &= \frac{m_B g - m_A g \sin\theta - \mu_k m_A g \cos\theta}{m_A + m_B} \\ &= \frac{(10.0\,\text{kg})\left(9.80\,\text{m/s}^2\right)(1 - \sin 37° - 0.30 \cos 37°)}{20.0\,\text{kg}} \\ &= 0.78\,\text{m/s}^2. \end{aligned}$$

**NOTE** It is worth comparing this equation for acceleration $a$ with that obtained in Example 5–5: if we set $\theta = 0$ in the equation just above, the plane is horizontal as in Example 5–5, and we obtain $a = (m_B g - \mu_k m_A g)/(m_A + m_B)$ just as in Example 5–5.

# 5–2 Uniform Circular Motion—Kinematics

An object moves in a straight line if the net force on it acts in the direction of motion, or the net force is zero. If the net force acts at an angle to the direction of motion at any moment, then the object moves in a curved path. An example of the latter is projectile motion, which we discussed in Chapter 3. Another important case is that of an object moving in a circle, such as a ball at the end of a string revolving around one's head, or the nearly circular motion of the Moon about the Earth.

An object that moves in a circle at constant speed $v$ is said to experience **uniform circular motion**. The *magnitude* of the velocity remains constant in this case, but the *direction* of the velocity continuously changes as the object moves around the circle (Fig. 5–10). Because acceleration is defined as the rate of change of velocity, a change in direction of velocity is an acceleration, just as a change in its magnitude is. Thus, an object revolving in a circle is continuously accelerating, even when the speed remains constant ($v_1 = v_2 = v$ in Fig. 5–10). We now investigate this acceleration quantitatively.

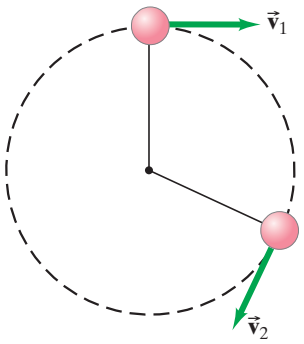

**FIGURE 5–10** A small object moving in a circle, showing how the velocity changes. At each point, the instantaneous velocity is in a direction tangent to the circular path.

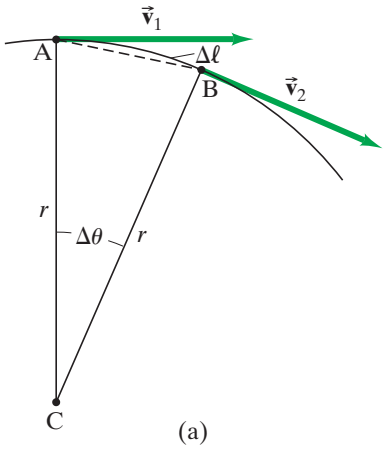

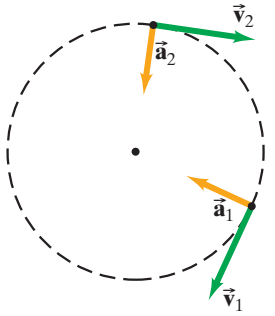

**FIGURE 5–11** Determining the change in velocity, $\Delta\vec{\mathbf{v}}$, for a particle moving in a circle. The length $\Delta\ell$ is the distance along the arc, from A to B.

**⚠ CAUTION**

*In uniform circular motion, the speed is constant, but the acceleration is not zero*

**FIGURE 5–12** For uniform circular motion, $\vec{\mathbf{a}}$ is always perpendicular to $\vec{\mathbf{v}}$.

Acceleration is defined as

$$\vec{\mathbf{a}} = \lim_{\Delta t \to 0} \frac{\Delta\vec{\mathbf{v}}}{\Delta t} = \frac{d\vec{\mathbf{v}}}{dt},$$

where $\Delta\vec{\mathbf{v}}$ is the change in velocity during the short time interval $\Delta t$. We will eventually consider the situation in which $\Delta t$ approaches zero and thus obtain the instantaneous acceleration. But for purposes of making a clear drawing (Fig. 5–11), we consider a nonzero time interval. During the time interval $\Delta t$, the particle in Fig. 5–11a moves from point A to point B, covering a distance $\Delta\ell$ *along the arc* which subtends an angle $\Delta\theta$. The change in the velocity vector is $\vec{\mathbf{v}}_2 - \vec{\mathbf{v}}_1 = \Delta\vec{\mathbf{v}}$, and is shown in Fig. 5–11b.

Now we let $\Delta t$ be very small, approaching zero. Then $\Delta\ell$ and $\Delta\theta$ are also very small, and $\vec{\mathbf{v}}_2$ will approach being parallel to $\vec{\mathbf{v}}_1$ (Fig. 5–11c); $\Delta\vec{\mathbf{v}}$ will be perpendicular to them (Fig. 5–11b). Thus $\Delta\vec{\mathbf{v}}$ points toward the center of the circle. Since $\vec{\mathbf{a}}$, by definition, is in the same direction as $\Delta\vec{\mathbf{v}}$ (equation above), it too must point toward the center of the circle. Therefore, this acceleration is called **centripetal acceleration** ("center-pointing" acceleration) or **radial acceleration** (since it is directed along the radius, toward the center of the circle), and we denote it by $\vec{\mathbf{a}}_R$.

Now that we have determined the direction, next we find the magnitude of the radial (centripetal) acceleration, $a_R$. Because the line CA in Fig. 5–11a is perpendicular to $\vec{\mathbf{v}}_1$, and line CB is perpendicular to $\vec{\mathbf{v}}_2$, then the angle $\Delta\theta$ between CA and CB is also the angle between $\vec{\mathbf{v}}_1$ and $\vec{\mathbf{v}}_2$. Hence the vectors $\vec{\mathbf{v}}_1$, $\vec{\mathbf{v}}_2$, and $\Delta\vec{\mathbf{v}}$ in Fig. 5–11b form a triangle that is geometrically similar[†] to triangle ACB in Fig. 5–11a. If we take $\Delta\theta$ to be very small (letting $\Delta t$ be very small) and setting $v = v_1 = v_2$ because the magnitude of the velocity is assumed not to change, we can write

$$\frac{\Delta v}{v} \approx \frac{\Delta\ell}{r},$$

or

$$\Delta v \approx \frac{v}{r}\Delta\ell.$$

This is an exact equality when $\Delta t$ approaches zero, for then the arc length $\Delta\ell$ equals the chord length AB. We want to find the instantaneous acceleration, $a_R$, so we write the expression above as an equality, giving

$$a_R = \lim_{\Delta t \to 0} \frac{\Delta v}{\Delta t} = \lim_{\Delta t \to 0} \frac{v}{r}\frac{\Delta\ell}{\Delta t}.$$

Then, because

$$\lim_{\Delta t \to 0} \frac{\Delta\ell}{\Delta t}$$

is the linear speed, $v$, of the object, we have for the centripetal (radial) acceleration

$$a_R = \frac{v^2}{r}. \qquad \text{[centripetal (radial) acceleration]} \quad \textbf{(5–1)}$$

Equation 5–1 is valid at any instant in circular motion, and even when $v$ is not constant. It is valid also for a portion of a circle, as for a car going around a curve, and $r$ is referred to as the **radius of curvature** of the curve.

To summarize, *an object moving in a circle of radius r at constant speed v has an acceleration whose direction is toward the center of the circle and whose magnitude is* $a_R = v^2/r$. It makes sense that this acceleration depends on $v$ and $r$: the greater the speed $v$, the faster the velocity changes direction; and the larger the radius, the less rapidly the velocity changes direction.

The acceleration vector points toward the center of the circle when $v$ is constant. But the velocity vector always points in the direction of motion, which is tangential to the circle. Thus the velocity and acceleration vectors are perpendicular to each other at every point in the path for uniform circular motion (Fig. 5–12). Beware of thinking that acceleration and velocity are always in the same direction. For an object falling vertically, $\vec{\mathbf{a}}$ and $\vec{\mathbf{v}}$ are indeed parallel. But in uniform circular motion, $\vec{\mathbf{a}}$ and $\vec{\mathbf{v}}$ are perpendicular, not parallel (nor were they parallel in projectile motion, Section 3–7).

**EXERCISE C** Can Equations 2–12, the kinematic equations for constant acceleration, be used for uniform circular motion? For example, could Eq. 2–12b be used to calculate the time for the revolving ball in Fig. 5–12 to make one revolution?

[†]Appendix A contains a review of geometry.

Circular motion is often described in terms of the **frequency** $f$, the number of revolutions per second. The **period** $T$ of an object revolving in a circle is the time required for one complete revolution. Period and frequency are related by

$$T = \frac{1}{f}. \qquad \textbf{(5–2)}$$

For example, if an object revolves at a frequency of 3 rev/s, then each revolution (rev) takes $\frac{1}{3}$ s. An object revolving in a circle (of circumference $2\pi r$) at constant speed $v$ travels a distance $2\pi r$ in one revolution which takes a time $T$. Thus

$$v = \frac{\text{distance}}{\text{time}} = \frac{2\pi r}{T}.$$

**EXAMPLE 5–8** **Acceleration of a revolving ball.** A 150-g ball at the end of a string is revolving uniformly in a horizontal circle of radius 0.600 m, as in Fig. 5–10 or 5–12. The ball makes 2.00 revolutions in a second. What is its centripetal acceleration?

**APPROACH** The centripetal acceleration is $a_R = v^2/r$. We are given $r$, and we can find the speed of the ball, $v$, from the given radius and frequency.

**SOLUTION** If the ball makes 2.00 complete revolutions per second, then the ball travels in a complete circle in a time interval equal to 0.500 s, which is its period $T$. The distance traveled in this time is the circumference of the circle, $2\pi r$, where $r$ is the radius of the circle. Therefore, the ball has speed

$$v = \frac{2\pi r}{T} = \frac{2\pi(0.600\text{ m})}{(0.500\text{ s})} = 7.54\text{ m/s}.$$

The centripetal acceleration[†] is

$$a_R = \frac{v^2}{r} = \frac{(7.54\text{ m/s})^2}{(0.600\text{ m})} = 94.7\text{ m/s}^2.$$

**EXERCISE D** In Example 5–8, if the radius is doubled to 1.20 m, but the period stays the same, the centripetal acceleration will change by a factor of:
(*a*) 2; (*b*) 4; (*c*) $\frac{1}{2}$; (*d*) $\frac{1}{4}$; (*e*) none of these.

**EXAMPLE 5–9** **Moon's centripetal acceleration.** The Moon's nearly circular orbit about the Earth has a radius of about 384,000 km and a period $T$ of 27.3 days. Determine the acceleration of the Moon toward the Earth.

**APPROACH** Again we need to find the velocity $v$ in order to find $a_R$. We will need to convert to SI units to get $v$ in m/s.

**SOLUTION** In one orbit around the Earth, the Moon travels a distance $2\pi r$, where $r = 3.84 \times 10^8$ m is the radius of its circular path. The time required for one complete orbit is the Moon's period of 27.3 d, which in seconds is $T = (27.3\text{ d})(24.0\text{ h/d})(3600\text{ s/h}) = 2.36 \times 10^6$ s. The speed of the Moon in its orbit about the Earth is $v = 2\pi r/T$. Therefore,

$$a_R = \frac{v^2}{r} = \frac{(2\pi r)^2}{T^2 r} = \frac{4\pi^2 r}{T^2} = \frac{4\pi^2(3.84 \times 10^8\text{ m})}{(2.36 \times 10^6\text{ s})^2}$$
$$= 0.00272\text{ m/s}^2 = 2.72 \times 10^{-3}\text{ m/s}^2.$$

We can write this acceleration in terms of $g = 9.80\text{ m/s}^2$ (the acceleration of gravity at the Earth's surface) as

$$a = 2.72 \times 10^{-3}\text{ m/s}^2\left(\frac{g}{9.80\text{ m/s}^2}\right) = 2.78 \times 10^{-4} g.$$

**NOTE** The centripetal acceleration of the Moon, $a = 2.78 \times 10^{-4}\, g$, is *not* the acceleration of gravity for objects at the Moon's surface due to the Moon's gravity. Rather, it is the acceleration due to the *Earth's* gravity for any object (such as the Moon) that is 384,000 km from the Earth. Notice how small this acceleration is compared to the acceleration of objects near the Earth's surface.

**⚠ CAUTION**
*Distinguish the Moon's gravity on objects at its surface, from the Earth's gravity acting on the Moon (this Example)*

[†]Differences in the final digit can depend on whether you keep all digits in your calculator for $v$ (which gives $a_R = 94.7\text{ m/s}^2$), or if you use $v = 7.54$ m/s (which gives $a_R = 94.8\text{ m/s}^2$). Both results are valid since our assumed accuracy is about $\pm 0.1\text{ m/s}^2$ (see Section 1–3).

PHYSICS APPLIED
*Centrifuge*

## *Centrifugation

Centrifuges, and very high speed ultracentrifuges, are used to sediment materials quickly and to separate materials. Test tubes held in the centrifuge rotor are accelerated to very high rotational speeds: see Fig. 5–13, where one test tube is shown in two positions as the rotor turns. The small green dot represents a small particle, perhaps a macromolecule, in a fluid-filled test tube. At position A the particle has a tendency to move in a straight line, but the fluid resists the motion of the particles, exerting a centripetal force that keeps the particles moving nearly in a circle. The resistive force exerted by the fluid (liquid, gas, or gel, depending on the application) usually does not quite equal $mv^2/r$, and the particles move slowly toward the bottom of the tube. A centrifuge provides an "effective gravity" much larger than normal gravity because of the high rotational speeds, thus causing more rapid sedimentation.

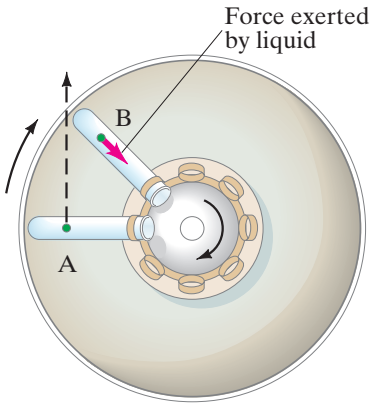

**FIGURE 5–13** Two positions of a rotating test tube in a centrifuge (top view). At A, the green dot represents a macromolecule or other particle being sedimented. It would tend to follow the dashed line, heading toward the bottom of the tube, but the fluid resists this motion by exerting a force on the particle as shown at point B.

**EXAMPLE 5–10** **Ultracentrifuge.** The rotor of an ultracentrifuge rotates at 50,000 rpm (revolutions per minute). A particle in a test tube (Fig. 5–13) is 6.00 cm from the rotation axis. Calculate its centripetal acceleration, in "$g$'s."

**APPROACH** We calculate the centripetal acceleration from $a_R = v^2/r$.

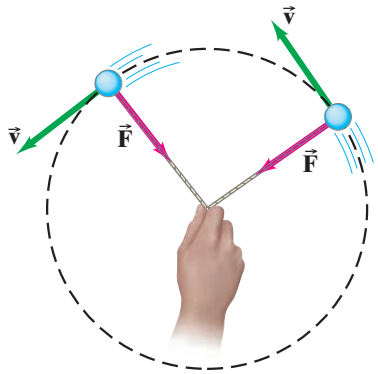
**SOLUTION** The test tube makes $5.00 \times 10^4$ revolutions each minute, or, dividing by 60 s/min, 833 rev/s. The time to make one revolution, the period $T$, is

$$T = \frac{1}{f} = \frac{1}{(833\ \text{rev/s})} = 1.20 \times 10^{-3}\ \text{s/rev}.$$

The particle revolves in a circle of circumference $2\pi r = (2\pi)(0.0600\ \text{m}) = 0.377\ \text{m}$ per revolution. The speed of the particle is then

$$v = \frac{2\pi r}{T} = \left(\frac{0.377\ \text{m/rev}}{1.20 \times 10^{-3}\ \text{s/rev}}\right) = 3.14 \times 10^2\ \text{m/s}.$$

The centripetal acceleration is



$$a_R = \frac{v^2}{r} = \frac{(3.14 \times 10^2\ \text{m/s})^2}{0.0600\ \text{m}} = 1.64 \times 10^6\ \text{m/s}^2,$$

which, dividing by $g = 9.80\ \text{m/s}^2$, is $1.67 \times 10^5\ g$'s $= 167{,}000\ g$'s.

Other uses of centrifugation include:
(1) *Astronauts* can undergo training in large centrifuges as experience for taking off from Earth at several $g$'s.
(2) *Enrichment* of uranium: natural uranium is 99.3% uranium-238. The lighter form, U-235, is only 0.7%, but is the type (isotope) usable for nuclear fission in nuclear power plants and nuclear bombs. Complex centrifuges can partially separate the two isotopes, increasing (or "enriching") the proportion of U-235. Power or research reactors need 3% to 20%, although some use natural uranium; bombs need greater enrichment ($\gtrsim 80\%$).

PHYSICS APPLIED
*Uranium enrichment by centrifugation*

**FIGURE 5–14** A force is required to keep an object moving in a circle. If the speed is constant, the force is directed toward the circle's center.

# 5–3 Dynamics of Uniform Circular Motion

According to Newton's second law $(\Sigma\vec{F} = m\vec{a})$, an object that is accelerating must have a net force acting on it. An object moving in a circle, such as a ball on the end of a string, must therefore have a force applied to it to keep it moving in that circle. That is, a net force is necessary to give it centripetal acceleration. The magnitude of the required force can be calculated using Newton's second law for the radial component, $\Sigma F_R = ma_R$, where $a_R$ is the centripetal acceleration, $a_R = v^2/r$, and $\Sigma F_R$ is the total (or net) force in the radial direction:

$$\Sigma F_R = ma_R = m\frac{v^2}{r}. \qquad \text{[circular motion]} \quad \textbf{(5–3)}$$

For uniform circular motion $(v = \text{constant})$, the total acceleration is $a_R$, which is directed toward the center of the circle at all times. Thus the *net force too must be directed toward the center of the circle* (Fig. 5–14). If no net force were exerted on the object, it would not move in a circle but in a straight line, as Newton's first law tells us.

The direction of the net force is continually changing so that it is always directed toward the center of the circle, perpendicular to $\vec{\mathbf{v}}$. This force is sometimes called a centripetal ("pointing toward the center") force. "Centripetal force" does not indicate some new kind of force; it only describes the *direction* of the net force needed to provide a circular path: the net force is directed toward the circle's center. The net force *must be applied by other objects*. For example, to swing a ball in a circle on the end of a string, you pull on the string and the string exerts the force on the ball. (Try it.) Here, the "centripetal force" that provides the centripetal acceleration is tension in the string. In other cases it can be gravity (on the Moon, for example); it could also be a normal force, a friction force, or even an electric force.

**CAUTION**

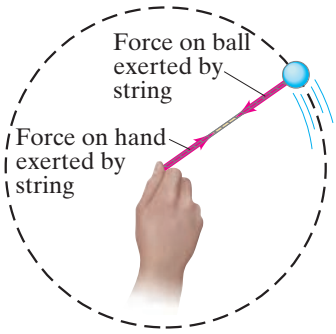
*Centripetal force is not a new kind of force (Every force must be exerted by an object)*

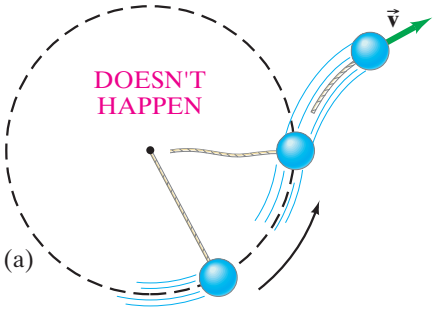
There is a common misconception that an object moving in a circle has an outward force acting on it, a so-called centrifugal ("center-fleeing") force. This is incorrect: *there is no outward force* on the revolving object. Consider, for example, a person swinging a ball on the end of a string around her head (Fig. 5–15). If you have ever done this yourself, you know that you feel a force pulling outward on your hand. The misconception arises when this pull is interpreted as an outward "centrifugal" force pulling on the ball that is transmitted along the string to your hand. This is not what is happening at all. To keep the ball moving in a circle, you pull *inwardly* on the string, and the string exerts this inward force on the ball. The ball exerts an equal and opposite force on the string (Newton's third law), and *this* is the outward force your hand feels (see Fig. 5–15).

**CAUTION**

*There is no real "centrifugal force"*

The force *on the ball* in Fig. 5–15 is the one exerted *inwardly* on it by you, via the string. To see even more convincing evidence that a "centrifugal force" does not act on the ball, consider what happens when you let go of the string. If a centrifugal force were acting, the ball would fly outward, as shown in Fig. 5–16a. But it doesn't; the ball flies off tangentially (Fig. 5–16b), in the direction of the velocity it had at the moment it was released, because the inward force no longer acts. Try it and see!





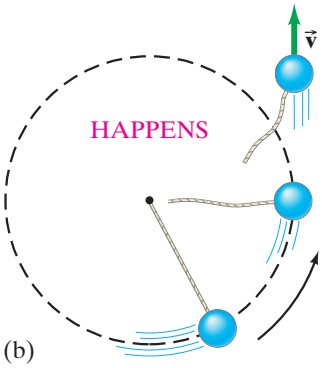


**FIGURE 5–15** Swinging a ball on the end of a string (looking down from above).

**EXERCISE E** Return to the Chapter-Opening Question, page 116, and answer it again now. Try to explain why you may have answered differently the first time.

(c)

**FIGURE 5–16** If centrifugal force existed, the revolving ball would fly outward as in (a) when released. In fact, it flies off tangentially as in (b). For example, in (c) sparks fly in straight lines tangentially from the edge of a rotating grinding wheel.

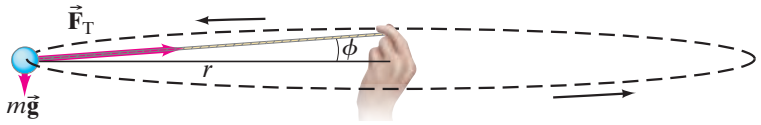

**FIGURE 5–17**
Example 5–11.

**EXAMPLE 5–11** **ESTIMATE** **Force on revolving ball (horizontal).** Estimate the force a person must exert on a string attached to a 0.150-kg ball to make the ball revolve in a horizontal circle of radius 0.600 m. The ball makes 2.00 revolutions per second ($T = 0.500\,\text{s}$), as in Example 5–8. Ignore the string's mass.

**APPROACH** First we need to draw the free-body diagram for the ball. The forces acting on the ball are the force of gravity, $m\vec{\mathbf{g}}$ downward, and the tension force $\vec{\mathbf{F}}_T$ that the string exerts toward the hand at the center (which occurs because the person exerts that same force on the string). The free-body diagram for the ball is shown in Fig. 5–17. The ball's weight complicates matters and makes it impossible to revolve a ball with the cord perfectly horizontal. We estimate the force assuming the weight is small, and letting $\phi \approx 0$ in Fig. 5–17. Thus $\vec{\mathbf{F}}_T$ will act nearly horizontally and, in any case, provides the force necessary to give the ball its centripetal acceleration.

**SOLUTION** We apply Newton's second law to the radial direction, which we assume is horizontal:

$$(\Sigma F)_R = ma_R,$$

where $a_R = v^2/r$ and $v = 2\pi r/T = 2\pi(0.600\,\text{m})/(0.500\,\text{s}) = 7.54\,\text{m/s}$. Thus

$$F_T = m\frac{v^2}{r} = (0.150\,\text{kg})\frac{(7.54\,\text{m/s})^2}{(0.600\,\text{m})} \approx 14\,\text{N}.$$

**NOTE** We keep only two significant figures in the answer because we ignored the ball's weight; it is $mg = (0.150\,\text{kg})(9.80\,\text{m/s}^2) = 1.5\,\text{N}$, about $\frac{1}{10}$ of our result, which is small but maybe not so small as to justify stating a more precise answer for $F_T$.

**NOTE** To include the effect of $m\vec{\mathbf{g}}$, resolve $\vec{\mathbf{F}}_T$ in Fig. 5–17 into components, and set the horizontal component of $\vec{\mathbf{F}}_T$ equal to $mv^2/r$ and its vertical component equal to $mg$.

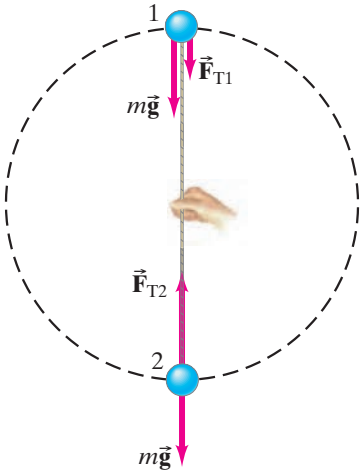

**FIGURE 5–18** Example 5–12. Free-body diagrams for positions 1 and 2.

**EXAMPLE 5–12** **Revolving ball (vertical circle).** A 0.150-kg ball on the end of a 1.10-m-long cord (negligible mass) is swung in a *vertical* circle. (*a*) Determine the minimum speed the ball must have at the top of its arc so that the ball continues moving in a circle. (*b*) Calculate the tension in the cord at the bottom of the arc, assuming the ball is moving at twice the speed of part (*a*).

**APPROACH** The ball moves in a vertical circle and is *not* undergoing uniform circular motion. The radius is assumed constant, but the speed $v$ changes because of gravity. Nonetheless, Eq. 5–1 ($a_R = v^2/r$) is valid at each point along the circle, and we use it at the top and bottom points. The free-body diagram is shown in Fig. 5–18 for both positions.

**SOLUTION** (*a*) At the top (point 1), two forces act on the ball: $m\vec{\mathbf{g}}$, the force of gravity, and $\vec{\mathbf{F}}_{T1}$, the tension force the cord exerts at point 1. Both act downward, and their vector sum acts to give the ball its centripetal acceleration $a_R$. We apply Newton's second law, for the vertical direction, choosing downward as positive since the acceleration is downward (toward the center):

$$(\Sigma F)_R = ma_R$$

$$F_{T1} + mg = m\frac{v_1^2}{r}. \qquad \text{[at top]}$$

From this equation we can see that the tension force $F_{T1}$ at point 1 will get larger if $v_1$ (ball's speed at top of circle) is made larger, as expected. But we are asked for the *minimum* speed to keep the ball moving in a circle. The cord will remain taut as long as there is tension in it. But if the tension disappears (because $v_1$ is too small) the cord can go limp, and the ball will fall out of its circular path. Thus, the minimum speed will occur if $F_{T1} = 0$, for which the equation above becomes

$$mg = m\frac{v_1^2}{r}. \qquad \text{[minimum speed at top]}$$

**⚠ CAUTION**
*Circular motion only if cord is under tension*

We solve for $v_1$, keeping an extra digit for use in ($b$):

$$v_1 = \sqrt{gr} = \sqrt{(9.80\,\text{m/s}^2)(1.10\,\text{m})} = 3.283\,\text{m/s} \approx 3.28\,\text{m/s}.$$

This is the minimum speed the ball must have at the top of the circle if it is to continue moving in a circular path.

($b$) When the ball is at the bottom of the circle (point 2 in Fig. 5–18), the cord exerts its tension force $F_{T2}$ upward, whereas the force of gravity, $m\vec{\mathbf{g}}$, still acts downward. Choosing *upward* as positive, Newton's second law gives:

$$(\Sigma F)_R = ma_R$$
$$F_{T2} - mg = m\frac{v_2^2}{r}. \qquad \text{[at bottom]}$$

The speed $v_2$ is given as twice that in ($a$), namely 6.566 m/s. We solve for $F_{T2}$:

$$F_{T2} = m\frac{v_2^2}{r} + mg$$
$$= (0.150\,\text{kg})\frac{(6.566\,\text{m/s})^2}{(1.10\,\text{m})} + (0.150\,\text{kg})(9.80\,\text{m/s}^2) = 7.35\,\text{N}.$$

**EXERCISE F** A rider on a Ferris wheel moves in a vertical circle of radius $r$ at constant speed $v$ (Fig. 5–19). Is the normal force that the seat exerts on the rider at the top of the wheel ($a$) less than, ($b$) more than, or ($c$) the same as, the force the seat exerts at the bottom of the wheel?

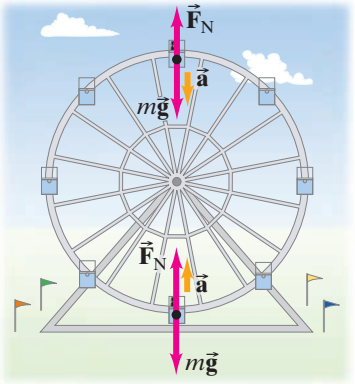

**FIGURE 5–19** Exercise F.

**EXAMPLE 5–13** **Conical pendulum.** A small ball of mass $m$, suspended by a cord of length $\ell$, revolves in a horizontal circle of radius $r = \ell\sin\theta$, where $\theta$ is the angle the string makes with the vertical (Fig. 5–20). ($a$) In what direction is the acceleration of the ball, and what causes the acceleration? ($b$) Calculate the speed and period (time required for one revolution) of the ball in terms of $\ell$, $\theta$, $g$, and $m$.

**APPROACH** We can answer ($a$) by looking at Fig. 5–20, which shows the forces on the revolving ball at one instant: the acceleration points horizontally toward the center of the ball's circular path (not along the cord). The force responsible for the acceleration is the *net* force which here is the vector sum of the forces acting on the mass $m$: its weight $\vec{\mathbf{F}}_G$ (of magnitude $F_G = mg$), and the force exerted by the tension in the cord, $\vec{\mathbf{F}}_T$, which has horizontal and vertical components of magnitude $F_T\sin\theta$ and $F_T\cos\theta$.

**SOLUTION** ($b$) We apply Newton's second law to the horizontal and vertical directions. In the vertical direction, there is no motion, so the acceleration is zero and the net force in the vertical direction is zero:

$$F_T\cos\theta - mg = 0,$$

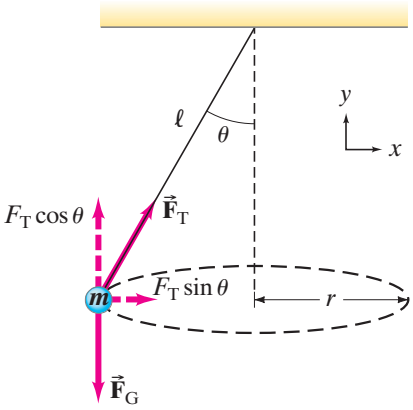
or

$$F_T = \frac{mg}{\cos\theta}.$$

In the horizontal direction there is only one force, of magnitude $F_T\sin\theta$, that acts toward the center of the circle and gives rise to the acceleration $v^2/r$. Newton's second law tells us:

$$F_T\sin\theta = m\frac{v^2}{r}.$$

We solve the second equation for $v$, and substitute for $F_T$ from above (and use $r = \ell\sin\theta$):



$$v = \sqrt{\frac{rF_T\sin\theta}{m}} = \sqrt{\frac{r}{m}\left(\frac{mg}{\cos\theta}\right)\sin\theta} = \sqrt{\frac{\ell g\sin^2\theta}{\cos\theta}}.$$

The period $T$ is the time required to make one revolution, a distance of $2\pi r = 2\pi\ell\sin\theta$. The speed $v$ can thus be written $v = 2\pi\ell\sin\theta/T$; then

$$T = \frac{2\pi\ell\sin\theta}{v} = \frac{2\pi\ell\sin\theta}{\sqrt{\ell g\sin^2\theta/\cos\theta}} = 2\pi\sqrt{\frac{\ell\cos\theta}{g}}.$$

**NOTE** The speed and period do not depend on the mass $m$ of the ball. They do depend on $\ell$ and $\theta$.

**FIGURE 5–20** Example 5–13. Conical pendulum.

PROBLEM SOLVING

**Uniform Circular Motion**

1. **Draw a free-body diagram**, showing all the forces acting on each object under consideration. Be sure you can identify the source of each force (tension in a cord, Earth's gravity, friction, normal force, and so on). Don't put in something that doesn't belong (like a centrifugal force).
2. **Determine** which of the forces, or which of their components, act to provide the centripetal acceleration—that is, all the **forces or components that act radially**, toward or away from the center of the circular path. The sum of these forces (or components) provides the centripetal acceleration, $a_R = v^2/r$.
3. **Choose a convenient coordinate system**, preferably with one axis along the acceleration direction at a chosen instant.
4. **Apply Newton's second law** to the radial component:

$$\Sigma F_R = ma_R = m\frac{v^2}{r}. \qquad \text{[radial direction]}$$

# 5–4 Highway Curves: Banked and Unbanked

PHYSICS APPLIED
*Driving around a curve*

An example of circular dynamics occurs when an automobile rounds a curve, say to the left. In such a situation, you may feel that you are thrust outward toward the right side door. But there is no mysterious centrifugal force pulling on you.

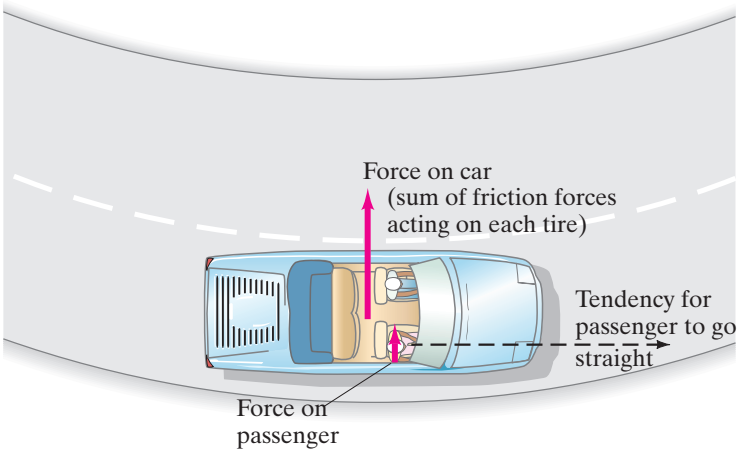


**FIGURE 5–21** The road exerts a radially inward force (friction against the tires) on a car to make it move in a circle. The car exerts an inward force on the passenger.

**FIGURE 5–22** Race car heading into a curve. From the tire marks we see that most cars experienced a sufficient friction force to give them the needed centripetal acceleration for rounding the curve safely. But, we also see tire tracks of cars on which there was not sufficient force—and which unfortunately followed more nearly straight-line paths.

What is happening is that you tend to move in a straight line, whereas the car has begun to follow a curved path. To make you go in the curved path, the seat (friction) or the door of the car (direct contact) exerts a force on you (Fig. 5–21). The car also must have a force exerted on it toward the center of the curve if it is to move in that curve. On a flat road, this force is supplied by friction between the tires and the pavement.

If the wheels and tires of the car are rolling normally without slipping or sliding, the bottom of the tire is at rest against the road at each instant. So the friction force the road exerts on the tires is static friction. But if static friction is not great enough, as under icy conditions or high speed, the static friction force is less than $mv^2/r$ and the car will skid out of a circular path into a more nearly straight path. See Fig. 5–22. Once a car skids or slides, the friction force becomes kinetic friction, which is smaller than static friction.

**EXAMPLE 5–14** **Skidding on a curve.** A 1000-kg car rounds a curve on a horizontal flat road of radius 50 m at a speed of 15 m/s (54 km/h). Will the car follow the curve, or will it skid? Assume: (*a*) the pavement is dry and the coefficient of static friction is $\mu_s = 0.60$; (*b*) the pavement is icy and $\mu_s = 0.25$.

**APPROACH** The forces on the car are gravity $mg$ downward, the normal force $F_N$ exerted upward by the road, and a horizontal friction force due to the level road. They are shown in Fig. 5–23, which is the free-body diagram for the car. The car will follow the curve if the maximum static friction force is greater than the mass times the centripetal acceleration.

**SOLUTION** In the vertical direction ($y$) there is no acceleration. Newton's second law tells us that the normal force $F_N$ on the car is equal to the weight $mg$ since the road is flat:

$$0 = \Sigma F_y = F_N - mg$$

so

$$F_N = mg = (1000\,\text{kg})(9.80\,\text{m/s}^2) = 9800\,\text{N}.$$

In the horizontal direction the only force is friction, and we must compare it to the force needed to produce the centripetal acceleration to see if it is sufficient. The net horizontal force required to keep the car moving in a circle around the curve is

$$(\Sigma F)_R = ma_R = m\frac{v^2}{r} = (1000\,\text{kg})\frac{(15\,\text{m/s})^2}{(50\,\text{m})} = 4500\,\text{N}.$$

Now we compute the maximum total static friction force (the sum of the friction forces acting on each of the four tires) to see if it can be large enough to provide a safe centripetal acceleration. For (*a*), $\mu_s = 0.60$, and the maximum friction force attainable (recall from Section 5–1 that $F_{fr} \leq \mu_s F_N$) is

$$(F_{fr})_{max} = \mu_s F_N = (0.60)(9800\,\text{N}) = 5880\,\text{N}.$$

Since a force of only 4500 N is needed, and that is, in fact, how much will be exerted by the road as a static friction force, the car can follow the curve. But in (*b*) the maximum static friction force possible is

$$(F_{fr})_{max} = \mu_s F_N = (0.25)(9800\,\text{N}) = 2450\,\text{N}.$$

The car will skid because the ground cannot exert sufficient force (4500 N is needed) to keep it moving in a curve of radius 50 m at a speed of 54 km/h.

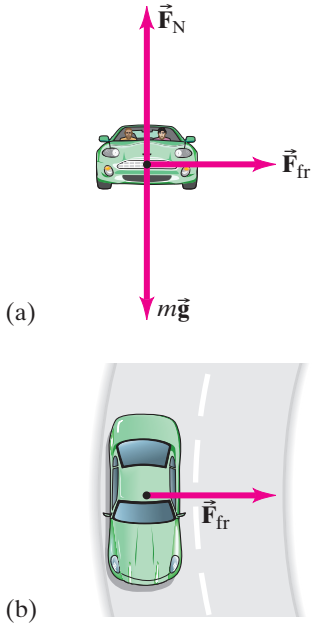

**FIGURE 5–23** Example 5–14. Forces on a car rounding a curve on a level road. (a) Front view, (b) top view.

The possibility of skidding is worse if the wheels lock (stop rotating) when the brakes are applied too hard. When the tires are rolling, static friction exists. But if the wheels lock (stop rotating), the tires slide and the friction force, which is now kinetic friction, is less. More importantly, the *direction* of the friction force changes suddenly if the wheels lock. Static friction can point perpendicular to the velocity, as in Fig. 5–23b; but if the car slides, kinetic friction points *opposite* to the velocity. The force no longer points toward the center of the circle, and the car cannot continue in a curved path (see Fig. 5–22). Even worse, if the road is wet or icy, locking of the wheels occurs with less force on the brake pedal since there is less road friction to keep the wheels turning rather than sliding. **Antilock brakes (ABS)**, which all modern cars have, are designed to limit brake pressure just before the point where sliding would occur, by means of delicate sensors and a fast computer. But be careful if you drive an antique or older car.

**PHYSICS APPLIED**
*Antilock brakes*

**EXERCISE G** To negotiate a flat (unbanked) curve at a *faster* speed, a driver puts a couple of sand bags in his van aiming to increase the force of friction between the tires and the road. Will the sand bags help? Why or why not?

**PHYSICS APPLIED**

*Banked curves*

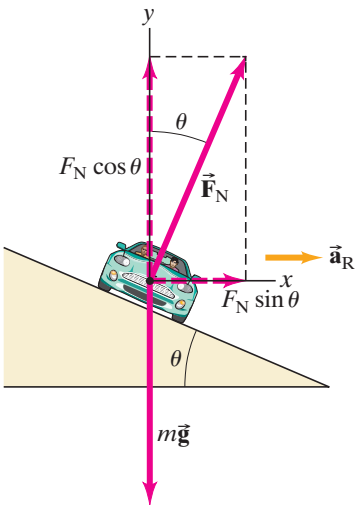

**FIGURE 5–24** Normal force on a car rounding a banked curve, resolved into its horizontal and vertical components. The centripetal acceleration is horizontal (*not* parallel to the sloping road). The friction force on the tires, not shown, could point up or down along the slope, depending on the car's speed. The friction force will be zero for one particular speed. Note that here we choose the $x$ axis horizontal (not along the plane) because the centripetal force is horizontal.

**CAUTION**

*$F_N$ is not always equal to $mg$*

The *banking of curves* can reduce the chance of skidding. The normal force exerted by a banked road, acting perpendicular to the road, will have a component toward the center of the circle (Fig. 5–24), thus reducing the reliance on friction. For a given banking angle $\theta$, there will be one speed for which no friction at all is required. This will be the case when the horizontal component of the normal force toward the center of the curve, $F_N \sin\theta$ (see Fig. 5–24), is just equal to the force required to give a vehicle its centripetal acceleration—that is, when

$$F_N \sin\theta = m\frac{v^2}{r}. \qquad \text{[no friction required]}$$

The banking angle of a road, $\theta$, is chosen so that this condition holds for a particular speed, called the "design speed."

**EXAMPLE 5–15** **Banking angle.** (*a*) For a car traveling with speed $v$ around a curve of radius $r$, determine a formula for the angle at which a road should be banked so that no friction is required. (*b*) What is this angle for a road which has a curve of radius 50 m with a design speed of 50 km/h?

**APPROACH** Even though the road is banked, the car is still moving along a horizontal circle, so the centripetal acceleration needs to be horizontal. We choose our $x$ and $y$ axes as horizontal and vertical so that $a_R$, which is horizontal, is along the $x$ axis at the moment shown in Fig. 5–24. The forces on the car are the Earth's gravity $mg$ downward, and the normal force $F_N$ exerted by the road perpendicular to its surface. See Fig. 5–24, where the components of $F_N$ are also shown. We don't need to consider the friction of the road because we are designing a road to be banked so as to eliminate dependence on friction.

**SOLUTION** (*a*) Since there is no vertical motion, $a_y = 0$ and $\Sigma F_y = ma_y$ gives

$$F_N \cos\theta - mg = 0$$

or

$$F_N = \frac{mg}{\cos\theta}.$$

[Note in this case that $F_N \geq mg$ because $\cos\theta \leq 1$. Compare Example 5–14.] We substitute this relation for $F_N$ into the equation for the horizontal motion,

$$F_N \sin\theta = m\frac{v^2}{r},$$

which becomes

$$\frac{mg}{\cos\theta}\sin\theta = m\frac{v^2}{r}$$

or

$$\tan\theta = \frac{v^2}{rg}.$$

This is the formula for the banking angle $\theta$: no friction is needed at this speed $v$.

(*b*) For $r = 50\,\text{m}$ and $v = 50\,\text{km/h}$ $(= 14\,\text{m/s})$,

$$\tan\theta = \frac{(14\,\text{m/s})^2}{(50\,\text{m})(9.8\,\text{m/s}^2)} = 0.40,$$

so $\theta = \tan^{-1}(0.40) = 22°$.

**NOTE** Any friction force on the tires, not shown in Fig. 5–24, would point up or down along the banked slope (perpendicular to $\vec{F}_N$), depending on the car's speed.

**EXERCISE H** Can a heavy truck and a small car travel safely at the same speed around an icy banked-curve road? Why or why not?

# 5–5 Nonuniform Circular Motion

Circular motion at constant speed occurs when the net force on an object is exerted toward the center of the circle. If the net force is not directed toward the center but is at an angle, as shown in Fig. 5–25a, the force has two components. The component directed toward the center of the circle, $\vec{\mathbf{F}}_R$, gives rise to the centripetal acceleration, $\vec{\mathbf{a}}_R$, and keeps the object moving in a circle. The component tangent to the circle, $\vec{\mathbf{F}}_{tan}$, acts to increase (or decrease) the speed, and thus gives rise to a component of the acceleration tangent to the circle, $\vec{\mathbf{a}}_{tan}$. When the speed of the object is changing, a tangential component of force is acting.

When you first start revolving a ball on the end of a string around your head, you must give it tangential acceleration. You do this by pulling on the string with your hand displaced from the center of the circle. In athletics, a hammer thrower accelerates the hammer tangentially in a similar way so that it reaches a high speed before release.

The tangential component of the acceleration, $a_{tan}$, has magnitude equal to the rate of change of the *magnitude* of the object's velocity:

$$a_{tan} = \frac{dv}{dt}. \qquad \textbf{(5–4)}$$

The radial (centripetal) acceleration arises from the change in *direction* of the velocity and, as we have seen, has magnitude

$$a_R = \frac{v^2}{r}.$$

The tangential acceleration always points in a direction tangent to the circle, and is in the direction of motion (parallel to $\vec{\mathbf{v}}$, which is always tangent to the circle) if the speed is increasing, as shown in Fig. 5–25b. If the speed is decreasing, $\vec{\mathbf{a}}_{tan}$ points antiparallel to $\vec{\mathbf{v}}$. In either case, $\vec{\mathbf{a}}_{tan}$ and $\vec{\mathbf{a}}_R$ are always perpendicular to each other; and *their directions change* continually as the object moves along its circular path. The total vector acceleration $\vec{\mathbf{a}}$ is the sum of the two components:

$$\vec{\mathbf{a}} = \vec{\mathbf{a}}_{tan} + \vec{\mathbf{a}}_R. \qquad \textbf{(5–5)}$$

Since $\vec{\mathbf{a}}_R$ and $\vec{\mathbf{a}}_{tan}$ are always perpendicular to each other, the magnitude of $\vec{\mathbf{a}}$ at any moment is

$$a = \sqrt{a_{tan}^2 + a_R^2}.$$

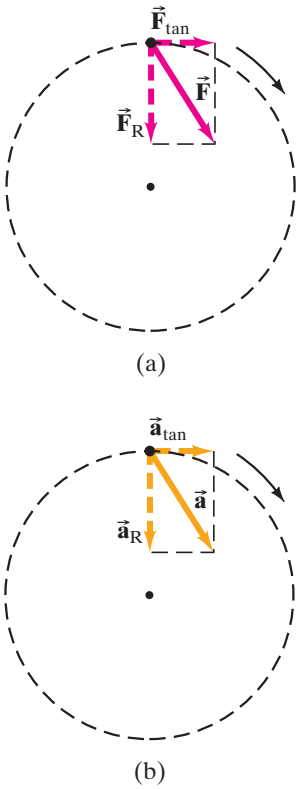

**FIGURE 5–25** The speed of an object moving in a circle changes if the force on it has a tangential component, $F_{tan}$. Part (a) shows the force $\vec{\mathbf{F}}$ and its vector components; part (b) shows the acceleration vector and its vector components.

**EXAMPLE 5–16** **Two components of acceleration.** A race car starts from rest and accelerates at a uniform rate to a speed of 35 m/s in 11 s, moving on a circular track of radius 250 m. Assuming constant tangential acceleration, find (*a*) the tangential acceleration, and (*b*) the radial acceleration, at the instant when the speed is $v = 15$ m/s.

**APPROACH** The tangential acceleration relates to the change in speed of the car, and can be calculated as $a_{tan} = \Delta v/\Delta t$. The centripetal acceleration relates to the change in the *direction* of the velocity vector and is calculated using $a_R = v^2/r$.

**SOLUTION** (*a*) During the 11-s time interval, we assume the tangential acceleration $a_{tan}$ is constant. Its magnitude is

$$a_{tan} = \frac{\Delta v}{\Delta t} = \frac{(35\text{ m/s} - 0\text{ m/s})}{11\text{ s}} = 3.2\text{ m/s}^2.$$

(*b*) When $v = 15$ m/s, the radial acceleration is

$$a_R = \frac{v^2}{r} = \frac{(15\text{ m/s})^2}{(250\text{ m})} = 0.90\text{ m/s}^2.$$

**NOTE** The radial (centripetal) acceleration increases continually as the speed increases, whereas the tangential acceleration stays constant in this Example.

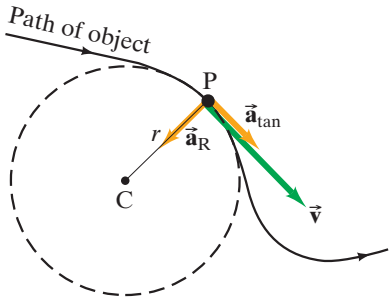

**FIGURE 5–26** Object following a curved path (solid line). At point P the path has a radius of curvature $r$. The object has velocity $\vec{\mathbf{v}}$, tangential acceleration $\vec{\mathbf{a}}_{\tan}$ (the object is here increasing in speed), and radial (centripetal) acceleration $\vec{\mathbf{a}}_{\mathrm{R}}$ (magnitude $a_{\mathrm{R}} = v^2/r$) which points toward the center of curvature C.

**EXERCISE I** When the speed of the race car in Example 5–16 increases to 30 m/s, how are (*a*) $a_{\tan}$ and (*b*) $a_{\mathrm{R}}$ changed?

These concepts can be used for an object moving along any curved path, such as that shown in Fig. 5–26. We can treat any portion of a curve as an arc of a circle with a *radius of curvature r*. The velocity at any point is always tangent to the path. The acceleration can be written, in general, as a vector sum of two components: the tangential component $a_{\tan} = dv/dt$, and the radial (centripetal) component $a_{\mathrm{R}} = v^2/r$.

## *5–6 Velocity-Dependent Forces: Drag and Terminal Velocity

When an object slides along a surface, the force of friction acting on the object is nearly independent of how fast the object is moving. But other types of resistive forces do depend on the object's velocity. An important example is for an object moving through a liquid or gas such as air resistance on a falling object. A fluid offers resistance to the motion of an object moving through it, and this resistive force, or **drag force**, depends on the velocity of the object.[†]

The way the drag force varies with velocity is complicated in general. But for small objects at very low speeds, a good approximation can often be made by assuming that the drag force, $F_{\mathrm{D}}$, is directly proportional to the magnitude of the velocity, $v$:

$$F_{\mathrm{D}} = -bv. \qquad \textbf{(5–6)}$$

The minus sign is necessary because the drag force opposes the motion. Here $b$ is a constant (approximately) that depends on the viscosity of the fluid and on the size and shape of the object. Equation 5–6 works well for small objects moving at low speed in a viscous liquid. It also works for very small objects moving in air at very low speeds, such as dust particles. For objects moving at high speeds, such as an airplane, a sky diver, a baseball, or an automobile, the force of air resistance can be better approximated as being proportional to $v^2$:

$$F_{\mathrm{D}} \propto v^2.$$

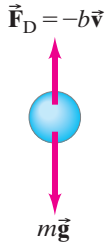
For accurate calculations, however, more complicated forms and numerical integration generally need to be used. For objects moving through liquids, Eq. 5–6 works well for everyday objects at normal speeds (like a boat in water).

Let us consider an object that falls from rest, through air or other fluid, under the action of gravity and a resistive force proportional to $v$. The forces acting on the object are the force of gravity, $mg$, acting downward, and the drag force, $-bv$, acting upward (Fig. 5–27a). Since the velocity $\vec{\mathbf{v}}$ points downward, let us take the positive direction as downward. Then the net force on the object can be written

$$\Sigma F = mg - bv.$$

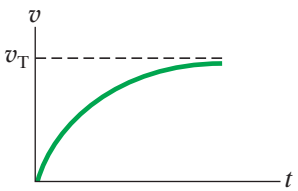
From Newton's second law $\Sigma F = ma$, we have

$$mg - bv = m\frac{dv}{dt}, \qquad \textbf{(5–7)}$$



where we have written the acceleration according to its definition as rate of change of velocity, $a = dv/dt$. At $t = 0$, we set $v = 0$ and the acceleration $dv/dt = g$. As the object falls and increases in speed, the resistive force increases, and this reduces the acceleration, $dv/dt$ (see Fig. 5–27b). The velocity continues to increase, but at a slower rate. Eventually, the velocity becomes so large that the magnitude of the resistive force, $bv$, approaches that of the gravitational force, $mg$; when the two are equal, we have

$$mg - bv = 0. \qquad \textbf{(5–8)}$$



At this point $dv/dt = 0$ and the object no longer increases in speed. It has reached its **terminal velocity** and continues to fall at this constant velocity until it hits the ground. This sequence of events is shown in the graph of Fig. 5–27b.

**PHYSICS APPLIED**
*Air resistance*

**FIGURE 5–27** (a) Forces acting on an object falling downward. (b) Graph of the velocity of an object falling due to gravity when the air resistance drag force is $F_{\mathrm{D}} = -bv$. Initially, $v = 0$ and $dv/dt = g$, but as time goes on $dv/dt$ (= slope of curve) decreases because of $F_{\mathrm{D}}$. Eventually, $v$ approaches a maximum value, $v_{\mathrm{T}}$, the terminal velocity, which occurs when $F_{\mathrm{D}}$ has magnitude equal to $mg$.

(a)

(b)

[†]Any buoyant force (Chapter 13) is ignored in this Section.

The value of the terminal velocity $v_T$ can be obtained from Eq. 5–8,

$$v_T = \frac{mg}{b}. \tag{5–9}$$

If the resistive force is assumed proportional to $v^2$, or an even higher power of $v$, the sequence of events is similar and a terminal velocity reached, although it will not be given by Eq. 5–9.

**EXAMPLE 5–17** **Force proportional to velocity.** Determine the velocity as a function of time for an object falling vertically from rest when there is a resistive force linearly proportional to $v$. Take downward as positive.

**APPROACH** This is a derivation and we start with Eq. 5–7, which we rewrite as

$$\frac{dv}{dt} = g - \frac{b}{m}v.$$

**SOLUTION** In this equation there are two variables, $v$ and $t$. We collect variables of the same type on one or the other side of the equation:[†]

$$\frac{1}{1 - \frac{bv}{mg}}dv = g\,dt.$$

Now we integrate this equation from $t = 0$ when $v = 0$ to a later time $t$ when the speed is $v$:

$$\int_0^v \frac{1}{1 - \frac{bv}{mg}}dv = g\int_0^t dt$$

which gives

$$-\frac{mg}{b}\left[\ln\left(1 - \frac{bv}{mg}\right) - \ln 1\right] = gt$$

where we have used (Appendix B) $\int dx/(c + ax) = (1/a)\ln(c + ax)$, where $c = 1$ and $a = -b/mg$. (Recall ln is the natural logarithm, Appendix A–7.) We rewrite the last displayed equation, setting $\ln 1 = 0$, as

$$\ln\left(1 - \frac{bv}{mg}\right) = -\frac{b}{m}t.$$

Next we raise each side of this equation to the exponential [the natural log and the exponential are inverse operations of each other: $e^{\ln x} = x$, or $\ln\left(e^x\right) = x$] and obtain

$$1 - \frac{bv}{mg} = e^{-\frac{b}{m}t}$$

so

$$v = \frac{mg}{b}\left(1 - e^{-\frac{b}{m}t}\right).$$

This relation gives the velocity $v$ as a function of time and corresponds to the graph of Fig. 5–27b. As a check, note that at $t = 0$, we get $v = (mg/b)(1 - 1) = 0$, and

$$a(t = 0) = \frac{dv}{dt} = \frac{mg}{b}\frac{d}{dt}\left(1 - e^{-\frac{b}{m}t}\right) = \frac{mg}{b}\left(\frac{b}{m}\right)e^{-0} = g,$$

as expected (see also Eq. 5–7). At large $t$, $e^{-\frac{b}{m}t}$ approaches zero, so $v$ approaches $mg/b$, which is the terminal velocity, $v_T$, as we saw earlier. If we set $\tau = m/b$, then $v = v_T\left(1 - e^{-t/\tau}\right)$. So $\tau = m/b$ is the time required for the velocity to reach 63% of the terminal velocity (since $e^{-1} = 0.37$). Figure 5–27b shows a plot of speed $v$ vs. time $t$, where the terminal velocity $v_T = mg/b$.

[†]We rearranged it like this also so that the logarithm that we obtain below will be dimensionless, just as $\theta$ is for $\sin\theta$ or $\cos\theta$. See Appendix A–7.

# Summary

When two objects slide over one another, the force of **friction** that each object exerts on the other can be written approximately as $F_{fr} = \mu_k F_N$, where $F_N$ is the **normal force** (the force each object exerts on the other perpendicular to their contact surfaces), and $\mu_k$ is the coefficient of **kinetic friction**. If the objects are at rest relative to each other, even though one is pushed or pulled relative to the other, then $F_{fr}$ is just large enough to hold them at rest and satisfies the inequality $F_{fr} \leq \mu_s F_N$, where $\mu_s$ is the coefficient of **static friction**.

An object moving in a circle of radius $r$ with constant speed $v$ is said to be in **uniform circular motion**. It has a **radial acceleration** $a_R$ that is directed radially toward the center of the circle (also called **centripetal acceleration**), and has magnitude

$$a_R = \frac{v^2}{r}. \qquad \textbf{(5–1)}$$

The velocity vector and the acceleration vector $\vec{\mathbf{a}}_R$ are continually changing in direction, but are perpendicular to each other at each moment.

A force is needed to keep an object revolving uniformly in a circle, and the direction of this force is toward the center of the circle. This force may be due to gravity (as for the Moon), to tension in a cord, to a component of the normal force, or to another type of force or a combination of forces.

But there is no outward "centrifugal force" acting on an object moving in circular motion.

When the speed of circular motion is not constant, the acceleration has two components, tangential as well as radial. The force too has tangential and radial components.

[*A **drag force** acts on an object moving through a fluid, such as air or water. The drag force $F_D$ can often be approximated by $F_D = -bv$ or $F_D \propto v^2$, where $v$ is the speed of the object relative to the fluid.]

# Questions

1. A heavy crate rests on the bed of a flatbed truck. When the truck accelerates, the crate remains where it is on the truck, so it, too, accelerates. What force causes the crate to accelerate?
2. A block is given a push so that it slides up a ramp. After the block reaches its highest point, it slides back down, but the magnitude of its acceleration is less on the descent than on the ascent. Why?
3. *Cross-country skiers* prefer their skis to have a large coefficient of static friction but a small coefficient of kinetic friction. Explain why. [*Hint*: Think of uphill and downhill.]
4. In the equation for static friction in Section 5–1, what is the significance of the $<$ sign? When should you use the equals sign in the static friction equation?
5. It is not easy to walk on an icy sidewalk without slipping. Even your gait looks different than on dry pavement. Describe what you need to do differently on the icy surface and why.
6. Why is the stopping distance of a truck much shorter than for a train going the same speed?
7. A car rounds a curve at a steady 50 km/h. If it rounds the same curve at a steady 70 km/h, will its acceleration be any different? Explain.
8. Will the acceleration of a car be the same when a car travels around a sharp curve at a constant 60 km/h as when it travels around a gentle curve at the same speed? Explain.
9. Describe all the forces acting on a child riding a horse on a merry-go-round. Which of these forces provides the centripetal acceleration of the child?
10. A child on a sled comes flying over the crest of a small hill, as shown in Fig. 5–28. His sled does not leave the ground, but he feels the normal force between his chest and the sled decrease as he goes over the hill. Explain this decrease using Newton's second law.

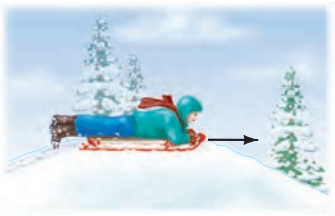


**FIGURE 5–28**
Question 10.

11. Sometimes it is said that water is removed from clothes in a spin dryer by centrifugal force throwing the water outward. Is this correct? Discuss.
12. Technical reports often specify only the rpm for centrifuge experiments. Why is this inadequate?
13. A girl is whirling a ball on a string around her head in a horizontal plane. She wants to let go at precisely the right time so that the ball will hit a target on the other side of the yard. When should she let go of the string?
14. The game of *tetherball* is played with a ball tied to a pole with a string. When the ball is struck, it whirls around the pole as shown in Fig. 5–29. In what direction is the acceleration of the ball, and what causes the acceleration?

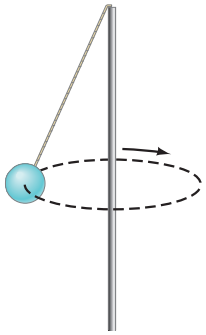

**FIGURE 5–29**
Question 14.

15. Astronauts who spend long periods in outer space could be adversely affected by weightlessness. One way to simulate gravity is to shape the spaceship like a cylindrical shell that rotates, with the astronauts walking on the inside surface (Fig. 5–30). Explain how this simulates gravity. Consider (*a*) how objects fall, (*b*) the force we feel on our feet, and (*c*) any other aspects of gravity you can think of.

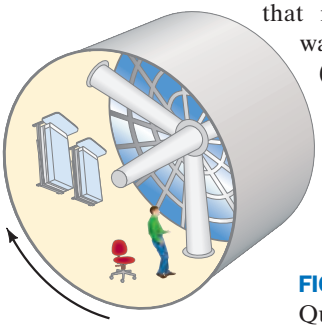

**FIGURE 5–30**
Question 15.

16. A bucket of water can be whirled in a vertical circle without the water spilling out, even at the top of the circle when the bucket is upside down. Explain.

**17.** A car maintains a constant speed $v$ as it traverses the hill and valley shown in Fig. 5–31. Both the hill and valley have a radius of curvature $R$. At which point, A, B, or C, is the normal force acting on the car (*a*) the largest, (*b*) the smallest? Explain. (*c*) Where would the driver feel heaviest and (*d*) lightest? Explain. (*e*) How fast can the car go without losing contact with the road at A?

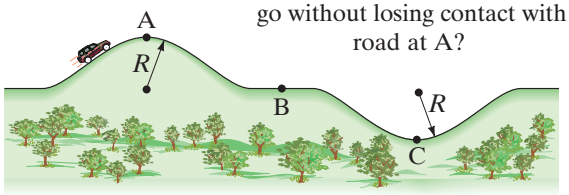

**FIGURE 5–31** Question 17.

**18.** Why do bicycle riders lean in when rounding a curve at high speed?

**19.** Why do *airplanes bank* when they turn? How would you compute the banking angle given the airspeed and radius of the turn? [*Hint*: Assume an aerodynamic "lift" force acts perpendicular to the wings.]

***20.** For a drag force of the form $F = -bv$, what are the units of $b$?

***21.** Suppose two forces act on an object, one force proportional to $v$ and the other proportional to $v^2$. Which force dominates at high speed?

# MisConceptual Questions

**1.** A 50-N crate sits on a horizontal floor where the coefficient of static friction between the crate and the floor is 0.50. A 20-N force is applied to the crate acting to the right. What is the resulting static friction force acting on the crate?
(*a*) 20 N to the right.
(*b*) 20 N to the left.
(*c*) 25 N to the right.
(*d*) 25 N to the left.
(*e*) None of the above; the crate starts to move.

**2.** What is the maximum acceleration a car can undergo if the coefficient of static friction between the tires and the ground is 0.8? Assume (i) 2-wheel drive, (ii) 4-wheel drive. [*Hint*: Consider the normal force on each tire, assumed equal.]
(*a*) 0.4 *g*, 0.4 *g*.
(*b*) 0.4 *g*, 0.8 *g*.
(*c*) 0.8 *g*, 0.4 *g*.
(*d*) 0.8 *g*, 0.8 *g*.
(*e*) Cannot tell without more information.

**3.** Which of the following point towards the center of the circle in uniform circular motion?
(*a*) Acceleration.
(*b*) Velocity, acceleration, net force.
(*c*) Velocity, acceleration.
(*d*) Velocity, net force.
(*e*) Acceleration, net force.

**4.** In a rotating vertical cylinder (Rotor-ride) a rider finds herself pressed with her back to the rotating wall. Which is the correct free-body diagram for her (Fig. 5–32)?

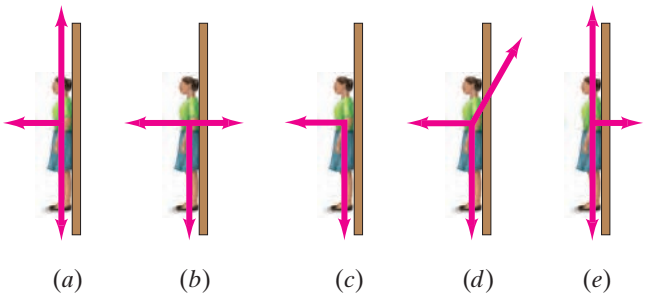

**FIGURE 5–32** MisConceptual Question 4.

**5.** A Ping-Pong ball is shot into a circular tube that is lying flat (horizontal) on a tabletop. When the Ping-Pong ball exits the tube, which path will it follow in Fig. 5–33?

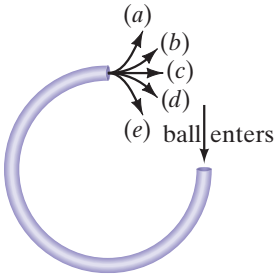

**FIGURE 5–33**
MisConceptual Question 5.

**6.** A child has a ball on the end of a cord, and whirls the ball in a vertical circle. Assuming the speed of the ball is constant (an approximation), when would the tension in the cord be greatest?
(*a*) At the top of the circle.
(*b*) At the bottom of the circle.
(*c*) A little after the bottom of the circle when the ball is climbing.
(*d*) A little before the bottom of the circle when the ball is descending quickly.
(*e*) Nowhere; the cord is pulled the same amount at all points.

**7.** While driving fast around a sharp right turn, you find yourself pressing against the left car door. What is happening?
(*a*) Centrifugal force is pushing you into the door.
(*b*) The door is exerting a rightward force on you.
(*c*) Both of the above.
(*d*) Neither of the above.

**8.** A car drives at steady speed around a perfectly circular track.
(*a*) The car's acceleration is zero.
(*b*) The net force on the car is zero.
(*c*) Both the acceleration and net force on the car point outward.
(*d*) Both the acceleration and net force on the car point inward.
(*e*) If there is no friction, the acceleration is outward.

**9.** What supplies the force that keeps a car on the road as it rounds a curve?
(*a*) The force of the steering mechanism on the tires.
(*b*) The forward component of the force of the tires on the road.
(*c*) A sideways component of the force of the tires on the road.
(*d*) A component of the force of the road on the tires that is directed along the road.
(*e*) A component of the force of the road on the tires that is directed sideways.

**10.** You are flung sideways when your car travels around a sharp curve because
(*a*) you tend to continue moving in a straight line.
(*b*) there is a centrifugal force acting on you.
(*c*) the car exerts an outward force on you.
(*d*) of gravity.

**11.** A roller coaster rounds the bottom of a circular loop at a nearly constant speed. At this point the net force on the coaster cart is
(*a*) zero.
(*b*) directed upward.
(*c*) directed downward.
(*d*) Cannot tell without knowing the exact speed.

**12.** A car is traveling around a banked curve at a speed greater than the design speed. What is needed to help the car make the turn?
(*a*) There must be a frictional force pointing up the bank.
(*b*) There must be a frictional force pointing down the bank.
(*c*) No additional force is needed; the banking of the road is sufficient.

**13.** A car travels around an unbanked curve of constant radius at a steadily decreasing speed. In what direction is the acceleration?
(*a*) In the direction of motion.
(*b*) Opposite the direction of motion.
(*c*) Perpendicular to the direction of motion.
(*d*) None of the above.

# Problems

## 5–1 Friction and Newton's Laws

**1.** (I) If the coefficient of kinetic friction between a 26-kg crate and the floor is 0.30, what horizontal force is required to move the crate at a steady speed across the floor? What horizontal force is required if $\mu_k$ is zero?

**2.** (I) A force of 35.0 N is required to start a 4.0-kg box moving across a horizontal concrete floor. (*a*) What is the coefficient of static friction between the box and the floor? (*b*) If the 35.0-N force continues, the box accelerates at 0.60 m/s$^2$. What is the coefficient of kinetic friction?

**3.** (II) Suppose you are standing on a train accelerating at 0.20 *g*. What minimum coefficient of static friction must exist between your feet and the floor if you are not to slide?

**4.** (II) The coefficient of static friction between hard rubber and normal street pavement is about 0.90. On how steep a hill (maximum angle) can you leave a car parked?

**5.** (II) (*a*) A box sits at rest on a rough 28° inclined plane. Draw the free-body diagram, showing all the forces acting on the box. (*b*) How would the diagram change if the box were sliding down the plane? (*c*) How would it change if the box were sliding up the plane after an initial shove?

**6.** (II) A 25.0-kg box is released on a 27° incline and accelerates down the incline at 0.36 m/s$^2$. Find the friction force impeding its motion. What is the coefficient of kinetic friction?

**7.** (II) A car can decelerate at $a_x = -3.80$ m/s$^2$ without skidding when coming to rest on a level road. What would its deceleration be if the road is inclined at 9.3° and the car moves uphill? Assume the same static friction coefficient.

**8.** (II) A wet bar of soap slides freely down a ramp 7.5 m long inclined at 8.0°. Starting from rest, how long does it take to reach the bottom? Assume $\mu_k = 0.060$.

**9.** (II) Show that if a skier moves at constant speed straight down a slope of angle $\theta$ (Example 5–6), then the coefficient of kinetic friction between skis and snow is $\mu_k = \tan\theta$. Ignore air resistance.

**10.** (II) A box is given a push so that it slides across the floor. How far will it go, given that the coefficient of kinetic friction is 0.15 and the push imparts an initial speed of 3.5 m/s?

**11.** (II) (*a*) Show that the minimum stopping distance for an automobile traveling on a level road at speed $v$ is equal to $v^2/(2\,\mu_s g)$, where $\mu_s$ is the coefficient of static friction between the tires and the road, and $g$ is the acceleration of gravity. (*b*) What is this distance for a 1200-kg car traveling 95 km/h if $\mu_s = 0.65$?

**12.** (II) A 1360-kg car pulls a 350-kg trailer. The car exerts a horizontal force of $3.6 \times 10^3$ N against the ground in order to accelerate. What force does the car exert on the trailer? Assume an effective friction coefficient of 0.15 for the trailer.

**13.** (II) A car starts down a long slippery hill inclined at 15°. The brakes are applied at the top of the hill where the car's speed is 22.0 m/s. If the coefficient of static friction between the road and the tires is 0.35 and the car slows at its maximum possible rate, how far will the car travel down the hill before stopping?

**14.** (II) Drag-race tires in contact with an asphalt surface have a very high coefficient of static friction. Assuming a constant acceleration and no slipping of tires, estimate the coefficient of static friction needed for a drag racer to cover 1.0 km in 12 s, starting from rest.

**15.** (II) The girl and sled in Conceptual Example 5–4 have a combined mass of 31 kg. The coefficient of kinetic friction between the sled and the snow is 0.12. (*a*) If you push the sled, as in Fig. 5–6a at an angle of 25°, what magnitude of force is needed to maintain the sled's motion at a constant speed? (*b*) If you pull the sled, as in Fig. 5–6b at an angle of 25°, what magnitude of force is needed to maintain the sled's motion at a constant speed?

**16.** (II) Police investigators, examining the scene of an accident involving a car and an old truck, measure 72-m-long skid marks for the truck, which nearly came to a stop before colliding with the car at rest. The coefficient of kinetic friction between rubber and the pavement is about 0.80. Estimate the initial speed of the truck assuming a level road.

**17.** (II) Piles of snow on slippery roofs can become dangerous projectiles as they melt. Consider a chunk of snow at the ridge of a roof with a slope of 24°. (*a*) What is the minimum value of the coefficient of static friction that will keep the snow from sliding down? (*b*) As the snow begins to melt, the coefficient of static friction decreases and the snow finally slips. Assuming that the distance from a chunk of snow to the edge of the roof is 6.0 m and the coefficient of kinetic friction is 0.20, calculate the speed of the snow chunk when it slides off the roof. (*c*) If the edge of the roof is 10.0 m above ground, how far out does the snow hit the ground? (*d*) Estimate the speed of the snow when it hits the ground.

**18.** (II) A small box is held in place against a rough vertical wall by someone pushing on it with a force directed upward at 22° above the horizontal. The coefficients of static and kinetic friction between the box and wall are 0.40 and 0.30, respectively. The box slides down unless the applied force has magnitude 23 N. What is the mass of the box?

**19.** (II) Two crates, of mass 65 kg and 125 kg, are in contact and at rest on a horizontal surface (Fig. 5–34). A 650-N force is exerted on the 65-kg crate. If the coefficient of kinetic friction is 0.18, calculate (*a*) the acceleration of the system, and (*b*) the force that each crate exerts on the other. (*c*) Repeat with the crates reversed.

**FIGURE 5–34** Problem 19.

**20.** (II) The crate shown in Fig. 5–35 lies on a plane tilted at an angle $\theta = 25.0°$ to the horizontal, with $\mu_k = 0.19$. (*a*) Determine the acceleration of the crate as it slides down the plane. (*b*) If the crate starts from rest 8.75 m up the plane from its base, what will be the crate's speed when it reaches the bottom of the incline?

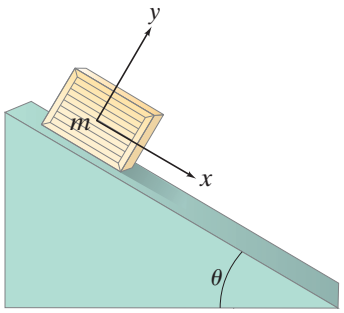

**FIGURE 5–35** Crate on inclined plane. Problems 20 and 21.

**21.** (II) A crate is given an initial speed of 3.0 m/s up the 25.0° plane shown in Fig. 5–35. (*a*) How far up the plane will it go? (*b*) How much time elapses before it returns to its starting point? Assume $\mu_k = 0.17$.

**22.** (II) A flatbed truck is carrying a heavy crate. The coefficient of static friction between the crate and the bed of the truck is 0.75. What is the maximum rate at which the driver can decelerate and still avoid having the crate slide against the cab of the truck?

**23.** (II) In Fig. 5–36 the coefficient of static friction between mass $m_A$ and the table is 0.40, whereas the coefficient of kinetic friction is 0.30. (*a*) What minimum value of $m_A$ will keep the system from starting to move? (*b*) What value(s) of $m_A$ will keep the system moving at constant speed? [Ignore masses of the cord and the (frictionless) pulley.]

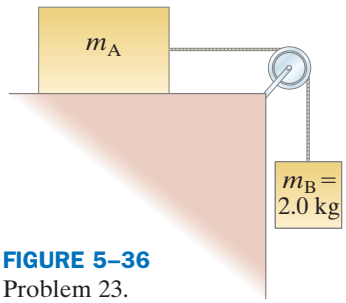

**FIGURE 5–36** Problem 23.

**24.** (II) A 68-kg snowboarder has an initial velocity of 5.0 m/s at the top of a 28° incline (Fig. 5–37). After sliding down the 110-m-long incline (assume a coefficient of kinetic friction $\mu_k = 0.18$), the snowboarder has attained a velocity $v$. The snowboarder then slides along a flat surface (on which $\mu_k = 0.15$) and comes to rest after a distance $x$. Use Newton's second law to find the snowboarder's acceleration while on the incline and while on the flat surface. Then use these accelerations to determine $x$. Ignore air resistance.

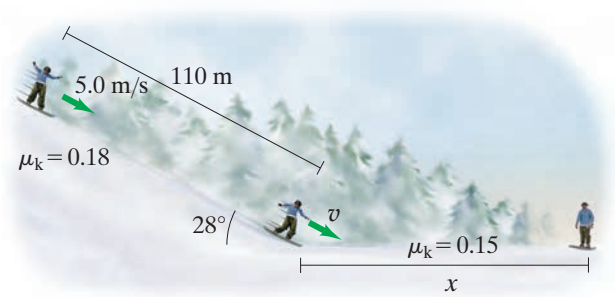

**FIGURE 5–37** Problem 24.

**25.** (II) A package of mass $m$ is dropped vertically onto a horizontal conveyor belt whose speed is $v = 1.5$ m/s, and the coefficient of kinetic friction between the package and the belt is $\mu_k = 0.70$. (*a*) For how much time does the package slide on the belt (until it is at rest relative to the belt)? (*b*) How far does the package move during this time?

**26.** (II) Two masses $m_A = 2.0$ kg and $m_B = 5.0$ kg are on inclines and are connected together by a string as shown in Fig. 5–38. The coefficient of kinetic friction between each mass and its incline is $\mu_k = 0.30$. If $m_A$ moves up, and $m_B$ moves down, determine their acceleration. Ignore masses of the cord and the pulley (assume frictionless).

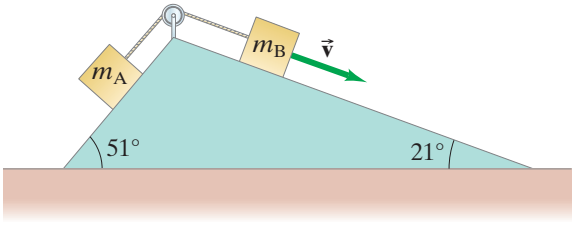

**FIGURE 5–38** Problem 26.

**27.** (II) A child slides down a slide with a 28° incline, and at the bottom her speed is precisely half what it would have been if the slide had been frictionless. Calculate the coefficient of kinetic friction between the slide and the child.

**28.** (II) (*a*) Suppose the coefficient of kinetic friction between $m_A$ and the ramp in Fig. 5–39 is $\mu_k = 0.15$, and that $m_A = m_B = 2.7$ kg. As $m_B$ moves down, determine the magnitude of the acceleration of $m_A$ and $m_B$, given $\theta = 34°$. (*b*) What smallest value of $\mu_k$ will keep the system from accelerating? [Ignore masses of cord and (frictionless) pulley.]

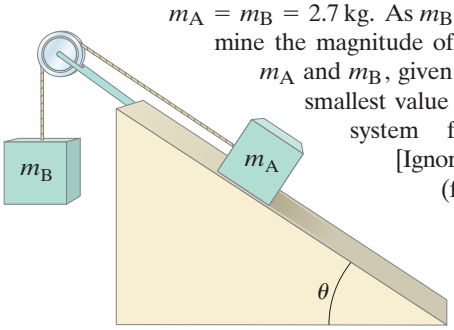

**FIGURE 5–39** Problem 28.

**29.** (II) Two blocks made of different materials connected together by a thin cord slide down a ramp inclined at an angle $\theta$ to the horizontal, Fig. 5–40 (block B is above block A). The masses of the blocks are $m_A$ and $m_B$, and the coefficients of friction are $\mu_A$ and $\mu_B$. If $m_A = m_B = 4.0\,\text{kg}$, and $\mu_A = 0.20$ and $\mu_B = 0.30$, determine (*a*) the acceleration of the blocks and (*b*) the tension in the cord, for an angle $\theta = 32°$.

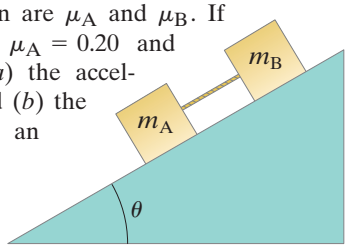

**FIGURE 5–40**
Problems 29 and 30.

**30.** (III) For two blocks, connected by a cord and sliding down the incline shown in Fig. 5–40 (see Problem 29), describe the motion (*a*) if $\mu_A < \mu_B$, and (*b*) if $\mu_A > \mu_B$. (*c*) Determine a formula for the acceleration of each block and the tension $F_T$ in the cord in terms of $m_A$, $m_B$, and $\theta$; interpret your results in light of your answers to (*a*) and (*b*).

**31.** (III) A 2.5-kg block is placed on a table as shown in Fig. 5–41. The coefficient of kinetic friction between the block and the table is 0.35. The block is connected by massless ropes over pulleys (whose mass and friction can be ignored) to a 5.0-kg block on the right, and a 3.0-kg block on the left, as shown in Fig. 5–41. Find the acceleration of the block on the table if it is moving to the right.

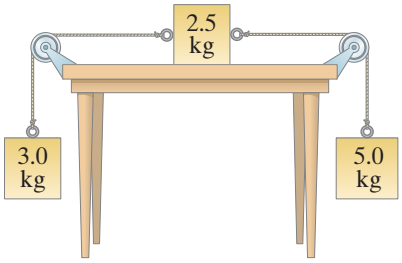

**FIGURE 5–41**
Problem 31.

**32.** (III) A 3.0-kg block sits on top of a 5.0-kg block which is on a horizontal surface. The blocks are connected (Fig. 5–42) by a cord over a pulley (ignore mass and friction). The 5.0-kg block is pulled to the right with a force $\vec{\mathbf{F}}$. The coefficient of static friction between all surfaces is 0.60 and the kinetic coefficient is 0.40. (*a*) What is the minimum value of $F$ needed to move the two blocks? (*b*) If the force is 10% greater than your answer for (*a*), what is the acceleration of each block?

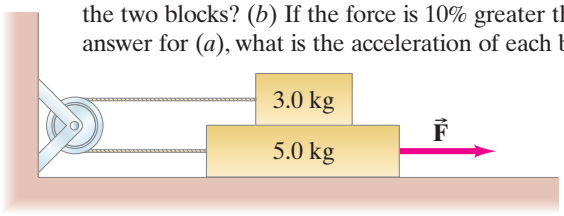

**FIGURE 5–42** Problem 32.

**33.** (III) A 4.0-kg block is stacked on top of a 12.0-kg block, which is accelerating along a horizontal table at $a = 5.2\,\text{m/s}^2$ (Fig. 5–43). Let $\mu_k = \mu_s = \mu$. (*a*) What minimum coefficient of friction $\mu$ between the two blocks will prevent the 4.0-kg block from sliding off? (*b*) If $\mu$ is only half this minimum value, what is the acceleration of the 4.0-kg block with respect to the table, and (*c*) with respect to the 12.0-kg block? (*d*) What is the force that must be applied to the 12.0-kg block in (*a*) and in (*b*), assuming that the table is frictionless?

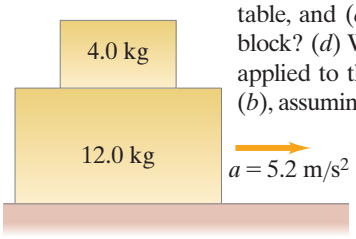

**FIGURE 5–43**
Problem 33.

**34.** (III) A small block of mass $m$ rests on the rough, sloping side of a triangular block of mass $M$ which itself rests on a horizontal frictionless table as shown in Fig. 5–44. If the coefficient of static friction is $\mu$, determine the minimum horizontal force $F$ applied to $M$ that will cause the small block $m$ to start moving up the incline.

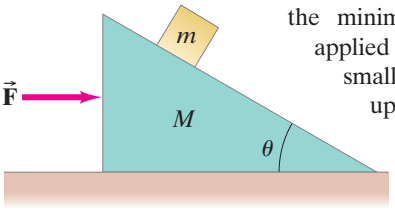

**FIGURE 5–44**
Problem 34.

## 5–2 to 5–4 Uniform Circular Motion

**35.** (I) What is the maximum speed with which a 1200-kg car can round a turn of radius 90.0 m on a flat road if the coefficient of static friction between tires and road is 0.65? Is this result independent of the mass of the car?

**36.** (I) A child sitting 1.40 m from the center of a merry-go-round moves with a speed of 1.30 m/s. Calculate (*a*) the centripetal acceleration of the child and (*b*) the net horizontal force exerted on the child (mass = 22.5 kg).

**37.** (I) A horizontal force of 310 N is exerted on a 2.0-kg ball as it rotates (at arm's length) uniformly in a horizontal circle of radius 0.90 m. Calculate the speed of the ball.

**38.** (I) A jet plane traveling 1890 km/h (525 m/s) pulls out of a dive by moving in an arc of radius 4.80 km. What is the plane's acceleration in $g$'s?

**39.** (II) How large must the coefficient of static friction be between the tires and the road if a car is to round a level curve of radius 85 m at a speed of 95 km/h?

**40.** (II) A 0.45-kg ball, attached to the end of a horizontal cord, is revolved in a circle of radius 1.3 m on a frictionless horizontal surface. If the cord will break when the tension in it exceeds 75 N, what is the maximum speed the ball can have?

**41.** (II) On an ice rink two skaters of equal mass grab hands and spin in a mutual circle once every 2.5 s. If we assume their arms are each 0.80 m long and their individual masses are 55.0 kg, how hard are they pulling on one another?

***42.** (II) How fast (in rpm) must a centrifuge rotate if a particle 8.00 cm from the axis of rotation is to experience an acceleration of 125,000 $g$'s?

**43.** (II) A car drives in a spiral path of gradually decreasing radius in a large empty parking lot. The speed is held constant at 10.0 m/s, and the car starts at a distance of 50.0 m from the center of the spiral. If the coefficient of static friction is 0.80, how far is the car from the center when it first starts to skid?

**44.** (II) Redo Example 5–11, precisely this time, by not ignoring the weight of the ball which revolves on a string 0.600 m long. In particular, find the magnitude of $\vec{\mathbf{F}}_T$, and the angle it makes with the horizontal. [*Hint*: Set the horizontal component of $\vec{\mathbf{F}}_T$ equal to $ma_R$; also, since there is no vertical motion, what can you say about the vertical component of $\vec{\mathbf{F}}_T$?]

**45.** (II) Highway curves are marked with a suggested speed. If this speed is based on what would be safe in wet weather, estimate the radius of curvature for an unbanked curve marked 50 km/h. Use Table 5–1 (coefficient of friction).

**46.** (II) Is it possible to whirl a bucket of water fast enough in a vertical circle so that the water won't fall out? If so, what is the minimum speed? Define all quantities needed.

**47.** (II) At what minimum speed must a roller coaster be traveling so that passengers upside down at the top of a circle (Fig. 5–45) do not fall out? Assume a radius of curvature of 7.6 m.

**FIGURE 5–45**
Problem 47.

**48.** (II) A bucket of mass 2.00 kg is whirled in a vertical circle of radius 1.10 m. At the lowest point of its motion the tension in the rope supporting the bucket is 25.0 N. (*a*) Find the speed of the bucket. (*b*) How fast must the bucket move at the top of the circle so that the rope does not go slack?

**49.** (II) A car drives straight down toward the bottom of a valley and up the other side on a road whose bottom has a radius of curvature of 125 m. At the very bottom, the normal force on the driver is twice his weight. At what speed was the car traveling?

**50.** (II) How many revolutions per minute would a 22-m-diameter Ferris wheel need to make for the passengers to feel "weightless" at the topmost point?

**51.** (II) A 1250-kg car rounds a curve of radius 68 m banked at an angle of 14°. If the car is traveling at 85 km/h, will a friction force be required? If so, how much and in what direction?

**52.** (II) A jet pilot takes his aircraft in a vertical loop (Fig. 5–46). (*a*) If the jet is moving at a speed of 1200 km/h at the lowest point of the loop, determine the minimum radius of the circle so that the centripetal acceleration at the lowest point does not exceed 5.0 *g*'s. (*b*) Calculate the 78-kg pilot's effective weight (the force with which the seat pushes up on him) at the bottom of the circle, and (*c*) at the top of the circle (assume the same speed).

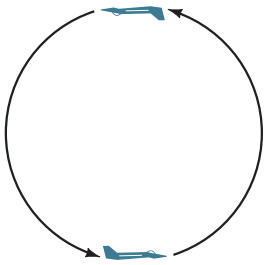

**FIGURE 5–46**
Problem 52.

**53.** (II) While fishing, you get bored and start to swing a sinker weight around in a circle below you on a 0.45-m piece of fishing line. The weight makes a complete circle every 0.65 s. What is the angle that the fishing line makes with the vertical? [*Hint*: See Fig. 5–20.]

**54.** (II) A proposed *space station* consists of a circular tube that will rotate about its center (like a tubular bicycle tire), Fig. 5–47. The circle formed by the tube has a diameter of about 1.1 km. What must be the rotation speed (revolutions per day) if an effect nearly equal to gravity at the surface of the Earth, 0.90 *g*, is to be felt by astronauts walking inside? Which part of the tube do they walk on?

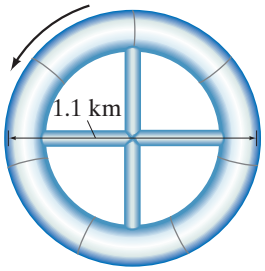

**FIGURE 5–47**
Problem 54.

**55.** (II) A bug walks outward from the center of a turntable that is rotating at 65 rpm. If the coefficient of static friction between the bug and the turntable is 0.42, how far out from the center does the bug get before it starts to slip on the turntable? What happens to the bug after it moves farther out past that point?

**56.** (II) A coin is placed 10.5 cm from the axis of a rotating turntable of variable speed. When the speed of the turntable is slowly increased, the coin remains fixed on the turntable until a rate of 38.0 rpm (revolutions per minute) is reached, at which point the coin slides off. What is the coefficient of static friction between the coin and the turntable?

**57.** (II) A 975-kg car (including driver) crosses the rounded top of a hill (radius = 88.0 m) at 14.0 m/s. Determine (*a*) the normal force exerted by the road on the car, (*b*) the normal force exerted by the car on the 72.0-kg driver, and (*c*) the car speed at which the car would leave the road (Fig. 5–48).

**FIGURE 5–48** Problem 57.

**58.** (II) Two blocks, with masses $m_A$ and $m_B$, are connected to each other and to a central post by thin rods as shown in Fig. 5–49. The blocks revolve about the post at the same frequency $f$ (revolutions per second) on a frictionless horizontal surface at distances $r_A$ and $r_B$ from the post. Derive an algebraic expression for the tension in each rod.

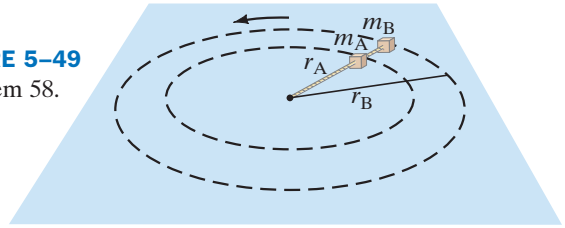

**FIGURE 5–49**
Problem 58.

**59.** (II) A device for training astronauts and jet fighter pilots is designed to rotate a trainee in a horizontal circle of radius 11.0 m. If the force felt by a trainee is 7.45 times her own weight, how fast is she revolving? Express your answer in both m/s and rev/s.

**60.** (II) Tarzan plans to cross a gorge by swinging in an arc from a hanging vine (Fig. 5–50). If his arms are capable of exerting a force of 1350 N on the vine, what is the maximum speed he can tolerate at the lowest point of his swing? His mass is 78 kg and the vine is 4.8 m long.

**FIGURE 5–50**
Problem 60.

**61.** (II) A pilot performs an evasive maneuver by diving vertically at a constant 310 m/s. If he can withstand an acceleration of 9.0 *g*'s without blacking out, at what altitude must he begin to pull his plane out of the dive (moving in a vertical circular path) to avoid crashing into the sea?

**62.** (III) The position of a particle moving in the *xy* plane is given by $\vec{\mathbf{r}} = (2.0\,\text{m})\cos[(3.0\,\text{rad/s})t]\,\hat{\mathbf{i}} + (2.0\,\text{m})\sin[(3.0\,\text{rad/s})t]\,\hat{\mathbf{j}}$, where $r$ is in meters and $t$ is in seconds. (*a*) Show that this represents circular motion of radius 2.0 m centered at the origin. (*b*) Calculate the velocity and acceleration vectors as functions of time. (*c*) Calculate the speed and magnitude of the acceleration. (*d*) Show that $a = v^2/r$. (*e*) Show that the acceleration vector always points toward the center of the circle.

**63.** (III) If a curve with a radius of 85 m is properly banked for a car traveling 65 km/h, what must be the coefficient of static friction for a car not to skid when traveling at 95 km/h?

**64.** (III) A curve of radius 75 m is banked for a design speed of 85 km/h. If the coefficient of static friction is 0.30 (wet pavement), at what range of speeds can a car safely make the curve? [*Hint*: Consider the direction of the friction force when the car goes too slow or too fast.]

### 5–5 Nonuniform Circular Motion

**65.** (I) Determine the tangential and centripetal components of the net force exerted on the car (by the ground) in Example 5–16 when its speed is 12 m/s. The car's mass is 950 kg.

**66.** (II) A car at the Indianapolis 500 accelerates uniformly, going from rest to 270 km/h in a semicircular arc with a radius of 220 m. Determine the tangential and radial acceleration of the car when it is halfway through the arc, assuming constant tangential acceleration. If the curve were flat, what coefficient of static friction would be necessary between the tires and the road to provide this acceleration with no slipping or skidding?

**67.** (II) For each of the cases described below, sketch and label the total acceleration vector, the radial acceleration vector, and the tangential acceleration vector. (*a*) A car speeds up as it rounds a curve of constant radius. (*b*) A car is going a constant 65 km/h as it rounds a curve of constant radius. (*c*) A car slows down while rounding a curve of constant radius.

**68.** (II) A particle starting from rest revolves with uniformly increasing speed in a clockwise circle in the *xy* plane. The center of the circle is at the origin of an *xy* coordinate system. At $t = 0$, the particle is at $x = 0.0, y = 2.0$ m. At $t = 2.0$ s, it has made one-quarter of a revolution and is at $x = 2.0$ m, $y = 0.0$. Determine (*a*) its speed at $t = 2.0$ s, (*b*) the average velocity vector, and (*c*) the average acceleration vector during this interval.

**69.** (II) An object moves in a circle of radius 22 m with its speed given by $v = 3.2 + 1.8t^2$, with $v$ in meters per second and $t$ in seconds. At $t = 3.0$ s, find (*a*) the tangential acceleration and (*b*) the radial acceleration.

**70.** (III) A particle rotates in a circle of radius 3.80 m. At a particular instant its acceleration is 1.15 m/s$^2$ in a direction that makes an angle of 38.0° to its direction of motion. Determine its speed (*a*) at this moment and (*b*) 3.00 s later, assuming constant tangential acceleration.

**71.** (III) An object of mass $m$ is constrained to move in a circle of radius $r$. Its tangential acceleration as a function of time is given by $a_{\tan} = b + ct^2$, where $b$ and $c$ are constants. If $v = v_0$ at $t = 0$, determine the tangential and radial components of the force, $F_{\tan}$ and $F_R$, acting on the object at any time $t > 0$.

### *5–6 Velocity-Dependent Forces

***72.** (I) Use *dimensional analysis* (Section 1–7) in Example 5–17 to determine if the time constant $\tau$ is $\tau = m/b$ or $\tau = b/m$.

***73.** (II) The terminal velocity of a $3 \times 10^{-5}$ kg raindrop is about 9 m/s. Assuming a drag force $F_D = -bv$, determine (*a*) the value of the constant $b$ and (*b*) the time required for such a drop, starting from rest, to reach 63% of terminal velocity.

***74.** (II) Determine a formula for the position and acceleration of a falling object as a function of time if the object starts from rest at $t = 0$ and undergoes a resistive force $F = -bv$, as in Example 5–17.

***75.** (II) The drag force on large objects such as cars, planes, and sky divers moving through air is more nearly $F_D = -cv^2$. (*a*) For this quadratic dependence on $v$, determine a formula for the terminal velocity $v_T$, of a vertically falling object. (*b*) Determine the value of the constant $c$ for a 75-kg sky diver who has a terminal velocity of about 60 m/s. (*c*) Sketch a curve like that of Fig. 5–27b for this case of $F_D \propto v^2$. For the same terminal velocity, would this curve lie above or below that in Fig. 5–27? Explain why.

***76.** (III) An object moving vertically has $\vec{\mathbf{v}} = \vec{\mathbf{v}}_0$ at $t = 0$. Determine a formula for its velocity as a function of time assuming a resistive force $F = -bv$ as well as gravity for two cases: (*a*) $\vec{\mathbf{v}}_0$ is downward and (*b*) $\vec{\mathbf{v}}_0$ is upward.

***77.** (III) A bicyclist can coast down a 7.8° hill at a steady 9.5 km/h. If the drag force is proportional to the square of the speed $v$, so that $F_D = -cv^2$, calculate (*a*) the value of the constant $c$ and (*b*) the average force that must be applied in order to descend the hill at 25 km/h. The mass of the cyclist plus bicycle is 80.0 kg. Ignore other types of friction.

***78.** (III) A block of mass $m$ slides along a horizontal surface lubricated with a thick oil which provides a drag force proportional to the square root of velocity:

$$F_D = -bv^{\frac{1}{2}}.$$

If $v = v_0$ at $t = 0$, determine $v$ and $x$ as functions of time.

***79.** (III) A motorboat traveling at a speed of 2.4 m/s shuts off its engines at $t = 0$. How far does it travel before coming to rest if it is noted that after 3.0 s its speed has dropped to half its original value? Assume that the drag force of the water is proportional to $v$.

## General Problems

**80.** A coffee cup on the horizontal dashboard of a car slides forward when the driver decelerates from 45 km/h to rest in 3.5 s or less, but not if she decelerates in a longer time. What is the coefficient of static friction between the cup and the dash? Assume the road and the dashboard are level (horizontal).

**81.** A 1.6-kg silverware drawer does not slide readily. The owner gradually pulls with more and more force, and when the applied force reaches 9.0 N, the drawer suddenly opens, throwing all the utensils to the floor. What is the coefficient of static friction between the drawer and the cabinet?

**82.** A roller coaster reaches the top of the steepest hill with a speed of 6.0 km/h. It then descends the hill, which is at an average angle of 45° and is 45.0 m long. What will its speed be when it reaches the bottom? Assume $\mu_k = 0.14$.

**83.** An 18.0-kg box is released on a 32.0° incline and accelerates down the incline at 0.220 m/s$^2$. Find the friction force impeding its motion. How large is the coefficient of friction?

**84.** A flat puck (mass $M$) is revolved in a circle on a frictionless air hockey table top, and is held in this orbit by a light cord which is connected to a dangling mass (mass $m$) through a central hole as shown in Fig. 5–51. Show that the speed of the puck is given by $v = \sqrt{mgR/M}$.

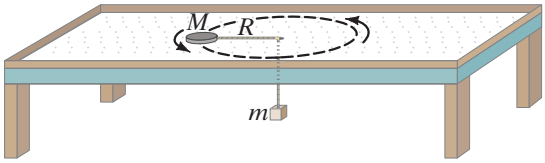

**FIGURE 5–51** Problem 84.

**85.** In a "Rotor-ride" at a carnival, people rotate in a vertical cylindrically walled "room." See Fig. 5–52. If the room radius is 5.5 m, and the rotation frequency 0.50 revolutions per second when the floor drops out, what minimum coefficient of static friction keeps the people from slipping down? People on this ride said they were "pressed against the wall." Is there really an outward force pressing them against the wall? If so, what is its source? If not, what is the proper description of their situation (besides nausea)? [*Hint*: Draw a free-body diagram for a person.]

**FIGURE 5–52** Problem 85.

**86.** At time $t = 0$, a car at the starting line of a circular race track of radius 410 m is moving at 11 m/s. The car's speed increases at a constant rate of 0.22 m/s$^2$. (*a*) At what time does the centripetal acceleration of the car equal $g$? (*b*) How many laps has the car made on the track at this time?

**87.** Determine the tangential and centripetal components of the net force exerted on a car (by the ground) when its speed is 27 m/s, and it has accelerated to this speed from rest in 11 s on a curve of radius 450 m. The car's mass is 1150 kg.

**88.** The 70.0-kg climber in Fig. 5–53 is supported in the "chimney" by the friction forces exerted on his shoes and back. The static coefficients of friction between his shoes and the wall, and between his back and the wall, are 0.80 and 0.60, respectively. What is the minimum normal force he must exert? Assume the walls are vertical and that the static friction forces are both at their maximum. Ignore his grip on the rope.

**FIGURE 5–53** Problem 88.

**89.** A small mass $m$ is set on the surface of a sphere, Fig. 5–54. If the coefficient of static friction is $\mu_s = 0.70$, at what angle $\phi$ would the mass start sliding?

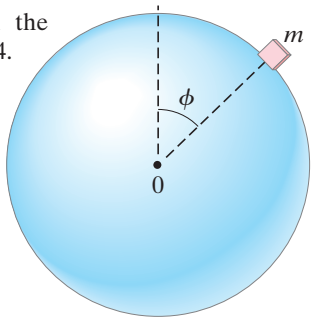

**FIGURE 5–54** Problem 89.

**90.** A train traveling at a constant speed rounds a curve of radius 215 m. A lamp suspended from the ceiling swings out to an angle of 18.5° throughout the curve. What is the speed of the train? [*Hint*: See Example 4–15.]

**91.** Calculate (*a*) the centripetal acceleration of the Earth in its orbit around the Sun, and (*b*) the net force exerted on the Earth. What exerts this force on the Earth? Assume that the Earth's orbit is a circle of radius $1.50 \times 10^{11}$ m, and it takes 365 days to make one complete orbit.

**92.** Consider a train that rounds a curve with a radius of 530 m at a speed of 160 km/h (approximately 100 mi/h). (*a*) Calculate the friction force needed on a train passenger of mass 55 kg if the track is not banked and the train does not tilt. (*b*) Calculate the friction force on the passenger if the train tilts at an angle of 8.0° toward the center of the curve.

**93.** A ball of mass 0.75 kg is attached to a vertical post by strings of length 1.1 m and 1.7 m, as shown in Fig. 5–55. If the ball is set moving in a horizontal circle, find (*a*) the maximum speed for the lower string to be slack (tension in cord = 0), and (*b*) the tension in each string if the ball is moving at twice the speed found in part (*a*).

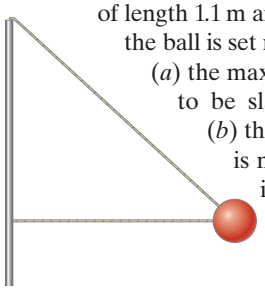

**FIGURE 5–55** Problem 93.

**94.** A small block of mass $m$ is given an initial speed $v_0$ up a ramp inclined at angle $\theta$ to the horizontal. It travels a distance $d$ up the ramp and comes to rest. (*a*) Determine a formula for the coefficient of kinetic friction between block and ramp. (*b*) What can you say about the value of the coefficient of static friction?

**95.** A 28.0-kg block is connected to an empty 2.00-kg bucket by a cord running over a frictionless pulley (Fig. 5–56). The coefficient of static friction between the table and the block is 0.42 and the coefficient of kinetic friction between the table and the block is 0.34. Sand is gradually added to the bucket until the system just begins to move. (*a*) Calculate the mass of sand added to the bucket. (*b*) Calculate the acceleration of the system.

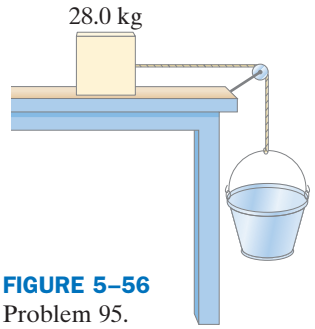

**FIGURE 5–56** Problem 95.

**96.** A car is heading along a flat slippery road at a speed of 95 km/h. The minimum distance within which it can stop (because of ABS) is 66 m. Estimate the radius of the sharpest curve the car can negotiate on an icy flat surface at the same speed without skidding out.

**97.** An airplane traveling at 510 km/h needs to reverse its course. The pilot decides to accomplish this by banking the wings at an angle of 38° while moving in a level circular path. (*a*) Find the time needed to reverse course. (*b*) Describe any additional force the passengers experience during the turn. [*Hint*: Assume an aerodynamic "lift" force that acts perpendicularly to the flat wings; see Fig. 5–57.]

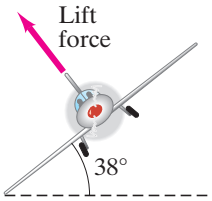

**FIGURE 5–57** Problem 97.

**98.** A banked curve of radius $R$ in a new highway is designed so that a car traveling at speed $v_0$ can negotiate the turn safely on glare ice (zero friction). If a car travels too slowly, then it will slip toward the center of the circle. If it travels too fast, it will slip away from the center of the circle. If the coefficient of static friction increases, it becomes possible for a car to stay on the road while traveling at a speed within a range from $v_{\text{min}}$ to $v_{\text{max}}$. Derive formulas for $v_{\text{min}}$ and $v_{\text{max}}$ as functions of $\mu_s$, $v_0$, and $R$.

**99.** *Earth is not quite an inertial frame.* We often make measurements in a reference frame fixed on the Earth, assuming Earth is an inertial reference frame [Section 4–2]. But the Earth rotates, so this assumption is not quite valid. Show that this assumption is off by 3 parts in 1000 by calculating the acceleration of an object at Earth's equator due to Earth's daily rotation, and compare to $g = 9.80\ \text{m/s}^2$, the acceleration due to gravity.

**100.** A small bead of mass $m$ is constrained to slide without friction inside a circular vertical hoop of radius $r$ which rotates about a vertical axis (Fig. 5–58) at a frequency $f$. (*a*) Determine the angle $\theta$ where the bead will be in equilibrium within the hoop—that is, where it will have no tendency to move up or down along the hoop. (*b*) If $f = 2.00$ rev/s and $r = 25.0$ cm, what is $\theta$? (*c*) Can the bead ride as high as the center of the circle ($\theta = 90°$)? Explain.

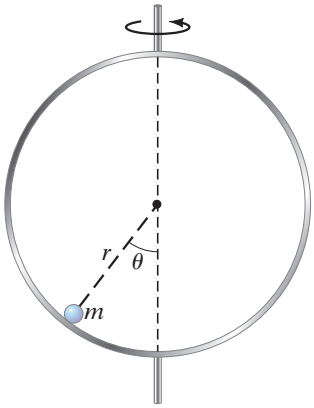

**FIGURE 5–58** Problem 100.

***101.** Use *dimensional analysis* (Section 1–7) to obtain the form for the centripetal acceleration, $a_R = v^2/r$.

**102.** A car starts rolling down a 1-in-4 hill (1-in-4 means that for each 4 m traveled along the road, the elevation change is 1 m). How fast is it going when it reaches the bottom after traveling 55 m? (*a*) Ignore friction. (*b*) Assume an effective coefficient of *rolling friction* equal to 0.10.

**103.** The sides of a cone make an angle $\phi$ with the vertical, with its point down. A small cube of mass $m$ is placed on the inside of the cone, and the cone is revolved at a frequency $f$ (revolutions per second) about its symmetry axis. If the coefficient of static friction is $\mu_s$, at what positions on the cone can the cube be placed without sliding on the cone? (Give the maximum and minimum distances, $r$, from the axis).

**104.** A 68-kg water skier is being accelerated by a ski boat on a flat ("glassy") lake. The coefficient of kinetic friction between the skier's skis and the water surface is $\mu_k = 0.25$ (Fig. 5–59). (*a*) What is the skier's acceleration if the rope pulling the skier behind the boat applies a horizontal tension force of magnitude $F_T = 240$ N to the skier ($\theta = 0°$)? (*b*) What is the skier's horizontal acceleration if the rope pulling the skier exerts a force of $F_T = 240$ N on the skier at an upward angle $\theta = 12°$? (*c*) Explain why the skier's acceleration in part (*b*) is greater than that in part (*a*).

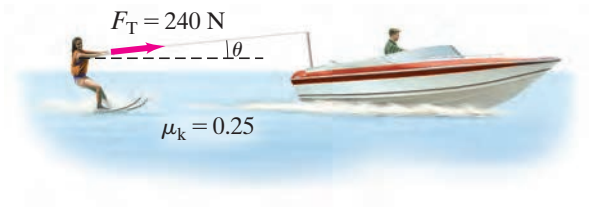

**FIGURE 5–59** Problem 104.

**105.** A ball of mass $m = 1.0$ kg at the end of a thin cord of length $r = 0.80$ m revolves in a vertical circle about point O, as shown in Fig. 5–60. During the time we observe it, the only forces acting on the ball are gravity and the tension in the cord. The motion is circular but not uniform because of the force of gravity. The ball increases in speed as it descends and slows down as it rises on the other side of the circle. At the moment the cord makes an angle $\theta = 30°$ below the horizontal, the ball's speed is 6.0 m/s. At this point, determine the tangential acceleration, the radial acceleration, and the tension in the cord, $F_T$. Take $\theta$ increasing downward as shown.

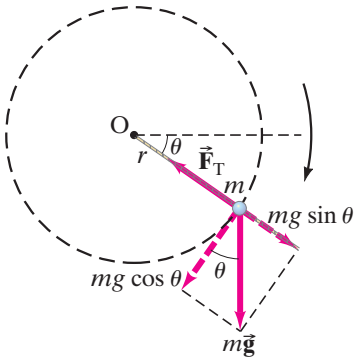

**FIGURE 5–60** Problem 105.

**106.** A car drives at a constant speed around a banked circular track with a diameter of 145 m. The motion of the car can be described in a coordinate system with its origin at the center of the circle. At a particular instant the car's acceleration in the horizontal plane is given by

$$\vec{\mathbf{a}} = (-15.7\hat{\mathbf{i}} - 23.2\hat{\mathbf{j}})\ \text{m/s}^2.$$

(*a*) What is the car's speed? (*b*) Where ($x$ and $y$) is the car at this instant?

## ANSWERS TO EXERCISES

**A:** (*c*).
**B:** The box will slow down and stop.
**C:** No—the acceleration is not constant (in direction).
**D:** (*a*), it doubles.
**E:** (*d*).
**F:** (*a*).
**G:** No. Because $a = F_{\text{fr}}/m = \mu mg/m = \mu g$.
**H:** Yes. $\theta$ does not depend on $m$ (Example 5–15).
**I:** (*a*) No change; (*b*) 4 times larger.

The astronauts in the upper left of this photo are working on a space vehicle. As they orbit the Earth—at a rather high speed—they experience apparent weightlessness. The Moon, in the background, also is orbiting the Earth at high speed. What keeps the Moon and the space vehicle (and its astronauts) from moving off in a straight line away from Earth? It is the force of gravity. Newton's law of universal gravitation states that all objects attract all other objects with a force proportional to their masses and inversely proportional to the square of the distance between them.

CHAPTER 6

# Gravitation and Newton's Synthesis

**CHAPTER-OPENING QUESTION—Guess now!**

A space station revolves around the Earth as a satellite, 100 km above Earth's surface. What is the net force on an astronaut at rest inside the space station?

**(a)** Equal to her weight on Earth.
**(b)** A little less than her weight on Earth.
**(c)** Less than half her weight on Earth.
**(d)** Zero (she is weightless).
**(e)** Somewhat larger than her weight on Earth.

Sir Isaac Newton not only put forth the three great laws of motion that serve as the foundation for the study of dynamics. He also conceived of another great law to describe one of the basic forces in nature, gravitation; and he applied it to understand the motion of the planets. This new law, published in 1687 in his book *Philosophiae Naturalis Principia Mathematica* (the *Principia*, for short), is called Newton's law of universal gravitation. It was the capstone of Newton's analysis of the physical world. Indeed, Newtonian mechanics, with its three laws of motion and the law of universal gravitation, was accepted for centuries as a mechanical basis for the way the universe works.

# 6–1 Newton's Law of Universal Gravitation

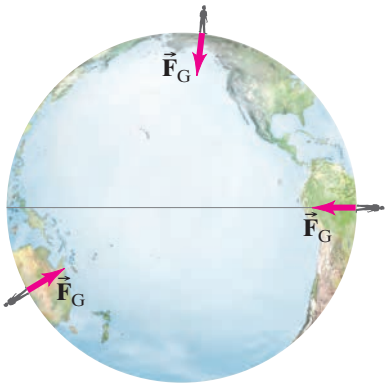

**FIGURE 6–1** Anywhere on Earth, whether in Alaska, Australia, or Peru, the force of gravity acts downward toward the center of the Earth.

Among his many great accomplishments, Sir Isaac Newton examined the motion of the heavenly bodies—the planets and the Moon. In particular, he wondered about the nature of the force that must act to keep the Moon in its nearly circular orbit around the Earth.

Newton was also thinking about the problem of gravity. Since falling objects accelerate, Newton had concluded that they must have a force exerted on them, a force we call the force of gravity. Whenever an object has a force exerted *on* it, that force is exerted *by* some other object. But what *exerts* the force of gravity? Every object on the surface of the Earth feels the force of gravity $F_G$, and no matter where the object is, the force is directed toward the center of the Earth (Fig. 6–1). Newton concluded that it must be the Earth itself that exerts the gravitational force on objects at its surface.

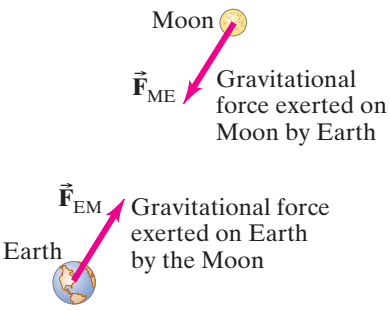
According to legend, Newton noticed an apple drop from a tree. He is said to have been struck with a sudden inspiration: If gravity acts at the tops of trees, and even at the tops of mountains, then perhaps it acts all the way to the Moon! With this idea that it is Earth's gravity that holds the Moon in its orbit, Newton developed his great theory of gravitation. But there was controversy at the time. Many thinkers had trouble accepting the idea of a force "acting at a distance." Typical forces act through contact—your hand pushes a cart and pulls a wagon, a bat hits a ball, and so on. But gravity acts without contact, said Newton: the Earth exerts a force on a falling apple and on the Moon, even though there is no contact, and the two objects may even be very far apart.

Newton set about determining the magnitude of the gravitational force that the Earth exerts on the Moon as compared to the gravitational force on objects at the Earth's surface. The centripetal acceleration of the Moon is calculated from $a_R = v^2/r$ (see Example 5–9) and gives $a_R = 0.00272\,\text{m/s}^2$. In terms of the acceleration due to gravity at the Earth's surface, $g = 9.80\,\text{m/s}^2$,

$$a_R = \frac{0.00272\,\text{m/s}^2}{9.80\,\text{m/s}^2}\,g \approx \frac{1}{3600}\,g.$$

That is, the acceleration of the Moon toward the Earth is about $\frac{1}{3600}$ as great as the acceleration of objects at the Earth's surface. The Moon is 384,000 km from the Earth, which is about 60 times the Earth's radius of 6380 km. That is, the Moon is 60 times farther from the Earth's center than are objects at the Earth's surface. But $60 \times 60 = 60^2 = 3600$. Again that number 3600! Newton concluded that the gravitational force $F_G$ exerted by the Earth on any object decreases with the *square* of its distance, $r$, from the Earth's center:

$$F_G \propto \frac{1}{r^2}.$$



The Moon is 60 Earth radii away, so it feels a gravitational force only $\frac{1}{60^2} = \frac{1}{3600}$ times as strong as it would if it were at a point on the Earth's surface.

Newton realized that the force of gravity on an object depends not only on distance but also on the object's mass. In fact, it is directly proportional to its mass, as we have seen (Eq. 4–3). According to Newton's third law, when the Earth exerts its gravitational force on any object, such as the Moon, that object exerts an equal and opposite force on the Earth (Fig. 6–2). Because of this *symmetry*, Newton reasoned, the magnitude of the force of gravity must be proportional to *both* the masses. Thus

$$F_G \propto \frac{m_E m_{obj}}{r^2},$$

where $m_E$ and $m_{obj}$ are the masses of the Earth and the other object, respectively, and $r$ is the distance from the Earth's center to the center of the other object.

**FIGURE 6–2** The gravitational force one object exerts on a second object is directed toward the first object; and, by Newton's third law, is equal and opposite to the force exerted by the second object on the first. In the case shown, the gravitational force on the Moon due to Earth, $\vec{F}_{ME}$, is equal and opposite to the gravitational force on Earth due to the Moon, $\vec{F}_{EM}$. That is, $\vec{F}_{ME} = -\vec{F}_{EM}$.

Newton went further in his analysis of gravity. He examined the orbits of the planets, and using Kepler's laws (Section 6–5) he concluded that the force needed to hold different planets in their orbits around the Sun diminishes as the inverse square of their distance from the Sun. This led him to believe that the gravitational force acts between the Sun and each of the planets to keep them in their orbits. And if gravity acts between these objects, why not between all objects? Thus he proposed his **law of universal gravitation**, which we can state as follows:

*NEWTON'S LAW OF UNIVERSAL GRAVITATION*

**Every particle in the universe attracts every other particle with a force that is proportional to the product of their masses and inversely proportional to the square of the distance between them. This force acts along the line joining the two particles.**

The magnitude of the gravitational force can be written as

$$F_G = G\frac{m_1 m_2}{r^2}, \qquad \textbf{(6–1)}$$

*NEWTON'S LAW OF UNIVERSAL GRAVITATION*

where $m_1$ and $m_2$ are the masses of the two particles, $r$ is the distance between them, and $G$ is a universal constant. $G$ is called the **gravitational constant**, and it must be measured experimentally.

Equation 6–1 is called an **inverse square law** because the force is inversely proportional to $r^2$.

The value of $G$ must be very small, since we are not aware of any force of attraction between ordinary-sized objects, such as between two baseballs. The gravitational force between two ordinary objects was first measured by Henry Cavendish in 1798, over 100 years after Newton published his law. To detect and measure the incredibly small force between ordinary objects, he used an apparatus like that shown in Fig. 6–3. Cavendish confirmed Newton's hypothesis that two objects attract one another and that Eq. 6–1 accurately describes this force. In addition, because Cavendish could measure $F_G$, $m_1$, $m_2$, and $r$ accurately, he was able to determine the value of the constant $G$ as well. The accepted value today is

$$G = 6.67 \times 10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2.$$

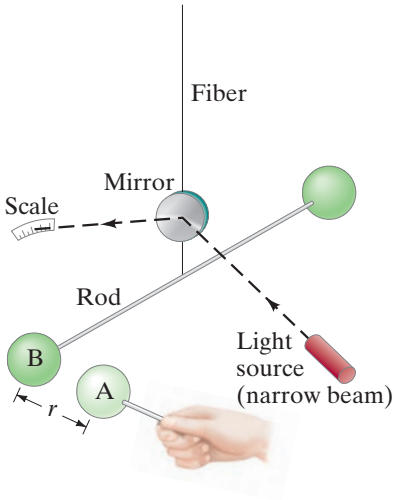
(See Table inside front cover for values of all constants to highest known precision.)

Strictly speaking, Eq. 6–1 gives the magnitude of the gravitational force that one particle exerts on a second particle that is a distance $r$ away. For an extended object (that is, not a point), we must consider how to measure the distance $r$. A correct calculation treats each extended body as a collection of particles, and the total force is the sum of the forces due to all the particles. The sum over all these particles is often done using integral calculus, which Newton himself invented. When extended bodies are small compared to the distance between them (as for the Earth–Sun system), little inaccuracy results from considering them as point particles.

Newton was able to show (see derivation in Appendix E) that the *gravitational force exerted on a particle outside a uniform sphere is the same as if the entire mass of the sphere was concentrated at its center*. Thus Eq. 6–1 gives the correct force between two uniform spheres where $r$ is the distance between their centers.

**EXAMPLE 6–1 ESTIMATE Can you attract another person gravitationally?**

A 50-kg person and a 70-kg person are sitting on a bench close to each other. Estimate the magnitude of the gravitational force each exerts on the other.



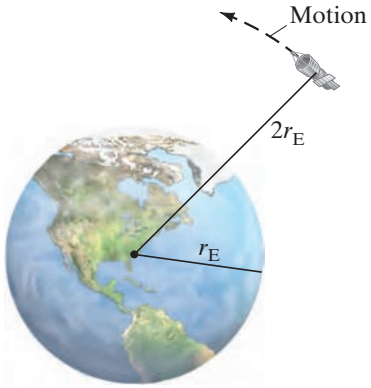
**APPROACH** This is an estimate: we let the distance between the centers of the two people be about $\frac{1}{2}$ m (about as close as you can get).

**SOLUTION** We use Eq. 6–1, which gives

$$F_G = G\frac{m_1 m_2}{r^2} \approx \frac{(6.67 \times 10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(50\,\text{kg})(70\,\text{kg})}{(0.5\,\text{m})^2} \approx 10^{-6}\,\text{N},$$

rounded off to an order of magnitude. Such a force is unnoticeably small unless extremely sensitive instruments are used $\left(< \frac{1}{100{,}000}\text{ of a pound}\right)$.

**FIGURE 6–3** Schematic diagram of Cavendish's apparatus. Two spheres are attached to a light horizontal rod, which is suspended at its center by a thin fiber. When a third sphere (labeled A) is brought close to one of the suspended spheres (B), the gravitational force causes sphere B to move, and this twists the fiber slightly. The tiny movement is magnified by the use of a narrow light beam directed at a mirror mounted on the fiber. The beam reflects onto a scale. Previous determination of how large a force will twist the fiber a given amount then allows the experimenter to determine the magnitude of the gravitational force between two objects, A and B.



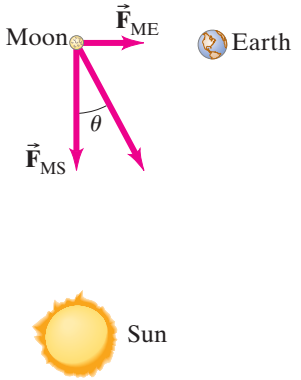


**FIGURE 6–4** Example 6–2; a spacecraft in a circular orbit at 6380 km ($= r_E$) above the Earth, so $r = 2r_E$.

**FIGURE 6–5** Example 6–3. Orientation of Sun (S), Earth (E), and Moon (M) at right angles to each other (not to scale).

**EXAMPLE 6–2** **Spacecraft at $2r_E$.** What is the force of gravity acting on a 2000-kg spacecraft when it orbits two Earth radii from the Earth's center (that is, it stays a distance $r_E = 6380\,\text{km}$ above the Earth's surface, Fig. 6–4)? The mass of the Earth is $m_E = 5.98 \times 10^{24}\,\text{kg}$. Assume a circular orbit.

**APPROACH** We could plug all the numbers into Eq. 6–1, but there is a simpler approach. The spacecraft is twice as far from the Earth's center as when it is at the surface of the Earth. Therefore, since the force of gravity $F_G$ decreases as the square of the distance (and $\frac{1}{2^2} = \frac{1}{4}$), the force of gravity on the spacecraft will be only one-fourth its weight at the Earth's surface.

**SOLUTION** At the surface of the Earth, $F_G = mg$. At a distance from the Earth's center of $2r_E$, $F_G$ is $\frac{1}{4}$ as great:

$$F_G = \tfrac{1}{4}mg = \tfrac{1}{4}(2000\,\text{kg})(9.80\,\text{m/s}^2) = 4900\,\text{N}.$$

**EXAMPLE 6–3** **Force on the Moon.** Find the net force on the Moon ($m_M = 7.35 \times 10^{22}\,\text{kg}$) due to the gravitational attraction of both the Earth ($m_E = 5.98 \times 10^{24}\,\text{kg}$) and the Sun ($m_S = 1.99 \times 10^{30}\,\text{kg}$), assuming they are at right angles to each other as in Fig. 6–5.

**APPROACH** The forces on our object, the Moon, are the gravitational force exerted on the Moon by the Earth $F_{ME}$ and the force exerted by the Sun $F_{MS}$, as shown in the free-body diagram of Fig. 6–5. We use the law of universal gravitation to find the magnitude of each force, and then add the two forces as vectors.

**SOLUTION** The Earth is $3.84 \times 10^5\,\text{km} = 3.84 \times 10^8\,\text{m}$ from the Moon, so $F_{ME}$ (the gravitational force on the Moon due to the Earth) is

$$F_{ME} = \frac{(6.67\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(7.35\times10^{22}\,\text{kg})(5.98\times10^{24}\,\text{kg})}{(3.84\times10^{8}\,\text{m})^2} = 1.99\times10^{20}\,\text{N}.$$

The Earth is $1.50 \times 10^8\,\text{km}$ from the Sun and so is the Moon (the Earth-Moon distance is small compared to this), so $F_{MS}$ (the gravitational force on the Moon due to the Sun) is

$$F_{MS} = \frac{(6.67\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(7.35\times10^{22}\,\text{kg})(1.99\times10^{30}\,\text{kg})}{(1.50\times10^{11}\,\text{m})^2} = 4.34\times10^{20}\,\text{N}.$$

The two forces act at right angles in the case we are considering (Fig. 6–5), so we can apply the Pythagorean theorem to find the magnitude of the total force:

$$F = \sqrt{(1.99 \times 10^{20}\,\text{N})^2 + (4.34 \times 10^{20}\,\text{N})^2} = 4.77 \times 10^{20}\,\text{N}.$$

The force acts at an angle $\theta$ (Fig. 6–5) given by $\theta = \tan^{-1}(1.99/4.34) = 24.6°$.

**NOTE** The two forces, $F_{ME}$ and $F_{MS}$, have the same order of magnitude ($10^{20}\,\text{N}$). This may be surprising. Is it reasonable? The Moon is much farther from the Sun than from Earth (a factor of $10^{11}\,\text{m}/10^8\,\text{m} \approx 10^3$), but the Sun is much more massive (a factor of $10^{30}\,\text{kg}/10^{25}\,\text{kg} \approx 10^5$). Mass divided by distance squared ($10^5/10^6$) comes out within an order of magnitude, and we have ignored factors of 3 or more. Yes, it is reasonable.

**⚠ CAUTION**

*Distinguish between Newton's second law and the law of universal gravitation*

Note carefully that the law of universal gravitation describes a *particular* force (gravity), whereas Newton's second law of motion ($F = ma$) tells how an object accelerates due to *any* type of force.

## Spherical Shells

Newton was able to show, using the calculus he invented for the purpose, that a thin uniform spherical shell exerts a force on a particle *outside* it as if all the shell's mass were at its center; and that such a thin uniform shell exerts *zero* force on a particle *inside* the shell. (The derivation is given in Appendix E.)

The Earth can be modeled as a series of concentric shells starting at its center, each shell uniform but perhaps having a different density to take into account Earth's varying density in various layers. As a simple example, suppose the Earth were uniform throughout: What is the gravitational force on a particle placed exactly halfway from Earth's center to its surface? Only the mass *inside* this radius $r = \frac{1}{2} r_E$ would exert a net force on this particle. The mass of a sphere is proportional to its volume $V = \frac{4}{3}\pi r^3$, so the mass $m$ inside $r = \frac{1}{2} r_E$ is $\left(\frac{1}{2}\right)^3 = \frac{1}{8}$ the mass of the entire Earth. The gravitational force on the particle at $r = \frac{1}{2} r_E$, which is proportional to $m/r^2$ (Eq. 6–1), is reduced to $\left(\frac{1}{8}\right)/\left(\frac{1}{2}\right)^2 = \frac{1}{2}$ the gravitational force it would experience at Earth's surface. An elegant way to deal with these results is the use of Gauss's law, discussed in Chapter 22 (Example 22–4).

# 6–2 Vector Form of Newton's Law of Universal Gravitation

We can write Newton's law of universal gravitation in vector form as

$$\vec{\mathbf{F}}_{12} = -G\frac{m_1 m_2}{r_{21}^2}\hat{\mathbf{r}}_{21}, \tag{6–2}$$

where $\vec{\mathbf{F}}_{12}$ is the vector force *on* particle 1 (of mass $m_1$) exerted *by* particle 2 (of mass $m_2$), which is a distance $r_{21}$ away. The unit vector $\hat{\mathbf{r}}_{21}$ points from particle 2 toward particle 1 along the line joining them so that $\hat{\mathbf{r}}_{21} = \vec{\mathbf{r}}_{21}/r_{21}$, where $\vec{\mathbf{r}}_{21}$ is the displacement vector as shown in Fig. 6–6. The minus sign in Eq. 6–2 is necessary because the force on particle 1 due to particle 2 points toward $m_2$, in the direction opposite to $\hat{\mathbf{r}}_{21}$. The displacement vector $\vec{\mathbf{r}}_{12}$ is a vector of the same magnitude as $\vec{\mathbf{r}}_{21}$, but it points in the opposite direction so that

$$\vec{\mathbf{r}}_{12} = -\vec{\mathbf{r}}_{21}.$$

By Newton's third law, the force $\vec{\mathbf{F}}_{21}$ acting on $m_2$ exerted by $m_1$ must have the same magnitude as $\vec{\mathbf{F}}_{12}$ but acts in the opposite direction (Fig. 6–7), so that

$$\vec{\mathbf{F}}_{21} = -\vec{\mathbf{F}}_{12} = G\frac{m_1 m_2}{r_{21}^2}\hat{\mathbf{r}}_{21} = -G\frac{m_2 m_1}{r_{12}^2}\hat{\mathbf{r}}_{12}.$$

The force of gravity exerted on one particle by a second particle is always directed toward the second particle, as in Fig. 6–6. When many particles interact, the total gravitational force on a given particle is the vector sum of the forces exerted by each of the others. For example, the total force on particle number 1 is

$$\vec{\mathbf{F}}_1 = \vec{\mathbf{F}}_{12} + \vec{\mathbf{F}}_{13} + \vec{\mathbf{F}}_{14} + \cdots + \vec{\mathbf{F}}_{1n} = \sum_{i=2}^{n} \vec{\mathbf{F}}_{1i} \tag{6–3}$$

where $\vec{\mathbf{F}}_{1i}$ means the force on particle 1 exerted by particle $i$, and $n$ is the total number of particles.

This vector notation can be very helpful, especially when sums over many particles are needed. However, in many cases we do not need to be so formal and we can deal with directions by making careful diagrams.

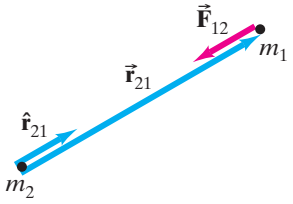

**FIGURE 6–6** The displacement vector $\vec{\mathbf{r}}_{21}$ points from particle of mass $m_2$ to particle of mass $m_1$. The unit vector shown, $\hat{\mathbf{r}}_{21}$ is in the same direction as $\vec{\mathbf{r}}_{21}$, but is defined as having length one.

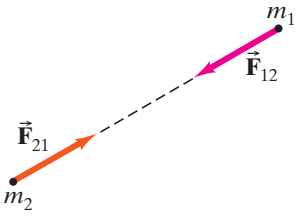

**FIGURE 6–7** By Newton's third law, the gravitational force on particle 1 exerted by particle 2, $\vec{\mathbf{F}}_{12}$, is equal and opposite to that on particle 2 exerted by particle 1, $\vec{\mathbf{F}}_{21}$; that is $\vec{\mathbf{F}}_{21} = -\vec{\mathbf{F}}_{12}$.

# 6–3 Gravity Near the Earth's Surface

When Eq. 6–1 is applied to the gravitational force between the Earth and an object at its surface, $m_1$ becomes the mass of the Earth $m_E$, $m_2$ becomes the mass of the object $m$, and $r$ becomes the distance of the object from the Earth's center, which is the radius of the Earth $r_E$. This force of gravity due to the Earth is the weight of the object on Earth, which we have been writing as $mg$.

Thus,

$$mg = G\frac{mm_E}{r_E^2}.$$

We can solve this for $g$, the acceleration of gravity at the Earth's surface:

$$g = G\frac{m_E}{r_E^2}. \tag{6–4}$$

**CAUTION**
*Distinguish G from g*

Thus, the acceleration of gravity at the surface of the Earth, $g$, is determined by $m_E$ and $r_E$. (Don't confuse $G$ with $g$; they are very different quantities, but are related by Eq. 6–4.)

Until $G$ was measured, the mass of the Earth was not known. But once $G$ was measured, Eq. 6–4 could be used to calculate the Earth's mass, and Cavendish was the first to do so. Since $g = 9.80\,\text{m/s}^2$ and the radius of the Earth is $r_E = 6.38 \times 10^6\,\text{m}$, then, from Eq. 6–4, we obtain the mass of the Earth to be

$$m_E = \frac{gr_E^2}{G} = \frac{(9.80\,\text{m/s}^2)(6.38 \times 10^6\,\text{m})^2}{6.67 \times 10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2} = 5.98 \times 10^{24}\,\text{kg}.$$

Equation 6–4 can be applied to other planets, where $g$, $m$, and $r$ would refer to that planet.

**FIGURE 6–8** Example 6–4. Mount Everest, 8850 m (29,035 ft) above sea level; in the foreground, the author with sherpas at 5500 m (18,000 ft).

**EXAMPLE 6–4** **ESTIMATE** **Gravity on Everest.** Estimate the effective value of $g$ on the top of Mt. Everest, 8850 m (29,035 ft) above sea level (Fig. 6–8). That is, what is the acceleration due to gravity of objects allowed to fall freely at this altitude? Ignore the mass of the mountain itself.

**APPROACH** The force of gravity (and the acceleration due to gravity $g$) depends on the distance from the center of the Earth, so there will be an effective value $g'$ on top of Mt. Everest which will be smaller than $g$ at sea level. We assume the Earth is a uniform sphere (a reasonable "estimate").

**SOLUTION** We use Eq. 6–4, with $r_E$ replaced by $r = 6380\,\text{km} + 8.9\,\text{km} = 6389\,\text{km} = 6.389 \times 10^6\,\text{m}$:

$$g' = G\frac{m_E}{r^2} = \frac{(6.67 \times 10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(5.98 \times 10^{24}\,\text{kg})}{(6.389 \times 10^6\,\text{m})^2} = 9.77\,\text{m/s}^2,$$

which is a reduction of about 3 parts in a thousand (0.3%).

**TABLE 6–1**
**Acceleration Due to Gravity at Various Locations on Earth**

| Location | Elevation (m) | $g$ (m/s$^2$) |
|---|---|---|
| New York | 0 | 9.803 |
| San Francisco | 0 | 9.800 |
| Denver | 1650 | 9.796 |
| Pikes Peak | 4300 | 9.789 |
| Sydney, Australia | 0 | 9.798 |
| Equator | 0 | 9.780 |
| North Pole (calculated) | 0 | 9.832 |

Note that Eq. 6–4 does not give precise values for $g$ at different locations because the Earth is not a perfect sphere. The Earth not only has mountains and valleys, and it bulges at the equator, but also its mass is not distributed precisely uniformly (see Table 6–1). The Earth's rotation also affects the value of $g$ (see Example 6–5). However, for most practical purposes when an object is near the Earth's surface, we will simply use $g = 9.80\,\text{m/s}^2$ and write the weight of an object as $mg$.

**EXERCISE A** Suppose you could double the mass of a planet but kept its volume the same. How would the acceleration of gravity, $g$, at the surface change?

**PHYSICS APPLIED**
*Geology—mineral and oil exploration*

The value of $g$ can vary locally on the Earth's surface because of the presence of irregularities and rocks of different densities. Such variations in $g$, known as "gravity anomalies," are very small—on the order of 1 part per $10^6$ or $10^7$ in the value of $g$. But they can be measured ("gravimeters" today can detect variations in $g$ to 1 part in $10^9$). Geophysicists use such measurements as part of their investigations into the structure of the Earth's crust, and in mineral and oil exploration. Mineral deposits, for example, often have a greater density than surrounding material; because of the greater mass in a given volume, $g$ can have a slightly greater value on top of such a deposit than at its flanks. "Salt domes," under which petroleum is often found, have a lower than average density and searches for a slight reduction in the value of $g$ in certain locales have led to the discovery of oil.

**EXAMPLE 6–5** **Effect of Earth's rotation on $g$.** Assuming the Earth is a perfect sphere, determine how the Earth's rotation affects the value of $g$ at the equator compared to its value at the poles.

**APPROACH** Figure 6–9 shows a person of mass $m$ standing on a doctor's scale at two places on the Earth. At the North Pole there are two forces acting on the mass $m$ (the person): the force of gravity, $\vec{\mathbf{F}}_G = m\vec{\mathbf{g}}$, and the force with which the scale pushes up on the person, $\vec{\mathbf{w}}$. We call this latter force $w$ because it is what the scale reads as the weight of the person, and by Newton's third law it equals the force down on the scale due to the person. Since the person is not accelerating, Newton's second law tells us

$$mg - w = 0,$$

so $w = mg$. Thus the weight $w$ that the scale registers equals $mg$, which is no surprise. Next, at the equator, there *is* an acceleration because points on the equator are rotating. The same magnitude of the force of gravity $F_G = mg$ acts downward (we are letting $g$ represent the acceleration of gravity in the absence of rotation and we ignore the slight bulging of the equator). The scale pushes upward with a force $w'$; $w'$ is also the force with which the person pushes down on the scale (Newton's third law) and hence is the weight registered on the scale. From Newton's second law we now have (see Fig. 6–9)

$$mg - w' = m\frac{v^2}{r_E},$$

because the person of mass $m$ now has a centripetal acceleration due to Earth's rotation; $r_E = 6.38 \times 10^6\,\text{m}$ is the Earth's radius and $v$ is the speed of $m$ due to the Earth's daily rotation.

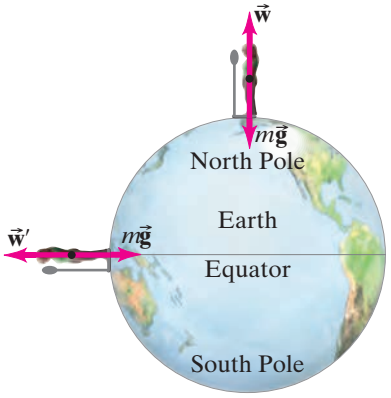

**FIGURE 6–9** Example 6–5: the pull of gravity at the North Pole and at the equator, and what you weigh at those places ($w$, $w'$).

**SOLUTION** First we determine the speed $v$ of an object at rest on the Earth's equator, rembering that Earth makes one rotation (distance = circumference of Earth $= 2\pi r_E$) in 1 day $= (24\,\text{h})(60\,\text{min/h})(60\,\text{s/min}) = 8.64 \times 10^4\,\text{s}$:

$$v = \frac{2\pi r_E}{1\,\text{day}} = \frac{(6.283)(6.38 \times 10^6\,\text{m})}{(8.64 \times 10^4\,\text{s})}$$
$$= 4.64 \times 10^2\,\text{m/s}.$$

The effective weight is $w' = mg'$ where $g'$ is the effective value of $g$, and so $g' = w'/m$. Solving the equation above for $w'$, we have

$$w' = m\left(g - \frac{v^2}{r_E}\right),$$

so

$$g' = \frac{w'}{m} = g - \frac{v^2}{r_E}.$$

Hence

$$\Delta g = g - g' = \frac{v^2}{r_E} = \frac{(4.64 \times 10^2\,\text{m/s})^2}{(6.38 \times 10^6\,\text{m})}$$
$$= 0.0337\,\text{m/s}^2,$$

which is about $\Delta g \approx 0.003\,g$, a difference of 0.3%.

**NOTE** In Table 6–1 we see that the difference in $g$ at the pole and equator is actually greater than this: $(9.832 - 9.780)\,\text{m/s}^2 = 0.052\,\text{m/s}^2$. This discrepancy is due mainly to the Earth being slightly fatter at the equator (by 21 km) than at the poles. Do you weigh less at the equator?

**NOTE** The calculation of the effective value of $g$ at latitudes other than at the poles or equator is a two-dimensional problem because $\vec{\mathbf{F}}_G$ acts radially toward the Earth's center whereas the centripetal acceleration is directed perpendicular to the axis of rotation, parallel to the equator and that means that a plumb line (the effective direction of $g$) is not precisely vertical except at the equator and the poles.

### Earth as Inertial Reference Frame

We often make the assumption that reference frames fixed on the Earth are inertial reference frames. Our calculation in Example 6–5 above shows that this assumption can result in errors no larger than about 0.3% in the use of Newton's second law, for example. We discuss the effects of Earth's rotation and reference frames in more detail in Chapter 11, including the Coriolis effect.

## 6–4 Satellites and "Weightlessness"

### Satellite Motion

**PHYSICS APPLIED**
*Artificial Earth satellites*

Artificial satellites circling the Earth are now commonplace (Fig. 6–10). A satellite is put into orbit by accelerating it to a sufficiently high tangential speed with the use of rockets, as shown in Fig. 6–11. If the speed is too high, the spacecraft will not be confined by the Earth's gravity and will escape, never to return. If the speed is too low, it will return to Earth. Satellites are usually put into circular (or nearly circular) orbits, because such orbits require the least takeoff speed.

**FIGURE 6–10** A satellite, the International Space Station, circling the Earth.

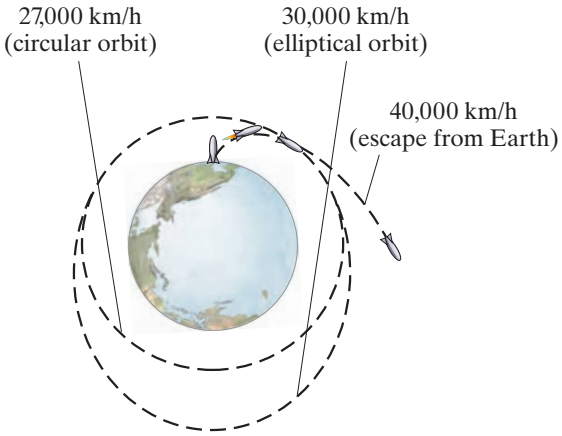

**FIGURE 6–11** Artificial satellites launched at different speeds.

**FIGURE 6–12** A moving satellite "falls" out of a straight-line path toward the Earth.

It is sometimes asked: "What keeps a satellite up?" The answer is: its high speed. If a satellite in orbit stopped moving, it would fall directly to Earth. But at the very high speed a satellite has, it would quickly fly out into space (Fig. 6–12) if it weren't for the gravitational force of the Earth pulling it into orbit. In fact, a satellite in orbit *is* falling (accelerating) toward Earth, but its high tangential speed keeps it from hitting Earth.

For satellites that move in a circle (at least approximately), the needed acceleration is centripetal and equals $v^2/r$. The force that gives a satellite this acceleration is the force of gravity exerted by the Earth, and since a satellite may be at a considerable distance from the Earth, we must use Newton's law of universal gravitation (Eq. 6–1) for the force acting on it. When we apply Newton's second law, $\Sigma F_R = ma_R$ in the radial direction, we find

$$G\frac{mm_E}{r^2} = m\frac{v^2}{r}, \qquad \textbf{(6–5)}$$

where $m$ is the mass of the satellite. This equation relates the distance of the satellite from the Earth's center, $r$, to its speed, $v$, in a circular orbit. Note that only one force—gravity—is acting on the satellite, and that $r$ is the sum of the Earth's radius $r_E$ plus the satellite's height $h$ above the Earth: $r = r_E + h$. If we solve Eq. 6–5 for $v$, we find $v = \sqrt{Gm_E/r}$ and we see that a satellite's speed does not depend on its own mass, $m$. Satellites of different mass orbiting at the same distance above Earth have the same speed; this also means they have the same *orbital period* (time to travel one revolution around the Earth).

**EXAMPLE 6–6** **Geostationary satellite.** A *geostationary* satellite is one that stays above the same point on the Earth, which is possible only if it is above a point on the equator. Why? Because the center of a satellite orbit is always at the center of the Earth; so it is not possible to have a satellite orbiting above a fixed point on the Earth at any latitude other than 0°. Geostationary satellites are commonly used for TV and radio transmission, for weather forecasting, and as communication relays.† Determine (*a*) the height above the Earth's surface such a satellite must orbit, and (*b*) such a satellite's speed. (*c*) Compare to the speed of a satellite orbiting 200 km above Earth's surface.

**PHYSICS APPLIED**
*Geostationary satellites*

**APPROACH** To remain above the same point on Earth as the Earth rotates, the satellite must have a period of 24 hours. We can apply Newton's second law, $F = ma$, where $a = v^2/r$ if we assume the orbit is circular.

**SOLUTION** (*a*) The only force on the satellite is the gravitational force due to the Earth. (We can ignore the gravitational force exerted by the Sun. Why?) We apply Eq. 6–5 assuming the satellite moves in a circle:

$$G\frac{m_{\text{Sat}}\,m_{\text{E}}}{r^2} = m_{\text{Sat}}\frac{v^2}{r}.$$

This equation has two unknowns, $r$ and $v$. So we need a second equation. Our satellite revolves around the Earth with the same period that the Earth rotates on its axis, namely once in 24 hours. Thus the speed of the satellite must be

$$v = \frac{2\pi r}{T},$$

where $T = 1\text{ day} = (24\text{ h})(3600\text{ s/h}) = 86{,}400\text{ s}$. We substitute this into the "satellite equation" above and obtain (after canceling $m_{\text{Sat}}$ on both sides):

$$G\frac{m_{\text{E}}}{r^2} = \frac{(2\pi r)^2}{rT^2}.$$

After canceling an $r$, we can solve for $r^3$:

$$r^3 = \frac{Gm_{\text{E}}T^2}{4\pi^2} = \frac{(6.67\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(5.98\times10^{24}\,\text{kg})(86{,}400\,\text{s})^2}{4\pi^2}$$
$$= 7.54\times10^{22}\,\text{m}^3.$$

We take the cube root and find

$$r = 4.22\times10^7\,\text{m},$$

or 42,200 km from the Earth's center. We subtract the Earth's radius of 6380 km to find that a geostationary satellite must orbit about 36,000 km (about $6r_{\text{E}}$) above the Earth's surface.

(*b*) We solve for $v$ in the satellite equation, Eq. 6–5:

$$v = \sqrt{\frac{Gm_{\text{E}}}{r}} = \sqrt{\frac{(6.67\times10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(5.98\times10^{24}\,\text{kg})}{(4.22\times10^7\,\text{m})}} = 3070\,\text{m/s},$$

or about 11,000 km/h ($\approx$ 7000 mi/h). We get the same result if we use $v = 2\pi r/T$.

(*c*) The equation in part (*b*) for $v$ shows $v \propto \sqrt{1/r}$. So for $r = r_{\text{E}} + h = 6380\text{ km} + 200\text{ km} = 6580\text{ km}$, we get

$$v' = v\sqrt{\frac{r}{r'}} = (3070\,\text{m/s})\sqrt{\frac{(42{,}200\,\text{km})}{(6580\,\text{km})}} = 7770\,\text{m/s},$$

or about 28,000 km/h ($\approx$ 17,000 mi/h).

**NOTE** *Polar satellites*, which pass over the north and south poles, cover all parts of the Earth and are also used in applications like weather forecasting.

†Geostationary satellites are useful because receiving and transmitting antennas at a given place on Earth can stay fixed on such a satellite (no tracking and no switching satellites is needed).

**EXERCISE B** Two satellites orbit the Earth in circular orbits of the same radius. One satellite is twice as massive as the other. Which of the following statements is true about the speeds of these satellites? (*a*) The heavier satellite moves twice as fast as the lighter one. (*b*) The two satellites have the same speed. (*c*) The lighter satellite moves twice as fast as the heavier one. (*d*) The heavier satellite moves four times as fast as the lighter one.

## Weightlessness

People and other objects in a satellite circling the Earth are said to experience apparent weightlessness. Let us first look at a simpler case: a falling elevator. In Fig. 6–13a, an elevator is at rest with a bag hanging from a spring scale. The scale reading indicates the downward force exerted on it by the bag. This force, exerted *on* the scale, is equal and opposite to the force exerted *by* the scale upward on the bag, and we call its magnitude $w$. Two forces act on the bag: the downward gravitational force and the upward force exerted by the scale equal to $w$. Because the bag is not accelerating ($a = 0$) when we apply $\Sigma F = ma$ to the bag in Fig. 6–13a we obtain

$$w - mg = 0,$$

where $mg$ is the weight of the bag. Thus, $w = mg$, and since the scale indicates the force $w$ exerted on it by the bag, it registers a force equal to the weight of the bag, as we expect.

Now let the elevator have an acceleration, $a$. Applying Newton's second law, $\Sigma F = ma$, to the bag as seen from an inertial reference frame (the elevator itself is not now an inertial frame) we have

$$w - mg = ma.$$

Solving for $w$, we have

$$w = mg + ma. \qquad [a \text{ is } + \text{ upward}]$$

We have chosen the positive direction up. Thus, if the acceleration $a$ is up, $a$ is positive; and the scale, which measures $w$, will read more than $mg$. We call $w'$ the *apparent weight* of the bag, which in this case would be greater than its actual weight ($mg$). If the elevator accelerates downward, $a$ will be negative and $w'$, the apparent weight, will be less than $mg$. The direction of the velocity $\vec{\mathbf{v}}$ doesn't matter. Only the direction of the acceleration $\vec{\mathbf{a}}$ (and its magnitude) influences the scale reading.

Suppose the elevator's acceleration is $\frac{1}{2}g$ upward; then we find

$$w' = mg + m(\tfrac{1}{2}g) = \tfrac{3}{2}mg.$$

That is, the scale reads $1\frac{1}{2}$ times the actual weight of the bag (Fig. 6–13b). The apparent weight of the bag is $1\frac{1}{2}$ times its real weight. The same is true of the person: her apparent weight (equal to the normal force exerted on her by the elevator floor) is $1\frac{1}{2}$ times her real weight. We can say that she is experiencing $1\frac{1}{2}g$'s, just as astronauts experience so many $g$'s at a rocket's launch.

If, instead, the elevator's acceleration is $a = -\frac{1}{2}g$ (downward), then $w' = mg - \frac{1}{2}mg = \frac{1}{2}mg$. That is, the scale reads half the actual weight. If the elevator is in *free fall* (for example, if the cables break), then $a = -g$ and $w' = mg - mg = 0$. The scale reads zero. See Fig. 6–13c. The bag appears weightless. If the person in the elevator accelerating at $-g$ let go of a box, it would not fall to the floor. True, the box would be falling with acceleration $g$. But so would the floor of the elevator and the person. The box would hover right in front of the person. This phenomenon is called **apparent weightlessness** because in the reference frame of the person, objects don't fall or seem to have weight—yet gravity does not disappear. Gravity is still acting on each object, whose weight is still $mg$. The person and other objects seem weightless only because the elevator is accelerating in free fall, and there is no contact force on the person to make her feel the weight.

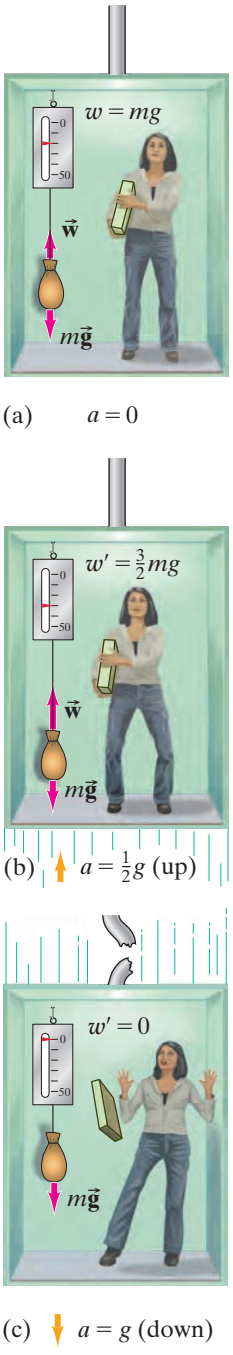

**FIGURE 6–13** (a) An object in an elevator at rest exerts a force on a spring scale equal to its weight. (b) In an elevator accelerating upward at $\frac{1}{2}g$, the object's apparent weight is $1\frac{1}{2}$ times larger than its true weight. (c) In a freely falling elevator, the object experiences "weightlessness": the scale reads zero.

The "weightlessness" experienced by people in a satellite orbit close to the Earth (Fig. 6–14) is the same apparent weightlessness experienced in a freely falling elevator. It may seem strange, at first, to think of a satellite as freely falling. But a satellite is indeed falling toward the Earth, as was shown in Fig. 6–12. The force of gravity causes it to "fall" out of its natural straight-line path. The acceleration of the satellite must be the acceleration due to gravity at that point, because the only force acting on it is gravity. Thus, although the force of gravity acts on objects within the satellite, the objects experience an apparent weightlessness because they, and the satellite, are accelerating together as in free fall.

**EXERCISE C** Return to the Chapter-Opening Question, page 145, and answer it again now. Try to explain why you may have answered differently the first time.

Figure 6–15 shows some examples of "free fall," or apparent weightlessness, experienced by people on Earth for brief moments.

A completely different situation occurs if a spacecraft is out in space far from the Earth, the Moon, and other attracting bodies. The force of gravity due to the Earth and other celestial bodies will then be quite small because of the distances involved, and persons in such a spacecraft would experience real weightlessness.

**EXERCISE D** Could astronauts in a spacecraft far out in space easily play catch with a bowling ball ($m = 7\,\text{kg}$)?

**FIGURE 6–14** This astronaut is outside the International Space Station. He must feel very free because he is experiencing apparent weightlessness.

**FIGURE 6–15** Experiencing "weightlessness" on Earth.

## 6–5 Planets, Kepler's Laws, and Newton's Synthesis

Where did we first get the idea of planets? Have you ever escaped the lights of the city to gaze late at night at the multitude of stars in the night sky? It is a moving experience. Thousands of years ago, the ancients saw this sight every cloudless night, and were fascinated. They noted that the vast majority of stars, bright or dim, seemed to maintain fixed positions relative to each other. The ancients imagined these **fixed stars** as being attached to a huge inverted bowl, or sphere. This **celestial sphere** revolved around the Earth almost exactly once a day (Fig. 6–16), from east to west. Among all the stars that were visible to the naked eye (there were no telescopes until much later, about 1600), the ancients saw five stars that changed position relative to the fixed stars over weeks and months. These five wandering stars were called **planets** (Greek for wandering). Planets were thus visible at night as tiny points of light like other stars.

The ancient idea that the Sun, Moon, and planets revolve around the Earth is called the **geocentric** view (geo = Earth in Greek). It was developed into a fine theoretical system by Ptolemy in the second century B.C. Today we view the solar system as a **heliocentric** system (helios = Sun in Greek), where the Earth is just another planet, between Venus and Mars, orbiting around the Sun.

**FIGURE 6–16** Time exposure showing movement of stars over a period of several hours.

Although a heliocentric view was proposed in ancient times, it was largely ignored until Renaissance Italy of the fifteenth century. The real theory change began with the heliocentric theory of Nicolaus Copernicus (1473–1543) and then was greatly advanced by the experimental observations of Galileo around 1610 using his newly developed 30× telescope. Galileo observed that the planet Jupiter has moons (like a miniature solar system) and that Venus has phases like our Moon, not explainable by Ptolemy's geocentric system. [Galileo's famous encounter with the Church had little to do with religious faith, but rather with politics, a bit of rudeness, and that the Pope at that time was also a secular ruler. Today it is generally agreed that science and faith are different approaches and are not in conflict.]

## Kepler's Laws

Also about 1600, more than a half century before Newton proposed his three laws of motion and his law of universal gravitation, the German astronomer Johannes Kepler (1571–1630) had worked out a detailed description of the motion of the planets around the Sun. Kepler's work resulted in part from the many years he spent examining data collected (without a telescope) by Tycho Brahe (1546–1601) on the positions of the planets in their motion through the night sky.

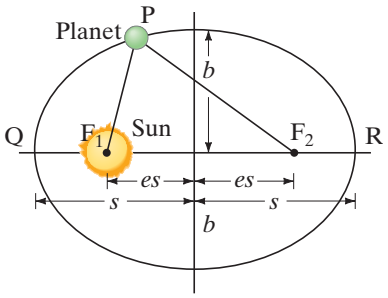

**FIGURE 6–17** *Kepler's first law*. An ellipse is a closed curve such that the sum of the distances from any point P on the curve to two fixed points (called the foci, $F_1$ and $F_2$) remains constant. That is, the sum of the distances, $F_1P + F_2P$, is the same for all points on the curve. A circle is a special case of an ellipse in which the two foci coincide, at the center of the circle. The semimajor axis is $s$ (that is, the long axis is $2s$) and the semiminor axis is $b$, as shown. The *eccentricity*, $e$, is defined as the ratio of the distance from either focus to the center divided by the semimajor axis $s$. Thus $es$ is the distance from the center to either focus, as shown. For a circle, $e = 0$. The Earth and most of the other planets have nearly circular orbits. For Earth $e = 0.017$.

Among Kepler's writings were three empirical findings that we now refer to as **Kepler's laws of planetary motion**. These are summarized as follows, with additional explanation in Figs. 6–17 and 6–18.

*Kepler's first law*: The path of each planet about the Sun is an ellipse with the Sun at one focus (Fig. 6–17).

*Kepler's second law*: Each planet moves so that an imaginary line drawn from the Sun to the planet sweeps out equal areas in equal periods of time (Fig. 6–18).

*Kepler's third law*: The ratio of the squares of the periods of any two planets revolving about the Sun is equal to the ratio of the cubes of their semimajor axes. [The semimajor axis is half the long (major) axis of the orbit, as shown in Fig. 6–17, and represents the planet's mean distance from the Sun.[†]] That is, if $T_1$ and $T_2$ represent the periods (the time needed for one revolution about the Sun) for any two planets, and $s_1$ and $s_2$ represent their semimajor axes, then

$$\left(\frac{T_1}{T_2}\right)^2 = \left(\frac{s_1}{s_2}\right)^3.$$

We can rewrite Kepler's third law as

$$\frac{s_1^3}{T_1^2} = \frac{s_2^3}{T_2^2},$$

meaning that $s^3/T^2$ should be the same for each planet. Present-day data are given in Table 6–2; see the last column.

In Examples and Problems we usually will assume the orbits are circles, although it is not quite true in general.

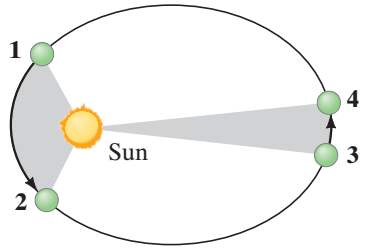

**FIGURE 6–18** *Kepler's second law*. The two shaded regions have equal areas. The planet moves from point 1 to point 2 in the same time as it takes to move from point 3 to point 4. Planets move fastest when closest to the Sun. Exaggerated scale.

[†]The semimajor axis is equal to the planet's mean distance from the Sun in the sense that it equals half the sum of the planet's nearest and farthest distances from the Sun (points Q and R in Fig. 6–17). Most planetary orbits are close to circles, and for a circle the semimajor axis is the radius of the circle.

**EXAMPLE 6–7** **Where is Mars?** Mars' period (its "year") was noted by Kepler to be about 687 days (Earth days), which is $(687\text{ d}/365\text{ d/yr}) = 1.88\text{ yr}$ (Earth years). Determine the mean distance of Mars from the Sun using the Earth as a reference.

**APPROACH** We are given the ratio of the periods of Mars and Earth. We can find the mean distance from Mars to the Sun using Kepler's third law, given the Earth–Sun distance as $1.50 \times 10^{11}$ m (Table 6–2; also Table inside front cover).

**SOLUTION** Let the distance of Mars from the Sun be $s_{MS}$, and the Earth–Sun distance be $s_{ES} = 1.50 \times 10^{11}$ m. From Kepler's third law:

$$\frac{s_{MS}}{s_{ES}} = \left(\frac{T_M}{T_E}\right)^{\frac{2}{3}} = \left(\frac{1.88\text{ yr}}{1\text{ yr}}\right)^{\frac{2}{3}} = 1.52.$$

So Mars is 1.52 times the Earth's distance from the Sun, or $2.28 \times 10^{11}$ m.

**TABLE 6–2 Planetary Data Applied to Kepler's Third Law**

| Planet | Mean Distance to Sun, $s$ ($10^6$ km) | Period, $T$ (Earth yr) | $s^3/T^2$ $\left(10^{24}\,\frac{\text{km}^3}{\text{yr}^2}\right)$ |
|---|---|---|---|
| Mercury | 57.9 | 0.241 | 3.34 |
| Venus | 108.2 | 0.615 | 3.35 |
| Earth | 149.6 | 1.000 | 3.35 |
| Mars | 227.9 | 1.88 | 3.35 |
| Jupiter | 778.3 | 11.86 | 3.35 |
| Saturn | 1427 | 29.5 | 3.34 |
| Uranus | 2870 | 84.0 | 3.35 |
| Neptune | 4497 | 165 | 3.34 |
| [Pluto]† | 5900 | 248 | 3.34 |

†Pluto, since its discovery in 1930, was considered a ninth planet. But its small mass and the recent discovery of other objects beyond Neptune with similar masses has led to calling these smaller objects, including Pluto, "dwarf planets." We keep it in the Table to indicate its great distance, and its consistency with Kepler's third law.

## Kepler's Third Law Derived, Sun's Mass, Perturbations

We can derive Kepler's second law, as we shall see in Chapter 11. Here we derive Kepler's third law using Newton's law of universal gravitation (Kepler lived before Newton, and based his laws on experiment); we do it for the special case of a circular orbit, in which case the semimajor axis is the radius $r$ of the circle. (Most planetary orbits are close to a circle.) First, we write Newton's second law of motion, $\Sigma F = ma$. For $F$ we use the law of universal gravitation (Eq. 6–1) for the force between the Sun and a planet of mass $m_1$, and for $a$ the centripetal acceleration, $v^2/r$. We assume the mass of the Sun $M_S$ is much greater than the mass of its planets, so we ignore the effects of the planets on each other. Then

$$\Sigma F = ma$$

$$G\frac{m_1 M_S}{r_1^2} = m_1\frac{v_1^2}{r_1}.$$

Here $m_1$ is the mass of a particular planet, $r_1$ its distance from the Sun, and $v_1$ its speed in orbit; $M_S$ is the mass of the Sun, since it is the gravitational attraction of the Sun that keeps each planet in its orbit. The period $T_1$ of the planet is the time required for one complete orbit, which is a distance equal to $2\pi r_1$, the circumference of a circle. Thus $v_1 = 2\pi r_1/T_1$. We substitute this into the previous equation:

$$G\frac{m_1 M_S}{r_1^2} = m_1\frac{4\pi^2 r_1}{T_1^2}.$$

We rearrange this to get

$$\frac{T_1^2}{r_1^3} = \frac{4\pi^2}{GM_S}. \qquad \textbf{(6–6)}$$

We derived this for planet 1 (say, Mars). The same derivation would apply for a second planet (say, Saturn) orbiting the Sun,

$$\frac{T_2^2}{r_2^3} = \frac{4\pi^2}{GM_S},$$

where $T_2$ and $r_2$ are the period and orbit radius, respectively, for the second planet. Since the right sides of the two previous equations are equal, we have $T_1^2/r_1^3 = T_2^2/r_2^3$ or, rearranging,

$$\left(\frac{T_1}{T_2}\right)^2 = \left(\frac{r_1}{r_2}\right)^3, \qquad \textbf{(6–7)}$$

*Kepler's third law*

which is Kepler's third law. Equations 6–6 and 6–7 are valid also for elliptical orbits if we replace $r$ with the semimajor axis $s$.

**PHYSICS APPLIED**
*Determining the Sun's mass*

**EXAMPLE 6–8** **The Sun's mass determined.** Determine the mass of the Sun given the Earth's distance from the Sun as $r_{ES} = 1.5 \times 10^{11}$ m.

**APPROACH** Equation 6–6 relates the mass of the Sun $M_S$ to the period and distance of any planet. We use the Earth.

**SOLUTION** The Earth's period is $T_E = 1\text{ yr} = (365\frac{1}{4}\text{ d})(24\text{ h/d})(3600\text{ s/h}) = 3.16 \times 10^7$ s. We solve Eq. 6–6 for $M_S$:

$$M_S = \frac{4\pi^2 r_{ES}^3}{G T_E^2} = \frac{4\pi^2 (1.5 \times 10^{11}\text{ m})^3}{(6.67 \times 10^{-11}\text{ N}\cdot\text{m}^2/\text{kg}^2)(3.16 \times 10^7\text{ s})^2} = 2.0 \times 10^{30}\text{ kg}.$$

**EXERCISE E** Suppose there were a planet in circular orbit exactly halfway between the orbits of Mars and Jupiter. What would its period be in Earth-years? Use Table 6–2.

**PHYSICS APPLIED**
*Perturbations and discovery of planets*

Accurate measurements on the orbits of the planets indicated that they did not precisely follow Kepler's laws. For example, slight deviations from perfectly elliptical orbits were observed. Newton was aware that this was to be expected because any planet would be attracted gravitationally not only by the Sun but also (to a much lesser extent) by the other planets. Such deviations, or **perturbations**, in the orbit of Saturn were a hint that helped Newton formulate the law of universal gravitation, that *all* objects attract each other gravitationally. Observation of other perturbations later led to the discovery of Neptune. Deviations in the orbit of Uranus could not all be accounted for by perturbations due to the other known planets. Careful calculation in the nineteenth century indicated that these deviations could be accounted for if another planet existed farther out in the solar system. The position of this planet was predicted from the deviations in the orbit of Uranus, and telescopes focused on that region of the sky quickly found it; the new planet was called Neptune. Similar but much smaller perturbations of Neptune's orbit led to the discovery of Pluto in 1930.

## Other Centers for Kepler's Laws

**CAUTION**
*Compare orbits of objects only around the same center*

The derivation of Eq. 6–7, Kepler's third law, compared two planets revolving around the Sun. But the derivation is general enough to be applied to other systems. For example, we could apply Eq. 6–7 to compare an artificial satellite and our Moon, both revolving around Earth (then $M_S$ would be replaced by $M_E$, the mass of the Earth). Or we could apply Eq. 6–7 to compare two moons revolving around Jupiter. But be careful: Kepler's third law, Eq. 6–7, applies only to objects orbiting the *same* attracting center. Do not use Eq. 6–7 to compare, say, the Moon's orbit around the Earth to the orbit of Mars around the Sun: they depend on different attracting centers.

## Distant Planetary Systems

**PHYSICS APPLIED**
*Planets around other stars*

Starting in the mid-1990s, planets revolving around distant stars (Fig. 6–19) were inferred from the regular "wobble" in position of certain stars. The wobble was nicely explained as being due to the gravitational attraction of planet(s) revolving around the star. Many such "extrasolar" planets are now known.

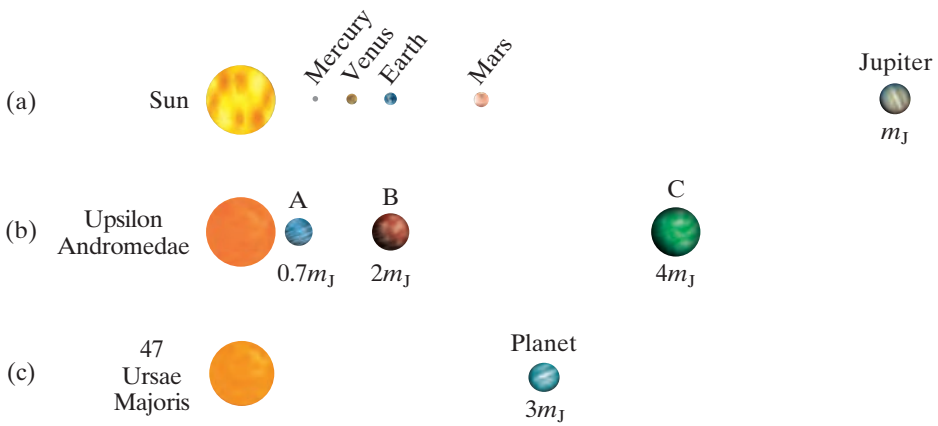

**FIGURE 6–19** Our solar system (a) is compared to recently discovered planets orbiting (b) the star Upsilon Andromedae with at least three planets, and (c) the star 47 Ursae Majoris; $m_J$ is the mass of Jupiter. (Sizes are not to scale.)

## Newton's Synthesis

Kepler arrived at his laws through careful analysis of experimental data. Fifty years later, Newton showed that Kepler's laws could be derived mathematically from the law of universal gravitation and the laws of motion. Newton also showed that for any reasonable form for the gravitational force law, only one that depends on the inverse square of the distance is consistent with Kepler's laws. He thus used Kepler's laws as evidence in favor of his law of universal gravitation, Eq. 6–1.

The development by Newton of the law of universal gravitation and the three laws of motion was a major intellectual achievement. With these laws, he was able to describe the motion of objects on Earth and of the far-away planets seen in the night sky. The motions of the planets through the heavens and of objects on Earth were seen to follow the same laws (not recognized previously). For this reason, and also because Newton integrated the results of earlier scientists into his system, we sometimes speak of **Newton's synthesis**.

The laws formulated by Newton are referred to as **causal laws**. By **causality** we mean that one occurrence can cause another. When a rock strikes a window, we infer the rock *causes* the window to break. This idea of "cause and effect" relates to Newton's laws: the acceleration of an object was seen to be *caused* by the net force acting on it.

As a result of Newton's theories, the universe came to be viewed by many as a machine whose parts move in a **deterministic** way. This deterministic view of the universe had to be modified in the twentieth century (Chapter 38).

## Ocean Tides

The reason for the Earth's tides, and why there are two high and two low tides (Fig. 6–20) about every 25 hours, was a subject of interest to thinkers for thousands of years. Newton gave the first clear explanation by arguing that the gravitational attraction of the Moon causes the tides. Because the gravitational force decreases with the square of the distance, the Moon pulls harder on that part of the Earth closest to it. The water in the oceans is pulled toward the Moon, resulting in a high tide on the side of the Earth facing the Moon. Simultaneously, a high tide occurs on the opposite side of the Earth (Fig. 6–21). Why this second high tide? The far side of the Earth is farther from the Moon and so experiences less gravitational attraction by the Moon than does the center of the Earth. (We might visualize this as the Earth being pulled away from the water on the far side.)[†]

High tides do not correspond precisely to the time when the Moon is directly overhead, because other forces are acting: the gravitational pull of the Sun, the rotation of the Earth, friction between the solid earth and the moving water.

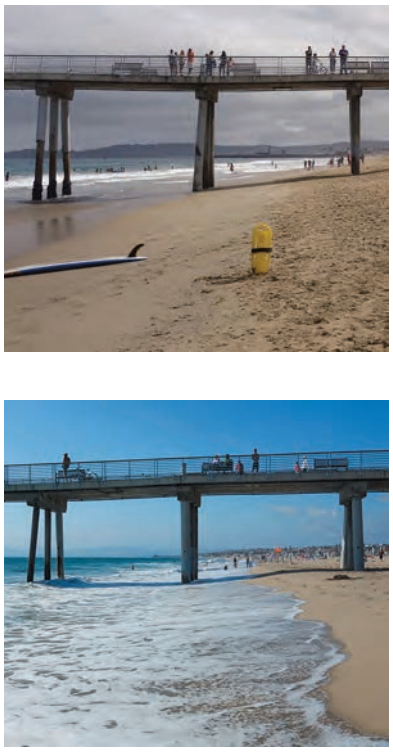

**FIGURE 6–20** Low tide and high tide at the same place.

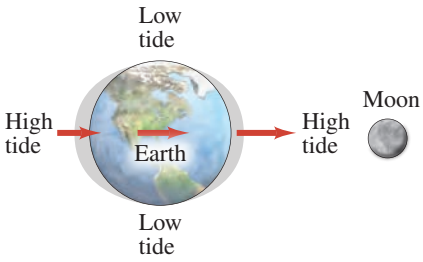

**FIGURE 6–21** Tides on the Earth due to the movement of water caused by the Moon's gravitational force (red arrows). [Not to scale.]

## *Does the Sun Orbit the Earth?

You may have heard someone say "People used to think the Sun goes around the Earth; but today we know the Earth goes around the Sun." The expression "today we know" is too strong. Yes, we usually like to say the Earth orbits the Sun. But we can also say the Sun goes around the Earth. Indeed we observe the Sun rising in the morning, moving until it is overhead at noon, and setting in the evening. It sure looks like the Sun is going around the Earth. And it is. You can believe your eyes. (You should!)

Frame of reference is the point. From the reference frame of the Earth, the Sun goes around the Earth. Its period is 1 day = 24 h. In the reference frame of the Sun, the Earth orbits the Sun (period = 365.256 days) as do the other planets. It is a matter of frame of reference.

But not only. We emphasize the description from the Sun's reference frame because the Sun is so massive that it exerts a strong gravitational force on all the planets, much greater than each planet exerts on other planets. So the description of the solar system with the orbits of the planets as ellipses relative to the Sun is the clearest description.

The Sun itself (and the Earth with it) revolves around the center of our Galaxy (see Fig. 44–2 or 6–39), which itself moves relative to other galaxies. Indeed, there is no one reference frame that we can consider as preferred or central.

[†]According to a historical anecdote (probably apocryphal), Napoleon was supposedly told by his admirals that he had nothing to fear from the British navy because it was run by superstitious people who believed the tides had something to do with the Moon!

## *Lagrange Point

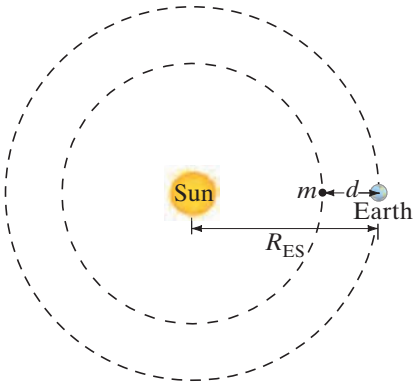

**FIGURE 6–22** Finding the position of the Lagrange Point L1 for a satellite that can remain along the revolving line between the Sun and Earth, at distance $d$ from the Earth. Thus a mass $m$ at L1 has the same period around the Sun as the Earth has. (Not to scale.)

**EXAMPLE 6–9 Lagrange Point.** The mathematician Joseph-Louis Lagrange discovered five special points in the vicinity of the Earth's orbit about the Sun where a small satellite (mass $m$) can orbit the Sun with the same period $T$ as Earth's ($= 1$ year). One of these "Lagrange Points," called L1, lies between the Earth (mass $M_E$) and Sun (mass $M_S$), on the line connecting them (Fig. 6–22). That is, the Earth and the satellite are always separated by a distance $d$. If the Earth's orbital radius is $R_{ES}$, then the satellite's orbital radius is $(R_{ES} - d)$. Determine $d$.

**APPROACH** We use Newton's law of universal gravitation and set it equal to the mass times the centripetal acceleration. But how could an object with a smaller orbit than Earth's have the same period as Earth? Kepler's third law clearly tells us a smaller orbit around the Sun results in a smaller period. But that law depends on only the Sun's gravitational attraction. Our satellite of mass $m$ is pulled by both the Sun and the Earth. We assume circular orbits ($v = 2\pi r/T$).

**SOLUTION** Because the satellite is assumed to have negligible mass in comparison to the masses of the Earth and Sun, to an excellent approximation the Earth's orbit will be determined solely by the Sun. Applying Newton's second law to the Earth ($F = Ma$ becomes $F_G = M_E v^2/r = M_E(2\pi r/T)^2/r$) gives

$$\frac{GM_E M_S}{R_{ES}^2} = M_E\frac{v^2}{R_{ES}} = \frac{M_E}{R_{ES}}\frac{(2\pi R_{ES})^2}{T^2}$$

or

$$\frac{GM_S}{R_{ES}^2} = \frac{4\pi^2 R_{ES}}{T^2}. \qquad \textbf{(i)}$$

Next we apply Newton's second law similarly to the satellite $m$ (which has the same period $T$ as Earth), including the pull of *both* Sun and Earth:

$$\frac{GM_S m}{(R_{ES}-d)^2} - \frac{GM_E m}{d^2} = m\frac{v^2}{R_{ES}-d} = m\frac{(2\pi)^2(R_{ES}-d)^2}{(R_{ES}-d)T^2},$$

which, rewriting the left and right expressions, becomes

$$\frac{GM_S}{R_{ES}^2}\left(1-\frac{d}{R_{ES}}\right)^{-2} - \frac{GM_E}{d^2} = \frac{4\pi^2 R_{ES}}{T^2}\left(1-\frac{d}{R_{ES}}\right).$$

We assume $d \ll R_{ES}$ (and hope it works out) so that we can use the binomial expansion $(1+x)^n \approx 1 + nx$, if $x \ll 1$. Setting $x = d/R_{ES} \ll 1$, we have

$$\frac{GM_S}{R_{ES}^2}\left(1+2\frac{d}{R_{ES}}\right) - \frac{GM_E}{d^2} = \frac{4\pi^2 R_{ES}}{T^2}\left(1-\frac{d}{R_{ES}}\right). \qquad \textbf{(ii)}$$

Substituting $GM_S/R_{ES}^2$ in place of $4\pi^2 R_{ES}/T^2$ [from Eq. (i)] into Eq. (ii) we find

$$\frac{GM_S}{R_{ES}^2}\left(1+2\frac{d}{R_{ES}}\right) - \frac{GM_E}{d^2} = \frac{GM_S}{R_{ES}^2}\left(1-\frac{d}{R_{ES}}\right).$$

Simplifying, we have

$$\frac{GM_S}{R_{ES}^2}\left(3\frac{d}{R_{ES}}\right) = \frac{GM_E}{d^2}.$$

We solve for $d$ to find

$$d = \left(\frac{M_E}{3M_S}\right)^{\frac{1}{3}} R_{ES}.$$

Substituting in values we find

$$d = 1.0\times10^{-2}R_{ES} = 1.5\times10^6\,\text{km}.$$

**NOTE** Since $d/R_{ES} = 10^{-2}$, we were justified in using the binomial expansion.

**NOTE** Placing a satellite at L1 has two advantages: the satellite's view of the Sun is never eclipsed by the Earth, and it is always close enough to Earth to transmit data easily. The L1 point of the Earth–Sun system is currently home to the Solar and Heliospheric Observatory (SOHO) satellite, Fig. 6–23.

**FIGURE 6–23** Artist's rendition of the Solar and Heliospheric Observatory (SOHO) satellite in orbit.

## 6–6 Moon Rises an Hour Later Each Day

From the Earth's reference frame, our Moon revolves on average in 24 h, 50 min, which means the Moon rises nearly an hour later each day; and it is at its highest point in the sky about an hour later each day. When the Moon is on the direct opposite side of Earth from the Sun, the Sun's light fully illuminates the Moon and we call it a **Full moon** (Fig. 6–24a). When the Moon is on the same side of the Earth as the Sun, and nearly aligned with both, we see the Moon as a thin sliver—most or all of it is in shadow ( = a **New moon**). The phases of the Moon (new, first quarter, full, third quarter) take it from one Full moon to the next Full moon in 29.53 days (= **synodic period**) on average, as seen from the Earth as reference frame (Fig. 6–24e). In the Sun's frame of reference, the Moon revolves around the Earth in 27.32 days (**sidereal period**, Fig. 6–24d). This small difference arises because, when the Moon has made one complete revolution around the Earth, the Earth itself has moved in its orbit relative to the Sun. So the Moon needs more time ($\approx$ 2 days) to be fully aligned with the Sun and Earth and be a Full moon, Fig. 6–24e. The red dot in Figs. 6–24a, b, and e represents an observer at the same location on Earth, which in (a) is when the Full moon is rising and the Sun is just setting.

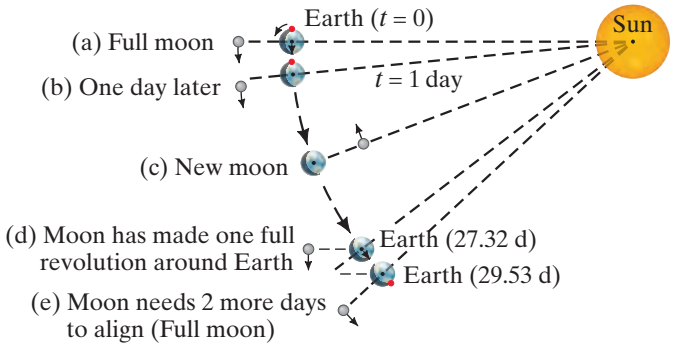

**FIGURE 6–24** Looking down, in the Sun's reference frame, on the plane of Earth's orbit around the Sun (not to scale), above Earth's north pole, showing our Moon making one revolution about Earth: (a) at a Full moon (the red dot is an observer at about 6 PM who can just see the Full moon rise); (b) exactly one day later (for the red dot to see the Moon rise, the Earth must rotate another 50 min); (c) after making a "half revolution" relative to Earth, the Moon is in line with the Sun, on the Sun's side, and is a New moon; (d) after the Moon makes one complete revolution around Earth relative to the Sun (sidereal period); (e) at the next Full moon (synodic period). At (a) and (e) there could be a **lunar eclipse** (Earth's shadow falling on the Moon) but this rarely happens because the plane of Moon's orbit is inclined to the plane of Earth's orbit, so the Moon is usually above or below the Earth's orbital plane. At (c) there could be a **solar eclipse**, also rare.

## 6–7 Types of Forces in Nature

We have already discussed that Newton's law of universal gravitation, Eq. 6–1, describes how a particular type of force—gravity—depends on the masses of the objects involved and the distance between them. Newton's second law, $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$, on the other hand, tells how an object will accelerate due to *any* type of force. But what are the types of forces that occur in nature besides gravity?

In the twentieth century, physicists came to recognize four fundamental forces in nature: (1) the gravitational force; (2) the electromagnetic force (we shall see later that electric and magnetic forces are intimately related); (3) the strong nuclear force (which holds protons and neutrons together to form atomic nuclei); and (4) the weak nuclear force (involved in radioactivity). In this Chapter, we discussed the gravitational force in detail. The electromagnetic force will be discussed in Chapters 21 to 31. The strong and weak nuclear forces, which are discussed in Chapters 41 to 43, operate at the level of the atomic nucleus and are much less obvious in our daily lives.

Physicists have been working on theories that would unify these four forces—that is, to consider some or all of these forces as different manifestations of the same basic force. The electromagnetic and weak nuclear forces have been theoretically united to form *electroweak* theory, in which the electromagnetic and weak forces are seen as two aspects of a single *electroweak force*. It is part of the "Standard Model" of fundamental particle interactions which includes the prediction of the Higgs boson, for which strong experimental evidence was announced in 2012 (see Chapter 43). Further attempts to unify the forces, such as in *grand unified theories* (GUT), are hot research topics today.

But where do everyday forces fit? Ordinary forces, other than gravity, such as pushes, pulls, and other *contact forces* like the normal force and friction, are today considered to be due to the electromagnetic force acting at the atomic level. For example, the force your fingers exert on a pencil is the result of electrical repulsion between the outer electrons of the atoms of your finger and those of the pencil.

## *6–8 Gravitational Field

Most of the forces we meet in everyday life are contact forces: you push or pull on a lawn mower, a tennis racket exerts a force on a tennis ball when they make contact, or a ball exerts a force on a window when they make contact. But the gravitational force acts over a distance: there is a force even when the two objects are not in contact. The Earth, for example, exerts a force on a falling apple. It also exerts a force on the Moon, 384,000 km away. And the Sun exerts a gravitational force on the Earth. The idea of a force *acting at a distance* was a difficult one for early thinkers. Newton himself felt uneasy with this concept when he published his law of universal gravitation.

**CAUTION**
*Forces acting over a distance*

Another point of view that helps with these conceptual difficulties is the concept of the **field**, developed in the nineteenth century by Michael Faraday (1791–1867) to aid understanding of electric and magnetic forces which also act over a distance. Only later was it applied to gravity. According to the field concept, a **gravitational field** surrounds every object that has mass, and this field permeates all of space. A second object at a particular location near the first object experiences a force because of the gravitational field that exists there. The *field* exerts the pull.

To be quantitative, we can define the **gravitational field** as the gravitational force per unit mass at any point in space. If we want to measure the gravitational field at any point, we place a small "test" mass $m$ at that point and measure the force $F$ exerted on it (making sure only gravitational forces are acting). Then the gravitational field at that point is defined as

$$g = \frac{F}{m}. \qquad \text{[gravitational field]} \quad \textbf{(6–8)}$$

The units of $g$ are N/kg.

From Eq. 6–8 we see that the gravitational field an object experiences has magnitude equal to the acceleration due to gravity at that point. (When we speak of acceleration, however, we use units $m/s^2$, which is equivalent to N/kg, since $1\,N = 1\,kg \cdot m/s^2$.)

If the gravitational field is due to a single spherically symmetric (or small) object of mass $M$, such as when $m$ is near the Earth's surface, then the gravitational field at a distance $r$ from $M$ has magnitude

$$g = \frac{1}{m} G\frac{mM}{r^2} = G\frac{M}{r^2}.$$

We see that the gravitational field $g$ does not depend on the test mass $m$.

In interplanetary space, the gravitational field at any point is the (vector) sum of terms due to the Earth, Sun, Moon, and other bodies that contribute. The gravitational field does not depend on the value of our test mass, $m$, but only on the masses (and locations) of the bodies that create the field there.

The field concept will be discussed in more detail relative to other forces in later Chapters.

# *6–9 Principle of Equivalence; Curvature of Space; Black Holes

We have dealt with two aspects of mass. In Chapter 4, we defined mass as a measure of the inertia of a body. Newton's second law relates the force acting on a body to its acceleration and its **inertial mass**, as we call it. We might say that inertial mass represents a resistance to any force.

In this Chapter we have dealt with mass as a property related to the gravitational force—that is, mass as a quantity that determines the strength of the gravitational force between two bodies. This we call the **gravitational mass**.

It is not obvious that the inertial mass of a body should be equal to its gravitational mass. The force of gravity might have depended on a different property of a body, just as the electrical force depends on a property called electric charge. Newton's and Cavendish's experiments indicated that the two types of mass are equal for any body, and modern experiments confirm it to a precision of about 1 part in $10^{12}$.

Albert Einstein (1879–1955) called this equivalence between gravitational and inertial masses the **principle of equivalence**, and he used it as a foundation for his *general theory of relativity* (*c*. 1916). The principle of equivalence can be stated in another way:

> *there is no experiment observers can perform to distinguish if an acceleration arises because of a gravitational force or because their reference frame is accelerating*.

If you were far out in space and an apple fell to the floor of your spacecraft, you might assume a gravitational force was acting on the apple. But it would also be possible that the apple fell because your spacecraft accelerated upward (relative to an inertial reference frame). The effects would be indistinguishable, according to the principle of equivalence, because the apple's inertial and gravitational masses—that determine how a body "reacts" to outside influences—are indistinguishable.

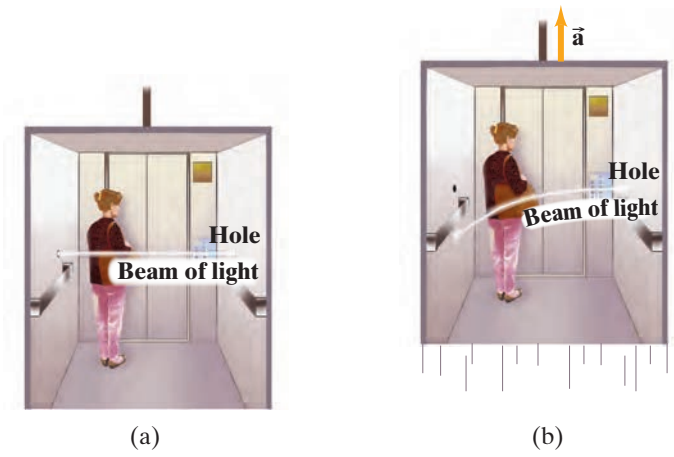

**FIGURE 6–25** (a) Light beam goes straight across an elevator that is not accelerating. (b) The light beam bends (exaggerated) in an elevator accelerating in an upward direction.

The principle of equivalence can be used to show that light ought to be deflected due to the gravitational force of a massive object. Let us consider a thought experiment in an elevator in free space where virtually no gravity acts. If a light beam enters a hole in the side of the elevator, the beam travels straight across the elevator and makes a spot on the opposite side if the elevator is at rest (Fig. 6–25a). If the elevator is accelerating upward as in Fig. 6–25b, the light beam is observed to curve downward. Why? Because during the time the light travels from one side of the elevator to the other, the elevator has moved upward at ever-increasing speed.

According to the equivalence principle, an upwardly accelerating reference frame is equivalent to a downward gravitational field. Hence, we can picture the curved light path in Fig. 6–25b as being the effect of a gravitational field.

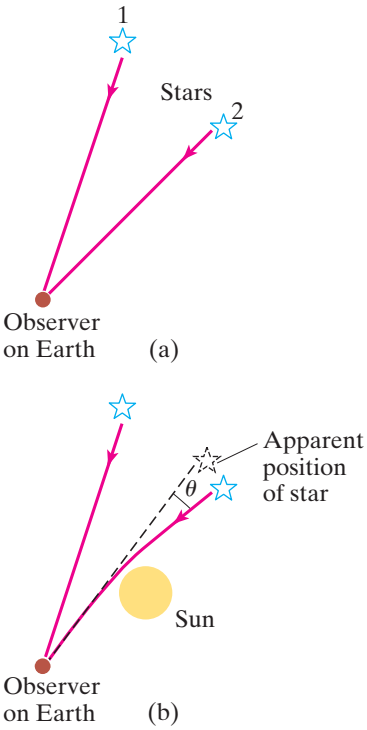

**FIGURE 6–26** (a) Two stars in the sky, observed from Earth. (b) If the light from one of these stars passes very near the Sun, whose gravity bends the rays, the star will appear higher than it actually is (follow the ray backwards). [Not to scale.]

Thus we expect gravity to exert a force on a beam of light and to bend it out of a straight-line path!

Einstein's general theory of relativity predicts that light should be affected by gravity. It was calculated that light from a distant star would be deflected by 1.75″ of arc (tiny but detectable) as it passed near the Sun, as shown in Fig. 6–26. Such a deflection was measured and confirmed in 1919 during an eclipse of the Sun. (The eclipse reduced the brightness of the Sun so that the stars in line with its edge at that moment would be visible.)

That a light beam can follow a curved path suggests that **space itself is curved** and that it is gravitational mass that causes the curvature. The curvature is greatest near very massive objects. To visualize this curvature of space, we might think of space as being like a thin rubber sheet; if a heavy weight is hung from it, it curves as shown in Fig. 6–27. The weight corresponds to a huge mass that causes space (space itself!) to curve.

The extreme curvature of space-time shown in Fig. 6–27 could be produced by a **black hole**, a star that becomes so dense and massive that gravity would be so strong that even light could not escape it. Light would be pulled back in by the force of gravity. Since no light could escape from such a massive star, we could not see it—it would be black. An object might pass by it and be deflected by its gravitational field, but if the object came too close it would be swallowed up, never to escape. Hence the name black holes. Experimentally there is good evidence for their existence. One likely possibility is a giant black hole at the center of our Galaxy and probably at the center of other galaxies.

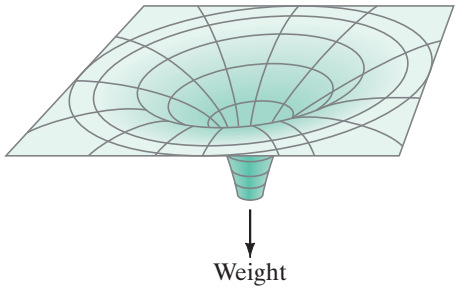

**FIGURE 6–27** Rubber-sheet analogy for space (technically space-time) curved by matter.

# Summary

Newton's **law of universal gravitation** states that every particle in the universe attracts every other particle with a force proportional to the product of their masses and inversely proportional to the square of the distance between them:

$$F_G = G\frac{m_1 m_2}{r^2}. \qquad \textbf{(6–1)}$$

The direction of this force is along the line joining the two particles, and is always attractive. It is this gravitational force that keeps the Moon revolving around the Earth and the planets revolving around the Sun.

The total gravitational force on any object is the vector sum of the forces exerted by all other objects; frequently the effects of all but one or two objects can be ignored.

Satellites revolving around the Earth are acted on by gravity, but "stay up" because of their high tangential speed.

Newton's three laws of motion, plus his law of universal gravitation, constituted a wide-ranging theory of the universe. With them, motion of objects on Earth and in the heavens could be accurately described. And they provided a theoretical base for **Kepler's laws** of planetary motion.

High and low **tides** are due mainly to the gravitational force exerted by the Moon.

The Moon rises about an hour later each day.

The four fundamental forces in nature are (1) the gravitational force, (2) electromagnetic force, (3) strong nuclear force, and (4) weak nuclear force. The first two fundamental forces are responsible for nearly all "everyday" forces.

[*According to the **field** concept, a **gravitational field** surrounds every object that has mass, and it permeates all of space. The gravitational field at any point in space is the vector sum of the fields due to all massive objects and can be defined as

$$g = \frac{F}{m} \qquad \textbf{(6–8)}$$

where $F$ is the force acting on a small "test" mass $m$ placed at that point.]

[*Inertial mass and gravitational mass are the same for any body, an experimental fact known as the **equivalence principle**. Even a light beam is affected by gravity, which suggests that space itself is curved. **Black holes** are such massive "stars" that not even light can escape.]

# Questions

1. Does an apple exert a gravitational force on the Earth? If so, how large a force? Consider an apple (*a*) attached to a tree and (*b*) falling.
2. The Sun's gravitational pull on the Earth is much larger than the Moon's. Yet the Moon's is mainly responsible for the tides. Explain. [*Hint*: Consider the difference in gravitational pull from one side of the Earth to the other.]
3. Will an object weigh more at the equator or at the poles? What two effects are at work? Do they oppose each other?
4. Why is more fuel required for a spacecraft to travel from the Earth to the Moon than for it to return from the Moon to the Earth?
5. The gravitational force on the Moon due to the Earth is only about half the force on the Moon due to the Sun (see Example 6–3). Why isn't the Moon pulled away from the Earth?
6. How did the scientists of Newton's era determine the distance from the Earth to the Moon, despite not knowing about spaceflight or the speed of light? [*Hint*: Think about why two eyes are useful for depth perception.]
7. If it were possible to drill a hole all the way through the Earth along a diameter, then it would be possible to drop a ball through the hole. When the ball was right at the center of the Earth, what would be the total gravitational force exerted on it by the Earth?
8. Why is it not possible to put a satellite in geostationary orbit above the North Pole?
9. Which pulls harder gravitationally, the Earth on the Moon, or the Moon on the Earth? Which accelerates more?
10. Would it require less speed to launch a satellite (*a*) toward the east or (*b*) toward the west? Consider the Earth's rotation direction, and explain your choice.
11. An antenna loosens and becomes detached from a satellite in a circular orbit around the Earth. Describe the antenna's subsequent motion. If it will land on the Earth, describe where; if not, describe how it could be made to land on the Earth.
12. Describe how careful measurements of the variation in $g$ in the vicinity of an ore deposit might be used to estimate the amount of ore present.
13. The Sun is below us at midnight, nearly in line with the Earth's center. Are we then heavier at midnight, due to the Sun's gravitational force on us, than we are at noon? Explain.
14. When will your apparent weight be the greatest, as measured by a scale in a moving elevator: when the elevator (*a*) accelerates downward, (*b*) accelerates upward, (*c*) is in free fall, or (*d*) moves upward at constant speed? In which case would your apparent weight be the least? When would it be the same as when you are on the ground? Explain.
15. If the Earth's mass were double what it actually is, in what ways would the Moon's orbit be different?
16. The source of the Mississippi River is closer to the center of the Earth than is its outlet in Louisiana (because the Earth is fatter at the equator than at the poles). Explain how the Mississippi can flow "uphill."
17. People sometimes ask, "What keeps a satellite up in its orbit around the Earth?" How would you respond?
18. Explain how a runner experiences "free fall" or "apparent weightlessness" between steps.
19. If you were in a satellite orbiting the Earth, how might you cope with walking, drinking, or putting a pair of scissors on a table?
20. Is the centripetal acceleration of Mars in its orbit around the Sun larger or smaller than the centripetal acceleration of the Earth? Explain.
21. The mass of the "planet" Pluto was not known until it was discovered to have a moon. Explain how this enabled an estimate of Pluto's mass.
22. The Earth moves faster in its orbit around the Sun in January than in July. Is the Earth closer to the Sun in January, or in July? Explain. [*Note*: This is not much of a factor in producing the *seasons*—the main factor is the tilt of the Earth's axis relative to the plane of its orbit.]
23. Kepler's laws tell us that a planet moves faster when it is closer to the Sun than when it is farther from the Sun. What causes this change in speed of the planet?

*24. Does your body directly sense a gravitational field? (Compare to what you would feel in free fall.)

*25. Discuss the conceptual differences between $g$ as acceleration due to gravity and $g$ as gravitational field.

# MisConceptual Questions

1. The Moon does not crash into the Earth because
   (*a*) the net force on it is zero.
   (*b*) it is beyond the main pull of the Earth's gravity.
   (*c*) it is being pulled by the Sun as well as by the Earth.
   (*d*) it is freely falling but it has a high tangential velocity.
2. In the International Space Station which orbits Earth, astronauts experience apparent weightlessness because
   (*a*) the station is so far away from the center of the Earth.
   (*b*) the station is kept in orbit by a centrifugal force that counteracts the Earth's gravity.
   (*c*) the astronauts and the station are in free fall towards the center of the Earth.
   (*d*) there is no gravity in space.
   (*e*) the station's high speed nullifies the effects of gravity.
3. Which pulls harder gravitationally, the Earth on the Moon, or the Moon on the Earth? Which accelerates more?
   (*a*) The Earth on the Moon; the Earth.
   (*b*) The Earth on the Moon; the Moon.
   (*c*) The Moon on the Earth; the Earth.
   (*d*) The Moon on the Earth; the Moon.
   (*e*) Both the same; the Earth.
   (*f*) Both the same; the Moon.
4. Two satellites orbit the Earth in circular orbits of the same radius. One satellite is twice as massive as the other. Which statement is true about the speeds of these satellites?
   (*a*) The heavier satellite moves twice as fast as the lighter one.
   (*b*) The two satellites have the same speed.
   (*c*) The lighter satellite moves twice as fast as the heavier one.
   (*d*) The ratio of their speeds depends on the details of how they were launched.

5. A space vehicle in orbit around the Earth carries its payload, a satellite, with its mechanical arm. Suddenly, the arm malfunctions and releases the payload. What will happen to the payload?
(*a*) It will fall straight down and hit the Earth.
(*b*) It will follow a curved path and eventually hit the Earth.
(*c*) It will remain in the same orbit with the space vehicle.
(*d*) It will drift out into deep space.

6. As you travel away from Earth's surface,
(*a*) your weight decreases and your mass remains the same.
(*b*) both your weight and mass decrease.
(*c*) both your weight and mass remain the same.
(*d*) your weight is always greater than your mass.

7. A person who weighs 450 N stands on a scale in an elevator. The scale will read zero if
(*a*) the elevator is accelerating up at 9.8 m/s$^2$.
(*b*) the elevator is moving at a constant speed of 9.8 m/s.
(*c*) the elevator is accelerating down at 9.8 m/s$^2$.
(*d*) The scale will never read zero.

8. What force keeps the Moon up in orbit around the Earth?
(*a*) No force. The Moon is constantly falling as it orbits the Earth at high speed.
(*b*) Centrifugal force.
(*c*) Centripetal force.
(*d*) The combined effects of centrifugal force and gravity.
(*e*) The Earth's gravity combined with its magnetic field.

9. The Full moon appears full because
(*a*) the Moon is at the best angle to reflect the city lights from Earth.
(*b*) the round part of the Moon faces Earth at that time of month.
(*c*) the Earth is between the Moon and the Sun and we see reflected sunlight.
(*d*) the Moon is closest to the Earth at that time of month.

10. According to Kepler's third law, if we know the ratio $s^3/T^2$ for one of the moons that orbit Jupiter, this ratio should be the same for
(*a*) the Moon orbiting the Earth.
(*b*) any moon orbiting Jupiter.
(*c*) Jupiter's orbit about the Sun.
(*d*) all of the above.
(*e*) none of the above.

*11. Your weight as you stand on the surface of the Earth is due to
(*a*) the Earth's rotation (if it stopped, you would fly off into space).
(*b*) the Earth's magnetic field.
(*c*) the Earth's gravitational field.
(*d*) the contact force between you and the Earth.

*12. Earth's gravitational field extends
(*a*) a little past the Moon.
(*b*) only as far as the Sun.
(*c*) to the edge of the solar system.
(*d*) beyond the edge of the solar system.

# Problems

## 6–1 to 6–3 Law of Universal Gravitation

1. (I) Calculate the force of Earth's gravity on a spacecraft 2.00 Earth radii above the Earth's surface if its mass is 1650 kg.
2. (I) At the surface of a certain planet, the gravitational acceleration $g$ has a magnitude of 12.0 m/s$^2$. A 28.0-kg brass ball is transported to this planet. What is (*a*) the mass of the brass ball on the Earth and on the planet, and (*b*) the weight of the brass ball on the Earth and on the planet?
3. (I) Calculate the acceleration due to gravity on the Moon, which has radius $1.74 \times 10^6$ m and mass $7.35 \times 10^{22}$ kg.
4. (I) A hypothetical planet has a radius 2.5 times that of Earth, but has the same mass. What is the acceleration due to gravity near its surface?
5. (I) A hypothetical planet has a mass 2.80 times that of Earth, but has the same radius. What is $g$ near its surface?
6. (II) If you doubled the mass and tripled the radius of a planet, by what factor would $g$ at its surface change?
7. (II) At what distance from the Earth's center will a spacecraft traveling directly from the Earth to the Moon experience zero net force because the Earth and Moon pull in opposite directions with equal force?
8. (II) Two objects attract each other gravitationally with a force of $6.5 \times 10^{-9}$ N when they are 0.25 m apart. Their total mass is 6.50 kg. Find their individual masses.
9. (II) An object 1600 m above the Earth's surface has lost what percent of its weight (compared to on Earth)?
10. (II) Four masses are arranged as shown in Fig. 6–28. Determine the $x$ and $y$ components of the gravitational force on the mass at the origin ($m$). Write the force in vector notation $(\hat{\mathbf{i}}, \hat{\mathbf{j}})$.

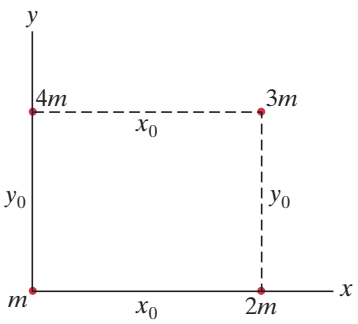

**FIGURE 6–28**
Problem 10.

11. (II) (*a*) Do you weigh more at the equator than in New York, or less? (*b*) By what percentage? See Table 6–1.
12. (II) Suppose the maximum distance you can throw a particular ball on Earth is 45.0 m. When you travel to another planet, the maximum distance for the same ball is 36.5 m. If the planet is the same size as Earth, what is its mass?
13. (II) Suppose the mass of the Earth were doubled, but it kept the same density (mass/volume) and spherical shape. How would the weight of objects at the Earth's surface change?
14. (II) Determine the mass of the Sun using the known value for the orbital period of the Earth and its distance from the Sun. [*Hint*: The force on the Earth due to the Sun is related to the centripetal acceleration of the Earth.] Compare your answer to that obtained using Kepler's laws, Example 6–8.

15. (II) Estimate the acceleration due to gravity at the surface of Europa (one of the moons of Jupiter) given that its mass is $4.9 \times 10^{22}$ kg and making the assumption that its mass per unit volume is the same as Earth's.

16. (II) Given that the acceleration of gravity at the surface of Mars is 0.38 of what it is on Earth, and that Mars' radius is 3400 km, determine the mass of Mars.

17. (II) You are explaining to friends why an astronaut feels weightless orbiting the Earth in a space station, and they respond that they thought gravity was just a lot weaker up there. Convince them that it isn't so by calculating how much weaker (in %) gravity is 380 km above the Earth's surface.

18. (II) Every few hundred years most of the planets line up on the same side of the Sun. Calculate the total force on the Earth due to Venus, Jupiter, and Saturn, assuming all four planets are in a line, Fig. 6–29. The masses are $m_V = 0.815\, m_E$, $m_J = 318\, m_E$, $m_{Sat} = 95.1\, m_E$, and the mean distances of the four planets from the Sun are 108, 150, 778, and 1430 million km. What fraction of the Sun's force on the Earth is this?

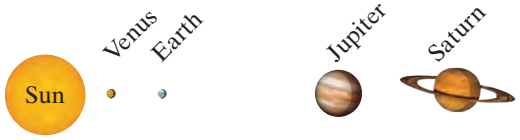

**FIGURE 6–29** Problem 18 (not to scale).

19. (II) Three meteorites in outer space lie along a straight line. At a certain instant in time, the meteorite on the right is 53 m from the center meteorite and the lefthand meteorite is 21 m from the center meteorite. If the mass of the righthand meteorite is 1300 kg and the net gravitational force on the center meteorite is zero, what is the mass of the lefthand meteorite?

20. (II) Determine the distance from the Earth's center to a point outside the Earth where the gravitational acceleration due to the Earth is $\frac{1}{10}$ of its value at the Earth's surface.

21. (II) A certain neutron star has four times the mass of our Sun packed into a sphere about 10 km in radius. Estimate the acceleration due to gravity at the surface of this monster.

22. (II) A certain *white dwarf* star was once an average star like our Sun. But now it is in the last stage of its evolution and is the size of our Moon but has the mass of our Sun. (*a*) Estimate the acceleration due to gravity on the surface of this star. (*b*) How much would a 65-kg person weigh on this star? Give as a percentage of the person's weight on Earth. (*c*) What would be the speed of a baseball dropped from a height of 1.0 m when it hit the surface?

23. (II) Two identical point masses, each of mass $M$, always remain separated by a distance of $2R$. A third mass $m$ is then placed a distance $x$ along the perpendicular bisector of the original two masses, as shown in Fig. 6–30. Show that the gravitational force on the third mass is directed inward along the perpendicular bisector and has a magnitude of

$$F = \frac{2GMmx}{(x^2 + R^2)^{\frac{3}{2}}}.$$

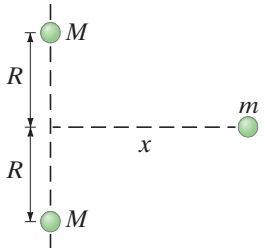

**FIGURE 6–30**
Problem 23.

24. (III) A mass $M$ is ring shaped with radius $r$. A small mass $m$ is placed at a distance $x$ along the ring's axis as shown in Fig. 6–31. Show that the gravitational force on the mass $m$ due to the ring is directed inward along the axis and has magnitude

$$F = \frac{GMmx}{(x^2 + r^2)^{\frac{3}{2}}}.$$

[*Hint*: Think of the ring as made up of many small point masses $dM$; sum over the forces due to each $dM$, and use *symmetry*.]

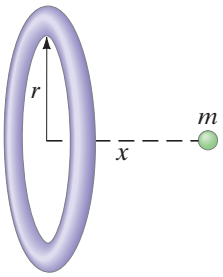

**FIGURE 6–31**
Problem 24.

25. (III) (*a*) Use the binomial expansion

$$(1 \pm x)^n = 1 \pm nx + \frac{n(n-1)}{2}x^2 \pm \cdots$$

to show that the value of $g$ is altered by approximately

$$\Delta g \approx -2g\frac{\Delta r}{r_E}$$

at a height $\Delta r$ above the Earth's surface, where $r_E$ is the radius of the Earth, as long as $\Delta r \ll r_E$. (*b*) What is the meaning of the minus sign in this relation? (*c*) Use this result to compute the effective value of $g$ at 125 km above the Earth's surface. Compare to a direct use of Eq. 6–1.

26. (III) The center of a 1.00-km-diameter spherical pocket of oil is 1.00 km beneath the Earth's surface. Estimate by what percentage the value of $g$ would differ, directly above the pocket of oil, from the expected value of $g$ for a uniform Earth. Assume the density of oil is $8.0 \times 10^2$ kg/m$^3$.

27. (III) Determine the magnitude and direction of the effective value of $\vec{\mathbf{g}}$ at a latitude of 45° on the Earth. Assume the Earth is a rotating sphere.

28. (III) It can be shown (Appendix E) that for a uniform sphere the force of gravity at a point inside the sphere depends only on the mass closer to the center than that point. The net force of gravity due to points outside the radius of the point cancels. How far would you have to drill into the Earth to reach a point where your weight is reduced by 5.0%? Approximate the Earth as a uniform sphere.

## 6–4 Satellites and Weightlessness

29. (I) A rocket releases a satellite into a circular orbit 780 km above the Earth. How fast must the rocket be moving (relative to Earth's center) when the release occurs?

30. (I) Calculate the speed of a satellite moving in a stable circular orbit around the Earth at a height of 5400 km.

31. (II) What will a spring scale read for the weight of a 58.0-kg woman in an elevator that moves (*a*) upward with constant speed 4.4 m/s, (*b*) downward with constant speed 4.4 m/s, (*c*) with an upward acceleration 0.18 $g$, (*d*) with a downward acceleration 0.18 $g$, and (*e*) in free fall?

32. (II) You know your mass is 62 kg, but when you stand on a bathroom scale in an elevator, it says your mass is 72 kg. What is the acceleration of the elevator, and in which direction?

33. (II) Astronomers using the Hubble Space Telescope deduced the presence of an extremely massive core in the distant *galaxy* M87, so dense that it could be a black hole (from which no light escapes). They did this by measuring the speed of gas clouds orbiting the core to be 780 km/s at a distance of 60 light-years $(= 5.7 \times 10^{17}\ \text{m})$ from the core. Deduce the mass of the core, and compare it to the mass of our Sun.

**34.** (II) An 18.0-kg monkey hangs from a cord suspended from the ceiling of an elevator. The cord can withstand a tension of 215 N and breaks as the elevator accelerates. What was the elevator's minimum acceleration (magnitude and direction)?

**35.** (II) Two satellites orbit Earth at altitudes of 8500 km and 17,000 km above the Earth's surface. (*a*) Which satellite is faster, and by what factor? (*b*) Which has the shorter period, and by what factor?

**36.** (II) Calculate the period of a satellite orbiting the Moon, 95 km above the Moon's surface. The Moon's radius is 1740 km.

**37.** (II) In a remote region of space, far from any other objects, a small ball is in a 30.0-cm-radius circular orbit around a 7.0-kg bowling ball. How long does it take the small ball to complete one orbit?

**38.** (II) Determine the time it takes for a satellite to orbit the Earth in a circular **near-Earth orbit**. A "near-Earth" orbit is at a height above the surface of the Earth that is very small compared to the radius of the Earth. [*Hint*: You may take the acceleration due to gravity as essentially the same as that on the surface.] Does your result depend on the mass of the satellite?

**39.** (II) What is the apparent weight of a 75-kg astronaut 2800 km from the center of the Moon in a space vehicle (*a*) moving at constant speed in a circular orbit, and (*b*) accelerating toward the Moon at 1.8 $m/s^2$? State "direction" in each case.

**40.** (II) Suppose a satellite is in a circular orbit not far above Earth's surface, and circles the Earth about once every 92 minutes. Find the centripetal acceleration of the satellite in its orbit. Express your answer in terms of $g$, the gravitational acceleration at the Earth's surface.

**41.** (II) At what rate must a cylindrical spaceship rotate (Fig. 6–32) if occupants are to experience simulated gravity of 0.70 $g$? Assume the spaceship's diameter is 28 m, and give your answer as the time needed for one revolution.

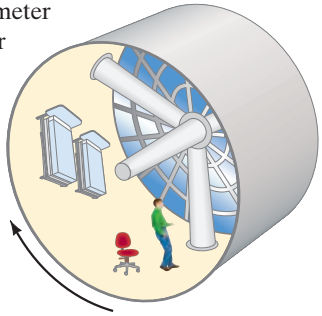

**FIGURE 6–32**
Problem 41.

**42.** (III) (*a*) Show that if a satellite orbits very near the surface of a planet with period $T$, the density (= mass per unit volume) of the planet is $\rho = m/V = 3\pi/GT^2$. (*b*) Estimate the density of the Earth, given that a satellite near the surface orbits with a period of 85 min. Approximate the Earth as a uniform sphere.

**43.** (III) Three small objects of identical mass $M$ form the vertices of an equilateral triangle of side $\ell$ and rotate in circular orbits about the center of the triangle. They are held in place by their mutual gravitation. What is the speed of each?

**44.** (III) An inclined plane, fixed to the inside of an elevator, makes a 38° angle with the floor. A mass $m$ slides on the plane without friction. What is its acceleration relative to the plane if the elevator (*a*) accelerates upward at 0.50 $g$, (*b*) accelerates downward at 0.50 $g$, (*c*) falls freely, and (*d*) moves upward at constant speed?

## 6–5 Kepler's Laws

**45.** (I) Neptune is an average distance of $4.5 \times 10^9$ km from the Sun. Estimate the length of the Neptunian year using the fact that the Earth is $1.50 \times 10^8$ km from the Sun on average.

**46.** (I) The *asteroid* Icarus, though only a few hundred meters across, orbits the Sun like the planets. Its period is 410 d. What is its mean distance from the Sun?

**47.** (I) Use Kepler's laws and the period of the Moon (27.4 d) to determine the period of an artificial satellite orbiting very near the Earth's surface.

**48.** (I) Determine the mass of the Earth from the known period and distance of the Moon.

**49.** (II) Table 6–3 gives the mean distance, period, and mass for the four largest moons of Jupiter (those discovered by Galileo in 1609). Determine the mass of Jupiter: (*a*) using the data for Io; (*b*) using data for each of the other three moons. Are the results consistent?

**TABLE 6–3 Principal Moons of Jupiter**
**(Problems 49, 50, and 56)**

| Moon | Mass (kg) | Period (Earth days) | Mean distance from Jupiter (km) |
|---|---|---|---|
| Io | $8.9 \times 10^{22}$ | 1.77 | $422 \times 10^3$ |
| Europa | $4.9 \times 10^{22}$ | 3.55 | $671 \times 10^3$ |
| Ganymede | $15 \times 10^{22}$ | 7.16 | $1070 \times 10^3$ |
| Callisto | $11 \times 10^{22}$ | 16.7 | $1883 \times 10^3$ |

**50.** (II) Determine the mean distance from Jupiter for each of Jupiter's principal moons, using Kepler's third law. Use the mean distance of Io and the periods given in Table 6–3. Compare your results to the values in Table 6–3.

**51.** (II) A science fiction writer imagines a planet that has three times the mass of the Earth orbiting a star that has twice the mass of our Sun. The writer wants the planet's "year" to be 10% longer than Earth's orbital period. At what mean distance should she place the planet from its star?

**52.** (II) Planet A and planet B are in circular orbits around a distant star. Planet A is 5.0 times farther from the star than is planet B. What is the ratio of their speeds $v_A/v_B$?

**53.** (II) *Halley's comet* orbits the Sun roughly once every 76 years. It comes very close to the surface of the Sun on its closest approach (Fig. 6–33). Estimate the farthest distance of the comet from the Sun. Is it still "in" the solar system? What planet's orbit is nearest when it is at that farthest distance?

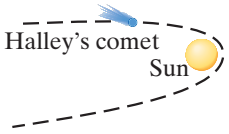

**FIGURE 6–33**
Problem 53.

**54.** (II) The **asteroid belt** between Mars and Jupiter consists of many fragments (which some space scientists think came from a planet that once orbited the Sun but was destroyed). (*a*) If the mean orbital radius of the asteroid belt (where the planet would have been) is about three times farther from the Sun than the Earth is, how long would it have taken this hypothetical planet to orbit the Sun? (*b*) Can we use these data to deduce the mass of this planet?

**55.** (II) (*a*) Use Kepler's second law to show that the ratio of the speeds of a planet at its nearest and farthest points from the Sun is equal to the inverse ratio of the near and far distances: $v_N/v_F = d_F/d_N$. (*b*) Given that the Earth's distance from the Sun varies from 1.47 to $1.52 \times 10^{11}$ m, determine the minimum and maximum velocities of the Earth in its orbit around the Sun.

**56.** (III) The orbital periods $T$ and mean orbital distances $r$ for Jupiter's four largest moons are given in Table 6–3. (*a*) Starting with Kepler's third law in the form (see Eq. 6–6)

$$T^2 = \left(\frac{4\pi^2}{Gm_J}\right)r^3,$$

where $m_J$ is the mass of Jupiter, show that this relation implies that a plot of $\log(T)$ vs. $\log(r)$ will yield a straight line. Explain what Kepler's third law predicts about the slope and $y$-intercept of this straight-line plot. (*b*) Using the data for Jupiter's four moons, plot $\log(T)$ vs. $\log(r)$ and show that you get a straight line. Determine the slope of this plot and compare it to the value you expect if the data are consistent with Kepler's third law. Determine the $y$-intercept of the plot and use it to compute the mass of Jupiter.

**57.** (III) The *comet Hale–Bopp* has an orbital period of 2400 years. (*a*) What is its mean distance from the Sun? (*b*) At its closest approach, the comet is about 1.0 astronomical unit from the Sun (1 AU = distance from Earth to the Sun). What is the farthest distance? (*c*) What is the ratio of the speed at the closest point to the speed at the farthest point?

### 6–6 Moon Rise

**58.** (III) (*a*) Explain why a Full moon always rises at sunset. (*b*) Explain how the position of the Moon in Fig. 6–24b cannot be seen yet by the person at the red dot (shown at 6 PM). (*c*) Explain why the red dot is where it is in parts (b) and (e), and show where it should be in part (d). (*d*) [PRETTY HARD:] Determine the average period of the Moon around the Earth (sidereal period) starting with the synodic period of 29.53 days as observed from Earth. [*Hint*: First determine the angle of the Moon in Fig. 6–24e relative to "horizontal," as in part (a).]

### *6–8 Gravitational Field

***59.** (II) Determine the magnitude and direction of the gravitational field midway between the Earth and Moon. Ignore effects of the Sun.

***60.** (II) (*a*) What is the gravitational field at the surface of the Earth due to the Sun? (*b*) Will this affect your weight significantly?

***61.** (III) Two identical particles, each of mass $m$, are located on the $x$ axis at $x = +x_0$ and $x = -x_0$. (*a*) Determine a formula for the gravitational field due to these two particles for points on the $y$ axis; that is, write $g$ as a function of $y$, $m$, $x_0$, and so on. (*b*) At what point (or points) on the $y$ axis is the magnitude of $g$ a maximum value, and what is its value there? [*Hint*: Take the derivative $dg/dy$.]

## General Problems

**62.** Calculate the centripetal acceleration of the Earth in its orbit around the Sun, and the net force exerted on the Earth. What exerts this force on the Earth? Assume that the Earth's orbit is a circle of radius $1.50 \times 10^{11}$ m.

**63.** **Binary star:** Two equal-mass stars maintain a constant distance $D$ apart (Fig. 6–34) of $8.0 \times 10^{11}$ m and revolve about a point midway between them at a rate of one revolution every 14.2 yr. (*a*) Why don't the two stars crash into one another due to the gravitational force between them? (*b*) What must be the mass $m$ of each star?

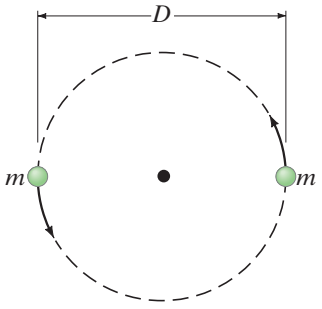

**FIGURE 6–34**
Problem 63.

**64.** How far above the Earth's surface will the acceleration due to gravity be half what it is at the surface?

**65.** How long would a day be if the Earth were rotating so fast that objects at the equator were apparently weightless?

**66.** Show that the rate of change of your weight is

$$-2G\frac{m_E m}{r^3}v$$

if you are traveling directly away from Earth at constant speed $v$. Your mass is $m$, and $r$ is your distance from the center of the Earth at any moment.

**67.** The *rings of Saturn* are composed of chunks of ice that orbit the planet. The inner radius of the rings is 73,000 km, and the outer radius is 170,000 km. Find the period of an orbiting chunk of ice at the inner radius and the period of a chunk at the outer radius. Compare your numbers with Saturn's own rotation period of 10 hours and 39 minutes. The mass of Saturn is $5.7 \times 10^{26}$ kg.

**68.** The **Navstar Global Positioning System** (GPS) utilizes a group of 24 satellites orbiting the Earth. Using "triangulation" and signals transmitted by these satellites, the position of a receiver on the Earth can be determined to within an accuracy of a few centimeters. The satellite orbits are distributed around the Earth, allowing continuous navigational "fixes." The satellites orbit at an altitude of approximately 11,000 nautical miles [1 nautical mile = 1.852 km = 6076 ft]. (*a*) Determine the speed of each satellite. (*b*) Determine the period of each satellite. [Originally, 1 *nautical mile* was defined as one minute ($\frac{1}{60}$ of a degree) of latitude on Earth's surface. 1 *knot* is a speed of 1 nautical mile/h.]

**69.** The *Near Earth Asteroid Rendezvous* (*NEAR*) spacecraft, after traveling 2.1 billion km, orbited the *asteroid* Eros with an orbital radius of about 20 km. Eros is roughly 40 km × 6 km × 6 km. Assume Eros has a density (mass/volume) of about $2.3 \times 10^3$ kg/m$^3$. (*a*) If Eros were a sphere with the same mass and density, what would its radius be? (*b*) What would $g$ be at the surface of a spherical Eros? (*c*) Estimate the orbital period of *NEAR* around Eros, as if Eros were a sphere.

**70.** The *Lunar Reconnaissance Orbiter* (LRO) is a NASA Moon-orbiting spacecraft in an orbit with an altitude of 50 km above the Moon's surface. What is the period of the LRO as it orbits the Moon?

**71.** Astronomers have observed an otherwise normal star, called S2, closely orbiting an extremely massive but small object at the center of our *Milky Way Galaxy* called SgrA. S2 moves in an elliptical orbit around SgrA with a period of 15.2 yr and an eccentricity $e = 0.87$ (Fig. 6–17). In 2002, S2 reached its closest approach to SgrA, a distance of only 123 AU ($1\text{ AU} = 1.50 \times 10^{11}\text{ m}$ is the mean Earth–Sun distance). Determine the mass $m$ of SgrA, the massive compact object (believed to be a supermassive black hole) at the center of our Galaxy. State $m$ in kg and in terms of the mass of our Sun.

**72.** A satellite circles a spherical planet of unknown mass in a circular orbit of radius $1.6 \times 10^7$ m. The magnitude of the gravitational force exerted on the satellite by the planet is 120 N. (*a*) What would be the magnitude of the gravitational force exerted on the satellite by the planet if the radius of the orbit were increased to $3.0 \times 10^7$ m? (*b*) If the satellite circles the planet once every 2.0 h in the larger orbit, what is the mass of the planet?

**73.** A Ferris wheel (Fig. 6–35), 22.0 m in diameter, rotates once every 12.5 s. What is the ratio of a person's apparent weight to her real weight at (*a*) the top, and (*b*) the bottom?

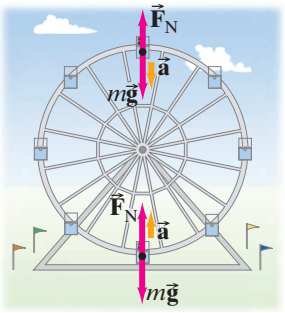

**FIGURE 6–35** Problem 73.

**74.** Estimate the value of the gravitational constant $G$ in Newton's law of universal gravitation using the following data: the acceleration due to gravity at the Earth's surface is about $10\text{ m/s}^2$; the Earth has a circumference of about $40 \times 10^6$ m; rocks found on the Earth's surface typically have densities of about $3000\text{ kg/m}^3$ and assume this density is constant throughout (even though you suspect it is not true).

**75.** Newton had the data listed in Table 6–4, plus the relative sizes of these objects: in terms of the Sun's radius $r_S$, the radii of Jupiter and Earth were $0.0997r_S$ and $0.0109r_S$. Newton used this information to determine that the average density $\rho$ (= mass/volume) of Jupiter is slightly less than that of the Sun, while the average density of the Earth is four times that of the Sun. Thus, without leaving his home planet, Newton was able to predict that the composition of the Sun and Jupiter is markedly different than that of Earth. Reproduce Newton's calculation and find his values for the ratios $\rho_J/\rho_{Sun}$ and $\rho_E/\rho_{Sun}$ (the modern values for these ratios are 0.93 and 3.91, respectively).

**TABLE 6–4 Problem 75**

| | Orbital Radius, $R$ (in AU = $1.50 \times 10^{11}$ m) | Orbital Period, $T$ (Earth days) |
|---|---|---|
| Venus about Sun | 0.724 | 224.70 |
| Callisto about Jupiter | 0.01253 | 16.69 |
| Moon about Earth | 0.003069 | 27.32 |

**76.** A uniform sphere has mass $M$ and radius $r$. A spherical cavity (no mass) of radius $r/2$ is then carved within this sphere as shown in Fig. 6–36 (the cavity's surface passes through the sphere's center and just touches the sphere's outer surface). The centers of the original sphere and the cavity lie on a straight line, which defines the $x$ axis. With what gravitational force will the hollowed-out sphere attract a point mass $m$ which lies on the $x$ axis a distance $d$ from the sphere's center? [*Hint*: Subtract the effect of the "small" sphere (the cavity) from that of the larger entire sphere.]

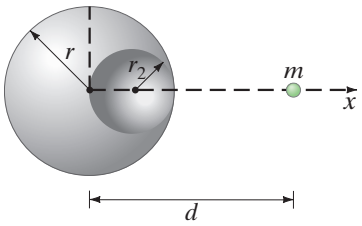

**FIGURE 6–36** Problem 76.

**77.** Jupiter is about 320 times as massive as the Earth. Thus, it has been claimed that a person would be crushed by the force of gravity on a planet the size of Jupiter because people cannot survive more than a few $g$'s. Calculate the number of $g$'s a person would experience at Jupiter's equator, using the following data for Jupiter: mass $= 1.9 \times 10^{27}$ kg, equatorial radius $= 7.1 \times 10^4$ km, rotation period = 9 hr 55 min. Take the centripetal acceleration into account.

**78.** The gravitational force at different places on Earth due to the Sun and the Moon depends on each point's distance from the Sun or Moon, and this variation is what causes the **tides**. Use the values inside the front cover of this book for the Earth–Moon distance $R_{EM}$, the Earth–Sun distance $R_{ES}$, the Moon's mass $m_M$, the Sun's mass $m_S$, and the Earth's radius $r_E$. (*a*) First consider two small pieces of the Earth, each of mass $m$, one on the side of the Earth nearest the Moon, the other on the side farthest from the Moon. Show that the ratio of the Moon's gravitational forces on these two masses is

$$\left(\frac{F_{near}}{F_{far}}\right)_M = 1.0687.$$

(*b*) Next consider two small pieces of the Earth, each of mass $m$, one on the nearest point of Earth to the Sun, the other at the farthest point from the Sun. Show that the ratio of the Sun's gravitational forces on these two masses is

$$\left(\frac{F_{near}}{F_{far}}\right)_S = 1.000171.$$

(*c*) Show that the ratio of the Sun's average gravitational force on the Earth ($F_S$) compared to the Moon's average gravitational force on the Earth ($F_M$) is

$$\left(\frac{F_S}{F_M}\right)_{avg} = 178.$$

Note that the Moon's smaller force varies much more across the Earth's diameter than the Sun's larger force. (*d*) Estimate the resulting "force difference" (the cause of the tides)

$$\Delta F = F_{near} - F_{far} = F_{far}\left(\frac{F_{near}}{F_{far}} - 1\right) \approx F_{avg}\left(\frac{F_{near}}{F_{far}} - 1\right)$$

for the Moon and for the Sun. Show that the ratio of the tide-causing force differences due to the Moon compared to the Sun is

$$\frac{\Delta F_M}{\Delta F_S} \approx 2.3.$$

Thus the Moon's influence on tide production is over two times as great as the Sun's.

79. A particle is released at a height $r_E$ (radius of Earth) above the Earth's surface. Determine its velocity when it hits the Earth. Ignore air resistance. [*Hint*: Use Newton's second law, the law of universal gravitation, the chain rule, and integrate.]

80. A plumb bob (a mass $m$ hanging on a string) is deflected from the vertical by an angle $\theta$ due to a massive mountain nearby (Fig. 6–37). (*a*) Find an approximate formula for $\theta$ in terms of the mass of the mountain, $m_M$, the distance to its center, $D_M$, and the radius and mass of the Earth. (*b*) Make a rough estimate of the mass of Mt. Everest, assuming it has the shape of a cone 4000 m high and base of diameter 4000 m. Assume its mass per unit volume is 3000 kg per $m^3$. (*c*) Estimate the angle $\theta$ of the plumb bob if it is 5 km from the center of Mt. Everest.

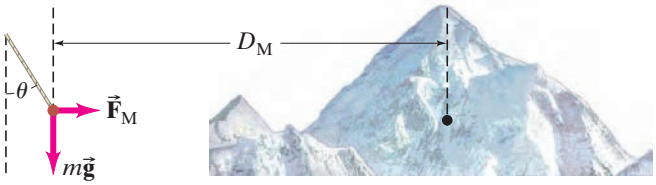

**FIGURE 6–37** Problem 80.

81. A science-fiction tale describes an artificial "planet" in the form of a band completely encircling a sun (Fig. 6–38). The inhabitants live on the inside surface (where it is always noon). Imagine that this sun is exactly like our own, that the distance to the band is the same as the Earth–Sun distance (to make the climate livable), and that the ring rotates quickly enough to produce an apparent gravity of $g$ as on Earth. What will be the period of revolution (this planet's year) in Earth days?

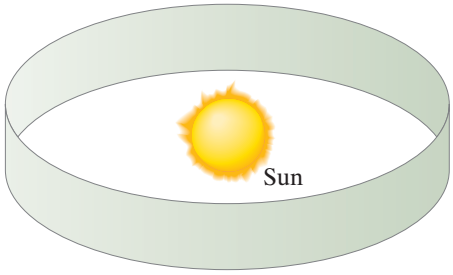

**FIGURE 6–38** Problem 81.

82. A satellite of mass 5200 kg orbits the Earth and has a period of 6800 s. Determine (*a*) the radius of its circular orbit, (*b*) the magnitude of the Earth's gravitational force on the satellite, and (*c*) the altitude of the satellite.

83. Suppose all the mass of the Earth were compacted into a small spherical ball. What radius must the sphere have so that the acceleration due to gravity at the Earth's new surface would equal the acceleration due to gravity at the surface of the Sun?

84. An asteroid of mass $m$ is in a circular orbit of radius $r$ around the Sun with a speed $v$. It has an impact with another asteroid of mass $M$ and is kicked into a new circular orbit with a speed of $1.5v$. What is the radius of the new orbit in terms of $r$?

85. Between the orbits of Mars and Jupiter, several thousand small objects called **asteroids** move in nearly circular orbits around the Sun. Consider an asteroid that is spherically shaped with radius $r$ and density 2700 kg/$m^3$. (*a*) You find yourself on the surface of this asteroid and throw a baseball at a speed of 22 m/s (about 50 mi/h). If the baseball is to travel around the asteroid in a circular orbit, what is the largest radius asteroid on which you are capable of accomplishing this feat? (*b*) After you throw the baseball, you turn around and face the opposite direction and catch the baseball. How much time $T$ elapses between your throw and your catch?

86. The Sun revolves around the center of our *Milky Way Galaxy* (Fig. 6–39) at a distance of about 30,000 light-years from the center $(1\,\text{ly} = 9.5 \times 10^{15}\,\text{m})$. If it takes about 200 million years to make one revolution, estimate the mass of our Galaxy. Assume that the mass distribution of our Galaxy is concentrated mostly in a central uniform sphere. If all the stars had about the mass of our Sun $(2 \times 10^{30}\,\text{kg})$, how many stars would there be in our Galaxy?

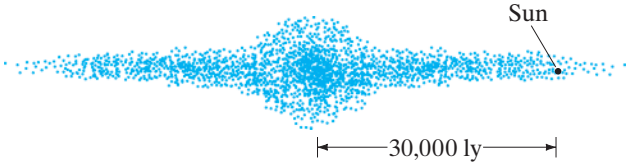

**FIGURE 6–39** Edge-on view of our Galaxy. Problem 86.

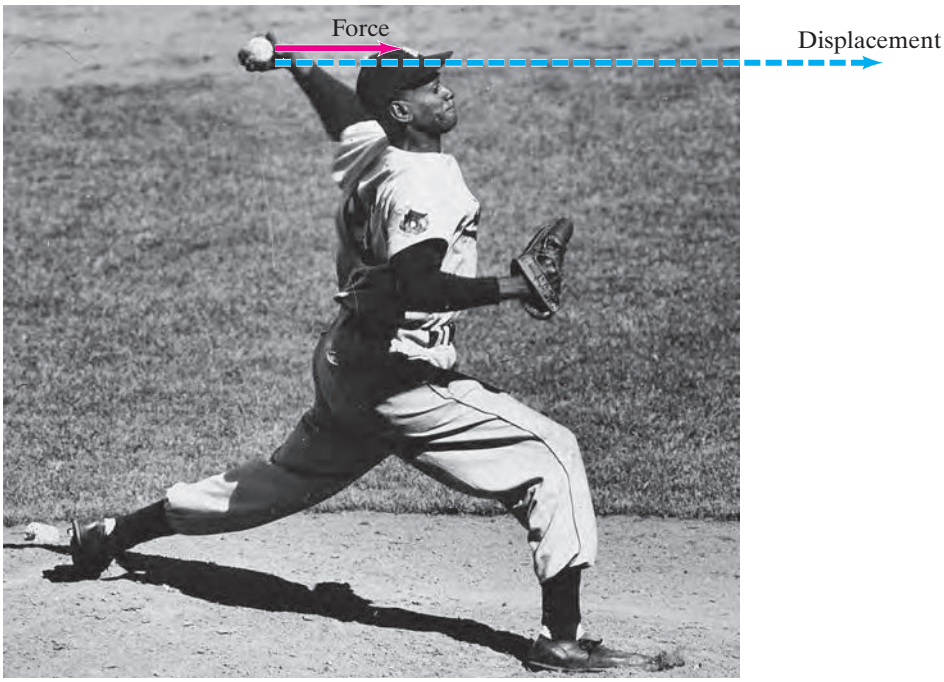
## ANSWERS TO EXERCISES



**A:** $g$ would double.

**B:** (*b*).

**C:** (*b*).

**D:** No; even though they are experiencing weightlessness, the massive ball would require a large force to accelerate when thrown and also to decelerate when caught (inertial mass, Newton's second law of motion).

**E:** 6.17 yr.

This baseball pitcher (Satchel Paige) is about to accelerate the baseball from rest to a high velocity by exerting a force on it. He will be doing work on the ball as he exerts the force over a displacement of perhaps several meters, from behind his head until he releases the ball with arm outstretched in front of him. The total work done on the ball will be equal to the kinetic energy ($\frac{1}{2}mv^2$) acquired by the ball, a result known as the work-energy principle.

CHAPTER 7

# Work and Energy

## CONTENTS

7–1 Work Done by a Constant Force
7–2 Scalar Product of Two Vectors
7–3 Work Done by a Varying Force
7–4 Kinetic Energy and the Work-Energy Principle

**CHAPTER-OPENING QUESTION—Guess now!**
You push very hard on a heavy desk, trying to move it. You do work on the desk:

**(a)** Whether or not it moves, as long as you are exerting a force.
**(b)** Only if it starts moving.
**(c)** Only if it doesn't move.
**(d)** Never—it does work on you.
**(e)** None of the above.

Until now we have been studying the translational motion of an object in terms of Newton's three laws of motion. In that analysis, *force* has played a central role as the quantity determining the motion. In this Chapter and the next two (8 and 9), we discuss an alternative analysis of the translational motion of objects in terms of the quantities *energy* and *momentum*. The significance of energy and momentum is that they are *conserved*. That is, in quite general circumstances they remain constant. That conserved quantities exist gives us not only a deeper insight into the nature of the world, but also gives us another way to approach solving practical problems.

The conservation laws of energy and momentum are especially valuable in dealing with systems of many objects, in which a detailed consideration of the forces involved would be difficult or impossible. These laws apply to a wide range of phenomena. They even apply in the atomic and subatomic worlds, where Newton's laws are not sufficient.

This Chapter is devoted to the very important concept of *energy* and the closely related concept of *work*. These two quantities are scalars and so have no direction associated with them, which often makes them easier to work with than vector quantities such as acceleration and force.

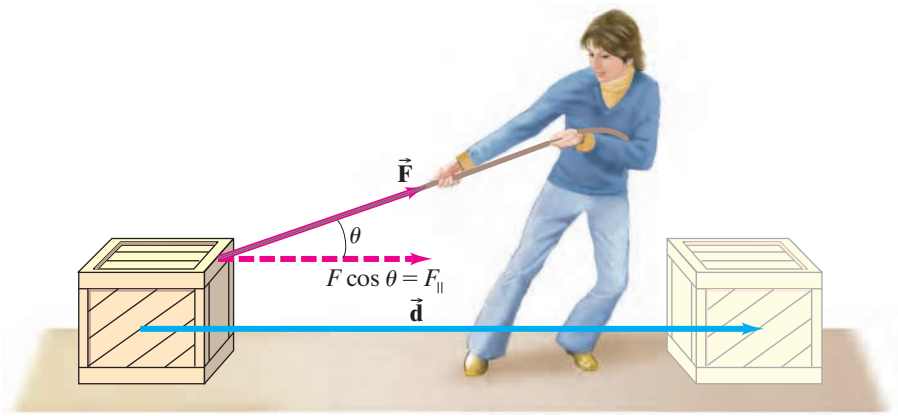


**FIGURE 7–1** A person pulling a crate along the floor. The work done on the crate by the force $\vec{\mathbf{F}}$ is $W = Fd\cos\theta$, where $\vec{\mathbf{d}}$ is the displacement and $\theta$ is the angle between the directions of the force vector and the displacement vector.

# 7–1 Work Done by a Constant Force

The word *work* has a variety of meanings in everyday language. But in physics, work is given a very specific meaning to describe what is accomplished when a force acts on an object, and the object moves through a distance. We consider only translational motion for now and, unless otherwise explained, objects are assumed to be rigid with no complicating internal motion, and can be treated like particles. Then the **work** done on an object by a constant force (constant in both magnitude and direction) is defined to be *the product of the magnitude of the displacement times the component of the force parallel to the displacement*. In equation form, we can write

$$W = F_{\parallel} d,$$

where $F_{\parallel}$ is the component of the constant force $\vec{\mathbf{F}}$ parallel to the displacement $\vec{\mathbf{d}}$. We can also write

$$W = Fd\cos\theta, \qquad \textbf{(7–1)}$$

where $F$ is the magnitude of the constant force, $d$ is the magnitude of the displacement of the object, and $\theta$ is the angle between the directions of the force and the displacement (Fig. 7–1). The $\cos\theta$ factor appears in Eq. 7–1 because $F\cos\theta\ (= F_{\parallel})$ is the component of $\vec{\mathbf{F}}$ that is parallel to $\vec{\mathbf{d}}$. Work is a scalar quantity—it has only magnitude, which can be positive or negative.

Let us consider the case in which the motion and the force are in the same direction, so $\theta = 0$ and $\cos\theta = 1$; in this case, $W = Fd$. For example, if you push a loaded grocery cart a distance of 50 m by exerting a horizontal force of 30 N on the cart, you do $30\,\text{N} \times 50\,\text{m} = 1500\,\text{N}\cdot\text{m}$ of work on the cart.

As this example shows, in SI units work is measured in newton-meters (N · m). A special name is given to this unit, the **joule** (J): $1\,\text{J} = 1\,\text{N}\cdot\text{m}$.

[In the cgs system, the unit of work is called the **erg** and is defined as $1\,\text{erg} = 1\,\text{dyne}\cdot\text{cm}$. In British units, work is measured in **foot-pounds**. Their equivalence is $1\,\text{J} = 10^7\,\text{erg} = 0.7376\,\text{ft}\cdot\text{lb}$.]

A force can be exerted on an object and yet do no work. If you hold a heavy bag of groceries in your hands at rest, you do no work on it. You do exert a force on the bag, but the displacement of the bag is zero, so the work done by you on the bag is $W = 0$. You need both a force and a displacement to do work. You also do no work on the bag of groceries if you carry it as you walk horizontally across the floor at constant velocity, as shown in Fig. 7–2. No horizontal force is required to move the bag at a constant velocity. The person shown in Fig. 7–2 does exert an upward force $\vec{\mathbf{F}}_{\text{P}}$ on the bag equal to its weight, $mg$. But this upward force is perpendicular to the horizontal displacement of the bag and thus is doing no work. This conclusion comes from our definition of work, Eq. 7–1: $W = 0$, because $\theta = 90°$ and $\cos 90° = 0$. Thus, when a particular force is perpendicular to the displacement, no work is done by that force. When you start or stop walking, there is a horizontal acceleration and you do briefly exert a horizontal force, and thus do work on the bag.

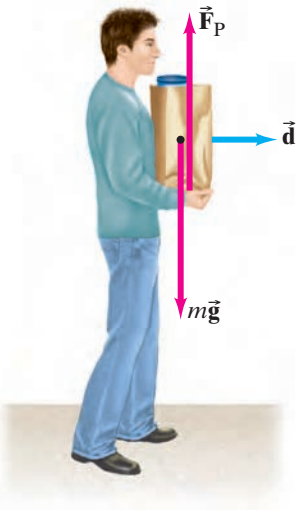

**FIGURE 7–2** A person walking at constant velocity does no work on the bag of groceries since $\vec{\mathbf{F}}_{\text{P}}$ is perpendicular to the displacement $\vec{\mathbf{d}}$. ($F_{\text{P}} = mg$, the weight of the bag.)

**⚠ CAUTION**
*Force without work*

**CAUTION**
*State that work is done on or by an object*

When we deal with work, as with force, it is necessary to specify whether we are talking about work done *by* a specific object or done *on* a specific object. It is also important to specify whether the work done is due to one particular force (and which one), or the total (net) work done by the *net force* on the object.

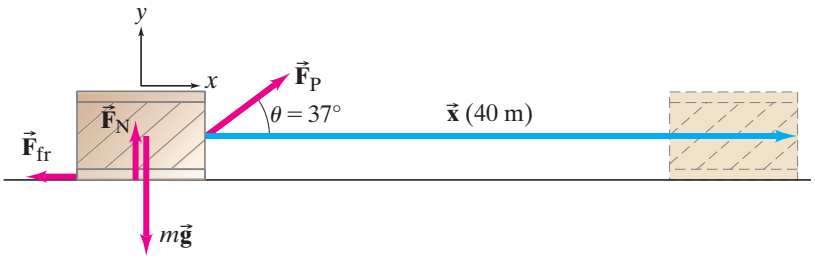

**FIGURE 7–3** Example 7–1. A 50-kg crate is pulled along a floor.

**EXAMPLE 7–1** **Work done on a crate.** A person pulls a 50-kg crate 40 m along a horizontal floor by a constant force $F_P = 100\,\text{N}$, which acts at a 37° angle as shown in Fig. 7–3. The floor is rough and exerts a friction force $F_{fr} = 50\,\text{N}$. Determine (*a*) the work done by each force acting on the crate, and (*b*) the net work done on the crate.

**APPROACH** We choose our coordinate system so that the vector that represents the 40-m displacement is $\vec{\mathbf{x}}$ (that is, along the $x$ axis). Four forces act on the crate, as shown in the free-body diagram in Fig. 7–3: the force exerted by the person $\vec{\mathbf{F}}_P$; the friction force $\vec{\mathbf{F}}_{fr}$; the gravitational force exerted by the Earth, $\vec{\mathbf{F}}_G = m\vec{\mathbf{g}}$; and the normal force $\vec{\mathbf{F}}_N$ exerted upward by the floor. The net force on the crate is the vector sum of these four forces.

**SOLUTION** (*a*) The work done by gravity $(\vec{\mathbf{F}}_G)$ and by the normal force $(\vec{\mathbf{F}}_N)$ is zero, because they are perpendicular to the displacement $\vec{\mathbf{x}}$ ($\theta = 90°$ in Eq. 7–1):

$$W_G = mgx\cos 90° = 0$$
$$W_N = F_N x\cos 90° = 0.$$

The work done by $\vec{\mathbf{F}}_P$ is

$$W_P = F_P x\cos\theta = (100\,\text{N})(40\,\text{m})\cos 37° = 3200\,\text{J}.$$

The work done by the friction force is

$$W_{fr} = F_{fr} x\cos 180° = (50\,\text{N})(40\,\text{m})(-1) = -2000\,\text{J}.$$

The angle between the displacement $\vec{\mathbf{x}}$ and $\vec{\mathbf{F}}_{fr}$ is 180° because they point in opposite directions. Since the force of friction is opposing the motion (and $\cos 180° = -1$), the work done by friction on the crate is *negative*.

(*b*) The net work can be calculated in two equivalent ways.
(1) The net work done on an object is the algebraic sum of the work done by each force, since work is a scalar:

$$W_{net} = W_G + W_N + W_P + W_{fr}$$
$$= 0 + 0 + 3200\,\text{J} - 2000\,\text{J} = 1200\,\text{J}.$$

(2) The net work can also be calculated by first determining the net force on the object and then taking the component of this net force along the displacement: $(F_{net})_x = F_P\cos\theta - F_{fr}$. Then the net work is

$$W_{net} = (F_{net})_x x = (F_P\cos\theta - F_{fr})x$$
$$= (100\,\text{N}\cos 37° - 50\,\text{N})(40\,\text{m}) = 1200\,\text{J}.$$

In the vertical ($y$) direction, there is no displacement and no work done.

**CAUTION**
*Negative work*

In Example 7–1 we saw that friction did *negative work*. In general, the work done by a force is negative whenever the force (or the component of the force, $F_{\parallel}$) acts in the direction opposite to the direction of motion.

**EXERCISE A** A box is dragged a distance $d$ across a floor by a force $\vec{\mathbf{F}}_P$ which makes an angle $\theta$ with the horizontal as in Fig. 7–1 or 7–3. If the magnitude of $\vec{\mathbf{F}}_P$ is held constant but the angle $\theta$ is increased, the work done by $\vec{\mathbf{F}}_P$ (*a*) remains the same; (*b*) increases; (*c*) decreases; (*d*) first increases, then decreases.

**EXERCISE B** Return to the Chapter-Opening Question, page 172, and answer it again now. Try to explain why you may have answered differently the first time.

PROBLEM SOLVING

## Work

1. **Draw a free-body diagram** showing all the forces acting on the object you choose to study.
2. **Choose** an $xy$ **coordinate system**. If the object is in motion, it may be convenient to choose one of the coordinate directions as the direction of one of the forces, or as the direction of motion. [Thus, for an object on an incline, you might choose one coordinate axis to be parallel to the incline.]
3. **Apply Newton's laws** to determine unknown forces.
4. Find the **work done *by* a specific force** *on* the object by using $W = Fd\cos\theta$ for a constant force. The work done is negative when a force opposes the displacement.
5. To find the **net work** done on the object, either ($a$) find the work done by each force and add the results algebraically; or ($b$) find the net force on the object, $F_{\text{net}}$, and then use it to find the net work done, which for constant net force is:

$$W_{\text{net}} = F_{\text{net}}\, d\cos\theta.$$

**EXAMPLE 7–2** **Work on a backpack.** ($a$) Determine the work a hiker must do on a 15.0-kg backpack to carry it up a hill of height $h = 10.0\,\text{m}$, as shown in Fig. 7–4a. Determine also ($b$) the work done by gravity on the backpack, and ($c$) the net work done on the backpack. For simplicity, assume the motion is smooth and at constant velocity (i.e., acceleration is zero).

**APPROACH** We explicitly follow the steps of the Problem Solving Strategy above.

**SOLUTION**

1. **Draw a free-body diagram**. The forces on the backpack are shown in Fig. 7–4b: the force of gravity, $m\vec{\mathbf{g}}$, acting downward; and $\vec{\mathbf{F}}_{\text{H}}$, the force the hiker must exert upward to support the backpack. The acceleration is zero, so horizontal forces on the backpack are negligible.
2. **Choose a coordinate system**. We are interested in the vertical motion of the backpack, so we choose the $y$ coordinate as positive vertically upward.
3. **Apply Newton's laws**. Newton's second law applied in the vertical direction to the backpack gives (with $a_y = 0$)

$$\Sigma F_y = ma_y$$
$$F_{\text{H}} - mg = 0.$$

So,

$$F_{\text{H}} = mg = (15.0\,\text{kg})(9.80\,\text{m/s}^2) = 147\,\text{N}.$$

4. **Work done by a specific force**. ($a$) To calculate the work done by the hiker on the backpack, we use Eq. 7–1, where $\theta$ is shown in Fig. 7–4c,

$$W_{\text{H}} = F_{\text{H}}(d\cos\theta),$$

and we note from Fig. 7–4a that $d\cos\theta = h$. So the work done by the hiker is

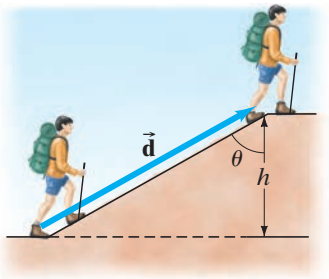
$$W_{\text{H}} = F_{\text{H}}(d\cos\theta) = F_{\text{H}}h = mgh = (147\,\text{N})(10.0\,\text{m}) = 1470\,\text{J}.$$

The work done depends only on the elevation change and not on the angle of the hill, $\theta$. The hiker would do the same work to lift the pack vertically by height $h$.

($b$) The work done by gravity on the backpack is (from Eq. 7–1 and Fig. 7–4c)

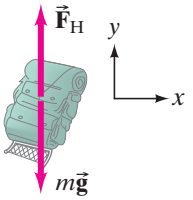
$$W_{\text{G}} = mg\,d\cos(180^\circ - \theta).$$

Since $\cos(180^\circ - \theta) = -\cos\theta$ (Appendix A–9), we have



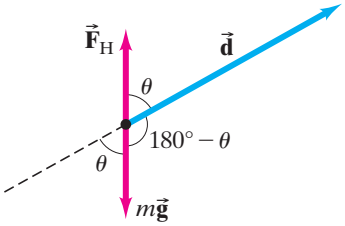
$$W_{\text{G}} = mg(-d\cos\theta)$$
$$= -mgh$$
$$= -(15.0\,\text{kg})(9.80\,\text{m/s}^2)(10.0\,\text{m}) = -1470\,\text{J}.$$

**NOTE** The work done by gravity (which is negative here) does not depend on the angle of the incline, only on the vertical height $h$ of the hill.



5. **Net work done**. ($c$) The *net* work done on the backpack is $W_{\text{net}} = 0$, because the net force on the backpack is zero (it is assumed not to accelerate significantly). We can also get the net work done by adding the work done by each force:

$$W_{\text{net}} = W_{\text{G}} + W_{\text{H}} = -1470\,\text{J} + 1470\,\text{J} = 0.$$



**NOTE** Even though the *net* work done by all the forces on the backpack is zero, the hiker *does* do work on the backpack equal to 1470 J.

(a)

(b)

(c)

**FIGURE 7–4** Example 7–2.

**PROBLEM SOLVING**
*Work done by gravity depends on height of hill (not on angle)*

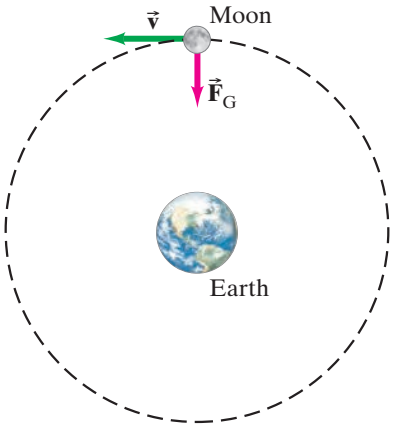


**FIGURE 7–5** Example 7–3.

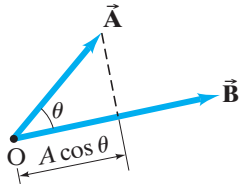
**CONCEPTUAL EXAMPLE 7–3** **Does the Earth do work on the Moon?**
The Moon revolves around the Earth in a nearly circular orbit, with approximately constant tangential speed, kept there by the gravitational force exerted by the Earth. Does gravity do (*a*) positive work, (*b*) negative work, or (*c*) no work at all on the Moon?

**RESPONSE** The gravitational force $\vec{\mathbf{F}}_G$ exerted by the Earth on the Moon (Fig. 7–5) acts toward the Earth and provides its centripetal acceleration, inward along the radius of the Moon's orbit. The Moon's displacement at any moment is tangent to the circle, in the direction of its velocity, perpendicular to the radius and perpendicular to the force of gravity. Hence the angle $\theta$ between the force $\vec{\mathbf{F}}_G$ and the instantaneous displacement of the Moon is 90°, and the work done by gravity is therefore zero $(\cos 90° = 0)$. This is why the Moon, as well as artificial satellites, can stay in orbit without expenditure of fuel: no work needs to be done against the force of gravity.

# 7–2 Scalar Product of Two Vectors

Although work is a scalar, it involves the product of two quantities, force and displacement, both of which are vectors. Therefore, we now investigate the multiplication of vectors, which will be useful throughout the book, and apply it to work.



Because vectors have direction as well as magnitude, they cannot be multiplied in the same way that scalars are. Instead we must *define* what the operation of vector multiplication means. Among the possible ways to define how to multiply vectors, there are three ways that we find useful in physics: (1) multiplication of a vector by a scalar, which was discussed in Section 3–3; (2) multiplication of one vector by a second vector to produce a scalar; (3) multiplication of one vector by a second vector to produce another vector. The third type, called the *vector product*, will be discussed later, in Section 11–2.

We now discuss the second type, called the *scalar product*, or *dot product* (because a dot is used to indicate the multiplication). If we have two vectors, $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$, then their **scalar** (or **dot**) **product** is defined to be

*Scalar product*

$$\vec{\mathbf{A}} \cdot \vec{\mathbf{B}} = AB\cos\theta, \qquad \textbf{(7–2)}$$

**FIGURE 7–6** The scalar product, or dot product, of two vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ is $\vec{\mathbf{A}} \cdot \vec{\mathbf{B}} = AB\cos\theta$. The scalar product can be interpreted as the magnitude of one vector ($B$ in this case) times the projection of the other vector, $A\cos\theta$, onto $\vec{\mathbf{B}}$.

where $A$ and $B$ are the magnitudes of the vectors and $\theta$ is the angle ($< 180°$) between them when their tails touch, Fig. 7–6. Since $A$, $B$, and $\cos\theta$ are scalars, then so is the scalar product $\vec{\mathbf{A}} \cdot \vec{\mathbf{B}}$ (read "A dot B").

This definition, Eq. 7–2, fits perfectly with our definition of the work done by a constant force, Eq. 7–1. That is, we can write the work done by a constant force as the scalar product of force and displacement:

$$W = \vec{\mathbf{F}} \cdot \vec{\mathbf{d}} = Fd\cos\theta. \qquad \textbf{(7–3)}$$

Indeed, the definition of scalar product, Eq. 7–2, is so chosen because many physically important quantities, such as work (and others we will meet later), can be described as the scalar product of two vectors.

An equivalent definition of the scalar product is that it is the product of the magnitude of one vector (say $B$) and the component (or projection) of the other vector along the direction of the first $(A\cos\theta)$. See Fig. 7–6.

Since $A$, $B$, and $\cos\theta$ are scalars, it doesn't matter in what order they are multiplied. Hence the scalar product is **commutative**:

$$\vec{\mathbf{A}} \cdot \vec{\mathbf{B}} = \vec{\mathbf{B}} \cdot \vec{\mathbf{A}}. \qquad \text{[commutative property]}$$

It is not difficult to show that the scalar product is also **distributive** (see Problem 33 for the proof):

$$\vec{\mathbf{A}} \cdot (\vec{\mathbf{B}} + \vec{\mathbf{C}}) = \vec{\mathbf{A}} \cdot \vec{\mathbf{B}} + \vec{\mathbf{A}} \cdot \vec{\mathbf{C}}. \qquad \text{[distributive property]}$$

Let us write our vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ in terms of their rectangular components using unit vectors (Section 3–5, Eq. 3–5) as

$$\vec{\mathbf{A}} = A_x\hat{\mathbf{i}} + A_y\hat{\mathbf{j}} + A_z\hat{\mathbf{k}}$$
$$\vec{\mathbf{B}} = B_x\hat{\mathbf{i}} + B_y\hat{\mathbf{j}} + B_z\hat{\mathbf{k}}.$$

We will take the scalar product, $\vec{\mathbf{A}}\cdot\vec{\mathbf{B}}$, of these two vectors, remembering that the unit vectors, $\hat{\mathbf{i}}$, $\hat{\mathbf{j}}$, and $\hat{\mathbf{k}}$, are perpendicular to each other

$$\hat{\mathbf{i}}\cdot\hat{\mathbf{i}} = \hat{\mathbf{j}}\cdot\hat{\mathbf{j}} = \hat{\mathbf{k}}\cdot\hat{\mathbf{k}} = 1$$
$$\hat{\mathbf{i}}\cdot\hat{\mathbf{j}} = \hat{\mathbf{i}}\cdot\hat{\mathbf{k}} = \hat{\mathbf{j}}\cdot\hat{\mathbf{k}} = 0.$$

Thus the scalar product can be written (using the distributive property) as

$$\vec{\mathbf{A}}\cdot\vec{\mathbf{B}} = (A_x\hat{\mathbf{i}} + A_y\hat{\mathbf{j}} + A_z\hat{\mathbf{k}})\cdot(B_x\hat{\mathbf{i}} + B_y\hat{\mathbf{j}} + B_z\hat{\mathbf{k}})$$
$$= A_xB_x + A_yB_y + A_zB_z. \qquad \textbf{(7–4)}$$

*Scalar (or dot) product*

Equation 7–4 is very useful.

If $\vec{\mathbf{A}}$ is perpendicular to $\vec{\mathbf{B}}$, then Eq. 7–2 tells us $\vec{\mathbf{A}}\cdot\vec{\mathbf{B}} = AB\cos 90° = 0$. But the converse, given that $\vec{\mathbf{A}}\cdot\vec{\mathbf{B}} = 0$, can come about in three different ways: $\vec{\mathbf{A}} = 0$, $\vec{\mathbf{B}} = 0$, or $\vec{\mathbf{A}} \perp \vec{\mathbf{B}}$.

**EXAMPLE 7–4** **Using the dot product.** The force shown in Fig. 7–7 has magnitude $F_P = 20\,\text{N}$ and makes an angle $\theta = 30°$ to the ground. Calculate the work done by this force using Eq. 7–4 when the wagon is dragged 100 m along the ground.

**FIGURE 7–7** Example 7–4. Work done by a force $\vec{\mathbf{F}}_P$ acting at an angle $\theta$ to the ground is $W = \vec{\mathbf{F}}_P\cdot\vec{\mathbf{d}}$.

**APPROACH** We choose the $x$ axis horizontal to the right and the $y$ axis vertically upward, and write $\vec{\mathbf{F}}_P$ and $\vec{\mathbf{d}}$ in terms of unit vectors.

**SOLUTION**

$$\vec{\mathbf{F}}_P = F_x\hat{\mathbf{i}} + F_y\hat{\mathbf{j}} = (F_P\cos 30°)\hat{\mathbf{i}} + (F_P\sin 30°)\hat{\mathbf{j}} = (17\,\text{N})\hat{\mathbf{i}} + (10\,\text{N})\hat{\mathbf{j}},$$

whereas $\vec{\mathbf{d}} = (100\,\text{m})\hat{\mathbf{i}}$. Then, using Eq. 7–4,

$$W = \vec{\mathbf{F}}_P\cdot\vec{\mathbf{d}} = (17\,\text{N})(100\,\text{m}) + (10\,\text{N})(0) + (0)(0) = 1700\,\text{J}.$$

Note that by choosing the $x$ axis along $\vec{\mathbf{d}}$ we simplified the calculation because $\vec{\mathbf{d}}$ then has only one component.

## 7–3 Work Done by a Varying Force

If the force acting on an object is constant, the work done by that force can be calculated using Eq. 7–1. In many cases, however, the force varies in magnitude or direction during a process. For example, as a rocket moves away from Earth, work is done to overcome the force of gravity, which varies as the inverse square of the distance from the Earth's center. Other examples are the force exerted by a spring, which increases with the amount of stretch, or the work done by a varying force exerted to pull a box or cart up an uneven hill.

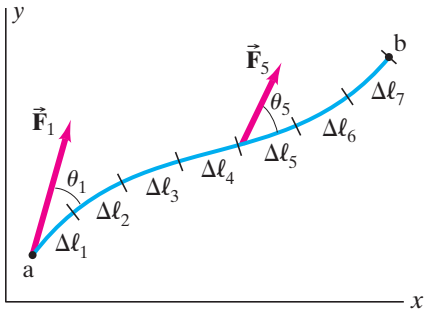


**FIGURE 7–8** A particle acted on by a variable force, $\vec{\mathbf{F}}$, moves along a path in the $xy$ plane as shown from point a to point b.

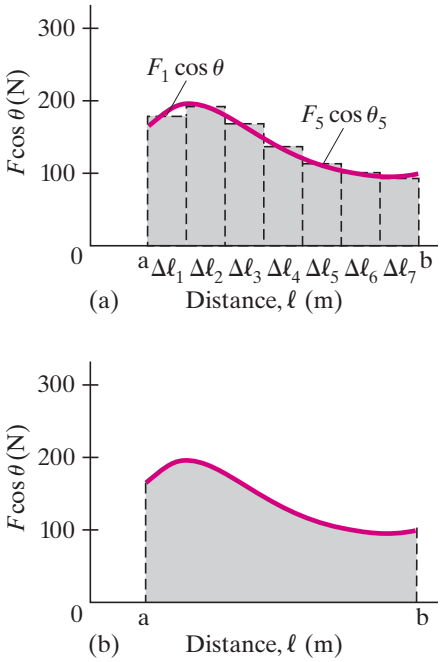

Figure 7–8 shows the path of an object in the $xy$ plane as it moves from point a to point b. The path has been divided into short intervals each of length $\Delta\ell_1$, $\Delta\ell_2, \ldots, \Delta\ell_7$. A force $\vec{\mathbf{F}}$ acts at each point on the path, and is indicated at two points as $\vec{\mathbf{F}}_1$ and $\vec{\mathbf{F}}_5$. During each small interval $\Delta\ell$, the force is approximately constant, assuming the intervals are taken small enough. For the first interval, the force does work $\Delta W$ of approximately (see Eq. 7–1)

$$\Delta W \approx F_1 \cos\theta_1 \Delta\ell_1.$$

In the second interval the work done is approximately $F_2 \cos\theta_2 \Delta\ell_2$, and so on. The total work done in moving the particle the total distance $\ell = \Delta\ell_1 + \Delta\ell_2 + \ldots + \Delta\ell_7$ is the sum of all these terms:

$$W \approx \sum_{i=1}^{7} F_i \cos\theta_i \Delta\ell_i. \tag{7–5}$$

**FIGURE 7–9** Work done by a force $F$ is (a) approximately equal to the sum of the areas of the rectangles (grey shading), (b) exactly equal to the area under the curve of $F\cos\theta$ vs. $\ell$.

We can examine this graphically by plotting $F\cos\theta$ versus the distance $\ell$ along the path as shown in Fig. 7–9a. The distance $\ell$ has been subdivided into the same seven intervals (see the vertical dashed lines). The value of $F\cos\theta$ at the center of each interval is indicated by the *horizontal* dashed lines. Each of the shaded rectangles has an area $(F_i\cos\theta)(\Delta\ell_i)$, which is a good estimate of the work done during the interval. The estimate of the work done along the entire path, given by Eq. 7–5, equals the sum of the areas of all the rectangles. If we subdivide the distance into a greater number of intervals, so that each $\Delta\ell_i$ is smaller, the estimate of the work done becomes more accurate (the assumption that $F$ is constant over each interval is more accurate).[†] Letting each $\Delta\ell_i$ approach zero (so we approach an infinite number of intervals), we obtain an exact result for the work done:

$$W = \lim_{\Delta\ell_i \to 0} \Sigma F_i \cos\theta_i \Delta\ell_i = \int_a^b F\cos\theta \, d\ell. \tag{7–6}$$

This limit as $\Delta\ell_i \to 0$ is the *integral* of $(F\cos\theta\, d\ell)$ from point a to point b. The symbol for the integral, $\int$, is an elongated $S$ to indicate an infinite sum; and $\Delta\ell$ has been replaced by $d\ell$, meaning an infinitesimal distance.

In this limit as $\Delta\ell$ approaches zero, the total area of the rectangles (Fig. 7–9a) approaches the area between the $(F\cos\theta)$ curve and the $\ell$ axis from a to b as shown shaded in Fig. 7–9b. That is, *the work done by a variable force in moving an object between two points is equal to the area under the* $(F\cos\theta)$ *versus* $(\ell)$ *curve between those two points.*

In the limit as $\Delta\ell$ approaches zero, the infinitesimal distance $d\ell$ equals the magnitude of the infinitesimal displacement vector $d\vec{\boldsymbol{\ell}}$. The direction of the vector $d\vec{\boldsymbol{\ell}}$ is along the tangent to the path at that point, so $\theta$ is the angle between $\vec{\mathbf{F}}$ and $d\vec{\boldsymbol{\ell}}$ at any point. Thus we can rewrite Eq. 7–6, using dot-product notation:

$$W = \int_a^b \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}}. \tag{7–7}$$

This is a *general definition of work* done by a force $\vec{\mathbf{F}}$. In this equation, a and b represent two points in space, $(x_a, y_a, z_a)$ and $(x_b, y_b, z_b)$. The integral in Eq. 7–7 is called a *line integral* since it is the integral of $F\cos\theta$ along the line that represents the path of the object. (Equation 7–1 for a constant force is a special case of Eq. 7–7.)

[†]We also discuss this "numerical integration" in Appendix C.

In rectangular coordinates, any force can be written

$$\vec{\mathbf{F}} = F_x\hat{\mathbf{i}} + F_y\hat{\mathbf{j}} + F_z\hat{\mathbf{k}}$$

and the displacement $d\vec{\boldsymbol{\ell}}$ is

$$d\vec{\boldsymbol{\ell}} = dx\,\hat{\mathbf{i}} + dy\,\hat{\mathbf{j}} + dz\,\hat{\mathbf{k}}.$$

Then the work done can be written (see Eq. 7–4)

$$W = \int_{x_a}^{x_b} F_x\,dx + \int_{y_a}^{y_b} F_y\,dy + \int_{z_a}^{z_b} F_z\,dz.$$

To actually use Eq. 7–6 or 7–7 to calculate the work, there are several options: (1) If $F\cos\theta$ is known as a function of position, a graph like that of Fig. 7–9b can be made and the area determined graphically. (2) Another possibility is to use numerical integration (numerical summing—see Appendix C), perhaps with the aid of a computer or calculator. (3) A third and important possibility is to use the analytical methods of integral calculus, when it is doable; to do so, we must be able to write $\vec{\mathbf{F}}$ as a function of position, $F(x, y, z)$, and we must know the path. Let's look at some specific examples.

## Work Done by a Spring Force

Let us determine the work needed to stretch or compress a coiled spring, such as that shown in Fig. 7–10. For a person to hold a spring either stretched or compressed by a displacement $x$ from its normal (relaxed) length requires a force $F_P$ that is directly proportional to $x$. That is,

$$F_P = kx,$$

where $k$ is a constant, called the **spring constant** (or **spring stiffness constant**), and is a measure of the stiffness of the particular spring. The spring itself exerts a force in the opposite direction (Fig. 7–10b or c):

$$F_S = -kx. \qquad \textbf{(7–8)}$$

This force is sometimes called a "restoring force" because the spring exerts its force in the direction opposite the displacement (hence the minus sign), and thus acts to restore the spring to its normal length. Equation 7–8 is known as the **spring equation** or **Hooke's law**, and is accurate for springs as long as $x$ is not too great (see Section 12–5) and no permanent deformation occurs.

Let us calculate the work a person does to stretch (or compress) a spring from its normal (unstretched) length, $x_a = 0$, to an extra length, $x_b = x$. We assume the stretching is done slowly, so that the acceleration is essentially zero. The force $\vec{\mathbf{F}}_P$ is exerted parallel to the axis of the spring, along the $x$ axis, so $\vec{\mathbf{F}}_P$ and $d\vec{\boldsymbol{\ell}}$ are parallel. Hence, since $d\vec{\boldsymbol{\ell}} = dx\,\hat{\mathbf{i}}$ in this case, the work done by the person is[†]

$$W_P = \int_{x_a=0}^{x_b=x} \left[F_P(x)\,\hat{\mathbf{i}}\right]\cdot\left[dx\hat{\mathbf{i}}\right] = \int_0^x F_P(x)\,dx = \int_0^x kx\,dx = \tfrac{1}{2}kx^2\Big|_0^x = \tfrac{1}{2}kx^2.$$

(As is frequently done, we have used $x$ to represent both the variable of integration, and the particular value of $x$ at the end of the interval $x_a = 0$ to $x_b = x$.) Thus we see that the work needed is proportional to the *square* of the distance stretched (or compressed), $x$.

This same result can be obtained by computing the area under the graph of $F$ vs. $x$ (with $\cos\theta = 1$ in this case) as shown in Fig. 7–11, and as we discussed on page 178 and Fig. 7–9. Since the area of a triangle of altitude $h = kx$ and base $b = x$ is $\frac{1}{2}hb = \frac{1}{2}kx^2$, then the work a person does to stretch or compress a spring an amount $x$ is

$$W = \tfrac{1}{2}(kx)(x) = \tfrac{1}{2}kx^2,$$

which is the same result as before. Because $W \propto x^2$, it takes the same amount of work to stretch a spring or compress it the same displacement $x$.

[†]See the Table of Integrals, Appendix B.

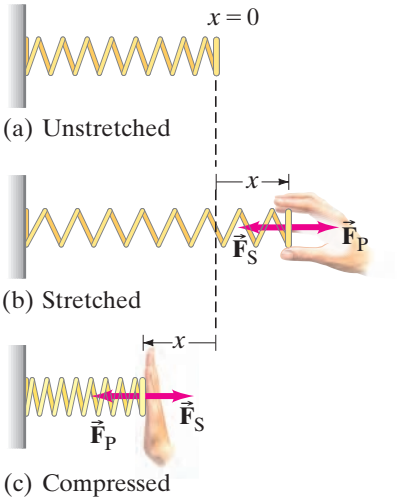

**FIGURE 7–10** (a) Spring in normal (unstretched) position. (b) Spring is stretched by a person exerting a force $\vec{\mathbf{F}}_P$ to the right (positive direction). The spring pulls back with a force $\vec{\mathbf{F}}_S$ where $F_S = -kx$. (c) Person compresses the spring ($x < 0$), and the spring pushes back with a force $F_S = -kx$ where $F_S > 0$ because $x < 0$.

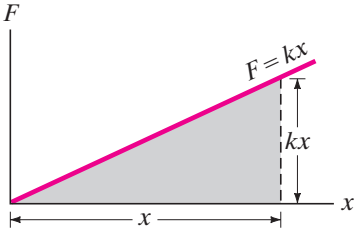

**FIGURE 7–11** Work done to stretch a spring a distance $x$ equals the triangular area under the curve $F = kx$. The area of a triangle is $\frac{1}{2}\times$ base $\times$ altitude, so $W = \frac{1}{2}(x)(kx) = \frac{1}{2}kx^2$.

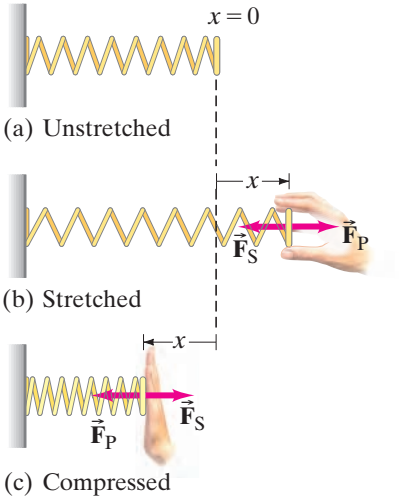

**FIGURE 7–10** Repeated for Example 7-5.

**EXAMPLE 7–5** **Work done on a spring.** (*a*) A person pulls on the spring in Fig. 7–10, stretching it 3.0 cm ($= x_{max}$), which requires a maximum force of 75 N. How much work does the person do? (*b*) If, instead, the person compresses the spring 3.0 cm, how much work does the person do?

**APPROACH** The force $F_P = kx$ holds at each point, including $x_{max}$. Hence $F_{max}$ occurs at $x = x_{max}$.

**SOLUTION** (*a*) First we need to calculate the spring constant $k$:

$$k = \frac{F_{max}}{x_{max}} = \frac{75\text{ N}}{0.030\text{ m}} = 2.5 \times 10^3\text{ N/m}.$$

Then the work done by the person on the spring is

$$W = \tfrac{1}{2}kx_{max}^2 = \tfrac{1}{2}(2.5 \times 10^3\text{ N/m})(0.030\text{ m})^2 = 1.1\text{ J}.$$

(*b*) The force that the person exerts is still $F_P = kx$, though now both $x$ and $F_P$ are negative ($x$ is positive to the right). The work done is

$$W_P = \int_{x=0}^{x=-0.030\text{ m}} F_P(x)\,dx = \int_0^{x=-0.030\text{ m}} kx\,dx = \tfrac{1}{2}kx^2\Big|_0^{-0.030\text{ m}}$$
$$= \tfrac{1}{2}(2.5 \times 10^3\text{ N/m})(-0.030\text{ m})^2 = 1.1\text{ J},$$

which is the same as for stretching it.

**NOTE** We cannot use $W = Fd$ (Eq. 7–1) for a spring because the force is not constant.

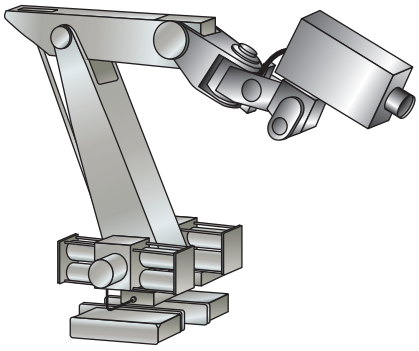

**FIGURE 7–12** Robot arm positions a video camera.

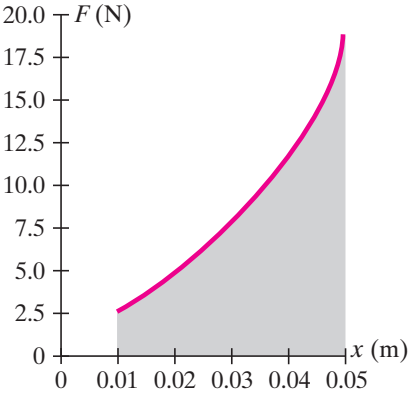
## A More Complex Force Law—Robot Arm

**EXAMPLE 7–6** **Force as function of *x*.** A robot arm that controls the position of a video camera (Fig. 7–12) in an automated surveillance system is manipulated by a motor that exerts a force on the arm. Assume that the force is given by

$$F(x) = F_0\left(1 + \frac{1}{6}\frac{x^2}{x_0^2}\right),$$

where $F_0 = 2.0\text{ N}$, $x_0 = 0.0070\text{ m}$, and $x$ is the position of the end of the arm. If the arm moves from $x_1 = 0.010\text{ m}$ to $x_2 = 0.050\text{ m}$, how much work did the motor do?

**APPROACH** The force applied by the motor is not a linear function of $x$. We can determine the integral $\int F(x)\,dx$, or the area under the $F(x)$ curve (shown as grey in Fig. 7–13).



**SOLUTION** We integrate to find the work done by the motor:

$$W_M = F_0\int_{x_1}^{x_2}\left(1 + \frac{x^2}{6x_0^2}\right)dx = F_0\int_{x_1}^{x_2}dx + \frac{F_0}{6x_0^2}\int_{x_1}^{x_2}x^2\,dx$$
$$= F_0\left(x + \frac{1}{6x_0^2}\frac{x^3}{3}\right)\Bigg|_{x_1}^{x_2}.$$

We put in the values given and obtain

$$W_M = 2.0\text{ N}\left[(0.050\text{ m} - 0.010\text{ m}) + \frac{(0.050\text{ m})^3 - (0.010\text{ m})^3}{(3)(6)(0.0070\text{ m})^2}\right] = 0.36\text{ J}.$$

**FIGURE 7–13** Example 7–6. The red curve represents the force on the robot arm as a function of position. The area under the curve (grey) equals the work done on the arm (and camera).

# 7–4 Kinetic Energy and the Work-Energy Principle

*Energy* is one of the most important concepts in science. Yet we cannot give a simple general definition of energy in only a few words. Nonetheless, each specific type of energy can be defined fairly simply. In this Chapter we define translational kinetic energy; in the next Chapter, we take up potential energy. In later Chapters we will examine other types of energy, such as that related to heat and electricity. The crucial aspect of energy is that the sum of all types, the *total energy*, is the same after any process as it was before: that is, energy is a conserved quantity.

For the purposes of this Chapter, we can define energy in the traditional way as "the ability to do work." This simple definition is not always applicable,[†] but it is valid for mechanical energy which we discuss in this Chapter and the next. We now define and discuss one of the basic types of energy, kinetic energy.

A moving object can do work on another object it strikes. A flying cannonball does work on a brick wall it knocks down; a moving hammer does work on a nail it drives into wood. In either case, a moving object exerts a force on a second object which undergoes a displacement. An object in motion has the ability to do work and thus can be said to have energy. The energy of motion is called **kinetic energy**, from the Greek word *kinetikos*, meaning "motion."

To obtain a quantitative definition for kinetic energy, let us consider a simple rigid object of mass $m$ (treated as a particle) that is moving in a straight line with an initial speed $v_1$. To accelerate it uniformly to a speed $v_2$, a constant net force $F_{\text{net}}$ is exerted on it parallel to its motion over a displacement $d$, Fig. 7–14.

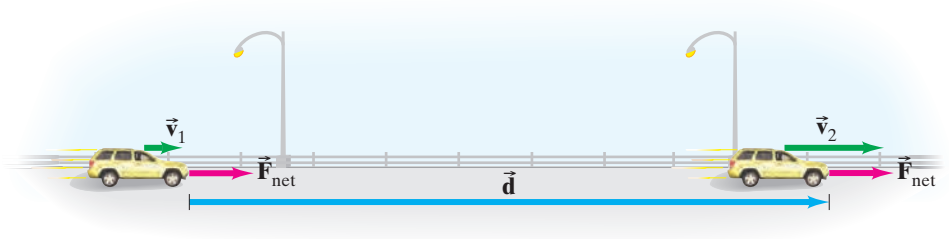


**FIGURE 7–14** A constant net force $F_{\text{net}}$ accelerates a car from speed $v_1$ to speed $v_2$ over a displacement $d$. The net work done is $W_{\text{net}} = F_{\text{net}}\, d$.

Then the net work done on the object is $W_{\text{net}} = F_{\text{net}}\, d$. We apply Newton's second law, $F_{\text{net}} = ma$, with the acceleration $a$ assumed constant, and use Eq. 2–12c $\left(v_2^2 = v_1^2 + 2ad\right)$ rewritten as

$$a = \frac{v_2^2 - v_1^2}{2d},$$

where $v_1$ is the initial speed and $v_2$ the final speed. Substituting this into $F_{\text{net}} = ma$, we determine the work done:

$$W_{\text{net}} = F_{\text{net}}\, d = mad = m\left(\frac{v_2^2 - v_1^2}{2d}\right)d = m\left(\frac{v_2^2 - v_1^2}{2}\right)$$

or

$$W_{\text{net}} = \tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2. \qquad \textbf{(7–9)}$$

We *define* the quantity $\frac{1}{2}mv^2$ to be the **translational kinetic energy**, $K$, of the object:

$$K = \tfrac{1}{2}mv^2. \qquad \textbf{(7–10)}$$

*Kinetic energy (defined)*

We often just call $\frac{1}{2}mv^2$ the "kinetic energy" except when we want to distinguish it from rotational kinetic energy, which we discuss in Chapter 10.

Equation 7–9, derived here for one-dimensional motion with a constant force, is valid in general for translational motion of an object in three dimensions and even if the force varies, as we will show at the end of this Section.

[†]Energy associated with heat is often not available to do work, as we will discuss in Chapter 20.

We can rewrite Eq. 7–9 as:

$$W_{\text{net}} = K_2 - K_1$$

or

WORK-ENERGY PRINCIPLE

$$W_{\text{net}} = \Delta K = \tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2. \qquad \textbf{(7–11)}$$

Equation 7–11 (or Eq. 7–9) is a useful result known as the **work-energy principle**. It can be stated in words:

WORK-ENERGY PRINCIPLE

> **The net work done on an object is equal to the change in the object's kinetic energy.**

**CAUTION**

*Work-energy valid only for* net *work*

Notice that we made use of Newton's second law, $F_{\text{net}} = ma$, where $F_{\text{net}}$ is the *net* force—the sum of all forces acting on the object. Thus, the work-energy principle is valid only if $W$ is the *net work* done on the object—that is, the work done by all forces acting on the object.

The work-energy principle is a very useful reformulation of Newton's laws. It tells us that if (positive) net work $W$ is done on an object, the object's kinetic energy increases by an amount $W$. The principle also holds true for the reverse situation: if the net work $W$ done on an object is negative, the object's kinetic energy decreases by an amount $W$. That is, a net force exerted on an object opposite to the object's direction of motion decreases its speed and its kinetic energy. An example is a moving hammer (Fig. 7–15) striking a nail. The net force on the hammer ($-\vec{\mathbf{F}}$ in Fig. 7–15, where $\vec{\mathbf{F}}$ is assumed constant for simplicity) acts toward the left, whereas the displacement $\vec{\mathbf{d}}$ of the hammer is toward the right. So the net work done on the hammer, $W_{\text{h}} = (F)(d)(\cos 180°) = -Fd$, is negative and the hammer's kinetic energy decreases (usually to zero).

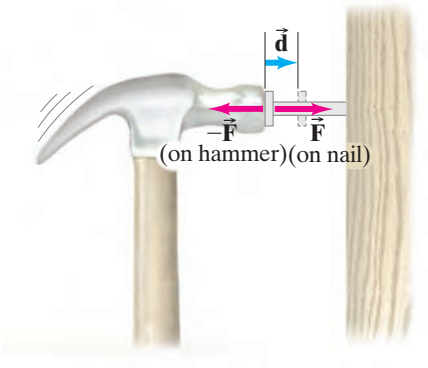

**FIGURE 7–15** A moving hammer strikes a nail and comes to rest. The hammer exerts a force $F$ on the nail; the nail exerts a force $-F$ on the hammer (Newton's third law). The work done on the nail by the hammer is positive $(W_{\text{n}} = Fd > 0)$. The work done on the hammer by the nail is negative $(W_{\text{h}} = -Fd)$.

Figure 7–15 also illustrates how energy can be considered the ability to do work. The hammer, as it slows down, does positive work on the nail: $W_{\text{n}} = (+F)(+d)(\cos 0°) = Fd$ and is positive. The decrease in kinetic energy of the hammer $(= Fd$ by Eq. 7–11) is equal to the work the hammer can do on another object, the nail in this case.

The translational kinetic energy $\left(= \tfrac{1}{2}mv^2\right)$ is directly proportional to the mass of the object, and it is also proportional to the *square* of the speed. Thus, if the mass is doubled, the kinetic energy is doubled. But if the speed is doubled, the object has four times as much kinetic energy and is therefore capable of doing four times as much work.

Because of the direct connection between work and kinetic energy, energy is measured in the same units as work: joules in SI units. [The energy unit is ergs in the cgs, and foot-pounds in the British system.] Like work, kinetic energy is a scalar quantity. The kinetic energy of a group of objects is the sum of the kinetic energies of the individual objects.

The work-energy principle can be applied to a particle, and also to an object that can be approximated as a particle, such as an object that is rigid or whose internal motions are insignificant. It is very useful in simple situations, as we will see in the following Examples. For now we assume the object undergoes only translational motion—no rotation.

**EXAMPLE 7–7** **Kinetic energy and work done on a baseball.** A 145-g baseball is thrown so that it acquires a speed of 25 m/s. (*a*) What is its kinetic energy? (*b*) What was the net work done on the ball to make it reach this speed, if it started from rest?

**APPROACH** We use $K = \tfrac{1}{2}mv^2$, and the work-energy principle, Eq. 7–11.

**SOLUTION** (*a*) The kinetic energy of the ball after the throw is

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(0.145\text{ kg})(25\text{ m/s})^2 = 45\text{ J}.$$

(*b*) Since the initial kinetic energy was zero, the net work done is just equal to the final kinetic energy, 45 J. (We ignored any rotation.)

**EXAMPLE 7–8** **ESTIMATE** **Work on a car, to increase its kinetic energy.** How much net work is required to accelerate a 1000-kg car from 20 m/s to 30 m/s (Fig. 7–16)?

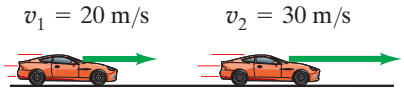

**FIGURE 7–16** Example 7–8.

**APPROACH** A car is a complex system. The engine turns the wheels and tires which push against the ground, and the ground pushes back on the tires (see Example 4–4). We aren't interested right now in those complications. Instead, we can get a useful result using the work-energy principle, but only if we model the car as a particle or simple rigid object.

**SOLUTION** The net work needed is equal to the increase in kinetic energy:

$$W = K_2 - K_1 = \tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2$$
$$= \tfrac{1}{2}(1000\,\text{kg})(30\,\text{m/s})^2 - \tfrac{1}{2}(1000\,\text{kg})(20\,\text{m/s})^2 = 2.5 \times 10^5\,\text{J}.$$

**EXERCISE C** (*a*) Make a guess: will the work needed to accelerate the car in Example 7–8 from rest to 20 m/s be more than, less than, or equal to the work already calculated to accelerate it from 20 m/s to 30 m/s? (*b*) Make the calculation.

**CONCEPTUAL EXAMPLE 7–9** **Work to stop a car.** A car traveling 60 km/h can brake to a stop within a distance $d$ of 20 m (Fig. 7–17a). If the car is going twice as fast, 120 km/h, what is its stopping distance (Fig. 7–17b)? Assume the maximum braking force is approximately independent of speed.

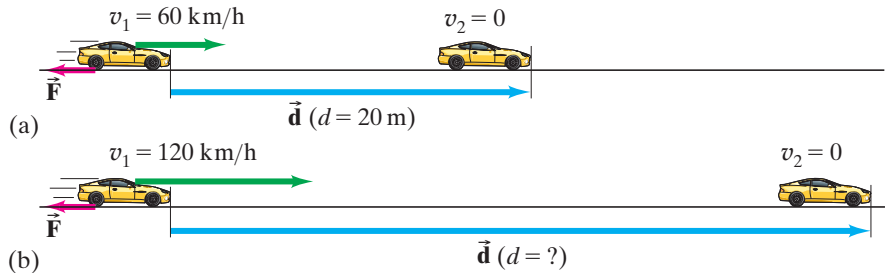

**FIGURE 7–17** Example 7–9.

**RESPONSE** Again we model the car as if it were a particle. Because the net stopping force $F$ is approximately constant, the work needed to stop the car, $Fd$, is proportional to the distance traveled. We apply the work-energy principle, noting that $\vec{\mathbf{F}}$ and $\vec{\mathbf{d}}$ are in opposite directions and that the final speed of the car is zero:

$$W_{\text{net}} = Fd\cos 180^\circ = -Fd.$$

Then

$$-Fd = \Delta K = \tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2$$
$$= 0 - \tfrac{1}{2}mv_1^2.$$

Thus, since the force and mass are constant, we see that the stopping distance, $d$, increases with the square of the speed:

$$d \propto v^2.$$

If the car's initial speed is doubled, the stopping distance is $(2)^2 = 4$ times as great, or 80 m.

**PHYSICS APPLIED**
*Car's stopping distance $\propto$ to initial speed squared*

**EXERCISE D** Can kinetic energy ever be negative?

**EXERCISE E** (*a*) If the kinetic energy of a baseball is doubled, by what factor has its speed increased? (*b*) If its speed is doubled, by what factor does its kinetic energy increase?

**EXAMPLE 7–10** **A compressed spring.** A horizontal spring has spring constant $k = 360\ \text{N/m}$. (*a*) How much work is required to compress it from its uncompressed length ($x = 0$) to $x = 11.0\ \text{cm}$? (*b*) If a 1.85-kg block is placed against this compressed spring and the spring is released, what will be the speed of the block when it separates from the spring at $x = 0$? Ignore friction. (*c*) Repeat part (*b*) but assume that the block is moving on a table as in Fig. 7–18 and that some kind of constant drag force $F_D = 7.0\ \text{N}$ is acting to slow it down, such as friction (or perhaps your finger).

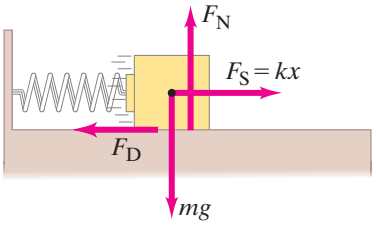

**FIGURE 7–18** Example 7–10.

**APPROACH** We use our result from Section 7–3 that the net work, $W$, needed to stretch or compress a spring by a distance $x$ is $W = \frac{1}{2}kx^2$. In (*b*) and (*c*) we use the work-energy principle.

**SOLUTION** (*a*) The work needed to compress the spring a distance $x = 0.110\ \text{m}$ is

$$W = \tfrac{1}{2}(360\ \text{N/m})(0.110\ \text{m})^2 = 2.18\ \text{J},$$

where we have converted all units to SI.

(*b*) In returning to its uncompressed length (from $x = 11.0\ \text{cm}$ to $x = 0$), the spring does 2.18 J of work on the block (same calculation as in part (*a*), only in reverse). According to the work-energy principle, the block acquires kinetic energy of 2.18 J. Since $K = \frac{1}{2}mv^2$, the block's speed must be

$$v = \sqrt{\frac{2K}{m}}$$
$$= \sqrt{\frac{2(2.18\ \text{J})}{1.85\ \text{kg}}} = 1.54\ \text{m/s}.$$

(*c*) There are two forces on the block: that exerted by the spring and that exerted by the drag force, $\vec{\mathbf{F}}_D$. Work done by a force such as friction is complicated. For one thing, heat (or, rather, "thermal energy") is produced—try rubbing your hands together. Nonetheless, the product $\vec{\mathbf{F}}_D \cdot \vec{\mathbf{d}}$ for the drag force, even when it is friction, can be used in the work-energy principle to give correct results for a particle-like object. The spring does 2.18 J of work on the block. The work done by the friction or drag force on the block, in the negative $x$ direction, is

$$W_D = -F_D x = -(7.0\ \text{N})(0.110\ \text{m}) = -0.77\ \text{J}.$$

This work is negative because the drag force acts in the direction opposite to the displacement $x$. The net work done on the block is $W_{\text{net}} = 2.18\ \text{J} - 0.77\ \text{J} = 1.41\ \text{J}$. From the work-energy principle, Eq. 7–11 (with $v_2 = v$ and $v_1 = 0$), we have

$$v = \sqrt{\frac{2W_{\text{net}}}{m}}$$
$$= \sqrt{\frac{2(1.41\ \text{J})}{1.85\ \text{kg}}} = 1.23\ \text{m/s}$$

for the block's speed at the moment it separates from the spring ($x = 0$).

## General Derivation of the Work-Energy Principle

We derived the work-energy principle, Eq. 7–11, for motion in one dimension with a constant force. It is valid even if the force is variable and the motion is in two or three dimensions, as we now show. Suppose the net force $\vec{\mathbf{F}}_{\text{net}}$ on a particle varies in both magnitude and direction, and the path of the particle is a curve as in Fig. 7–8. The net force may be considered to be a function of $\ell$, the distance along the curve. The net work done is (Eq. 7–6):

$$W_{\text{net}} = \int \vec{\mathbf{F}}_{\text{net}} \cdot d\vec{\boldsymbol{\ell}} = \int F_{\text{net}} \cos\theta \, d\ell = \int F_{\parallel} \, d\ell,$$

where $F_{\parallel}$ represents the component of the net force parallel to the curve at any point. By Newton's second law,

$$F_{\parallel} = ma_{\parallel} = m\frac{dv}{dt},$$

where $a_{\parallel}$, the component of acceleration parallel to the curve at any point, is equal to the rate of change of speed, $dv/dt$. We can think of $v$ as a function of $\ell$, and using the chain rule for derivatives, we have

$$\frac{dv}{dt} = \frac{dv}{d\ell}\frac{d\ell}{dt} = \frac{dv}{d\ell}v,$$

since $d\ell/dt$ is the speed $v$. Thus (letting 1 and 2 refer to the initial and final quantities, respectively):

$$W_{\text{net}} = \int_1^2 F_{\parallel} d\ell = \int_1^2 m\frac{dv}{dt} d\ell = \int_1^2 mv\frac{dv}{d\ell} d\ell = \int_1^2 mv \, dv,$$

which integrates to

$$W_{\text{net}} = \tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 = \Delta K.$$

This is again the work-energy principle, which we have now derived for motion in three dimensions with a variable net force, using the definitions of work and kinetic energy plus Newton's second law.

Notice in this derivation that only the component of $\vec{\mathbf{F}}_{\text{net}}$ parallel to the motion, $F_{\parallel}$, contributes to the work. Indeed, a force (or component of a force) acting perpendicular to the velocity vector does no work. Such a force changes only the direction of the velocity. It does not affect the magnitude of the velocity. One example of this is uniform circular motion in which an object moving with constant speed in a circle has a ("centripetal") force acting on it toward the center of the circle. This force does no work on the object, because (as we saw in Example 7–3) it is always perpendicular to the object's displacement $d\vec{\boldsymbol{\ell}}$.

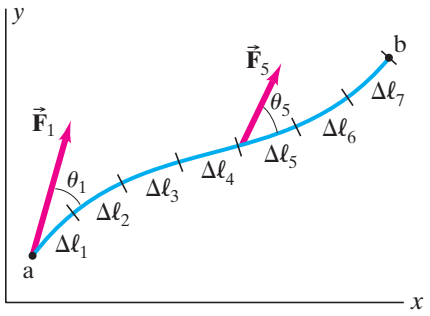

**FIGURE 7–8** (Repeated.) A particle acted on by a variable force, $\vec{\mathbf{F}}$, moves along the path shown from point a to point b.

# Summary

**Work** is done on an object by a force when the object moves through a distance, $d$. If the direction of a constant force $\vec{\mathbf{F}}$ makes an angle $\theta$ with the displacement $\vec{\mathbf{d}}$ of the object, the work done by this force is

$$W = Fd\cos\theta = \vec{\mathbf{F}} \cdot \vec{\mathbf{d}}, \qquad \textbf{(7–1, 7–3)}$$

where $\theta$ is the angle between $\vec{\mathbf{F}}$ and $\vec{\mathbf{d}}$.

The last expression is called the scalar product of $\vec{\mathbf{F}}$ and $\vec{\mathbf{d}}$. In general, the **scalar product** of any two vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ is defined as

$$\vec{\mathbf{A}} \cdot \vec{\mathbf{B}} = AB\cos\theta \qquad \textbf{(7–2)}$$

(also called the **dot product**) where $\theta$ is the angle between $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$. In rectangular coordinates we can also write

$$\vec{\mathbf{A}} \cdot \vec{\mathbf{B}} = A_x B_x + A_y B_y + A_z B_z. \qquad \textbf{(7–4)}$$

The work $W$ done by a variable force $\vec{\mathbf{F}}$ on an object that moves from point a to point b is

$$W = \int_a^b \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}} = \int_a^b F\cos\theta \, d\ell, \qquad \textbf{(7–7)}$$

where $d\vec{\boldsymbol{\ell}}$ represents an infinitesimal displacement along the path of the object and $\theta$ is the angle between $d\vec{\boldsymbol{\ell}}$ and $\vec{\mathbf{F}}$ at each point of the object's path.

The restoring force exerted by a spring stretched or compressed a distance $x$ is $F_S = -kx$, where $k$ is the **spring constant**. The work done to compress or stretch a spring a distance $x$ is $W = \frac{1}{2}kx^2$.

The translational **kinetic energy**, $K$, of an object of mass $m$ moving with speed $v$ is defined to be

$$K = \tfrac{1}{2}mv^2. \qquad \textbf{(7–10)}$$

The **work-energy principle** states that the net work done on an object (by the net force) equals the change in kinetic energy of the object:

$$W_{\text{net}} = \Delta K = \tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2. \qquad \textbf{(7–11)}$$

# Questions

1. In what ways is the word "work" as used in everyday language the same as defined in physics? In what ways is it different? Give examples of both.
2. A woman swimming upstream is not moving with respect to the shore. Is she doing any work? If she stops swimming and merely floats, is work done on her?
3. Can a centripetal force ever do work on an object? Explain.
4. Why is it tiring to push hard against a solid wall even though you are doing no work on the wall?
5. Does the scalar product of two vectors depend on the choice of coordinate system?
6. Can a dot product ever be negative? If yes, under what conditions?
7. Give an example of friction doing positive work.
8. Does the dot product of two vectors have direction as well as magnitude?
9. Can the normal force on an object ever do work? Explain.
10. You have two springs that are identical except that spring 1 is stiffer than spring 2 $(k_1 > k_2)$. On which spring is more work done: (*a*) if the two springs are compressed using the same force; (*b*) if they are compressed the same distance?
11. If the speed of a particle doubles, by what factor does its kinetic energy increase?
12. In Example 7–10, it was stated that the block separates from the compressed spring when the spring reaches its equilibrium length $(x = 0)$. Explain why separation doesn't take place before (or after) this point.
13. Does the net work done on a particle depend on the choice of reference frame? How does this affect the work-energy principle?

# MisConceptual Questions

1. You are carrying a 10-kg bag and moving at constant speed. In which case will you do the most work on the bag?
   (*a*) Walk horizontally for 5 m.
   (*b*) Run horizontally for 5 m.
   (*c*) Climb up a 5-m-long slope.
   (*d*) Climb up a 5-m-tall slope.
2. You push very hard on a car with a dead battery, trying to move it. You do work on the car:
   (*a*) only if it starts moving.
   (*b*) only if it doesn't move.
   (*c*) whether or not it moves, as long as you are exerting a force.
   (*d*) never—it does work on you.
   (*e*) None of the above.
3. A man holds a 1.00-kg box above his head for 2 minutes. The work done by the man during these 2 minutes is
   (*a*) 60 J.
   (*b*) 120 J.
   (*c*) 19.6 J.
   (*d*) 9.8 J.
   (*e*) 0 J.
4. You push a heavy crate *down* a ramp at a constant velocity. Only four forces act on the crate. Which force does the greatest magnitude of work on the crate?
   (*a*) The force of friction.
   (*b*) The force of gravity.
   (*c*) The normal force.
   (*d*) The force of you pushing.
   (*e*) The net force.
5. If you push twice as hard against a stationary brick wall, the amount of work you do
   (*a*) quadruples.
   (*b*) doubles.
   (*c*) is cut in half.
   (*d*) is zero.
   (*e*) remains constant but non-zero.
6. A *satellite* in circular orbit around the Earth moves at constant speed. This orbit is maintained by the force of gravity between the Earth and the satellite, yet no work is done on the satellite. How is this possible?
   (*a*) No work is done if there is no contact between objects.
   (*b*) No work is done because there is no gravity in space.
   (*c*) No work is done if the direction of motion is perpendicular to the force.
   (*d*) No work is done whenever objects move in a circle.
7. A delivery man carrying a package (Fig. 7–19) walks up the stairs to the second floor at constant speed (A), and along the hall at a constant speed (B). He accelerates to a run (C) and then (D) moves at a greater constant speed along the hall. During what portions of his motion is the delivery man doing work on the package? (Ignore friction.)
   (*a*) A only.
   (*b*) C only.
   (*c*) A and C only.
   (*d*) B and C only.
   (*e*) None of these portions.
   (*f*) Work is done throughout.

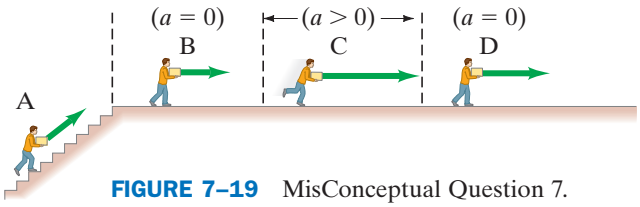

**FIGURE 7–19** MisConceptual Question 7.

8. You and a friend decide to go sledding and climb to the top of a hill. There are two paths: a short steep path to the bottom, and a longer, gentle path to the bottom. If you go down the steep path and your friend takes the gentler path, who has the greater speed at the bottom? Ignore friction.
   (*a*) You do.
   (*b*) Your friend does.
   (*c*) You both have the same speed.
   (*d*) The one who is heavier does.

9. Which of the following statements about work and energy are true?
   (*a*) Kinetic energy and work can only be positive.
   (*b*) Kinetic energy can only be positive; work can be positive or negative.
   (*c*) Both kinetic energy and work can be positive or negative.

10. An old truck moving at 50 km/h skids to a stop with locked brakes over a distance $d$. Over what distance will the truck skid to a stop with locked brakes if it is traveling at 150 km/h?
   (*a*) $d$.
   (*b*) $3d$.
   (*c*) Larger than $3d$.

11. A car accelerates from rest to 30 km/h. Later, on a highway it accelerates from 30 km/h to 60 km/h. Which takes more energy, going from 0 to 30, or from 30 to 60?
   (*a*) 0 to 30 km/h.
   (*b*) 30 to 60 km/h.
   (*c*) Both are the same.

12. Two blocks of mass $m_1$ and $m_2$ ($m_1 > m_2$) slide on a frictionless floor and have the same kinetic energy when they hit a long rough stretch ($\mu > 0$), which slows them down to a stop. Which one goes farther?
   (*a*) $m_1$.
   (*b*) $m_2$.
   (*c*) They will go the same distance.
   (*d*) Can't tell without knowing the initial speed of each.

13. Two stones, one twice the mass of the other, are dropped from a cliff. Just before hitting the ground, what is the kinetic energy of the heavy stone compared to the light one?
   (*a*) 1/4 as much.
   (*b*) 1/2 as much.
   (*c*) The same.
   (*d*) 2× as much.
   (*e*) 4× as much.

14. If an object has kinetic energy, then it must be
   (*a*) at an elevated position.
   (*b*) falling.
   (*c*) moving.
   (*d*) at rest.

# Problems

## 7–1 Work, Constant Force

1. (I) How much work is done by the gravitational force when a 280-kg pile driver falls 3.80 m?
2. (I) How high will a 1.85-kg rock go if thrown straight up by someone who does 70.0 J of work on it? Neglect air resistance.
3. (I) A 55.0-kg firefighter climbs a flight of stairs 28.0 m high at constant speed. How much work does she do?
4. (I) The head of a hammer with a mass of 1.2 kg is allowed to fall onto a nail from a height of 0.65 m. What is the maximum amount of work it could do on the nail? Why do people not just "let it fall" but add their own force to the hammer as it falls?
5. (II) How much work would movers do pushing a 46.0-kg crate 10.3 m horizontally across a rough floor without acceleration, if the effective coefficient of friction was 0.40?
6. (II) A 1200-N crate rests on the floor. How much work is required to move it at constant speed (*a*) 6.0 m along the floor against a friction force of 230 N, and (*b*) 6.0 m vertically?
7. (II) (*a*) What magnitude force is required to give a helicopter of mass $M$ an acceleration of $0.10g$ upward? (*b*) What work is done by this force as the helicopter moves a distance $h$ upward?
8. (II) What is the minimum work needed to push a 950-kg car 510 m up along a 9.0° incline? Ignore friction.
9. (II) Estimate the work you do to mow a lawn 10 m by 20 m with a 50-cm-wide mower. Assume you push with a horizontal force of about 15 N.
10. (II) In a certain library the first shelf is 15.0 cm off the ground, and the remaining four shelves are each spaced 38.0 cm above the previous one. If the average book has a mass of 1.25 kg with a height of 22.0 cm, and an average shelf holds 28 books (standing vertically), how much work is required to fill all the shelves, assuming the books are all laying flat on the floor to start?
11. (II) A **lever** such as that shown in Fig. 7–20 can be used to lift objects we might not otherwise be able to lift. Show that the ratio of output force, $F_O$, to input force, $F_I$, is related to the lengths $\ell_I$ and $\ell_O$ from the pivot by $F_O/F_I = \ell_I/\ell_O$. Ignore friction and the mass of the lever, and assume the work output equals the work input.

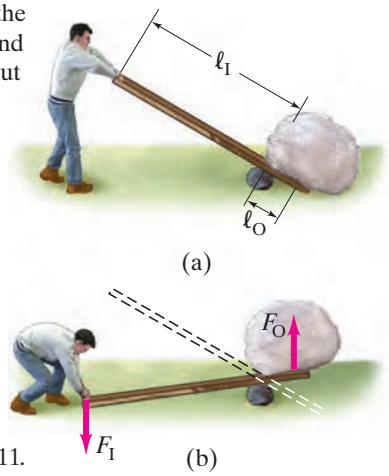

**FIGURE 7–20**
A lever. Problem 11.

12. (II) A box of mass 4.0 kg is accelerated from rest by a force across a floor at a rate of 2.0 m/s$^2$ for 8.0 s. Find the net work done on the box.
13. (II) Eight books, each 4.0 cm thick with mass 1.6 kg, lie flat on a table. How much work is required to stack them one on top of another?
14. (II) A *gondola* can carry 20 skiers, with a total mass of up to 2250 kg. The gondola ascends at a constant speed from the base of a mountain, at 2150 m, to the summit at 3625 m. (*a*) How much work does the motor do in moving a full gondola up the mountain? (*b*) How much work does gravity do on the gondola? (*c*) If the motor could generate 10% more work than found in (*a*), what is the acceleration of the gondola?
15. (II) A grocery cart with mass of 16 kg is pushed at constant speed up a 12° ramp by a force $F_P$ which acts at an angle of 17° below the horizontal. Find the work done by each of the forces $(m\vec{\mathbf{g}}, \vec{\mathbf{F}}_N, \vec{\mathbf{F}}_P)$ on the cart if the ramp is 7.5 m long.

**16.** (II) A 380-kg piano slides 4.6 m down a 30° incline and is kept from accelerating by a man who is pushing back on it *parallel to the incline* (Fig. 7–21). Determine: (*a*) the force exerted by the man, (*b*) the work done on the piano by the man, (*c*) the work done on the piano by the force of gravity, and (*d*) the net work done on the piano. Ignore friction.

**FIGURE 7–21**
Problem 16.

**17.** (II) Recall from Chapter 4, Example 4–14, that you can use a *pulley* and ropes to decrease the force needed to raise a heavy load (see Fig. 7–22). But for every meter the load is raised, how much rope must be pulled up? Explain.

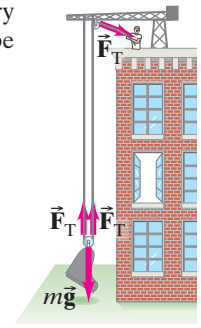

**FIGURE 7–22**
Problem 17.

## 7–2 Scalar Product

**18.** (I) What is the dot product of $\vec{\mathbf{A}} = 2.0x^2\hat{\mathbf{i}} - 4.0x\,\hat{\mathbf{j}} + 5.0\hat{\mathbf{k}}$ and $\vec{\mathbf{B}} = 11.0\,\hat{\mathbf{i}} + 2.5x\,\hat{\mathbf{j}}$?

**19.** (I) For any vector $\vec{\mathbf{V}} = V_x\hat{\mathbf{i}} + V_y\hat{\mathbf{j}} + V_z\hat{\mathbf{k}}$ show that

$$V_x = \hat{\mathbf{i}}\cdot\vec{\mathbf{V}}, \quad V_y = \hat{\mathbf{j}}\cdot\vec{\mathbf{V}}, \quad V_z = \hat{\mathbf{k}}\cdot\vec{\mathbf{V}}.$$

**20.** (I) Calculate the angle between the vectors:

$$\vec{\mathbf{A}} = 5.8\hat{\mathbf{i}} - 3.4\,\hat{\mathbf{j}} - 6.2\hat{\mathbf{k}} \text{ and } \vec{\mathbf{B}} = 8.2\hat{\mathbf{i}} + 4.3\,\hat{\mathbf{j}} - 7.0\hat{\mathbf{k}}.$$

**21.** (I) Show that $\vec{\mathbf{A}}\cdot(-\vec{\mathbf{B}}) = -\vec{\mathbf{A}}\cdot\vec{\mathbf{B}}$.

**22.** (I) Vector $\vec{\mathbf{V}}_1$ points along the $z$ axis and has magnitude $V_1 = 75$. Vector $\vec{\mathbf{V}}_2$ lies in the $xz$ plane, has magnitude $V_2 = 48$, and makes a $-48°$ angle with the $x$ axis (points below the $x$ axis). What is the scalar product $\vec{\mathbf{V}}_1\cdot\vec{\mathbf{V}}_2$?

**23.** (II) Given the vector $\vec{\mathbf{A}} = 3.0\hat{\mathbf{i}} + 1.8\,\hat{\mathbf{j}}$, find a vector $\vec{\mathbf{B}}$ in the $xy$ plane that is perpendicular to $\vec{\mathbf{A}}$.

**24.** (II) A constant force $\vec{\mathbf{F}} = (2.0\hat{\mathbf{i}} + 4.0\,\hat{\mathbf{j}})$ N acts on an object as it moves along a straight-line path. If the object's displacement is $\vec{\mathbf{d}} = (1.0\hat{\mathbf{i}} + 5.0\,\hat{\mathbf{j}})$ m, calculate the work done by $\vec{\mathbf{F}}$ using these alternate ways of writing the dot product: (*a*) $W = Fd\cos\theta$; (*b*) $W = F_x d_x + F_y d_y$.

**25.** (II) If $\vec{\mathbf{A}} = 9.0\hat{\mathbf{i}} - 8.5\,\hat{\mathbf{j}}$, $\vec{\mathbf{B}} = -8.0\hat{\mathbf{i}} + 6.1\,\hat{\mathbf{j}} + 4.2\hat{\mathbf{k}}$, and $\vec{\mathbf{C}} = 5.8\hat{\mathbf{i}} - 9.2\,\hat{\mathbf{j}}$, determine (*a*) $\vec{\mathbf{A}}\cdot(\vec{\mathbf{B}}+\vec{\mathbf{C}})$; (*b*) $(\vec{\mathbf{A}}+\vec{\mathbf{C}})\cdot\vec{\mathbf{B}}$; (*c*) $(\vec{\mathbf{B}}+\vec{\mathbf{A}})\cdot\vec{\mathbf{C}}$.

**26.** (II) In Section 7–2, there are two different expressions given for the dot product—Equations 7–2 and 7–4. For vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{C}}$ in Problem 25, show that the two different expressions give the same result. You will have to find the magnitude and direction of both of the vectors.

**27.** (II) Show that if two nonparallel vectors have the same magnitude, their sum must be perpendicular to their difference.

**28.** (II) Given vectors $\vec{\mathbf{A}} = -4.8\hat{\mathbf{i}} + 6.8\,\hat{\mathbf{j}}$ and $\vec{\mathbf{B}} = 9.6\hat{\mathbf{i}} + 6.7\,\hat{\mathbf{j}}$, determine the vector $\vec{\mathbf{C}}$ that lies in the $xy$ plane, is perpendicular to $\vec{\mathbf{B}}$, and whose dot product with $\vec{\mathbf{A}}$ is 18.0.

**29.** (II) Let $\vec{\mathbf{V}} = 20.0\hat{\mathbf{i}} + 26.0\,\hat{\mathbf{j}} - 14.0\hat{\mathbf{k}}$. What angles does this vector make with the $x$, $y$, and $z$ axes?

**30.** (II) Use the scalar product to prove the *law of cosines* for a triangle:

$$c^2 = a^2 + b^2 - 2ab\cos\theta,$$

where $a$, $b$, and $c$ are the lengths of the sides of a triangle and $\theta$ is the angle opposite side $c$.

**31.** (II) $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ are two vectors in the $xy$ plane that make angles $\alpha$ and $\beta$ with the $x$ axis respectively. Evaluate the scalar product of $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ and deduce the following trigonometric identity: $\cos(\alpha-\beta) = \cos\alpha\cos\beta + \sin\alpha\sin\beta$.

**32.** (II) Suppose $\vec{\mathbf{A}} = 1.0\hat{\mathbf{i}} + 1.0\,\hat{\mathbf{j}} - 2.0\hat{\mathbf{k}}$ and $\vec{\mathbf{B}} = -1.0\hat{\mathbf{i}} + 1.0\,\hat{\mathbf{j}} - 2.0\hat{\mathbf{k}}$. What is the angle between these two vectors? Explain the significance of the sign in your result.

**33.** (III) Show that the scalar product of two vectors is *distributive*: $\vec{\mathbf{A}}\cdot(\vec{\mathbf{B}}+\vec{\mathbf{C}}) = \vec{\mathbf{A}}\cdot\vec{\mathbf{B}} + \vec{\mathbf{A}}\cdot\vec{\mathbf{C}}$ [*Hint*: Use a diagram showing all three vectors in a plane and indicate dot products on the diagram.]

**34.** (III) Find a vector of unit length in the $xy$ plane that is perpendicular to $4.0\hat{\mathbf{i}} + 3.0\,\hat{\mathbf{j}}$.

**35.** (III) The *arrangement of atoms* in zinc is an example of "hexagonal close-packed" structure. Three of the nearest neighbors are found at the following ($x$, $y$, $z$) coordinates, given in nanometers ($10^{-9}$ m): atom 1 is at (0, 0, 0); atom 2 is at (0.230, 0.133, 0); atom 3 is at (0.077, 0.133, 0.247). Find the angle between two vectors: one that connects atom 1 with atom 2 and another that connects atom 1 with atom 3.

## 7–3 Work, Varying Force

**36.** (I) In pedaling a bicycle uphill, a cyclist exerts a downward force of 420 N during each stroke. If the diameter of the circle traced by each pedal is 36 cm, calculate how much work is done in each stroke.

**37.** (II) A spring has $k = 65$ N/m. Draw a graph like that in Fig. 7–11 and use it to determine the work needed to stretch the spring from $x = 3.0$ cm to $x = 7.5$ cm, where $x = 0$ refers to the spring's unstretched length.

**38.** (II) If the hill in Example 7–2 (Fig. 7–4) was not an even slope but rather an irregular curve as in Fig. 7–23, show that the same result would be obtained as in Example 7–2: namely, that the work done by gravity depends only on the height of the hill and not on its shape or the path taken.

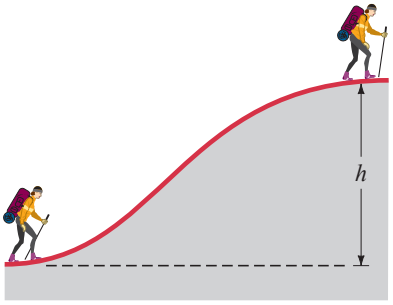

**FIGURE 7–23**
Problem 38.

**39.** (II) The net force exerted on a particle acts in the positive $x$ direction. Its magnitude increases linearly from zero at $x = 0$, to 380 N at $x = 3.0$ m. It remains constant at 380 N from $x = 3.0$ m to $x = 7.0$ m, and then decreases linearly to zero at $x = 12.0$ m. Determine the work done to move the particle from $x = 0$ to $x = 12.0$ m graphically, by determining the area under the $F_x$ versus $x$ graph.

**40.** (II) In Fig. 7–9 assume the distance axis is the $x$ axis and that a = 10.0 m and b = 30.0 m. Estimate the work done by this force in moving a 3.50-kg object from a to b.

**41.** (II) The force on a particle, acting along the $x$ axis, varies as shown in Fig. 7–24. Determine the work done by this force to move the particle along the $x$ axis: ($a$) from $x = 0.0$ to $x = 10.0$ m; ($b$) from $x = 0.0$ to $x = 15.0$ m.

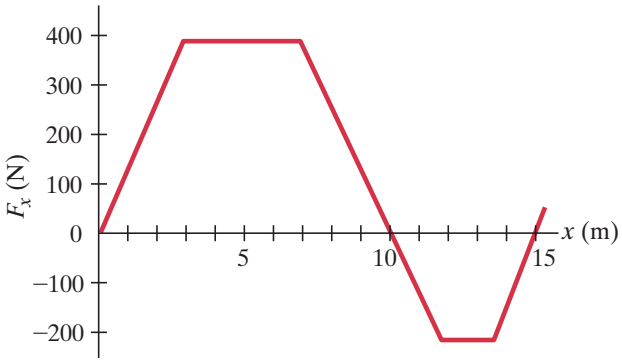

**FIGURE 7–24** Problem 41.

**42.** (II) A child is pulling a wagon down the sidewalk. For 5.0 m the wagon stays on the sidewalk and the child pulls with a horizontal force of 22 N. Then one wheel of the wagon goes off onto the grass so the child has to pull with a horizontal force of 38 N at an angle of 12° to the side for the next 3.0 m. Finally the wagon gets back on the sidewalk so the child makes the rest of the trip, 8.5 m, with a force of 22 N. How much total work did the child do on the wagon?

**43.** (II) The resistance of a packing material to a sharp object penetrating it is a force proportional to the fourth power of the penetration depth $x$; that is, $\vec{\mathbf{F}} = -bx^4\,\hat{\mathbf{i}}$. Calculate the work done to force a sharp object a distance $d$ into the material.

**44.** (II) At the top of a *pole vault*, an athlete actually can do work pushing on the pole before releasing it. Suppose the pushing force that the pole exerts back on the athlete is given by $F(y) = (1.5 \times 10^2\ \text{N/m})\,y - (1.9 \times 10^2\ \text{N/m}^2)\,y^2$ acting over a displacement from $y = 0$ ($y$ is vertical) to $y = 0.20$ m. How much work is done on the athlete?

**45.** (II) Consider a force $F_1 = A/\sqrt{x}$ which acts on an object during its journey along the $x$ axis from $x = 0.0$ to $x = 1.0$ m, where $A = 3.0\ \text{N} \cdot \text{m}^{1/2}$. Show that during this journey, even though $F_1$ is infinite at $x = 0.0$, the work $W$ done on the object by this force is finite, and determine $W$.

**46.** (II) Assume that a force acting on an object is given by $\vec{\mathbf{F}} = ax\,\hat{\mathbf{i}} + by\,\hat{\mathbf{j}}$ where the constants $a = 3.0\ \text{N} \cdot \text{m}^{-1}$ and $b = 4.0\ \text{N} \cdot \text{m}^{-1}$. Determine the work done on the object by this force as it moves in a straight line from the origin to $\vec{\mathbf{r}} = (10.0\,\hat{\mathbf{i}} + 20.0\,\hat{\mathbf{j}})$ m.

**47.** (II) If it requires 5.0 J of work to stretch a particular spring by 2.0 cm from its equilibrium length, how much more work will be required to stretch it an additional 4.0 cm?

**48.** (II) An object, moving along the circumference of a circle with radius $R$, is acted upon by a force of constant magnitude $F$. The force is directed at all times at a 30° angle with respect to the tangent to the circle as shown in Fig. 7–25. Determine the work done by this force when the object moves along the half circle from A to B.

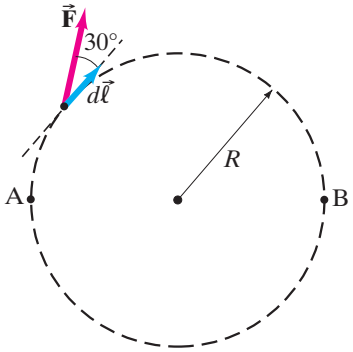

**FIGURE 7–25** Problem 48.

**49.** (II) The net force along the linear path of a particle of mass 480 g has been measured at 10.0-cm intervals, starting at $x = 0.0$, to be 26.0, 28.5, 28.8, 29.6, 32.8, 40.1, 46.6, 42.2, 48.8, 52.6, 55.8, 60.2, 60.6, 58.2, 53.7, 50.3, 45.6, 45.2, 43.2, 38.9, 35.1, 30.8, 27.2, 21.0, 22.2, and 18.6, all in newtons. Determine the total work done on the particle over this entire range.

**50.** (II) A 17,000-kg jet takes off from an aircraft carrier with the help of a *catapult* (Fig. 7–26a). The gases thrust out from the jet's engines exert a constant force of 130 kN on the jet; the horizontal force exerted on the jet by the steam-powered catapult is plotted in Fig. 7–26b. Determine the work done on the jet: ($a$) by the gases expelled by its engines during launch of the jet; and ($b$) by the catapult during launch of the jet.

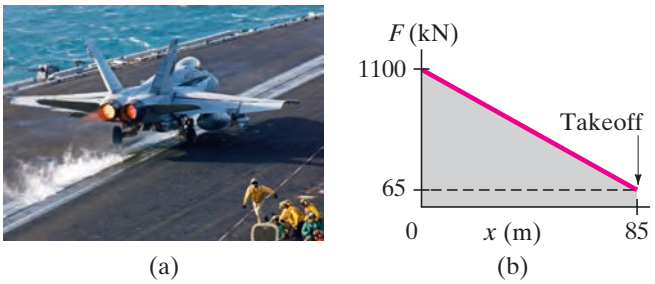

**FIGURE 7–26** Problem 50.

**51.** (III) A spring of spring constant $k$ and negligible mass is attached to a mass $m$ and the other end of the spring is pulled vertically in order to lift the mass. Find an expression for the amount of work that must be done on the spring before the mass begins to leave the ground.

**52.** (III) A 2800-kg space vehicle, initially at rest, falls vertically from a height of 2900 km above the Earth's surface. Determine how much work is done by the force of gravity in bringing the vehicle to the Earth's surface.

**53.** (III) A 3.0-m-long steel *chain* is stretched out along the top level of a horizontal scaffold at a construction site, in such a way that 2.0 m of the chain remains on the top level and 1.0 m hangs vertically, Fig. 7–27. At this point, the force on the hanging segment is sufficient to pull the entire chain over the edge. Once the chain is moving, the kinetic friction is so small that it can be neglected. How much work is performed on the chain by the force of gravity as the chain falls from the point where 2.0 m remains on the scaffold to the point where the entire chain has left the scaffold? (Assume that the chain has a linear weight density of 24 N/m.)

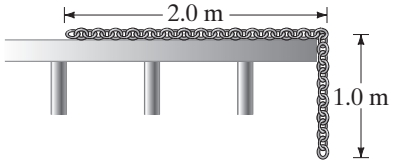

**FIGURE 7–27**
Problem 53.

## 7–4 Kinetic Energy; Work-Energy Principle

**54.** (I) At room temperature, an oxygen molecule, with mass of $5.31 \times 10^{-26}$ kg, typically has a kinetic energy of about $6.21 \times 10^{-21}$ J. How fast is it moving?

**55.** (I) (*a*) If the kinetic energy of a particle is tripled, by what factor has its speed increased? (*b*) If the speed of a particle is halved, by what factor does its kinetic energy change?

**56.** (I) How much work is required to stop an electron $(m = 9.11 \times 10^{-31}\,\text{kg})$ which is moving with a speed of $1.10 \times 10^{6}$ m/s?

**57.** (II) A 1300-kg car moving 20.0 m/s slows to a stop at a steady rate in a distance of 30 m. It then speeds back up to 20.0 m/s at constant acceleration over a distance of 100 m. What is the net work done on the car (*a*) in slowing down? (*b*) in speeding up? (*c*) overall?

**58.** (II) Two bullets are fired at the same time with the same kinetic energy. If one bullet has twice the mass of the other, which has the greater speed and by what factor? Which can do more work, and by what factor?

**59.** (II) A baseball $(m = 145\,\text{g})$ traveling 32 m/s moves a fielder's glove backward 22 cm when the ball is caught. What was the average force exerted by the ball on the glove?

**60.** (II) An 85-g arrow is fired from a bow whose string exerts an average force of 105 N on the arrow over a distance of 75 cm. What is the speed of the arrow as it leaves the bow?

**61.** (II) If the speed of a car is increased by 50%, by what factor will its minimum braking distance on a flat road be increased, assuming all else is the same? Ignore the driver's reaction time.

**62.** (II) At an accident scene on a level road, investigators measure a *car's skid* mark to be 78 m long. It was a rainy day and the coefficient of friction was estimated to be 0.30. (*a*) Use these data to determine the speed of the car when the driver slammed on (and locked) the brakes. (*b*) Why does the car's mass not matter? (*c*) What is wrong with a car that skids (see page 131)?

**63.** (II) You back your 1200-kg car into a large fixed horizontal spring, compressing it by 1.8 m. You stop, and when you take your foot off the brake, your car accelerates and separates from the spring at a speed of 28 km/h. What is the spring constant of the spring?

**64.** (II) A 3.5-kg object moving in two dimensions initially has a velocity $\vec{\mathbf{v}}_1 = (10.0\,\hat{\mathbf{i}} + 20.0\,\hat{\mathbf{j}})$ m/s. A net force $\vec{\mathbf{F}}$ then acts on the object for 2.0 s, after which the object's velocity is $\vec{\mathbf{v}}_2 = (15.0\,\hat{\mathbf{i}} + 30.0\,\hat{\mathbf{j}})$ m/s. Determine the work done by $\vec{\mathbf{F}}$ on the object.

**65.** (II) A box is initially moving 5.0 m/s across the floor. It slides to rest due to friction in a distance of 8.0 m. What is the coefficient of friction between the box and the floor?

**66.** (II) (*a*) How much work is done by the horizontal force $F_P = 150$ N on the 18-kg block of Fig. 7–28 when the force pushes the block 5.0 m up along the 32° frictionless incline? (*b*) How much work is done by the gravitational force on the block during this displacement? (*c*) How much work is done by the normal force? (*d*) What is the speed of the block (assume that it is zero initially) after this displacement?

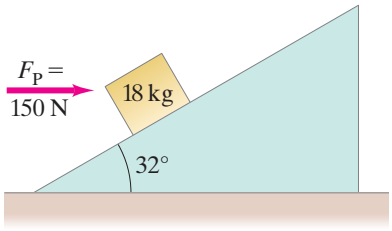

**FIGURE 7–28**
Problems 66 and 67.

**67.** (II) Repeat Problem 66 using a coefficient of friction $\mu_k = 0.13$.

**68.** (II) A car traveling at a velocity $v$ can stop in a minimum distance $d$. What would be the car's minimum stopping distance if it were traveling at a velocity of $2v$?

**69.** (II) A train is moving along a track with constant speed $v_1$ relative to the ground. A person on the train holds a ball of mass $m$ and throws it toward the front of the train with a speed $v_2$ relative to the train. Calculate the change in kinetic energy of the ball (*a*) in the Earth frame of reference, and (*b*) in the train frame of reference. (*c*) Relative to each frame of reference, how much work was done on the ball? (*d*) Explain why the results in part (*c*) are not the same for the two frames—after all, it's the same ball.

**70.** (II) A mass $m$ is attached to a spring which is held stretched a distance $x$ by a force $F$, Fig. 7–29, and then released. The spring pulls the mass to the left, towards its natural equilibrium length. Assuming there is no friction, determine the speed of the mass $m$ when the spring returns: (*a*) to its normal length $(x = 0)$; (*b*) to half its original extension $(x/2)$.

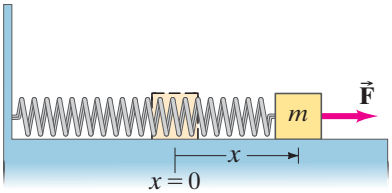

**FIGURE 7–29**
Problem 70.

**71.** (II) One car has twice the mass of a second car, but only half as much kinetic energy. When both cars increase their speed by 8.0 m/s, they then have the same kinetic energy. What were the original speeds of the two cars?

**72.** (II) A 265-kg load is lifted 18.0 m vertically with an acceleration $a = 0.140\,g$ by a single cable. Determine (*a*) the tension in the cable; (*b*) the net work done on the load; (*c*) the work done by the cable on the load; (*d*) the work done by gravity on the load; (*e*) the final speed of the load assuming it started from rest.

**73.** (III) An elevator cable breaks when a 975-kg elevator is 22.5 m above the top of a huge spring $(k = 8.00 \times 10^4\,\text{N/m})$ at the bottom of the shaft. Calculate (*a*) the work done by gravity on the elevator just before striking the spring; (*b*) the speed of the elevator just before striking the spring; (*c*) the amount the spring compresses (note that here work is done by both the spring and gravity).

# General Problems

**74.** *Spiderman* uses his spider webs to save a runaway train moving about 60 km/h, Fig. 7–30. His web stretches a few city blocks (500 m) before the $10^4$-kg train comes to a stop. Assuming the web acts like a spring, estimate the effective spring constant.

**FIGURE 7–30** Problem 74.

**75.** A 36.0-kg crate, starting from rest, is pulled across a floor with a constant horizontal force of 225 N. For the first 11.0 m the floor is frictionless, and for the next 15.0 m the coefficient of friction is 0.20. What is the final speed of the crate after being pulled these 26.0 m?

**76.** A 75-kg meteorite buries itself 4.5 m into soft mud. The force between the meteorite and the mud is given by $F(x) = (640\ \text{N/m}^3)x^3$, where $x$ is the depth in the mud. What was the speed of the meteorite when it initially impacted the mud?

**77.** The force required to compress an "*imperfect*" horizontal *spring* (doesn't follow Hooke's law) an amount $x$ is given by $F = 150x + 12x^3$, where $x$ is in meters and $F$ in newtons. If the spring is compressed 2.0 m, what speed will it give to a 3.0-kg ball held against it and then released?

**78.** A 6.10-kg block is pushed 9.25 m up a smooth 37.0° inclined plane by a horizontal force of 85.0 N. If the initial speed of the block is 3.25 m/s up the plane, calculate (*a*) the initial kinetic energy of the block; (*b*) the work done by the 85.0-N force; (*c*) the work done by gravity; (*d*) the work done by the normal force; (*e*) the final kinetic energy of the block.

**79.** A varying force is given by $F = Ae^{-kx}$, where $x$ is the position. $A$ and $k$ are constants that have units of N and $\text{m}^{-1}$, respectively. What is the work done when $x$ goes from 0.10 m to infinity?

**80.** The force needed to hold a particular spring compressed by a fairly large amount $x$ from its normal length is given by $F = kx + ax^3 + bx^4$. How much work must be done to compress this *nonlinear spring* by an amount $X$, starting from $x = 0$?

**81.** A force $\vec{\mathbf{F}} = (10.0\,\hat{\mathbf{i}} + 9.0\,\hat{\mathbf{j}} + 12.0\,\hat{\mathbf{k}})\,\text{kN}$ acts on a small object of mass 85 g. If the displacement of the object is $\vec{\mathbf{d}} = (5.0\,\hat{\mathbf{i}} + 4.0\,\hat{\mathbf{j}})\,\text{m}$, find the work done by the force. What is the angle between $\vec{\mathbf{F}}$ and $\vec{\mathbf{d}}$?

**82.** Two forces, $\vec{\mathbf{F}}_1 = (1.50\,\hat{\mathbf{i}} - 0.80\,\hat{\mathbf{j}} + 0.70\,\hat{\mathbf{k}})\,\text{N}$ and $\vec{\mathbf{F}}_2 = (-0.70\,\hat{\mathbf{i}} + 1.20\,\hat{\mathbf{j}})\,\text{N}$, are applied on a moving object of mass 0.20 kg. The displacement vector of the object while the two forces act is $\vec{\mathbf{d}} = (6.0\,\hat{\mathbf{i}} + 8.0\,\hat{\mathbf{j}} + 5.0\,\hat{\mathbf{k}})\,\text{m}$. What is the work done by the two forces?

**83.** In the game of *paintball*, players use guns powered by pressurized gas to propel 33-g gel capsules filled with paint at the opposing team. Game rules dictate that a paintball cannot leave the barrel of a gun with a speed greater than 85 m/s. Model the shot by assuming the pressurized gas applies a constant force $F$ to a 33-g capsule over the length of the 32-cm barrel. Determine $F$ by (*a*) using the work-energy principle, and (*b*) using the kinematic equations (Eqs. 2–12) and Newton's second law.

**84.** A softball having a mass of 0.25 kg is pitched horizontally at 120 km/h. By the time it reaches the plate, it may have slowed by 10%. Neglecting gravity, estimate the average force of air resistance during a pitch, if the distance between the plate and the pitcher is about 15 m.

**85.** We usually neglect the *mass of a spring* if it is small compared to the mass attached to it. But in some applications, the mass of the spring must be taken into account. Consider a spring of unstretched length $\ell$ and mass $M_S$ uniformly distributed along the length of the spring. A mass $m$ is attached to the end of the spring. One end of the spring is fixed and the mass $m$ is allowed to vibrate horizontally without friction (Fig. 7–31). Each point on the spring moves with a velocity proportional to the distance from that point to the fixed end. For example, if the mass on the end moves with speed $v_0$, the midpoint of the spring moves with speed $v_0/2$. Show that the kinetic energy of the mass plus spring when the mass $m$ is moving with velocity $v$ is

$$K = \tfrac{1}{2}Mv^2$$

where $M = m + \frac{1}{3}M_S$ is the "effective mass" of the system. [*Hint*: Let $D$ be the total length of the stretched spring. Then the velocity of an infinitesimal length $dx$ of spring, of mass $dM$, located at $x$ is $v(x) = v_0(x/D)$. Note also that $dM = dx\,(M_S/D)$.]

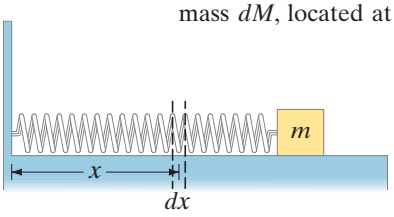

**FIGURE 7–31** Problem 85.

**86.** A 25-g projectile is fired into a cube of ballistic gel at a velocity of 360 m/s. If the projectile penetrates 15 cm into the gel before stopping, find the average force exerted by the gel onto the projectile. Use (*a*) kinematics and dynamics (Newton's laws) and (*b*) the work-energy principle.

**87.** An airplane pilot fell 370 m after jumping from an aircraft without his parachute opening. He landed in a snowbank, creating a crater 1.1 m deep, but survived with only minor injuries. Assuming the pilot's mass was 82 kg and his terminal velocity was 45 m/s, estimate: (*a*) the work done by the snow in bringing him to rest; (*b*) the average force exerted on him by the snow to stop him; and (*c*) the work done on him by air resistance as he fell. Model him as a particle.

**88.** Many cars have "3 mi/h (5 km/h) *bumpers*" that are designed to compress and rebound elastically without any physical damage at speeds below 5 km/h. If the material of the bumpers permanently deforms after a compression of 1.5 cm, but remains like an elastic spring up to that point, what must be the effective spring constant of the bumper material, assuming the car has a mass of 1050 kg and is tested by driving it into a solid wall?

**89.** A package of mass $m$ is placed onto a horizontal conveyor belt moving at speed $v$ (Fig. 7–32). The coefficient of kinetic friction between package and belt is $\mu_k$. (*a*) How long does it take the package to stop sliding on the belt? [*Hint*: Use $F = ma$.] (*b*) What is the package's displacement $d$ during this time? (*c*) How much work is done by the conveyor belt's motor? (*d*) How much of this work is done against friction and how much to accelerate the package?

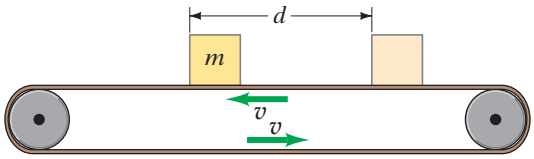

**FIGURE 7–32** Problem 89.

**90.** A cyclist starts from rest and coasts down a 4.0° hill. The mass of the cyclist plus bicycle is 85 kg. After the cyclist has traveled 180 m, (*a*) what was the net work done by gravity on the cyclist? (*b*) How fast is the cyclist going? Ignore friction and air resistance (very unrealistic).

**91.** What should be the spring constant $k$ of a spring designed to bring a 1500-kg car to rest from a speed of 90 km/h so that the occupants undergo a maximum acceleration of $5.0\,g$?

**92.** Assume a *cyclist* of weight $mg$ can exert a force on the pedals equal to $0.90\,mg$ on the average. If the pedals rotate in a circle of radius 18 cm, the wheels have a radius of 34 cm, and the front and back *sprockets* on which the chain runs have 42 and 19 teeth respectively (Fig. 7–33), determine the maximum slope of a hill the cyclist can climb at constant speed. Assume the mass of the bike is 12 kg and that of the rider is 65 kg. Ignore friction. Assume the cyclist's average force is always: (*a*) downward; (*b*) tangential to pedal motion.

**FIGURE 7–33** Problem 92.

**93.** A car passenger buckles himself in with a seat belt and holds his 18-kg toddler on his lap. Use the work-energy principle to answer the following questions. (*a*) While traveling 25 m/s, the driver has to make an emergency stop over a distance of 45 m. Assuming constant deceleration, how much force will the arms of the parent need to exert on the child during this deceleration period? Is this force achievable by an average parent? (*b*) Now assume that the car $(v = 25\text{ m/s})$ is in an accident and is brought to stop over a distance of 12 m. Assuming constant deceleration, how much force will the parent need to exert on the child? Is this force achievable by an average parent?

**94.** A simple pendulum consists of a small object of mass $m$ (the "bob") suspended by a cord of length $\ell$ (Fig. 7–34) of negligible mass. A force $\vec{\mathbf{F}}$ is applied in the horizontal direction (so $\vec{\mathbf{F}} = F\hat{\mathbf{i}}$), moving the bob very slowly so the acceleration is essentially zero. (Note that the magnitude of $\vec{\mathbf{F}}$ will need to vary with the angle $\theta$ that the cord makes with the vertical at any moment.) (*a*) Determine the work done by this force, $\vec{\mathbf{F}}$, to move the pendulum from $\theta = 0$ to $\theta = \theta_0$. (*b*) Determine the work done by the gravitational force on the bob, $\vec{\mathbf{F}}_G = m\vec{\mathbf{g}}$, and the work done by the force $\vec{\mathbf{F}}_T$ that the cord exerts on the bob.

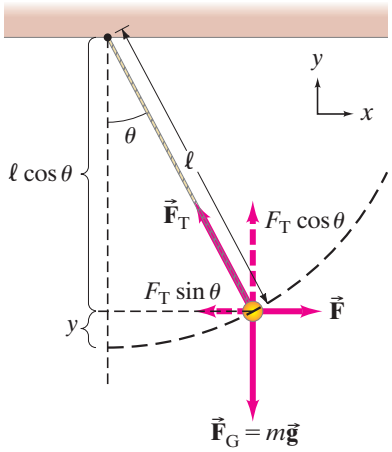

**FIGURE 7–34** Problem 94.

**95.** As an object moves along the $x$ axis from $x = 0.0\text{ m}$ to $x = 20.0\text{ m}$ it is acted upon by a force given by $F = (100 - (x - 10)^2)\text{ N}$. Determine the work done by the force on the object: (*a*) by first sketching the $F$ vs. $x$ graph and estimating the area under this curve; (*b*) by evaluating the integral $\int_{x=0.0\text{ m}}^{x=20\text{ m}} F\,dx$.

**96.** A small mass $m$ hangs at rest from a vertical rope of length $\ell$ that is fixed to the ceiling. A force $\vec{\mathbf{F}}$ then pushes on the mass, perpendicular to the taut rope at all times, until the rope is oriented at an angle $\theta = \theta_0$ and the mass has been raised by a vertical distance $h$ (Fig. 7–35). Assume the force's magnitude $F$ is adjusted so that the mass moves at constant speed along its curved trajectory. Show that the work done by $\vec{\mathbf{F}}$ during this process equals $mgh$, which is equivalent to the amount of work it takes to slowly lift a mass $m$ straight up by a height $h$. [*Hint*: When the angle is increased by $d\theta$ (in radians), the mass moves along an arc length $ds = \ell\,d\theta$.]

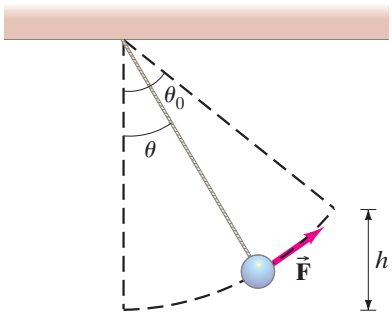

**FIGURE 7–35** Problem 96.

**97.** A 1200-kg car rolling on a horizontal surface has speed $v = 66$ km/h when it strikes a horizontal coiled spring and is brought to rest in a distance of 2.2 m. What is the spring constant of the spring?

**98.** A hand exerts a constant horizontal force on a block that is free to slide on a frictionless surface (Fig. 7–36). The block starts from rest at point A, and by the time it has traveled a distance $d$ to point B it is traveling with speed $v_B$. When the block has traveled another distance $d$ to point C, what will its speed be? Explain your reasoning.

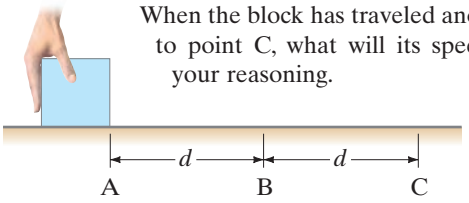

**FIGURE 7–36**
Question 98.

**99.** *Stretchable ropes* are used to safely arrest the fall of rock *climbers*. Suppose one end of a rope with unstretched length $\ell$ is anchored to a cliff and a climber of mass $m$ is attached to the other end. When the climber is a height $\ell$ above the anchor point, he slips and falls under the force of gravity for a distance $2\ell$, after which the rope becomes taut and stretches a distance $x$ as it stops the climber (see Fig. 7–37). Assume a stretchy rope behaves as a spring with spring constant $k$. (*a*) Applying the work-energy principle, show that

$$x = \frac{mg}{k}\left[1 + \sqrt{1 + \frac{4k\ell}{mg}}\right].$$

(*b*) Assuming $m = 85$ kg, $\ell = 8.0$ m and $k = 850$ N/m, determine $x/\ell$ (the fractional stretch of the rope) and $kx/mg$ (the force that the rope exerts on the climber compared to his own weight) at the moment the climber's fall has been stopped.

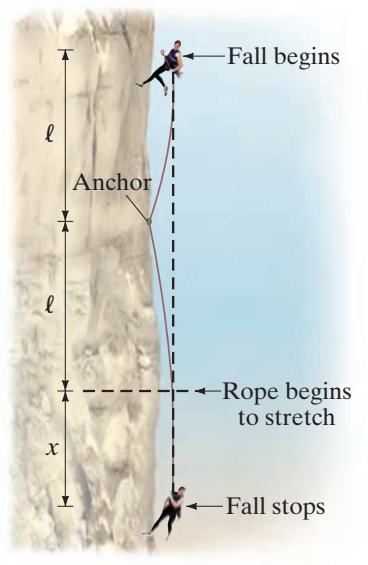

**FIGURE 7–37**
Problem 99.

**100.** A 2.0-kg block slides across a rough surface with a constant coefficient of kinetic friction of 0.50 (Fig. 7–38a). The block starts at $x = 0$ with an initial velocity of 4.9 m/s. Pushing the block is a force directed at 36.8° below the horizontal and whose magnitude increases with position as shown in Fig. 7–38b. (*a*) What is the initial kinetic energy of the block? (*b*) How much work is done by the applied force in the first 4.0 m? (*c*) What is the magnitude of the friction force at 0.0 m, and at 4.0 m? (*d*) Draw a line on the graph showing the magnitude of the friction force versus distance $x$. (*e*) What is the speed of the block at 4.0 m?

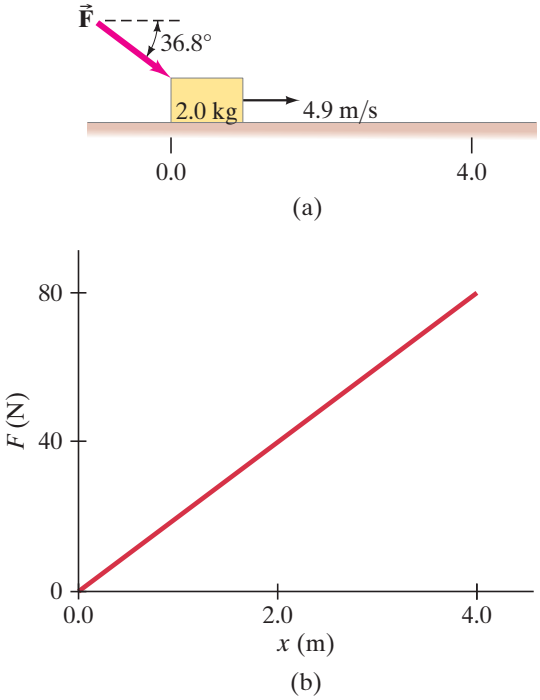

**FIGURE 7–38** Problem 100.

## ANSWERS TO EXERCISES

**A:** (*c*).
**B:** (*b*).
**C:** (*b*) $2.0 \times 10^5$ J. That is, less. (Because $v$ is squared.)
**D:** No, because the speed $v$ would be the square root of a negative number, which is not real.
**E:** (*a*) $\sqrt{2}$, (*b*) 4.

A polevaulter running toward the high bar has kinetic energy. When he plants the pole and puts his weight on it, his kinetic energy gets transformed: first into elastic potential energy of the bent pole and then into gravitational potential energy as his body rises. As he crosses the bar, the pole is straight and has given up all its elastic potential energy to the athlete's gravitational potential energy. Nearly all his initial kinetic energy has disappeared, becoming gravitational potential energy of his body at the great height of the bar (world record is over 6 m), which is exactly what he wants. In these, and all other energy transformations that continually take place in the world, the total energy is always conserved. Indeed, the conservation of energy is one of the most fundamental laws of physics, and finds applications in a wide range of fields.

**CHAPTER-OPENING QUESTION—Guess now!**

A skier starts at the top of a hill. On which run does her gravitational potential energy change the most: **(a)**, **(b)**, **(c)**, or **(d)**; or are they **(e)** all the same? On which run would her speed at the bottom be the fastest if the runs are icy and we assume no friction or air resistance? Recognizing that there is always some friction, answer the above two questions again. List your four answers now.

This chapter continues the discussion of the concepts of work and energy begun in Chapter 7 and introduces additional types of energy, in particular potential energy. Now we will see why the concept of energy is so important. The reason, ultimately, is that energy is conserved—the total energy *always* remains constant in any process. That a quantity can be defined which remains constant, as far as our best experiments can tell, is a remarkable statement about nature. The law of conservation of energy is, in fact, one of the great unifying principles of science.

The law of conservation of energy also gives us another tool, another approach, to solving problems. There are many situations for which an analysis based on Newton's laws would be difficult or impossible—the forces may not be known or accessible to measurement. But often these situations can be dealt with using the law of conservation of energy.

In this Chapter we will mainly treat objects as if they were particles or rigid objects that undergo only translational motion, with no internal or rotational motion.

## 8–1 Conservative and Nonconservative Forces

We will find it important to categorize forces into two types: conservative and nonconservative. By definition, we call any force a **conservative force** if

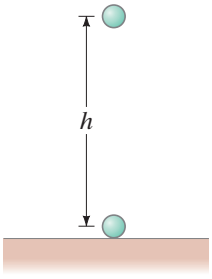
*DEFINITION OF CONSERVATIVE FORCE*

> **the work done by the force on an object moving from one point to another depends only on the initial and final positions of the object, and is independent of the particular path taken.**

A conservative force can be a function *only of position*, and cannot depend on other variables like time or velocity.

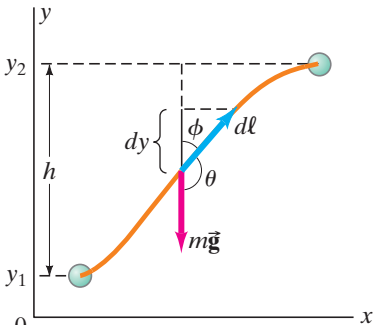
We can readily show that the force of gravity is a conservative force. The gravitational force (exerted by the Earth) on an object of mass $m$ near the Earth's surface is $\vec{\mathbf{F}} = m\vec{\mathbf{g}}$, where $\vec{\mathbf{g}}$ is a constant. The work done by this gravitational force on an object that falls a vertical distance $h$ is $W_G = Fd = mgh$ (see Fig. 8–1a). Now suppose that instead of moving vertically downward or upward, an object follows some arbitrary path in the $xy$ plane, as shown in Fig. 8–1b. The object starts at a vertical height $y_1$ and reaches a height $y_2$, where $y_2 - y_1 = h$. To calculate the work done by gravity, $W_G$, we use Eq. 7–7:

$$W_G = \int_1^2 \vec{\mathbf{F}}_G \cdot d\vec{\boldsymbol{\ell}} = \int_1^2 mg\cos\theta\, d\ell.$$



We now let $\phi = 180° - \theta$ be the angle between $d\vec{\boldsymbol{\ell}}$ and its vertical component $dy$, as shown in Fig. 8–1b. Then, since $\cos\theta = -\cos\phi$ (Appendix A–9) and $dy = d\ell\cos\phi$, we have

$$W_G = -\int_{y_1}^{y_2} mg\, dy = -mg(y_2 - y_1). \qquad \textbf{(8–1)}$$



Since $(y_2 - y_1)$ is the vertical height $h$, we see that the work done depends only on the vertical height and does *not* depend on the particular path taken! Hence, by definition, gravity is a conservative force.

Note that in the case shown in Fig. 8–1b, $y_2 > y_1$ and therefore the work done by gravity is negative. If on the other hand $y_2 < y_1$, so that the object is falling, then $W_G$ is positive.

**FIGURE 8–1** Object of mass $m$: (a) falls a height $h$ vertically; (b) is raised along an arbitrary two-dimensional path.

(a)

(b)

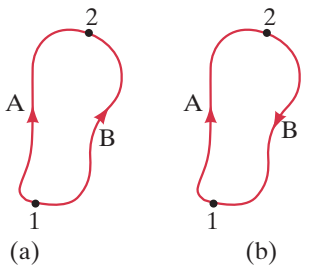


**FIGURE 8–2** (a) A tiny object moves from point 1 to point 2 via two different paths, A and B. (b) The object makes a round trip, via path A from point 1 to point 2 and via path B back to point 1.

We can give the definition of a conservative force in another, completely equivalent way:

> **a force is conservative if the net work done by the force on an object moving around any closed path is zero**.

To see why this second definition is equivalent to our first definition on page 195, consider a small object that moves from point 1 to point 2 via either of two paths labeled A and B in Fig. 8–2a. If we assume a conservative force acts on the object, the work done by this force is the same whether the object takes path A or path B, by our first definition. This work to get from point 1 to point 2 we will call $W$. Now consider the round trip shown in Fig. 8–2b. The object moves from 1 to 2 via path A and our force does work $W$ on the object. Our object then returns to point 1 via path B. How much work is done during the return? In going from 1 to 2 via path B the work done is $W$, which by definition equals $\int_1^2 \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}}$. In doing the reverse, going from 2 to 1 via path B, the force $\vec{\mathbf{F}}$ at each point is the same, but $d\vec{\boldsymbol{\ell}}$ is directed in precisely the opposite direction. Consequently $\vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}}$ has the opposite sign at each point so the total work done on our object in making the return trip from 2 to 1 must be $\int_2^1 \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}} = -W$. Hence the total work done in going from 1 to 2 and back to 1 is $W + (-W) = 0$, which proves the equivalence of the two above definitions for a conservative force.

The second definition of a conservative force illuminates an important aspect of such a force: the **work done by a conservative force is recoverable** in the sense that if positive work is done on an object on one part of a closed path, an equivalent amount of negative work will be done on the object on its return.

As we saw above, the force of gravity is conservative, and so is the elastic force $(F = -kx)$, as we see in the next Section.

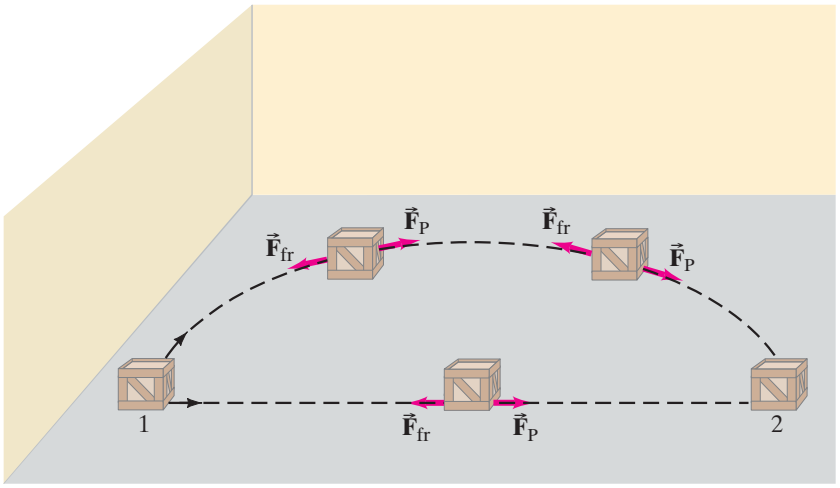

**FIGURE 8–3** A crate is pushed slowly at constant speed across a rough floor from position 1 to position 2 via two paths: one straight and one curved. The pushing force $\vec{\mathbf{F}}_{\mathrm{P}}$ is in the direction of motion at each point. (And the friction force opposes the motion.) Hence for a constant magnitude pushing force, the work $F_{\mathrm{P}}$ does is $W = F_{\mathrm{P}}d$, so if the distance traveled $d$ is greater (as for the curved path), then $W$ is greater. The work done does not depend *only* on points 1 and 2; it also depends on the path taken.

**TABLE 8–1 Conservative and Nonconservative Forces**

| Conservative Forces | Nonconservative Forces |
|---|---|
| Gravitational | Friction |
| Elastic | Air resistance |
| Electric | Tension in cord |
| | Motor or rocket propulsion |
| | Push or pull by a person |

Many forces, such as friction and a push or pull exerted by a person, are not conservative: they are **nonconservative forces** because any work they do depends on the path. For example, if you push a crate across a floor from one point to another, the work you do depends on whether the path taken is straight, or is curved. As shown in Fig. 8–3, if a crate is pushed slowly from point 1 to point 2 along the longer semicircular path, you do more work against friction than if you push it along the straight path. You do more work on the curved path because the distance is greater and, unlike the gravitational force, the pushing force $\vec{\mathbf{F}}_{\mathrm{P}}$ is in the direction of motion at each point. Thus the work done by the person in Fig. 8–3 does not depend *only* on points 1 and 2; it depends also on the path taken. The force of kinetic friction ($F_{\mathrm{fr}}$), also shown in Fig. 8–3, always opposes the motion; it too is a nonconservative force, and we discuss how to treat it later in this Chapter (Section 8–6). Table 8–1 lists a few conservative and nonconservative forces.

# 8–2 Potential Energy

In Chapter 7 we discussed the energy associated with a moving object, which is its kinetic energy $K = \frac{1}{2}mv^2$. Now we introduce **potential energy**, which is the energy associated with *forces* that depend on the position or configuration of an object (or objects) relative to the surroundings. Various types of potential energy can be defined, and each type is associated with a particular conservative force.

The wound-up spring of a toy is an example of potential energy. The spring acquired potential energy because work was done *on* it by the person winding the toy. As the spring unwinds, it exerts a force and does work to make the toy move.

## Gravitational Potential Energy

A common example of potential energy is *gravitational potential energy*. A brick held high above the ground has potential energy because of its position relative to the Earth. The raised brick has the ability to do work: if it is released, it falls to the ground due to the gravitational force, and can do work on a stake, driving it into the ground.

Let us seek the form for the gravitational potential energy of an object near the surface of the Earth. For an object of mass $m$ to be lifted vertically, an upward force at least equal to its weight, $mg$, must be exerted on it, say by a person's hand. To lift the object without acceleration, assuming gravity is the only other force acting on it, the person exerts an "external force," $F_{\text{ext}} = mg$. If it is raised a vertical height $h$, from position $y_1$ to $y_2$ in Fig. 8–4 (upward direction chosen positive), a person does work equal to the product of the "external" force she exerts, $F_{\text{ext}} = mg$ upward, multiplied by the vertical displacement $h$. That is,

$$W_{\text{ext}} = \vec{\mathbf{F}}_{\text{ext}} \cdot \vec{\mathbf{d}} = mgh\cos 0^\circ = mgh = mg(y_2 - y_1)$$

where both $\vec{\mathbf{F}}_{\text{ext}}$ and $\vec{\mathbf{d}}$ point upward. Gravity is also acting on the object as it moves from $y_1$ to $y_2$, and does work $W_{\text{G}}$ on the object equal to

$$W_{\text{G}} = \vec{\mathbf{F}}_{\text{G}} \cdot \vec{\mathbf{d}} = mgh\cos 180^\circ = -mgh = -mg(y_2 - y_1),$$

where $\theta = 180^\circ$ because $\vec{\mathbf{F}}_{\text{G}}$ and $\vec{\mathbf{d}}$ point in opposite directions. Since $\vec{\mathbf{F}}_{\text{G}}$ is downward and $\vec{\mathbf{d}}$ is upward, $W_{\text{G}}$ is negative. If the object follows an arbitrary path, as in Fig. 8–1b, the work done by gravity still depends only on the change in vertical height (Eq. 8–1): $W_{\text{G}} = -mg(y_2 - y_1) = -mgh$.

Next, if we allow the object at $y_2$ in Fig. 8–4 to fall freely from rest under the action of gravity, it acquires a velocity given by $v^2 = 2gh$ (Eq. 2–12c) after falling a height $h$. It then has kinetic energy $\frac{1}{2}mv^2 = \frac{1}{2}m(2gh) = mgh$, and if it strikes a stake it can do work on the stake equal to $mgh$.

Thus, to raise an object of mass $m$ to a height $h$ *requires* an amount of work equal to $mgh$. And once at height $h$, the object has the *ability* to do an amount of work equal to $mgh$. We can say that the work done in lifting the object has been stored as gravitational potential energy.

Indeed, we can define the *change* in gravitational potential energy $U$, when an object is moved from height $y_1$ to height $y_2$, as equal to the work done by the net external force that accomplishes this without acceleration:

$$\Delta U = U_2 - U_1 = W_{\text{ext}} = mg(y_2 - y_1). \qquad \textbf{(8–2a)}$$

A more direct way to define the *change in gravitational potential energy*, $\Delta U$, is that it is equal to the *negative of the work done by gravity* itself in the process (note Eq. 8–1):

$$\Delta U = U_2 - U_1 = -W_{\text{G}} = mg(y_2 - y_1). \qquad \textbf{(8–2b)}$$

Equations 8–2 define the change in gravitational potential energy when an object of mass $m$ moves between two points near the surface of the Earth. The **gravitational potential energy**, $U$, at any point a vertical height $y$ above some reference point (the origin of the coordinate system) can be defined as

$$U_{\text{grav}} = mgy. \qquad \text{[gravity only]} \quad \textbf{(8–3)}$$

Note that the potential energy is associated with the force of gravity between the Earth and the mass $m$. Hence $U_{\text{grav}}$ represents the gravitational potential energy, not simply of the mass $m$ alone, but of the mass–Earth system.

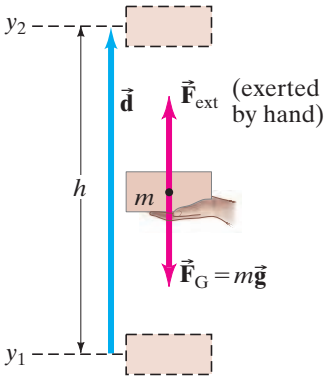

**FIGURE 8–4** A person exerts an upward force $F_{\text{ext}} = mg$ to lift a brick from $y_1$ to $y_2$.

**CAUTION**
*Change in potential energy is what is physically meaningful*

**CAUTION**
*Potential energy belongs to a system, not to a single object*

Gravitational potential energy depends on the *vertical height* of the object *above some reference level*, $U = mgy$. Sometimes you may wonder from what point to measure $y$. The gravitational potential energy of a book held high above a table, for example, depends on whether we measure $y$ from the top of the table, or from the floor, or from some other reference level. But what is physically important in any situation is the *change* in potential energy, $\Delta U$, because that is what is related to the work done, and it is $\Delta U$ that can be measured. We can thus choose to measure $y$ from any reference level that is convenient, but we must *choose the reference level at the start and be consistent throughout*. The *change* in potential energy between any two points does not depend on this choice.

Potential energy belongs to a *system*, and not to a single object alone. Potential energy is associated with a force, and a force on one object is always exerted by some other object. Thus potential energy is a property of the system as a whole. For an object raised to a height $y$ above the Earth's surface, the change in gravitational potential energy is $mgy$. The system here is the object plus the Earth, and properties of both are involved: object ($m$) and Earth ($g$). In general, a **system** is one or more objects that we choose to study.

The choice of what makes up a system is always ours, and we often try to choose a simple system. Below, when we deal with the potential energy of an object in contact with a spring, our system will be the object and the spring.

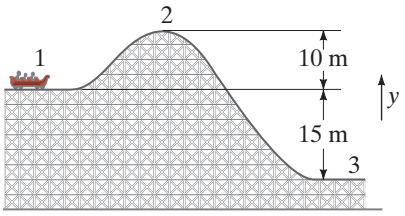

**FIGURE 8–5** Example 8–1.

**EXAMPLE 8–1 Potential energy changes for a roller coaster.** A 1000-kg roller-coaster car moves from point 1, Fig. 8–5, to point 2 and then to point 3. (*a*) What is the gravitational potential energy at points 2 and 3 relative to point 1? That is, take $y = 0$ at point 1. (*b*) What is the change in potential energy when the car goes from point 2 to point 3? (*c*) Repeat parts (*a*) and (*b*), but take the reference point $(y = 0)$ to be at point 3.

**APPROACH** We are interested in the potential energy of the car–Earth system. We take upward as the positive $y$ direction, and use the definition of gravitational potential energy to calculate the potential energy.

**SOLUTION** (*a*) We measure heights from point 1 $(y_1 = 0)$, which means initially that the gravitational potential energy is zero at $y_1$. At point 2, where $y_2 = 10\,\text{m}$,

$$U_2 = mgy_2 = (1000\,\text{kg})(9.8\,\text{m/s}^2)(10\,\text{m}) = 9.8 \times 10^4\,\text{J}.$$

At point 3, $y_3 = -15\,\text{m}$, since point 3 is below point 1. Therefore,

$$U_3 = mgy_3 = (1000\,\text{kg})(9.8\,\text{m/s}^2)(-15\,\text{m}) = -1.5 \times 10^5\,\text{J}.$$

(*b*) In going from point 2 to point 3, the potential energy change $(U_{\text{final}} - U_{\text{initial}})$ is

$$U_3 - U_2 = (-1.5 \times 10^5\,\text{J}) - (9.8 \times 10^4\,\text{J}) = -2.5 \times 10^5\,\text{J}.$$

The gravitational potential energy decreases by $2.5 \times 10^5\,\text{J}$.

(*c*) Now we set $y_3 = 0$. Then $y_1 = +15\,\text{m}$ at point 1, so the potential energy initially (at point 1) is

$$U_1 = (1000\,\text{kg})(9.8\,\text{m/s}^2)(15\,\text{m}) = 1.5 \times 10^5\,\text{J}.$$

At point 2, $y_2 = 25\,\text{m}$, so the potential energy is

$$U_2 = 2.5 \times 10^5\,\text{J}.$$

At point 3, $y_3 = 0$, so the potential energy is zero. The change in potential energy going from point 2 to point 3 is

$$U_3 - U_2 = 0 - 2.5 \times 10^5\,\text{J} = -2.5 \times 10^5\,\text{J},$$

which is the same as in part (*b*), as it should be.

**NOTE** Work done by gravity depends only on the vertical height, so changes in gravitational potential energy do not depend on the path taken.

**EXERCISE A** By how much does the gravitational potential energy change when a 1200-kg car climbs to the top of a 300-m-tall hill? (*a*) $3.6 \times 10^5\,\text{J}$; (*b*) $3.5 \times 10^6\,\text{J}$; (*c*) 4 J; (*d*) 40 J; (*e*) 39.2 J.

## Potential Energy in General

We have defined the change in gravitational potential energy (Eq. 8–2) to be equal to the negative of the work done by gravity when an object moves from height $y_1$ to $y_2$, which we now write as (see page 195)

$$\Delta U = -W_G = -\int_1^2 \vec{\mathbf{F}}_G \cdot d\vec{\boldsymbol{\ell}}.$$

There are other types of potential energy besides gravitational. Each type of potential energy is associated with a particular conservative force, and can be defined just as for gravity. In general, we define the **change in potential energy associated with a particular conservative force $\vec{\mathbf{F}}$ as the negative of the work done by that force**,

$$\Delta U = U_2 - U_1 = -\int_1^2 \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}} = -W, \qquad \textbf{(8–4)}$$

**when an object goes from position 1 to position 2**. However, we cannot use this definition to define a potential energy for every force. It makes sense only for conservative forces such as gravity, for which the integral depends only on the end points and not on the path taken. It does not apply to nonconservative forces like friction, because the integral in Eq. 8–4 would *not* have a unique value depending only on the end points 1 and 2. Thus the concept of potential energy cannot be defined and is meaningless for a nonconservative force.

*POTENTIAL ENERGY DEFINED*

**CAUTION**

*Potential energy can be defined only for conservative forces*

We can also define the change of potential energy associated with a particular conservative force in an equivalent way as: *the work done by an external (different) force to move the object without acceleration from one position to another.* That is, the external force acts against our conservative force. An example is the work done by a hand lifting an object upward (without acceleration) equals the change in gravitational potential energy.

## Elastic Potential Energy

Consider the simple coil spring shown in Fig. 8–6, whose mass is so small that we can ignore it. The spring has potential energy when it is compressed because, when it is released, it can do work on a ball. Like other elastic materials, a spring is described by Hooke's law (see Section 7–3) as long as the displacement $x$ is not too great. Let us take our coordinate system so the end of the uncompressed spring is at $x = 0$ (Fig. 8–6a) and $x$ is positive to the right. To hold the spring compressed (or stretched) a distance $x$ from its natural (unstretched) length requires the person's hand to exert an external force $F_{ext} = kx$ on the spring (Fig. 8–6b), where $k$ is the *spring constant* (Section 7–3). The spring itself exerts a force (Newton's third law) in the opposite direction on the hand (Fig. 8–6c):

$$F_S = -kx. \qquad \text{[spring force]}$$

The negative sign appears because the force $\vec{\mathbf{F}}_S$ is in the direction opposite to the displacement $x$. We can use the concept of potential energy for a simple (1–D) spring because $F_S$ depends only on position $x$. From Eq. 8–4, the change in potential energy when the spring is compressed or stretched from $x_1 = 0$ (its uncompressed position) to $x_2 = x$ (where $x$ can be + or −) is

$$\Delta U = U(x) - U(0) = -\int_1^2 \vec{\mathbf{F}}_S \cdot d\vec{\boldsymbol{\ell}} = -\int_0^x (-kx)\, dx = \tfrac{1}{2}kx^2.$$

Here, $U(x)$ means the potential energy at $x$, and $U(0)$ means $U$ at $x = 0$. It is usually convenient to choose the potential energy at $x = 0$ to be zero: $U(0) = 0$, so the potential energy of a spring compressed or stretched an amount $x$ from equilibrium is

$$U_{el}(x) = \tfrac{1}{2}kx^2. \qquad \text{[elastic spring]} \qquad \textbf{(8–5)}$$

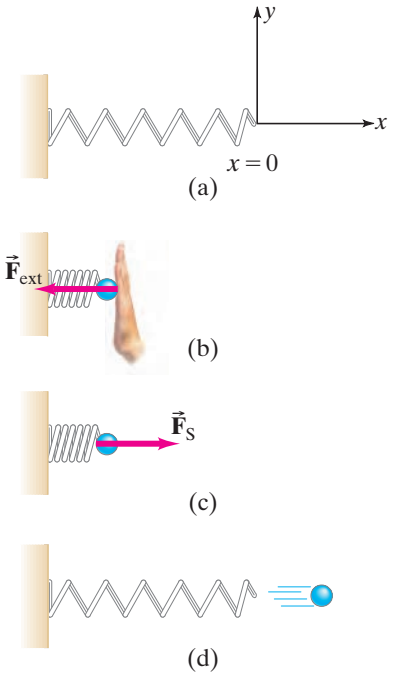

**FIGURE 8–6** (a) Spring in natural (uncompressed) position ($x = 0$). (b) Spring is compressed ($x < 0$) by a person exerting an external force $\vec{\mathbf{F}}_{ext}$ to the left. (c) The spring pushes back with a force $F_S = -kx$, where $F_S > 0$ because $x < 0$. (d) The spring can do work on a ball when released.

## Potential Energy Related to Force (1–D)

In the one-dimensional case, where a conservative force can be written as a function of $x$, say, the potential energy can be written as an indefinite integral

$$U(x) = -\int F(x)\, dx + C, \qquad \textbf{(8–6)}$$

where the constant $C$ can be chosen for convenience since only a change in $U$ is meaningful. We sometimes choose $C$ so that at $x = 0$, $U(0) = 0$.

For other forces we may choose $C$ so that when $x = \infty$ (infinitely far away), then $U(\infty) = 0$. Equation 8–6

$$U(x) = -\int F(x)\,dx + C, \tag{8–6}$$

tells us how to obtain $U(x)$ when given $F(x)$. If, instead, we are given $U(x)$, we can obtain $F(x)$ from Eq. 8–6 by taking the derivative of both sides, remembering that integration and differentiation are inverse operations:

$$\frac{d}{dx}\int F(x)\,dx = F(x).$$

Thus, from Eq. 8–6,

$$F(x) = -\frac{dU(x)}{dx}. \tag{8–7}$$

**EXAMPLE 8–2** **Determine $F$ from $U$.** Suppose $U(x) = -ax/(b^2 + x^2)$, where $a$ and $b$ are constants. What is $F$ as a function of $x$?

**APPROACH** Since $U(x)$ depends only on $x$, this is a one-dimensional problem.

**SOLUTION** Equation 8–7 gives

$$F(x) = -\frac{dU}{dx} = -\frac{d}{dx}\left[-\frac{ax}{b^2 + x^2}\right] = \frac{a}{b^2 + x^2} - \frac{ax}{(b^2 + x^2)^2}2x = \frac{a(b^2 - x^2)}{(b^2 + x^2)^2}.$$

## *Potential Energy in Three Dimensions

In three dimensions, we can write the relation between $\vec{\mathbf{F}}(x, y, z)$ and $U$ as:

$$F_x = -\frac{\partial U}{\partial x}, \quad F_y = -\frac{\partial U}{\partial y}, \quad F_z = -\frac{\partial U}{\partial z},$$

or

$$\vec{\mathbf{F}}(x, y, z) = -\hat{\mathbf{i}}\frac{\partial U}{\partial x} - \hat{\mathbf{j}}\frac{\partial U}{\partial y} - \hat{\mathbf{k}}\frac{\partial U}{\partial z}.$$

Here, $\partial/\partial x$, $\partial/\partial y$ and $\partial/\partial z$ are called partial derivatives; $\partial/\partial x$, for example, means that although $U$ may be a function of $x$, $y$, and $z$, written $U(x, y, z)$, we take the derivative only with respect to $x$ with the other variables held constant.

# 8–3 Mechanical Energy and Its Conservation

Let us consider a conservative system (meaning only conservative forces do work) in which energy is transformed from kinetic to potential or vice versa. Again, we must consider a system because potential energy does not exist for an isolated object. Our system might be a mass $m$ oscillating on the end of a spring or moving in the Earth's gravitational field.

According to the work-energy principle (Eq. 7–11), the net work $W_{\text{net}}$ done *on* an object is equal to its change in kinetic energy $K$:

$$W_{\text{net}} = \Delta K.$$

(If more than one object of our system has work done on it, then $W_{\text{net}}$ and $\Delta K$ can represent the sum for all of them.) If we assume a conservative system, we can write the work done on an object or objects by the conservative forces in terms of the change in total potential energy (see Eq. 8–4) between points 1 and 2:

$$\Delta U_{\text{total}} = -\int_1^2 \vec{\mathbf{F}}_{\text{net}} \cdot d\vec{\boldsymbol{\ell}} = -W_{\text{net}}. \tag{8–8}$$

We combine the previous two equations, letting $U$ be the total potential energy:

$$\Delta K + \Delta U = 0 \quad \text{[conservative forces only]} \tag{8–9a}$$

or

$$(K_2 - K_1) + (U_2 - U_1) = 0. \quad \text{[conservative forces only]} \tag{8–9b}$$

We now define a quantity $E$, called the **total mechanical energy** of our system, as the sum of the kinetic energy plus the potential energy of the system at any moment

$$E = K + U.$$

We can rewrite Eq. 8–9b as

$$K_2 + U_2 = K_1 + U_1 \qquad \text{[conservative forces only]} \quad \textbf{(8–10a)}$$

or

$$E_2 = E_1 = \text{constant.} \qquad \text{[conservative forces only]} \quad \textbf{(8–10b)}$$

CONSERVATION OF MECHANICAL ENERGY

Equations 8–10 express a useful and profound principle regarding the total mechanical energy of a system: namely that it is a **conserved quantity**. The total mechanical energy $E$ remains constant as long as no nonconservative forces do work. That is, the quantity $E = K + U$ at some initial time 1 is equal to $K + U$ at any later time 2.

To say it another way, consider Eq. 8–9a which tells us $\Delta U = -\Delta K$; that is, if the kinetic energy $K$ of a system increases, then the potential energy $U$ must decrease by an equivalent amount to compensate. Thus the total, $K + U$, remains constant:

**If only conservative forces do work, the total mechanical energy of a system neither increases nor decreases in any process. It stays constant—it is conserved.**

CONSERVATION OF MECHANICAL ENERGY

This is the **principle of conservation of mechanical energy** for conservative forces.

We now see the reason for the term "conservative force"—because for such forces, mechanical energy is conserved.

If only one object of a system† has significant kinetic energy, Eqs. 8–10 become

$$E = \tfrac{1}{2}mv^2 + U = \text{constant.} \qquad \text{[conservative forces only]} \quad \textbf{(8–11a)}$$

If we let $v_1$ and $U_1$ represent the velocity and potential energy at one instant, and $v_2$ and $U_2$ represent them at a second instant, then we can rewrite this as

$$\tfrac{1}{2}mv_1^2 + U_1 = \tfrac{1}{2}mv_2^2 + U_2. \qquad \text{[conservative system]} \quad \textbf{(8–11b)}$$

From this equation we can see again that it doesn't make any difference where we choose the potential energy to be zero: adding a constant to $U$ merely adds the same constant to both sides of Eq. 8–11b, and these cancel. A constant also doesn't affect the force obtained using Eq. 8–7, $F = -dU/dx$, since the derivative of a constant is zero. Only *changes* in the potential energy matter.

**CAUTION**
*It is $\Delta U$ that matters*

# 8–4 Problem Solving Using Conservation of Mechanical Energy

A simple example of the conservation of mechanical energy (neglecting air resistance) is a rock allowed to fall due to Earth's gravity from a height $h$ above the ground, as shown in Fig. 8–7. If the rock starts from rest, all of the initial energy is potential energy. As the rock falls, the potential energy $mgy$ decreases (because $y$ decreases), but the rock's kinetic energy increases to compensate, so that the sum of the two remains constant. At any point along the path, the total mechanical energy is given by

$$E = K + U = \tfrac{1}{2}mv^2 + mgy$$

where $y$ is the rock's height above the ground at a given instant and $v$ is its speed at that point. If we use subscript 1 for the rock at one point along its path (maybe the initial point), and subscript 2 when it is at some other point, then we can write

total mechanical energy at point 1 = total mechanical energy at point 2

or (see also Eq. 8–11b)

$$\tfrac{1}{2}mv_1^2 + mgy_1 = \tfrac{1}{2}mv_2^2 + mgy_2. \qquad \text{[gravity only]} \quad \textbf{(8–12)}$$

Just before the rock hits the ground, where we chose $y = 0$, all of the initial potential energy will have been transformed into kinetic energy.

†For an object falling under the influence of Earth's gravity, the kinetic energy of the Earth moving upwards can usually be ignored. For a mass oscillating at the end of a spring, the mass of the spring, and hence its kinetic energy, can often be ignored.

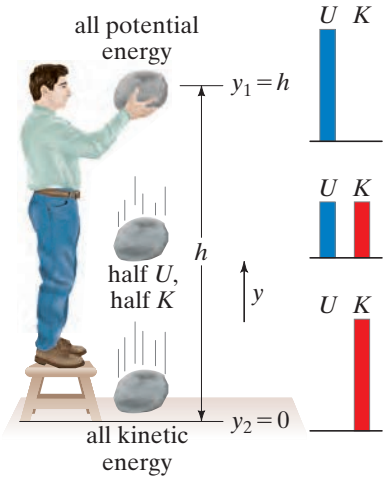

**FIGURE 8–7** The rock's potential energy changes to kinetic energy as it falls. Note bar graphs representing the amount of potential energy $U$ and kinetic energy $K$ for three different positions.

**EXAMPLE 8–3** **Falling rock.** If the original height of the rock in Fig. 8–7 is $y_1 = h = 3.0\,\text{m}$, calculate the rock's speed when it has fallen to 1.0 m above the ground.

**APPROACH** We apply the principle of conservation of mechanical energy, Eq. 8–12, with only gravity acting on the rock. We choose the ground as our reference level $(y = 0)$.

**SOLUTION** At the moment of release (point 1) the rock's position is $y_1 = 3.0\,\text{m}$ and it is at rest: $v_1 = 0$. We want to find $v_2$ when the rock is at position $y_2 = 1.0\,\text{m}$. Equation 8–12 gives

$$\tfrac{1}{2}mv_1^2 + mgy_1 = \tfrac{1}{2}mv_2^2 + mgy_2.$$

The $m$'s cancel out and $v_1 = 0$ so

$$gy_1 = \tfrac{1}{2}v_2^2 + gy_2.$$

Solving for $v_2$ we find

$$v_2 = \sqrt{2g(y_1 - y_2)} = \sqrt{2(9.8\,\text{m/s}^2)[(3.0\,\text{m}) - (1.0\,\text{m})]} = 6.3\,\text{m/s}.$$

The rock's speed 1.0 m above the ground is 6.3 m/s downward.

**NOTE** The velocity of the rock is independent of the rock's mass.

**EXERCISE B** In Example 8–3, what is the rock's speed just before it hits the ground? (*a*) 6.5 m/s; (*b*) 7.0 m/s; (*c*) 7.7 m/s; (*d*) 8.3 m/s; (*e*) 9.8 m/s.

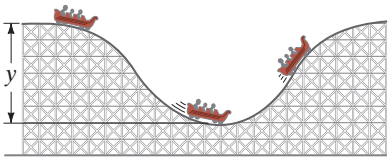

**FIGURE 8–8** A roller-coaster car (shown here in 3 different positions on the track) moving without friction illustrates the conservation of mechanical energy.

Equation 8–12 can be applied to any object moving without friction under the action of gravity. For example, Fig. 8–8 shows a roller-coaster car starting from rest at the top of a hill, and coasting without friction to the bottom and up the hill on the other side. True, there is another force besides gravity acting on the car, the normal force exerted by the tracks. But the normal force acts perpendicular to the direction of motion at each point and so does zero work. We ignore rotational motion of the car's wheels and treat the car as a particle undergoing simple translation. Initially, the car has only potential energy. As it coasts down the hill, it loses potential energy and gains kinetic energy, but the sum of the two remains constant. At the bottom of the hill it has its maximum kinetic energy, and as it climbs up the other side the kinetic energy changes back to potential energy. When the car comes to rest again at the same height from which it started, all of its energy will be potential energy. Given that the gravitational potential energy is proportional to the vertical height, energy conservation tells us that (in the absence of friction) the car comes to rest at a height equal to its original height. If the two hills are the same height, the car will just barely reach the top of the second hill when it stops. If the second hill is lower than the first, not all of the car's kinetic energy will be transformed to potential energy so the car will have speed to continue over the top and down the other side. If the second hill is higher, the car will reach a maximum height on it equal to its original height on the first hill. This is true (in the absence of friction) no matter how steep the hill is, since potential energy depends only on the vertical height.

**EXAMPLE 8–4** **Roller-coaster car speed using energy conservation.** Assuming the height of the hill in Fig. 8–8 is 40 m, and the roller-coaster car starts from rest at the top, calculate (*a*) the speed of the roller-coaster car at the bottom of the hill, and (*b*) at what height it will have half this speed. Take $y = 0$ at the bottom of the hill. Ignore frictional forces.

**APPROACH** We use conservation of mechanical energy. We choose point 1 to be where the car starts from rest $(v_1 = 0)$ at the top of the hill $(y_1 = 40\,\text{m})$. In part (*a*), point 2 is the bottom of the hill, which we choose as our reference level, so $y_2 = 0$. In part (*b*) we let $y_2$ be the unknown.

**SOLUTION** (*a*) We use Eq. 8–12 with $v_1 = 0$ and $y_2 = 0$, which gives

$$mgy_1 = \tfrac{1}{2}mv_2^2$$

or

$$v_2 = \sqrt{2gy_1} = \sqrt{2(9.8\,\text{m/s}^2)(40\,\text{m})} = 28\,\text{m/s}.$$

(*b*) Now $y_2$ is the unknown. We again use conservation of energy,

$$\tfrac{1}{2}mv_1^2 + mgy_1 = \tfrac{1}{2}mv_2^2 + mgy_2,$$

but now $v_2 = \frac{1}{2}(28\,\text{m/s}) = 14\,\text{m/s}$ and $v_1 = 0$. Solving for the unknown $y_2$ gives

$$y_2 = y_1 - \frac{v_2^2}{2g} = 40\,\text{m} - \frac{(14\,\text{m/s})^2}{2(9.8\,\text{m/s}^2)} = 30\,\text{m}.$$

That is, the car has a speed of 14 m/s when it is 30 *vertical* meters above the lowest point, both when descending the left-hand hill and when ascending the right-hand hill.

The mathematics of the roller-coaster Example 8–4 is almost the same as for the rock in Example 8–3. But there is an important difference between them. In Example 8–3 the motion is all vertical and could have been solved using force, acceleration, and the kinematic equations (Eqs. 2–12). For the "friction-free" roller coaster of Example 8–4, where the motion is not vertical, we could *not* have used Eqs. 2–12 because the acceleration $a$ is not constant on the curved track. But energy conservation gave us the answer readily.

**CONCEPTUAL EXAMPLE 8–5** **Speeds on two water slides.** Two water slides at a pool are shaped differently, but start at the same height $h$ (Fig. 8–9). Two riders, Paul and Jeanne, start from rest at the same time on different slides. (*a*) Which rider, Paul or Jeanne, is traveling faster at the bottom? (*b*) Which rider makes it to the bottom first? Ignore friction and assume both slides have the same path length.

**RESPONSE** (*a*) Each rider's initial potential energy $mgh$ gets transformed to kinetic energy, so the speed $v$ at the bottom is obtained from $\frac{1}{2}mv^2 = mgh$. The mass cancels and so the speed will be the same, regardless of the mass of the rider. Since they descend the same vertical height, they will finish with the same speed. (*b*) Note that Jeanne is consistently at a lower elevation than Paul at any instant, until the end. This means she has converted her potential energy to kinetic energy earlier. Consequently, she is traveling faster than Paul at each moment during the trip, and so gets to the bottom first.

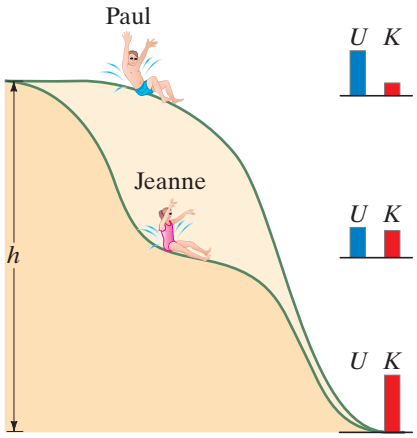

**FIGURE 8–9** Example 8–5. On the right are bar graphs for potential and kinetic energy, as in Fig. 8–7.

**EXERCISE C** Two balls are released from the same height above the floor. Ball A falls freely through the air, whereas ball B slides on a curved frictionless track to the floor. How do the speeds of the balls compare when they reach the floor?

There are many interesting examples of the conservation of energy in sports, such as the pole vault illustrated in Fig. 8–10. We often have to make approximations, but the sequence of events in broad outline for the pole vault is as follows. The initial kinetic energy of the running athlete is transformed into elastic potential energy of the bending pole and, as the athlete leaves the ground, into gravitational potential energy. When the vaulter reaches the top and the pole has straightened out again, the energy has all been transformed into gravitational potential energy (we ignore the vaulter's low horizontal speed over the bar). The pole does not supply any energy, but it acts as a device to *store* energy and thus aid in the transformation of kinetic energy into gravitational potential energy, which is the net result. The energy required to pass over the bar depends on how high the center of mass (CM) of the vaulter must be raised. (The CM is where we can treat the object as a "point" object for translational motion, as discussed in Chapter 9.)

**FIGURE 8–10** Transformation of energy during a pole vault: $K \rightarrow U_{\text{el}} \rightarrow U_{\text{G}}$.

**PHYSICS APPLIED**
*Sports*

**FIGURE 8–11** By bending her body, a pole vaulter can keep her center of mass so low that it may even pass below the bar.

By bending their bodies, pole vaulters keep their CM so low that it can actually pass slightly beneath the bar (Fig. 8–11), thus enabling them to cross over a higher bar than would otherwise be possible.

**EXAMPLE 8–6 ESTIMATE** **Pole vault.** Estimate the kinetic energy and the speed required for a 70-kg pole vaulter to just pass over a bar 5.0 m high. Assume the vaulter's center of mass is initially 0.90 m off the ground and reaches its maximum height at the level of the bar itself.

**APPROACH** We equate the total energy just before the vaulter places the end of the pole onto the ground (and the pole begins to bend and store potential energy) with the vaulter's total energy when passing over the bar (we ignore the small amount of kinetic energy at this point). We choose the initial position of the vaulter's center of mass to be $y_1 = 0$. The vaulter's center of mass must then be raised to a height $y_2 = 5.0\,\text{m} - 0.9\,\text{m} = 4.1\,\text{m}$.

**SOLUTION** We use Eq. 8–12,

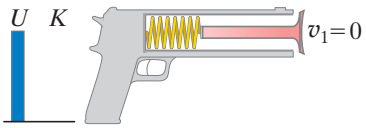
$$\tfrac{1}{2}mv_1^2 + 0 = 0 + mgy_2$$

so

$$K_1 = \tfrac{1}{2}mv_1^2 = mgy_2 = (70\,\text{kg})(9.8\,\text{m/s}^2)(4.1\,\text{m}) = 2.8\times10^3\,\text{J}.$$

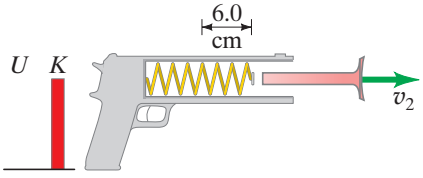
The speed is

$$v_1 = \sqrt{\frac{2K_1}{m}} = \sqrt{\frac{2(2800\,\text{J})}{70\,\text{kg}}} = 8.9\,\text{m/s} \approx 9\,\text{m/s}.$$



**NOTE** This is an approximation because we have ignored such things as the vaulter's speed while crossing over the bar, and mechanical energy transformed when the pole is planted in the ground. All would increase the needed initial kinetic energy.

As another example of the conservation of mechanical energy, let us consider an object of mass $m$ connected to a compressed horizontal spring (Fig. 8–6) whose own mass can be neglected and whose spring constant is $k$. When the spring is released, the mass $m$ has speed $v$ at any moment. The potential energy (PE) of the system (object plus spring) is $\frac{1}{2}kx^2$, where $x$ is the displacement of the spring from its unstretched length. If neither friction nor any other force is acting, conservation of mechanical energy tells us that



$$\tfrac{1}{2}mv_1^2 + \tfrac{1}{2}kx_1^2 = \tfrac{1}{2}mv_2^2 + \tfrac{1}{2}kx_2^2, \qquad \text{[elastic PE only]} \quad \textbf{(8–13)}$$

where the subscripts 1 and 2 refer to the velocity and displacement at two different moments.

**FIGURE 8–12** Example 8–7. (a) A dart is pushed against a spring, compressing it 6.0 cm. The dart is then released, and in (b) it leaves the spring at velocity $v_2$.

(a) $E = \frac{1}{2}kx_1^2$

(b) $E = \frac{1}{2}mv_2^2$

**EXAMPLE 8–7** **Toy dart gun.** A dart of mass 0.100 kg is pressed against the spring of a toy dart gun as shown in Fig. 8–12a. The spring (with spring constant $k = 250\,\text{N/m}$ and ignorable mass) is compressed 6.0 cm and released. If the dart detaches from the spring when the spring reaches its natural length $(x = 0)$, what speed does the dart acquire?

**APPROACH** The dart is initially at rest (point 1), so $K_1 = 0$. We ignore friction and use conservation of mechanical energy; the only potential energy is elastic.

**SOLUTION** We use Eq. 8–13 with point 1 being at the maximum compression of the spring, so $v_1 = 0$ (dart not yet released) and $x_1 = -0.060\,\text{m}$. Point 2 we choose to be the instant the dart flies off the end of the spring (Fig. 8–12b), so $x_2 = 0$ and we want to find $v_2$. Thus Eq. 8–13 can be written

$$0 + \tfrac{1}{2}kx_1^2 = \tfrac{1}{2}mv_2^2 + 0.$$

Then

$$v_2^2 = \frac{kx_1^2}{m} = \frac{(250\,\text{N/m})(-0.060\,\text{m})^2}{(0.100\,\text{kg})} = 9.0\,\text{m}^2/\text{s}^2,$$

and $v_2 = \sqrt{v_2^2} = 3.0\,\text{m/s}$.

**EXAMPLE 8–8** **Two kinds of potential energy.** A ball of mass $m = 2.60\,\text{kg}$, starting from rest, falls a vertical distance $h = 55.0\,\text{cm}$ before striking a vertical coiled spring, which it compresses an amount $Y = 15.0\,\text{cm}$ (Fig. 8–13). Determine the spring constant $k$ of the spring. Assume the spring has negligible mass, and ignore air resistance. Measure all distances from the point where the ball first touches the uncompressed spring (let $y = 0$ at this point).

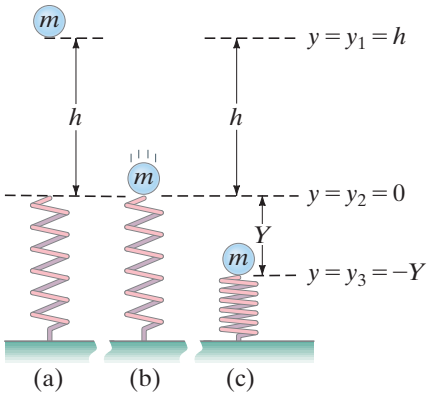


**FIGURE 8–13** Example 8–8.

**APPROACH** The forces acting on the ball are the gravitational pull of the Earth and the elastic force exerted by the spring. Both forces are conservative, so we can use conservation of mechanical energy, including both types of potential energy. We must be careful, however: gravity acts throughout the fall (Fig. 8–13), whereas the elastic force does not act until the ball touches the spring (Fig. 8–13b). We choose $y$ positive upward, and $y = 0$ at the end of the spring in its natural (uncompressed) state.

**SOLUTION** We divide this solution into two parts. (An alternate solution follows.) *Part 1*: Let us first consider the energy changes as the ball falls from a height $y_1 = h = 0.55\,\text{m}$ (Fig. 8–13a) to $y_2 = 0$, just as it touches the spring, Fig. 8–13b. Our system is the ball acted on by gravity plus the spring (which up to this point doesn't do anything). Thus

$$\begin{aligned} \tfrac{1}{2}mv_1^2 + mgy_1 &= \tfrac{1}{2}mv_2^2 + mgy_2 \\ 0 + mgh &= \tfrac{1}{2}mv_2^2 + 0. \end{aligned}$$

We solve for $v_2 = \sqrt{2gh} = \sqrt{2(9.80\,\text{m/s}^2)(0.550\,\text{m})} = 3.283\,\text{m/s} \approx 3.28\,\text{m/s}$. This is the speed of the ball just as it touches the top of the spring, Fig. 8–13b. *Part 2*: As the ball compresses the spring, Figs. 8–13b to c, there are two conservative forces on the ball—gravity and the spring force. So our conservation of energy equation is

$$\begin{aligned} E_2\,(\text{ball touches spring}) &= E_3\,(\text{spring compressed}) \\ \tfrac{1}{2}mv_2^2 + mgy_2 + \tfrac{1}{2}ky_2^2 &= \tfrac{1}{2}mv_3^2 + mgy_3 + \tfrac{1}{2}ky_3^2. \end{aligned}$$

Substituting $y_2 = 0$, $v_2 = 3.283\,\text{m/s}$, $v_3 = 0$ (the ball comes to rest for an instant), and $y_3 = -Y = -0.150\,\text{m}$, we have

$$\tfrac{1}{2}mv_2^2 + 0 + 0 = 0 - mgY + \tfrac{1}{2}k(-Y)^2.$$

We know $m$, $v_2$, and $Y$, so we can solve for $k$:

$$\begin{aligned} k &= \frac{2}{Y^2}\left[\tfrac{1}{2}mv_2^2 + mgY\right] = \frac{m}{Y^2}\left[v_2^2 + 2gY\right] \\ &= \frac{(2.60\,\text{kg})}{(0.150\,\text{m})^2}\left[(3.283\,\text{m/s})^2 + 2(9.80\,\text{m/s}^2)(0.150\,\text{m})\right] = 1590\,\text{N/m}. \end{aligned}$$

***Alternate Solution*** Instead of dividing the solution into two parts, we can do it all at once. After all, we get to choose what two points are used on the left and right of the energy equation. Let us write the energy equation for points 1 and 3 in Fig. 8–13. Point 1 is the initial point just before the ball starts to fall (Fig. 8–13a), so $v_1 = 0$, and $y_1 = h = 0.550\,\text{m}$. Point 3 is when the spring is fully compressed (Fig. 8–13c), so $v_3 = 0$, $y_3 = -Y = -0.150\,\text{m}$. The forces on the ball in this process are gravity and (at least part of the time) the spring. So conservation of energy tells us

**PROBLEM SOLVING**
*Alternate Solution*

$$\begin{aligned} \tfrac{1}{2}mv_1^2 + mgy_1 + \tfrac{1}{2}k(0)^2 &= \tfrac{1}{2}mv_3^2 + mgy_3 + \tfrac{1}{2}ky_3^2 \\ 0 + mgh + 0 &= 0 - mgY + \tfrac{1}{2}kY^2 \end{aligned}$$

where we have set $y = 0$ for the spring at point 1 because it is not acting: the spring is neither compressed nor stretched. We solve for $k$:

$$k = \frac{2mg(h + Y)}{Y^2} = \frac{2(2.60\,\text{kg})(9.80\,\text{m/s}^2)(0.550\,\text{m} + 0.150\,\text{m})}{(0.150\,\text{m})^2} = 1590\,\text{N/m}$$

just as in our first method of solution.

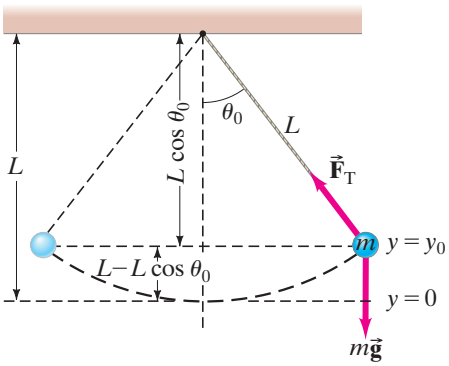

**FIGURE 8–14** Example 8–9: a simple pendulum; $y$ is measured positive upward, from the lowest point of the swing $(y = 0)$.

**EXAMPLE 8–9** **A swinging pendulum.** The simple pendulum shown in Fig. 8–14 consists of a small bob of mass $m$ suspended by a massless cord of length $L$. The bob is released (without a push) at $t = 0$, where the cord makes an angle $\theta = \theta_0$ to the vertical. (*a*) Describe the motion of the bob in terms of kinetic energy and potential energy. Then determine the speed of the bob (*b*) as a function of position $\theta$ as it swings back and forth, and (*c*) at the lowest point of the swing. (*d*) Find the tension in the cord, $\vec{\mathbf{F}}_T$. Ignore friction and air resistance.

**APPROACH** The bob has two forces acting on it at any moment: gravity, $mg$, and the force the cord (in tension) exerts on it, $\vec{\mathbf{F}}_T$. The tension force always acts perpendicular to the motion, so it does no work $(\vec{\mathbf{F}}_T \cdot d\vec{\ell} = 0)$. We need be concerned only with gravity, for which we can write the potential energy. We use the law of conservation of mechanical energy, except in (*d*) where we use Newton's second law.

**SOLUTION** (*a*) At the moment of release, the bob is at rest, so its kinetic energy $K = 0$. As the bob swings down, it loses potential energy and gains kinetic energy. At the lowest point its kinetic energy is a maximum and the potential energy is a minimum. The bob continues its swing until it reaches an equal height and angle $(\theta_0)$ on the opposite side, at which point the potential energy is a maximum and $K = 0$. It continues the swinging motion as $U \rightarrow K \rightarrow U$ and so on, but it can never go higher than $\theta = \pm\theta_0$ (conservation of mechanical energy).

(*b*) The cord is assumed to be massless, so we need to consider only the bob's kinetic energy, and the gravitational potential energy. The mechanical energy of the system is

$$E = \tfrac{1}{2}mv^2 + mgy,$$

where $y$ is the vertical height of the bob at any moment. We take $y = 0$ at the lowest point of the bob's swing. Hence at $t = 0$,

$$y = y_0 = L - L\cos\theta_0 = L(1 - \cos\theta_0)$$

as can be seen in Fig. 8–14. At the moment the bob is released at $y = y_0$,

$$E = mgy_0,$$

since $v = v_0 = 0$. At any other point along the swing

$$E = \tfrac{1}{2}mv^2 + mgy = mgy_0.$$

We solve this for $v$:

$$v = \sqrt{2g(y_0 - y)}.$$

In terms of the angle $\theta$ of the cord, we can write

$$(y_0 - y) = (L - L\cos\theta_0) - (L - L\cos\theta) = L(\cos\theta - \cos\theta_0)$$

so

$$v = \sqrt{2gL(\cos\theta - \cos\theta_0)}.$$

(*c*) At the lowest point, $y = 0$, so

$$v = \sqrt{2gy_0}$$

or

$$v = \sqrt{2gL(1 - \cos\theta_0)}.$$

(*d*) The tension in the cord is the force $\vec{\mathbf{F}}_T$ that the cord exerts on the bob. As we've seen, there is no work done by this force. But we can calculate the force $F_T$ by using Newton's second law $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$ and by noting that at any point the acceleration of the bob in the inward radial direction is $v^2/L$, since the bob is constrained to move in an arc of a circle of radius $L$ (see Eq. 5–1). In the radial direction, $\vec{\mathbf{F}}_T$ acts inward, and a component of gravity equal to $mg\cos\theta$ acts outward along a radius. Hence

$$m\frac{v^2}{L} = F_T - mg\cos\theta.$$

We solve for $F_T$ and use the result of part (*b*) for $v^2$:

$$F_T = m\left(\frac{v^2}{L} + g\cos\theta\right) = 2mg(\cos\theta - \cos\theta_0) + mg\cos\theta$$
$$= (3\cos\theta - 2\cos\theta_0)\,mg.$$

# 8–5 The Law of Conservation of Energy

We have seen that mechanical energy is conserved when conservative forces act. We have seen energy transformed from potential to kinetic (or vice versa), as when a rock (Fig. 8–7) or water (Fig. 8–15a) falls downward, and the total energy is conserved. We have also seen energy conserved when energy is transferred from one object to another, such as a compressed spring giving kinetic energy to a ball or dart (Fig. 8–6 or 8–12). Note that the spring does work on the ball or the dart. Indeed, we can state in general that

**work is done when energy is transformed from one type to another or transferred from one object to another.**

We now take into account nonconservative forces such as friction, since they are important in real situations. For example, consider again the roller-coaster car in Fig. 8–8, but this time let us include friction. The car will not in this case reach the same height on the second hill as it had on the first hill because of friction.

In this, and in other natural processes, the mechanical energy (sum of the kinetic and potential energies) does not remain constant but decreases. Because frictional forces reduce the mechanical energy (but *not* the total energy), they are called **dissipative forces**. Historically, the presence of dissipative forces hindered the formulation of a comprehensive conservation of energy law until well into the nineteenth century. It was only then that heat, which is always produced when there is friction (try rubbing your hands together), was interpreted in terms of energy. Quantitative studies in the nineteenth century (Chapter 19) demonstrated that if heat is considered as a transfer of energy (sometimes called **thermal energy**), then the total energy is conserved in any process. A block sliding freely across a table, for example, comes to rest because of friction. Its initial kinetic energy is all transformed into thermal energy. The block and table are a little warmer as a result of this process.

According to the atomic theory, thermal energy represents kinetic energy of rapidly moving molecules. We shall see in Chapter 18 that a rise in temperature corresponds to an increase in the average kinetic energy of the molecules. Because thermal energy represents the energy of atoms and molecules that make up an object, it is often called **internal energy**. Internal energy, from the atomic point of view, includes kinetic energy of molecules as well as potential energy (usually electrical in nature) due to the relative positions of atoms within molecules. For example the energy stored in food, or in a fuel such as gasoline, is regarded as electric potential energy (chemical bonds). The energy is released through chemical reactions (Fig. 8–15b). This is analogous to a compressed spring which, when released, can do work.

To establish the more general law of conservation of energy, nineteenth-century physicists had to recognize electrical, chemical, and other forms of energy in addition to heat, and to explore if in fact they could fit into a conservation law. For each type of force, conservative or nonconservative, it has always been possible to define a type of energy that corresponds to the work done by such a force, including nuclear energy. And it has been found experimentally that the total energy $E$ always remains constant. That is, the change in total energy, kinetic plus potential plus all other forms of energy, equals zero:

$$\Delta K + \Delta U + [\text{change in all other forms of energy}] = 0. \qquad \textbf{(8–14)}$$

This is one of the most important principles in physics. It is called the **law of conservation of energy** and can be stated as:

**The total energy is neither increased nor decreased in any process. Energy can be transformed from one form to another, and transferred from one object to another, but the total amount remains constant.**

For conservative mechanical systems, this law can be derived from Newton's laws (Section 8–3) and thus is equivalent to them. But in its full generality, the validity of the law of conservation of energy, encompassing all forms of energy including those associated with nonconservative forces like friction, rests on experimental observation.

**FIGURE 8–15** (a) Gravitational potential energy of water at the top of Yosemite Falls is transformed into kinetic energy as the water falls. (Some energy is transformed into heat by air resistance, and some into sound.) (b) The burning of fuel (a chemical reaction) releases energy to boil water in this old steam train in Scotland. The steam produced expands against a piston to do work in turning the wheels.

(a)

(b)

*LAW OF CONSERVATION OF ENERGY*

*LAW OF CONSERVATION OF ENERGY*

Even though Newton's laws have been found to fail in the submicroscopic world of the atom, the law of conservation of energy has been found to hold there and in every experimental situation so far tested.

## 8–6 Energy Conservation with Dissipative Forces: Solving Problems

In Section 8–4 we discussed several Examples of the law of conservation of energy for conservative systems. Now let us consider in detail some examples that involve nonconservative forces.

Suppose, for example, that the roller-coaster car rolling on the hills of Fig. 8–8 is subject to frictional forces. In going from some point 1 to a second point 2, the energy dissipated by the friction force $\vec{\mathbf{F}}_{\text{fr}}$ acting on the car (treating it as a particle) is $\int_1^2 \vec{\mathbf{F}}_{\text{fr}} \cdot d\vec{\boldsymbol{\ell}}$. If $\vec{\mathbf{F}}_{\text{fr}}$ is constant in magnitude, then $W_{\text{fr}} = -F_{\text{fr}}\ell$, where $\ell$ is the actual distance along the path traveled by the car from point 1 to point 2. (The minus sign appears because $\vec{\mathbf{F}}_{\text{fr}}$ and $d\vec{\boldsymbol{\ell}}$ are in opposite directions.) From the work-energy principle (Eq. 7–11), the net work $W_{\text{net}}$ done on an object is equal to the change in its kinetic energy $K$:

$$\Delta K = W_{\text{net}}.$$

We can separate $W_{\text{net}}$ into two parts:

$$W_{\text{net}} = W_{\text{C}} + W_{\text{NC}},$$

where $W_{\text{C}}$ is the work done by conservative forces (gravity for our car) and $W_{\text{NC}}$ is the work done by nonconservative forces (friction for our car). We saw in Eq. 8–4 that the work done by a conservative force can be written in terms of potential energy:

$$W_{\text{C}} = \int_1^2 \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}} = -\Delta U.$$

Thus $\Delta K = W_{\text{net}}$ means $\Delta K = W_{\text{C}} + W_{\text{NC}} = -\Delta U + W_{\text{NC}}$. Hence

*GENERAL WORK-ENERGY PRINCIPLE*

$$\Delta K + \Delta U = W_{\text{NC}}. \qquad \textbf{(8–15a)}$$

This equation represents the general form of the work-energy principle. It also represents the conservation of energy. For our car, $W_{\text{NC}}$ is the work done by the friction force and represents production of thermal energy. Equation 8–15a is valid in general. Based on our derivation from the work-energy principle, $W_{\text{NC}}$ on the right side of Eq. 8–15a must be the total work done by all forces that are not included in the potential energy term, $\Delta U$, on the left side.

Let us rewrite Eq. 8–15a for our roller-coaster car example of Fig. 8–8, setting $W_{\text{NC}} = -F_{\text{fr}}\ell$ as we discussed above:

$$W_{\text{NC}} = -F_{\text{fr}}\ell = \Delta K + \Delta U = (\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2) + (mgy_2 - mgy_1)$$

or

$$\tfrac{1}{2}mv_1^2 + mgy_1 = \tfrac{1}{2}mv_2^2 + mgy_2 + F_{\text{fr}}\ell. \qquad \left[\begin{array}{c}\text{gravity and}\\ \text{friction acting}\end{array}\right] \qquad \textbf{(8–15b)}$$

On the left we have the mechanical energy of the system initially. It equals the mechanical energy at any subsequent point along the path plus the amount of thermal (or internal) energy produced in the process. Total energy is conserved.

Other nonconservative forces can be treated similarly. If you are not sure about the sign of the extra term $\left(\int \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}}\right)$, use your intuition: is the mechanical energy increased or decreased in the process?

**EXERCISE D** Return to the Chapter-Opening Question, page 194, and answer it again now. Try to explain why you may have answered differently the first time.

**PROBLEM SOLVING**
*Use energy, or Newton's laws?*

You may wonder sometimes whether to approach a problem using work and energy, or instead to use Newton's laws. As a rough guideline, if the force(s) involved are constant, either approach may succeed. If the forces are not constant, and/or the path is not simple, energy may be the better approach.

Problem solving is not a process that can be done by simply following a set of rules. The following Problem Solving Strategy involving conservation of energy is *not* a prescription, but is a summary to help you get started solving problems involving energy.

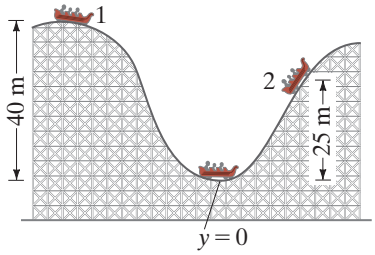
PROBLEM SOLVING

## Conservation of Energy

1. **Draw a picture** of the physical situation.
2. Determine **the system** for which you will apply energy conservation: the object or objects and the forces acting.
3. Ask yourself what quantity you are looking for, and **choose initial** (point 1) **and final** (point 2) **positions**.
4. If the object under investigation changes its height during the problem, then **choose a reference frame** with a convenient $y = 0$ level for gravitational potential energy; the lowest point is often a good choice.
   If springs are involved, choose the uncompressed (and unstretched) spring position to be $x$ (or $y$) $= 0$.
5. **Is mechanical energy conserved**? If no friction or other nonconservative forces act, then conservation of mechanical energy holds:
   $$K_1 + U_1 = K_2 + U_2.$$
6. **Apply conservation of energy**. If friction (or other nonconservative forces) are present, then an additional term of the form $\int \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}}$ will be needed. For a constant friction force acting over a distance $\ell$
   $$K_1 + U_1 = K_2 + U_2 + F_{\text{fr}}\ell.$$
   For other nonconservative forces use your intuition for the sign of $\int \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}}$: is the total mechanical energy increased or decreased in the process?
7. Use the equation(s) you develop to **solve** for the unknown quantity.

**EXAMPLE 8–10** **ESTIMATE** **Friction on the roller-coaster car.** The roller-coaster car in Example 8–4 reaches a vertical height of only 25 m on the second hill, where it slows to a momentary stop, Fig. 8–16. It traveled a total distance of 400 m along the track. Determine the thermal energy produced and estimate the average friction force (assume it is roughly constant) on the car, whose mass is 1000 kg.

**APPROACH** We explicitly follow the Problem Solving Strategy above.



**SOLUTION**

1. **Draw a picture**. See Fig. 8–16.
2. **The system**. The system is the roller-coaster car and the Earth (which exerts the gravitational force), plus the track which exerts the friction and normal forces on the car.† The normal force does no work because it is always perpendicular to the motion, so it does not affect the energy. Gravity is accounted for as potential energy, and friction as a term $F_{\text{fr}}\ell$.
3. **Choose initial and final positions**. We take point 1 to be the instant when the car started coasting (at the top of the first hill), and point 2 to be the instant it stopped at a height of 25 m on the second hill.
4. **Choose a reference frame**. We choose the lowest point in the motion to be $y = 0$ for the gravitational potential energy.
5. **Is mechanical energy conserved**? No. Friction is present.
6. **Apply conservation of energy**. There is friction acting on the car, so we use conservation of energy in the form of Eq. 8–15b, with $v_1 = 0$, $y_1 = 40\,\text{m}$, $v_2 = 0$, $y_2 = 25\,\text{m}$, and $\ell = 400\,\text{m}$. Thus
   $$0 + (1000\,\text{kg})(9.8\,\text{m/s}^2)(40\,\text{m}) = 0 + (1000\,\text{kg})(9.8\,\text{m/s}^2)(25\,\text{m}) + F_{\text{fr}}\ell.$$
7. **Solve**. We solve the above equation for $F_{\text{fr}}\ell$, the energy dissipated to thermal energy:
   $$F_{\text{fr}}\ell = mg\,\Delta h = (1000\,\text{kg})(9.8\,\text{m/s}^2)(40\,\text{m} - 25\,\text{m}) = 147{,}000\,\text{J}.$$
   The friction force, which acts over a distance of 400 m, averages out to be
   $$F_{\text{fr}} = (1.47 \times 10^5\,\text{J})/400\,\text{m} = 370\,\text{N}.$$

**NOTE** This result is only a rough average: the friction force at various points depends on the normal force, which varies with the slope angle.

†Alternatively, we could take only the car and Earth as our system, in which case friction would be an external force that reduces the mechanical energy, Eq. 8–15a.

**FIGURE 8–16** Example 8–10. Because of friction, a roller-coaster car does not reach the original height on the second hill. (Not to scale.)

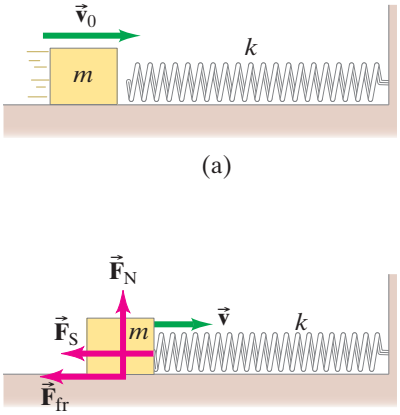


**FIGURE 8–17** Example 8–11.

**EXAMPLE 8–11** **Friction with a spring.** A block of mass $m$ sliding along a rough horizontal surface is traveling at a speed $v_0$ when it strikes a massless spring head-on (see Fig. 8–17) and compresses the spring a maximum distance $X$. If the spring has stiffness constant $k$, determine the coefficient of kinetic friction between block and surface.

**APPROACH** At the moment of collision, the block has $K = \frac{1}{2}mv_0^2$ and the spring is presumably uncompressed, so $U = 0$. Initially the mechanical energy of the system is $\frac{1}{2}mv_0^2$. By the time the spring reaches maximum compression, $K = 0$ and $U = \frac{1}{2}kX^2$. In the meantime, the friction force $(= \mu_k F_N = \mu_k mg)$ has transformed an amount of energy $F_{fr}X = \mu_k mgX$ into thermal energy. We take as our system the block, the spring, and the surface (frictional work).

**SOLUTION** Conservation of energy allows us to write

$$\text{energy (initial)} = \text{energy (final)}$$

$$\tfrac{1}{2}mv_0^2 = \tfrac{1}{2}kX^2 + \mu_k mgX.$$

We solve for $\mu_k$ and find

$$\mu_k = \frac{v_0^2}{2gX} - \frac{kX}{2mg}.$$

**NOTE** Gravitational potential energy does not change because the motion is horizontal ($y$ is constant in $mgy$).

## *Work-Energy versus Energy Conservation

The law of conservation of energy is more general and more powerful than the work-energy principle. The work-energy principle should not be viewed as a statement of conservation of energy, but is nonetheless useful for mechanical problems; and whether you use it, or use the more powerful conservation of energy, can depend on your *choice of the system* under study. If you choose as your system a particle or rigid object on which external forces do work, then you can use the work-energy principle: the work done by the external forces on your object equals the change in its kinetic energy. But if you choose a system on which no external forces do work, then apply conservation of energy to that system directly.

Consider, for example, a spring connected to a block on a frictionless table (Fig. 8–18). If you choose the block as your system, then the work done on the block by the spring equals the change in kinetic energy of the block: the work-energy principle. (Energy conservation does not apply to this system—the block's energy changes.) If instead you choose the block plus the spring as your system, no external forces do work (since the spring is part of the chosen system). To this system you need to apply conservation of energy: if you compress the spring and then release it, the spring still exerts a force[†] on the block, but the subsequent motion can be discussed in terms of kinetic energy $(\frac{1}{2}mv^2)$ plus potential energy $(\frac{1}{2}kx^2)$, whose total remains constant.

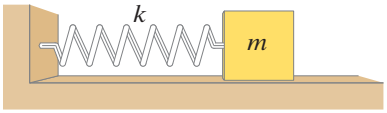

**FIGURE 8–18** A spring connected to a block on a frictionless table. If you choose your system to be the block plus spring, then

$$E = \tfrac{1}{2}mv^2 + \tfrac{1}{2}kx^2$$

is conserved.

# 8–7 Gravitational Potential Energy and Escape Velocity

We have been dealing with gravitational potential energy so far in this Chapter assuming the force of gravity is constant, $\vec{\mathbf{F}} = m\vec{\mathbf{g}}$. This is an accurate assumption for ordinary objects near the surface of the Earth. But to deal with gravity more generally, for points not close to the Earth's surface, we must remember that the gravitational force exerted by the Earth on a particle of mass $m$ decreases inversely

[†]The force the spring exerts on the block, and the force the block exerts back on the spring, are not "external" forces—they are within the system in this case.

as the square of the distance $r$ from the Earth's center. The precise relationship is given by Newton's law of universal gravitation (Sections 6–1 and 6–2):

$$\vec{\mathbf{F}} = -G\frac{mM_E}{r^2}\hat{\mathbf{r}} \qquad [r > r_E]$$

where $M_E$ is the mass of the Earth and $\hat{\mathbf{r}}$ is a unit vector (at the position of $m$) directed radially away from the Earth's center.[†] The minus sign indicates that the force on $m$ is directed toward the Earth's center, in the direction opposite to $\hat{\mathbf{r}}$. This equation can also be used to describe the gravitational force on a mass $m$ in the vicinity of other heavenly bodies, such as the Moon, a planet, or the Sun, in which case $M_E$ must be replaced by that body's mass.

Suppose an object of mass $m$ moves from one position to another along an arbitrary path (Fig. 8–19) so that its distance from the Earth's center changes from $r_1$ to $r_2$. The work done by the gravitational force is

$$W = \int_1^2 \vec{\mathbf{F}}\cdot d\vec{\boldsymbol{\ell}} = -GmM_E\int_1^2 \frac{\hat{r}\cdot d\vec{\boldsymbol{\ell}}}{r^2},$$

where $d\vec{\boldsymbol{\ell}}$ represents an infinitesimal displacement. But $\hat{\mathbf{r}}\cdot d\vec{\boldsymbol{\ell}} = dr$, which is the component of $d\vec{\boldsymbol{\ell}}$ along $\hat{\mathbf{r}}$ (see Fig. 8–19), then

$$W = -GmM_E\int_{r_1}^{r_2}\frac{dr}{r^2} = GmM_E\left(\frac{1}{r_2}-\frac{1}{r_1}\right)$$

or

$$W = \frac{GmM_E}{r_2} - \frac{GmM_E}{r_1}.$$

Because the value of this integral depends only on the position of the end points ($r_1$ and $r_2$) and not on the path taken, the gravitational force is a conservative force. We can therefore use the concept of potential energy for the gravitational force. Since the change in potential energy is always defined (Section 8–2) as the negative of the work done by the force, we have

$$\Delta U = U_2 - U_1 = -\frac{GmM_E}{r_2} + \frac{GmM_E}{r_1}. \qquad \textbf{(8–16)}$$

From Eq. 8–16 the potential energy at any distance $r$ from the Earth's center can be written:

$$U(r) = -\frac{GmM_E}{r} + C,$$

where $C$ is a constant. It is usual to choose $C = 0$, so that

$$U(r) = -\frac{GmM_E}{r}. \qquad \left[\begin{array}{c}\text{gravity}\\ (r > r_E)\end{array}\right] \qquad \textbf{(8–17)}$$

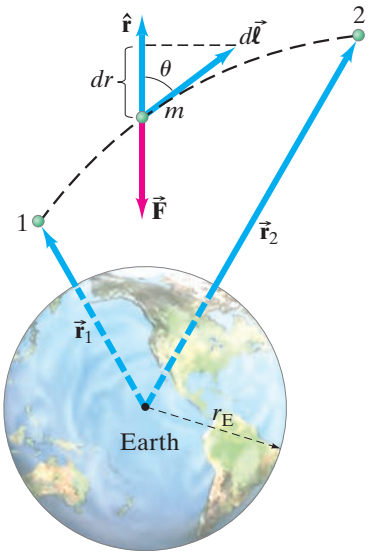
With this choice for $C$, $U = 0$ at $r = \infty$. As an object approaches the Earth, its potential energy decreases and is always negative (Fig. 8–20).

Equation 8–16 reduces to Eq. 8–2, $\Delta U = mg(y_2 - y_1)$, for objects near the surface of the Earth (see Problem 43).

For a particle of mass $m$, which experiences only the force of the Earth's gravity, the total energy is conserved because gravity is a conservative force. Therefore we can write

$$\tfrac{1}{2}mv_1^2 - G\frac{mM_E}{r_1} = \tfrac{1}{2}mv_2^2 - G\frac{mM_E}{r_2} = \text{constant}. \qquad \left[\begin{array}{c}\text{gravity}\\ \text{only}\end{array}\right] \qquad \textbf{(8–18)}$$

[†]We write $r > r_E$, where $r_E$ is the radius of Earth, because this equation only applies beyond the Earth's surface. Inside the Earth, things are more complicated—see Appendix E.



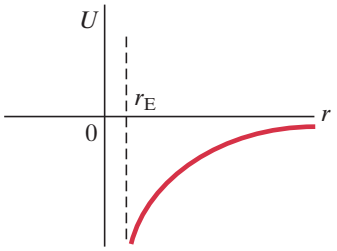


**FIGURE 8–19** Arbitrary path of particle of mass $m$ moving from point 1 to point 2.

**FIGURE 8–20** Gravitational potential energy plotted as a function of $r$, the distance from Earth's center. Valid only for points $r > r_E$, the radius of the Earth.

**EXAMPLE 8–12** **Package dropped from high-speed rocket.** A box of mass $m$ is allowed to fall from a rocket traveling outward from Earth at a speed of 1800 m/s when 1600 km above the Earth's surface. The box eventually falls to the Earth. Estimate its speed just before impact. Ignore air resistance.

**APPROACH** We use conservation of energy. The box initially has a speed relative to Earth equal to the speed of the rocket from which it falls.

**SOLUTION** Conservation of energy in this case is expressed by Eq. 8–18:

$$\tfrac{1}{2}mv_1^2 - G\frac{mM_E}{r_1} = \tfrac{1}{2}mv_2^2 - G\frac{mM_E}{r_2}$$

where $v_1 = 1.80 \times 10^3\,\text{m/s}$, $r_1 = (1.60 \times 10^6\,\text{m}) + (6.38 \times 10^6\,\text{m}) = 7.98 \times 10^6\,\text{m}$, and $r_2 = 6.38 \times 10^6\,\text{m}$ (the radius of the Earth). We solve for $v_2$:

$$\begin{aligned} v_2 &= \sqrt{v_1^2 - 2GM_E\left(\frac{1}{r_1} - \frac{1}{r_2}\right)} \\ &= \sqrt{(1.80 \times 10^3\,\text{m/s})^2 - 2(6.67 \times 10^{-11}\,\text{N}\cdot\text{m}^2/\text{kg}^2)(5.98 \times 10^{24}\,\text{kg}) \times \left(\frac{1}{7.98 \times 10^6\,\text{m}} - \frac{1}{6.38 \times 10^6\,\text{m}}\right)} \\ &= 5320\,\text{m/s}. \end{aligned}$$

**NOTE** In reality, the falling box's speed will be considerably less than this because of air resistance. Note that the direction of the velocity never entered into this calculation, and this is one of the advantages of the energy method. The rocket could have been heading away from the Earth, or toward it, or at some other angle, and the result would be the same.

## Escape Velocity

When an object is projected into the air from the Earth, it will return to Earth unless its speed is very high. But if the speed *is* high enough, it will continue out into space never to return to Earth (barring other forces or collisions). The minimum initial velocity needed to prevent an object from returning to the Earth is called the **escape velocity** from Earth, $v_{esc}$. To determine $v_{esc}$ from the Earth's surface (ignoring air resistance), we use Eq. 8–18 with $v_1 = v_{esc}$ and $r_1 = r_E = 6.38 \times 10^6\,\text{m}$, the radius of the Earth. Since we want the minimum speed for escape, we need the object to reach $r_2 = \infty$ with merely zero speed, $v_2 = 0$. Applying Eq. 8–18 we have

$$\tfrac{1}{2}mv_{esc}^2 - G\frac{mM_E}{r_E} = 0 + 0$$

or

$$v_{esc} = \sqrt{2GM_E/r_E} = 1.12 \times 10^4\,\text{m/s} \qquad \textbf{(8–19)}$$

or 11.2 km/s. This escape velocity is the same for all objects no matter what their mass is. Note that although a mass can escape from the Earth (or solar system) never to return, nonetheless the force on it due to the Earth's gravitational field $(F \propto 1/r^2)$ is never actually zero for any real (finite) value of $r$.

**EXAMPLE 8–13** **Escaping the Earth or the Moon.** (*a*) Compare the escape velocities of a rocket from the Earth and from the Moon. (*b*) Compare the energies required to launch the rockets. For the Moon, $M_M = 7.35 \times 10^{22}\,\text{kg}$ and $r_M = 1.74 \times 10^6\,\text{m}$, and for Earth, $M_E = 5.98 \times 10^{24}\,\text{kg}$ and $r_E = 6.38 \times 10^6\,\text{m}$.

**APPROACH** We use Eq. 8–19, replacing $M_E$ and $r_E$ with $M_M$ and $r_M$ for finding $v_{esc}$ from the Moon.

**SOLUTION** (*a*) Using Eq. 8–19, the ratio of the escape velocities is

$$\frac{v_{esc}(\text{Earth})}{v_{esc}(\text{Moon})} = \sqrt{\frac{M_E}{M_M}\frac{r_M}{r_E}} = 4.7.$$

To escape Earth requires a speed 4.7 times that required to escape the Moon. (*b*) The fuel that must be burned provides energy proportional to $v^2$ $(K = \frac{1}{2}mv^2)$; so to launch a rocket to escape Earth requires $(4.7)^2 = 22$ times as much energy as to escape from the Moon.

# 8–8 Power

**Power** is defined as the *rate at which work is done*. *Average power*, $\overline{P}$, equals the work $W$ done divided by the time $t$ it takes to do it:

$$\overline{P} = \frac{W}{t}. \qquad \textbf{(8–20a)}$$

The *instantaneous power*, $P$, is

$$P = \frac{dW}{dt}. \qquad \textbf{(8–20b)}$$

The work done in a process is equal to the energy transformed from one type to another (a rock falling), or transferred from one object to another. For example, as the potential energy stored in the spring of Fig. 8–6c is transformed to kinetic energy of the ball, the spring is doing work on the ball. Similarly, when you throw a ball or push a grocery cart, *whenever work is done, energy is being transformed from one type to another, or is being transferred from one object to another*.

Hence we can also say that power is the *rate at which energy is transformed*. Thus, average power can also be defined as:

$$\overline{P} = \frac{W}{t} = \frac{\text{energy transformed}}{\text{time}},$$

and instantaneous power as

$$P = \frac{dE}{dt}. \qquad \textbf{(8–20c)}$$

The power rating of an engine refers to how much chemical or electrical energy can be transformed into mechanical energy per unit of time. In SI units, power is measured in joules per second, and this unit is given a special name, the **watt** (W): 1 W = 1 J/s. We are most familiar with the watt for electrical devices, such as the rate at which a lightbulb or heater changes electric energy into light or thermal energy. But the watt is used for other types of energy transformation as well.

In the British system, the unit of power is the foot-pound per second ($\text{ft} \cdot \text{lb/s}$). For practical purposes a larger unit is often used, the **horsepower**. One horsepower[†] (hp) is defined as 550 $\text{ft} \cdot \text{lb/s}$, which equals 746 W. An engine's power is usually specified in hp or in kilowatts: $1\,\text{kW} \approx 1\frac{1}{3}\,\text{hp}$ $\left(1\,\text{kW} = (1000\,\text{W})/(746\,\text{W/hp}) \approx 1\frac{1}{3}\,\text{hp}\right)$.

To see the distinction between energy and power, consider the following example. A person is limited in the work he or she can do, not only by the total energy required, but also by how fast this energy is transformed: that is, by power. For example, a person may be able to walk a long distance or climb many flights of stairs before having to stop because so much energy has been expended. On the other hand, a person who runs very quickly up stairs may feel exhausted after only a flight or two. He or she is limited in this case by power, the rate at which his or her body can transform chemical energy into mechanical energy.

**EXAMPLE 8–14** **Stair-climbing power.** A 60-kg jogger runs up a long flight of stairs in 4.0 s (Fig. 8–21). The vertical height of the stairs is 4.5 m. (*a*) Estimate the jogger's power output in watts and horsepower. (*b*) How much energy did this require?

**APPROACH** The work done by the jogger is against gravity, and equals $W = mgy$. To find her average output, we divide $W$ by the time it took.

**SOLUTION** (*a*) The average power output was

$$\overline{P} = \frac{W}{t} = \frac{mgy}{t} = \frac{(60\,\text{kg})\left(9.8\,\text{m/s}^2\right)(4.5\,\text{m})}{4.0\,\text{s}} = 660\,\text{W}.$$

Since there are 746 W in 1 hp, the jogger is doing work at a rate of just under 1 hp. A human cannot do work at this rate for very long.

(*b*) The energy required is $E = \overline{P}t = (660\,\text{J/s})(4.0\,\text{s}) = 2600\,\text{J}$. This equals $W = mgy$.

**NOTE** The person had to transform more energy than this 2600 J. The total energy transformed by a person or an engine always includes some thermal energy (recall how hot you get running up stairs).

**FIGURE 8–21** Example 8–14.

[†]The unit was chosen by James Watt (1736–1819) to specify the power of his steam engines. He found that a good horse can work all day at an average rate of about 360 $\text{ft} \cdot \text{lb/s}$. To not be accused of exaggeration in the sale of his steam engines, he multiplied this by $1\frac{1}{2}$ when he defined the hp.

**PHYSICS APPLIED**
*Power needs of a car*

Automobiles do work to overcome the force of friction and air resistance, to climb hills, and to accelerate. A car is limited by the rate it can do work, which is why automobile engines are rated in horsepower or kilowatts. A car needs power most when it is climbing hills and when accelerating. In the next Example, we will calculate how much power is needed in these situations for a car of reasonable size. Even when a car travels on a level road at constant speed, it needs some power just to do work to overcome the retarding forces of internal friction and air resistance. These forces depend on the conditions and speed of the car, but are typically in the range 400 N to 1000 N.

It is often convenient to write the power in terms of the net force $\vec{\mathbf{F}}$ applied to an object and its velocity $\vec{\mathbf{v}}$. Since $P = dW/dt$ and $dW = \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}}$ (Eq. 7–7), then

$$P = \frac{dW}{dt} = \vec{\mathbf{F}} \cdot \frac{d\vec{\boldsymbol{\ell}}}{dt} = \vec{\mathbf{F}} \cdot \vec{\mathbf{v}}, \qquad \textbf{(8–21)}$$

where $d\vec{\boldsymbol{\ell}}/dt$ is the velocity of the object.

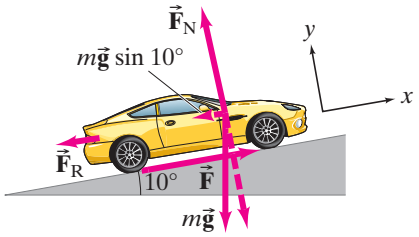

**FIGURE 8–22** Example 8–15: Calculation of power needed for a car to climb a hill.

**EXAMPLE 8–15** **Power needs of a car.** Calculate the power required of a 1400-kg car under the following circumstances: (*a*) the car climbs a 10° hill (a fairly steep hill) at a steady 80 km/h; and (*b*) the car accelerates along a level road from 90 to 110 km/h in 6.0 s to pass another car. Assume the average retarding force on the car is $F_R = 700\ \text{N}$ throughout. See Fig. 8–22.

**APPROACH** First we must be careful not to confuse $\vec{\mathbf{F}}_R$, which is due to air resistance and friction that retards the motion, with the force $\vec{\mathbf{F}}$ needed to accelerate the car, which is the frictional force exerted by the road on the tires—the reaction to the motor-driven tires pushing against the road. We must determine the magnitude of the force $F$ before calculating the power.

**SOLUTION** (*a*) To move at a steady speed up the hill, the car must, by Newton's second law, exert a force $F$ equal to the sum of the retarding force, 700 N, and the component of gravity parallel to the hill, $mg$ sin 10°. Thus

$$\begin{aligned} F &= 700\ \text{N} + mg \sin 10° \\ &= 700\ \text{N} + (1400\ \text{kg})(9.80\ \text{m/s}^2)(0.174) = 3100\ \text{N}. \end{aligned}$$

Since $\bar{v} = 80\ \text{km/h} = 22\ \text{m/s}$[†] and is parallel to $\vec{\mathbf{F}}$, then (Eq. 8–21) the power is

$$\bar{P} = F\bar{v} = (3100\ \text{N})(22\ \text{m/s}) = 6.80 \times 10^4\ \text{W} = 68.0\ \text{kW} = 91\ \text{hp}.$$

(*b*) The car accelerates from 25.0 m/s to 30.6 m/s (90 to 110 km/h) on the flat. The car must exert a force that overcomes the 700-N retarding force plus that required to give it the acceleration

$$\bar{a}_x = \frac{(30.6\ \text{m/s} - 25.0\ \text{m/s})}{6.0\ \text{s}} = 0.93\ \text{m/s}^2.$$

We apply Newton's second law with $x$ being the horizontal direction of motion (no component of gravity):

$$ma_x = \Sigma F_x = F - F_R.$$

We solve for the force required, $F$:

$$\begin{aligned} F &= ma_x + F_R \\ &= (1400\ \text{kg})(0.93\ \text{m/s}^2) + 700\ \text{N} = 1300\ \text{N} + 700\ \text{N} = 2000\ \text{N}. \end{aligned}$$

Since $P = \vec{\mathbf{F}} \cdot \vec{\mathbf{v}}$, the required power increases with speed and the motor in this case must be able to provide a maximum power output of

$$\bar{P} = (2000\ \text{N})(30.6\ \text{m/s}) = 6.12 \times 10^4\ \text{W} = 61.2\ \text{kW} = 82\ \text{hp}.$$

**NOTE** Even taking into account the fact that only 60 to 80% of the engine's power output reaches the wheels, it is clear from these calculations that an engine of 75 to 100 kW (100 to 130 hp) is adequate from a practical point of view.

We mentioned in Example 8–15 that only part of the energy output of a car engine reaches the wheels. Furthermore, in the engine itself, most of the energy from the burning of fuel does not do useful work. An important aspect

[†]Recall 1 km/h = 1000 m/3600 s = 0.278 m/s.

of all engines is their overall *efficiency* $e$, defined as the ratio of the useful power output of the engine, $P_{\text{out}}$, to the power input, $P_{\text{in}}$ (provided by burning of fuel):

$$e = \frac{P_{\text{out}}}{P_{\text{in}}}.$$

The efficiency is always less than 1.0 because no engine can create energy, and no engine can even transform energy from one form to another without some energy going to friction and thermal energy. For example, a car engine converts chemical energy released in the burning of fuel into mechanical energy that turns the wheels. Nearly 85% of the input energy is "wasted" as thermal energy that goes into the environment via the exhaust pipe (and radiator). Thus car engines are roughly only about 15% efficient. We discuss efficiency in detail in Chapter 20.

## 8–9 Potential Energy Diagrams; Stable and Unstable Equilibrium

If only conservative forces do work on an object, we can learn a great deal about its motion simply by examining a potential energy diagram—the graph of $U(x)$ versus $x$. An example of a potential energy diagram is shown in Fig. 8–23. The rather complex curve represents some complicated potential energy $U(x)$. The total energy $E = K + U$ is constant and can be represented as a horizontal line on this graph. Four interesting values for $E$ are shown, labeled $E_0$, $E_1$, $E_2$, and $E_3$. What the actual value of $E$ will be for a given system depends on the initial conditions. (For example, the total energy $E$ of a mass oscillating on the end of a spring depends on the amount the spring is initially compressed or stretched.) Kinetic energy $K = \frac{1}{2}mv^2$ cannot be less than zero ($v$ would be imaginary), and because $E = U + K =$ constant, then $U(x)$ must always be less than or equal to $E$ for all situations: $U(x) \leq E$. The minimum value that the total energy can have for the case shown in Fig. 8–23 is labeled $E_0$. For this value of $E$, the mass can only be at rest at $x = x_0$. The system has potential energy but no kinetic energy at this position.

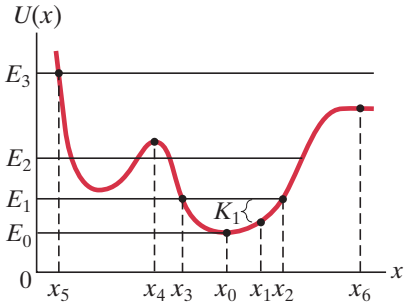

**FIGURE 8–23** A potential energy diagram.

If the system's total energy $E$ is greater than $E_0$, say it is $E_1$ on our plot, the system can have both kinetic and potential energy. Because energy is conserved,

$$K = E - U(x)$$

at any point $x$. Since the curve represents $U(x)$ at each $x$, the kinetic energy at any value of $x$ is represented by the distance between the $E$ line and the curve $U(x)$ at that value of $x$. In Fig. 8–23, the kinetic energy for an object at $x_1$, when its total energy is $E_1$, is indicated by the notation $K_1$.

An object with energy $E_1$ can oscillate only between the points $x_2$ and $x_3$. This is because if $x > x_2$ or $x < x_3$, the potential energy would be greater than $E$, meaning $K = \frac{1}{2}mv^2 < 0$ and $v$ would be imaginary, and so impossible. At $x_2$ and $x_3$ the speed is zero, since $E = U$ at these points. Hence $x_2$ and $x_3$ are called the **turning points** of the motion. If the object is at $x_0$, say, moving to the right, its kinetic energy (and speed) decreases until it reaches zero at $x = x_2$. The object then reverses direction, proceeding to the left and increasing in speed until it passes $x_0$ again. It continues to move, decreasing in speed until it reaches $x = x_3$, where again $v = 0$, and the object again reverses direction.

If the object has energy $E = E_2$ in Fig. 8–23, there are four turning points. The object can move in only one of the two potential energy "valleys," depending on where it is initially. It cannot get from one valley to the other because of the barrier between them—for example at a point such as $x_4$, $U > E_2$, which means $v$ would be imaginary.[†] For energy $E_3$, there is only one turning point since $U(x) < E_3$ for all $x > x_5$. Thus, if our object has $E = E_3$ and is moving initially to the left, it varies in speed as it passes the potential valleys (or **potential wells**) but eventually stops and turns around at $x = x_5$. The object then proceeds to the right indefinitely, never to return.

How do we know the object reverses direction at the turning points? Because of the force exerted on it. The force $F$ is related to the potential energy $U$ by Eq. 8–7, $F = -dU/dx$, so the force $F$ equals the negative of the slope of the $U$-versus-$x$ curve at any point $x$. At $x = x_2$ in Fig. 8–23, for example, the slope is positive so the force is negative, which means it acts to the left (toward decreasing values of $x$).

[†]Although this is true according to Newtonian physics, modern quantum mechanics predicts that objects can "tunnel" through such a barrier, and such processes have been observed at the atomic and subatomic level.

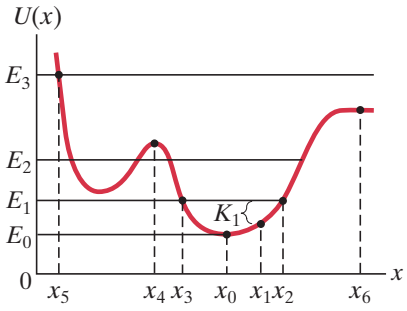

**FIGURE 8–23** (Repeated.) A potential energy diagram.

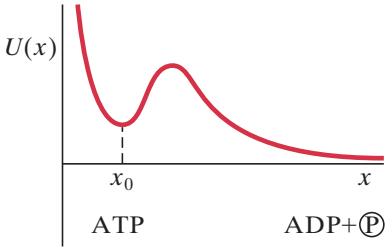
At $x = x_0$ the slope is zero, so $F = 0$. At such a point the particle is said to be in **equilibrium**. This term means simply that the net force on the object is zero. Hence, its acceleration is zero, and so if it is initially at rest, it remains at rest. If the object at rest at $x = x_0$ were moved slightly to the left or right, a nonzero force would act on it in the direction to move it back toward $x_0$. An object that returns toward its equilibrium point when displaced slightly is said to be at a point of **stable equilibrium**. Any *minimum* in the potential energy curve represents a point of stable equilibrium.



An object at $x = x_4$ would also be in equilibrium, since $F = -dU/dx = 0$. If the object were displaced a bit to either side of $x_4$, a force would act to pull the object *away* from the equilibrium point. Points like $x_4$, where the potential energy curve has a maximum, are points of **unstable equilibrium**. The object will *not* return to equilibrium if displaced slightly, but instead will move farther away.

When an object is in a region over which $U$ is constant, such as near $x = x_6$ in Fig. 8–23, the force is zero over some distance. The object is in equilibrium and if displaced slightly to one side the force is still zero. The object is said to be in **neutral equilibrium** in this region.

### *ATP – Storing Energy in Living Cells

Figure 8–24 is a simple potential energy diagram for a bond between a phosphate molecule (Ⓟ) and a second molecule (ADP) to form a molecule of ATP, **a**denosine **tri**phosphate. ATP is an important molecule in biological cells that stores energy for later use within cells. When the separation $x$ between the 2 molecules is large (let $x \to \infty$ = infinity) the phosphate and ADP are separate and we choose $U(\infty) = 0$ in Fig. 8–24. With the help of other "catalyst" molecules, these two molecules can get close enough to be bonded together to form ATP, whose potential energy at the stable position $x = x_0$ is greater: $U(x_0) > U(\infty) = 0$. The bump of $U(x)$ on the right is a "barrier" that keeps ATP stable. ATP will not break apart unless an unlikely collision occurs that can provide massive kinetic energy so that the total energy becomes greater than the barrier height. Or, much more likely, certain other molecules (enzymes) come close which are able to lower the barrier, so the bond is broken and the phosphate can be freed, which releases the "stored" energy, $\Delta U = U(x_0) - U(\infty) > 0$. The energy released can be used to help crucial biochemical reactions take place in the cell.

**FIGURE 8–24** Potential-energy diagram for the formation of ATP from ADP and phosphate (Ⓟ).

## *8–10 Gravitational Assist (Gravitational Slingshot)

Spacecraft heading to other planets, or the outer reaches of the solar system and beyond, are slowed by the Sun's gravitational field but can have their speed increased by passing near a planet or a planet's moon. This is an important way to reduce the fuel a spacecraft carries and reduce the energy required of the rocket to accelerate all that fuel (in the spacecraft) at launch (photo, Fig. 4–10).

In Fig. 8–25a we are in the reference frame of the planet Jupiter (J), at rest relative to Jupiter's position. The spacecraft, which has kinetic energy $K_{J0}$ when far from Jupiter (lower part Fig. 8–25a), is accelerated toward the planet by gravity and its trajectory bends toward the planet as its speed increases. As the spacecraft passes nearest the planet it reaches its maximum speed, $v_J$, and then as it moves away it slows down due to the planet's gravitational field pulling back on it. When far away again, and going in a different direction, its kinetic energy is again $K_{J0}$. The spacecraft's trajectory is *symmetric* here in *Jupiter's reference frame* about our chosen $x$ axis. (We ignore the change in the planet's velocity because its mass $M$ is vastly greater than the spacecraft's, $m$.) The subscript J means in Jupiter's reference frame; the subscript 0, such as $\vec{\mathbf{v}}_{J0}$, means the velocity of the spacecraft when far from Jupiter so that Jupiter's gravitational attraction is close to zero; the prime ($'$), such as $\vec{\mathbf{v}}'_{J0}$, means the velocity *after* the spacecraft has passed Jupiter, *after* the encounter.

Next we look at this encounter as *we* see it, in *our* reference frame of the Sun (and the Solar System as a whole). Figure 8–25b shows Jupiter moving to the right with velocity $\vec{\mathbf{u}}$ in its orbit around the Sun, at this moment taken to be along

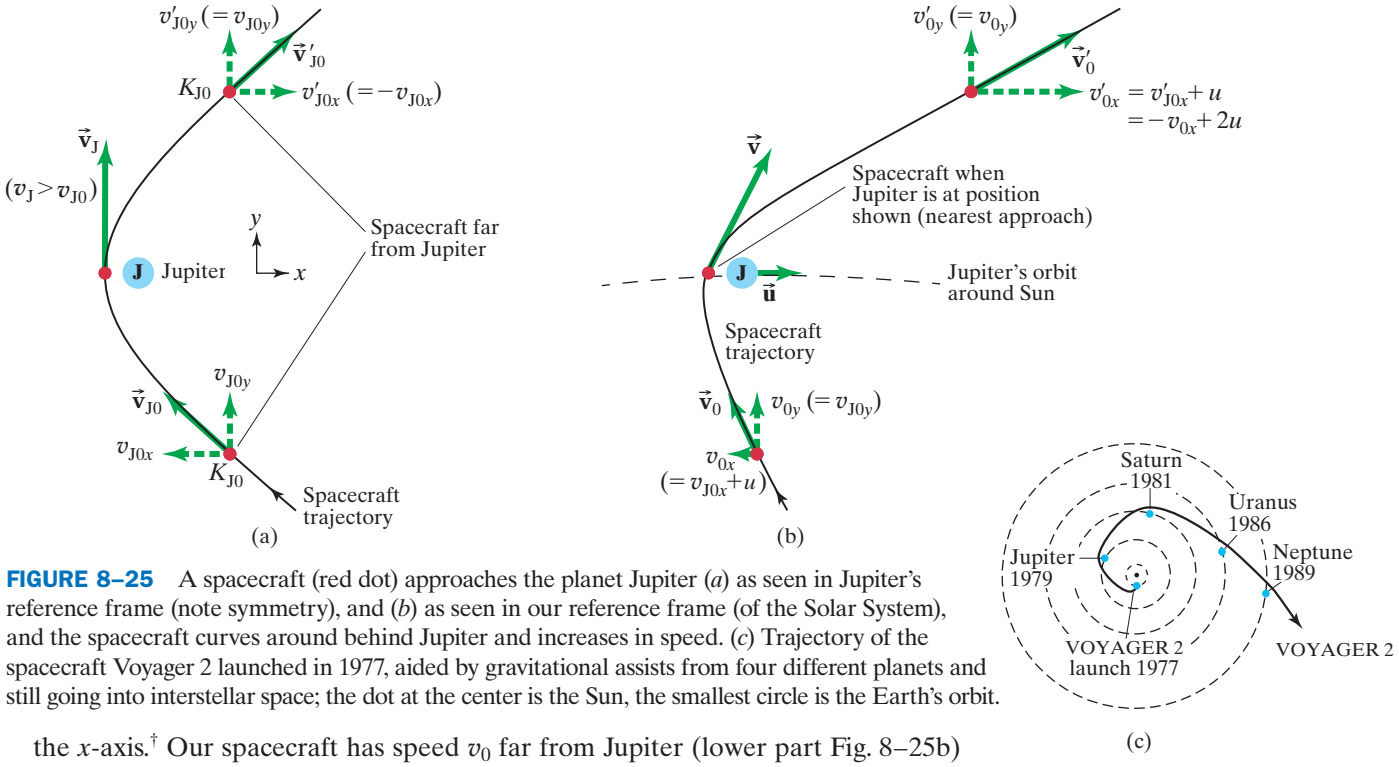


**FIGURE 8–25** A spacecraft (red dot) approaches the planet Jupiter (*a*) as seen in Jupiter's reference frame (note symmetry), and (*b*) as seen in our reference frame (of the Solar System), and the spacecraft curves around behind Jupiter and increases in speed. (*c*) Trajectory of the spacecraft Voyager 2 launched in 1977, aided by gravitational assists from four different planets and still going into interstellar space; the dot at the center is the Sun, the smallest circle is the Earth's orbit.

the $x$-axis.† Our spacecraft has speed $v_0$ far from Jupiter (lower part Fig. 8–25b) and speeds up due to Jupiter's gravity, having velocity $\vec{\mathbf{v}}$ at closest approach to Jupiter. Later, far from Jupiter (upper right), the spacecraft has speed $v'_0 (> v_0)$, as shown. Carefully inspect velocity components explained in Fig. 8–25b, and note that $v_{J0x}$ and $v_{0x}$ are negative because they point along the negative $x$ axis.

Let us calculate the change in kinetic energy of the spacecraft as a result of its encounter with Jupiter. We want to do this in our Solar System reference frame, Fig. 8–25b. First we need to look at the $x$-components of the spacecraft velocity (the $y$ components don't change). The spacecraft's "final" $x$-component of velocity, $v'_{0x}$, in terms of its "initial" incoming value, $v_{0x}$, is equal to its value in the Jupiter frame (J) plus the relative velocity $u$ of the two reference frames:

$$\begin{aligned} v'_{0x} &= v'_{J0x} + u \\ &= -v_{J0x} + u \qquad \text{[see upper part Fig. 8–25a]} \\ &= -(v_{0x} - u) + u = -v_{0x} + 2u \qquad \text{[see lower part Fig. 8–25b]} \end{aligned} \tag{8–22}$$

which is summarized in the upper part of Fig. 8–25b. The subscript J refers to Jupiter's reference frame; the subscripts $(_0)$ and $('_0)$ refer to the spacecraft far from Jupiter before and after the encounter. The change in the kinetic energy, final minus initial, is

$$\begin{aligned} \Delta K &= \tfrac{1}{2}m(v'^2_{0x} + v^2_{0y}) - \tfrac{1}{2}m(v^2_{0x} + v^2_{0y}) \\ &= \tfrac{1}{2}m(v^2_{0x} - 4uv_{0x} + 4u^2 - v^2_{0x}) = 2mu(u - v_{0x}). \end{aligned} \tag{8–23}$$

This result, Eq. 8–23, gives an increase in the spacecraft's kinetic energy because $v_{0x} < 0$ (Fig. 8–25b, bottom).

Energy is conserved because the planet (J) experiences an equal *loss* in kinetic energy, which affects the planet's motion unnoticeably because of its enormous mass.

If you want to *slow down* a spacecraft (perhaps to put it into orbit around a planet or moon), you will want to project it so it passes *in front* of the planet (J) and $v_{0x}$ must be in the *same* direction as $\vec{\mathbf{u}}$ $(> 0)$ and have magnitude greater than $u$. (See Problem 77.)

Figure 8–25c shows the trajectory of the Voyager 2 probe, launched in 1977 when the planets Jupiter, Saturn, Uranus and Neptune were in optimal positions to each provide an "assist", a rare alignment that will not happen again until the 22nd century. After all these decades, it is still able to send back data. It has now gone beyond the Solar System and entered interstellar space!

†In general, the velocity $\vec{\mathbf{u}}$ in Fig. 8–25b can have a $y$-component. We chose $\vec{\mathbf{u}}$ along the $x$ axis to keep the math simpler so the effect of gravitational assist is readily seen.

# Summary

A **conservative force** is one for which the work done by the force in moving an object from one position to another depends only on the two positions and not on the path taken. The work done by a conservative force is recoverable, which is not true for nonconservative forces, such as friction.

**Potential energy**, $U$, is energy associated with conservative forces that depend on the position or configuration of objects. Gravitational potential energy is

$$U_{\text{grav}} = mgy, \qquad \textbf{(8–3)}$$

where the mass $m$ is near the Earth's surface, a height $y$ above some reference point. Elastic potential energy is given by

$$U_{\text{el}} = \tfrac{1}{2}kx^2 \qquad \textbf{(8–5)}$$

for a spring with stiffness constant $k$ stretched or compressed a displacement $x$ from its equilibrium position. Other potential energies include chemical, electrical, and nuclear energy.

Potential energy is always associated with a conservative force, and the change in potential energy, $\Delta U$, between two positions under the action of a conservative force $\vec{\mathbf{F}}$ is defined as the negative of the work done by the force:

$$\Delta U = U_2 - U_1 = -\int_1^2 \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}}. \qquad \textbf{(8–4)}$$

Inversely, we can write, for the one-dimensional case,

$$F = -\frac{dU(x)}{dx}. \qquad \textbf{(8–7)}$$

Only *changes* in potential energy are physically meaningful, so the position where $U = 0$ can be chosen for convenience. Potential energy is not a property of an object but is associated with the interaction of two or more objects.

When only conservative forces act, the total **mechanical energy**, $E$, defined as the sum of kinetic and potential energies, is conserved:

$$E = K + U = \text{constant}. \qquad \textbf{(8–10)}$$

If nonconservative forces also act, additional types of energy are involved, such as thermal energy. It has been found experimentally that, when all forms of energy are included, the total energy is conserved. This is the **law of conservation of energy**:

$$\Delta K + \Delta U + \Delta(\text{other energy types}) = 0. \qquad \textbf{(8–14)}$$

The gravitational force as described by Newton's law of universal gravitation is a conservative force. The potential energy of an object of mass $m$ due to the gravitational force exerted on it by the Earth is given by

$$U(r) = -\frac{GmM_{\text{E}}}{r}, \qquad \textbf{(8–17)}$$

where $M_{\text{E}}$ is the mass of the Earth and $r$ is the distance of the object from the Earth's center ($r \geq$ radius of earth).

**Power** is defined as the rate at which work is done or the rate at which energy is transformed from one form to another, or transferred from one object to another:

$$P = \frac{dW}{dt} = \frac{dE}{dt}, \qquad \textbf{(8–20)}$$

or

$$P = \vec{\mathbf{F}} \cdot \vec{\mathbf{v}}. \qquad \textbf{(8–21)}$$

The SI unit of power is the **watt** $(1\,\text{W} = 1\,\text{J/s})$.

# Questions

1. List some everyday forces that are not conservative, and explain why they aren't.
2. You lift a heavy book from a table to a high shelf. List the forces on the book during this process, and state whether each is conservative or nonconservative.
3. Analyze the motion of a simple swinging pendulum in terms of energy, (*a*) ignoring friction, and (*b*) taking friction into account. (*c*) Explain why a grandfather clock has to be wound up.
4. Describe precisely what is "wrong" physically in the famous Escher drawing shown in Fig. 8–26.

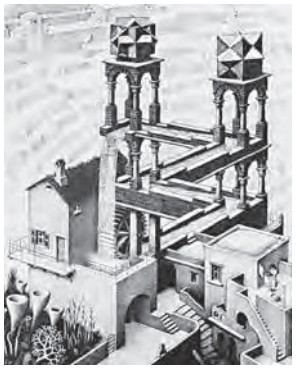

**FIGURE 8–26** Question 4.

5. A coil spring of mass $m$ rests upright on a table. If you compress the spring by pressing down with your hand and then release it, can the spring leave the table? Explain using the law of conservation of energy.
6. Experienced hikers prefer to step over a fallen log in their path rather than stepping on top and jumping down on the other side. Explain.
7. (*a*) Where does the kinetic energy come from when a car accelerates uniformly starting from rest? (*b*) How is the increase in kinetic energy related to the friction force the road exerts on the tires?
8. Can the total mechanical energy $E = K + U$ ever be negative? Explain.
9. Describe the energy transformations when a child hops around on a pogo stick.
10. (*a*) Only two conservative forces are discussed in this Chapter. What are they, and how are they accounted for when you are dealing with conservation of energy? (*b*) Not mentioned is the force of water on a swimmer. Is it conservative or nonconservative?
11. Recall from Chapter 4, Example 4–14, that you can use a *pulley* and ropes to decrease the force needed to raise a heavy load (see Fig. 8–27). But for every meter the piano is raised, how much rope must be pulled up at the top of the building? Account for this, using energy concepts.

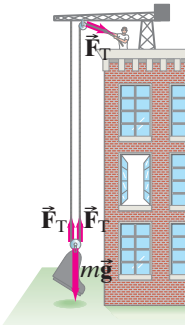

**FIGURE 8–27** Question 11

12. Two identical arrows, one with twice the speed of the other, are fired into a bale of hay. Assuming the hay exerts a constant "frictional" force on the arrows, the faster arrow will penetrate how much farther than the slower arrow? Explain.

13. In Fig. 8–28, water balloons are tossed from the roof of a building, all with the same speed but with different launch angles. Which one has the highest speed when it hits the ground? Ignore air resistance, and explain your answer.

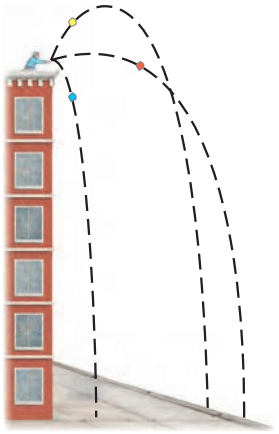

**FIGURE 8–28**
Question 13.

14. Suppose that you wish to launch a rocket from the surface of the Earth so that it escapes the Earth's gravitational field. You wish to use minimum fuel in doing this. From what point on the surface of the Earth should you make the launch and in what direction? Do the launch location and direction matter? Explain.

15. Suppose you lift a suitcase from the floor to a table. The work you do on the suitcase depends on which of the following: (*a*) whether you lift it straight up or along a more complicated path, (*b*) the time the lifting takes, (*c*) the height of the table, and/or (*d*) the weight of the suitcase? Explain.

16. Repeat Question 15 for the *power* needed instead of the work.

17. Why is it easier to climb a mountain via a zigzag trail rather than to climb straight up?

18. A pendulum is launched from a point that is a height $h$ above its lowest point in two different ways (Fig. 8–29). During both launches, the pendulum is given an initial speed of 3.0 m/s. On the first launch, the initial velocity of the pendulum is directed upward along the "swing," and on the second launch it is directed downward along the swing. Which launch will cause the highest speed when the pendulum bob passes the lowest point of its swing, ignoring air resistance? Explain.

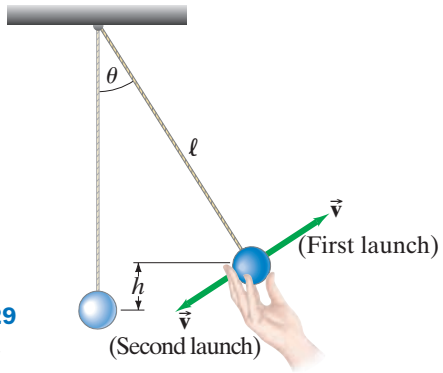

**FIGURE 8–29**
Question 18.

19. Figure 8–30 shows a potential energy curve, $U(x)$. (*a*) At which point does the force have greatest magnitude? (*b*) For each labeled point, state whether the force acts to the left or to the right, or is zero. (*c*) Where is there equilibrium and of what type is it?

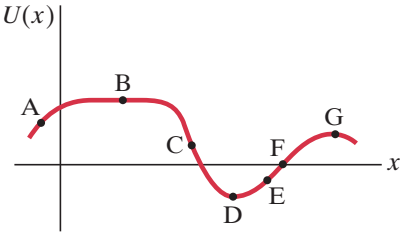

**FIGURE 8–30**
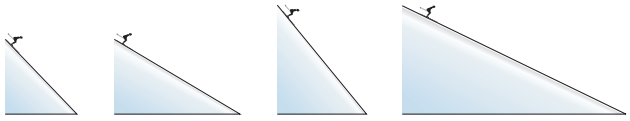
Question 19.

20. (*a*) Describe in detail the velocity changes of a particle that has energy $E_3$ in Fig. 8–23 as it moves from $x_6$ to $x_5$ and back to $x_6$. (*b*) Where is its kinetic energy the greatest and the least? Explain.

# MisConceptual Questions

1. A bowling ball is dropped from a height $h$ onto the center of a trampoline, which launches the ball back up into the air. How high will the ball rise?
   (*a*) Significantly less than $h$.
   (*b*) More than $h$. The exact amount depends on the mass of the ball and the springiness of the trampoline.
   (*c*) No more than $h$—probably a little less.
   (*d*) Cannot tell without knowing the characteristics of the trampoline.

2. A ball is thrown straight up. At what point does the ball have the most energy? Ignore air resistance.
   (*a*) At the highest point of its path.
   (*b*) When it is first thrown.
   (*c*) Just before it hits the ground.
   (*d*) When the ball is halfway to the highest point of its path.
   (*e*) Everywhere; the energy of the ball is the same at all of these points.



3. A man pushes a block up an incline at a constant speed. As the block moves up the incline,
   (*a*) its kinetic energy and potential energy both increase.
   (*b*) its kinetic energy increases and its potential energy remains the same.
   (*c*) its potential energy increases and its kinetic energy remains the same.
   (*d*) its potential energy increases and its kinetic energy decreases by the same amount.

4. As a skateboard rider rolls up a hill and slows down, she
   (*a*) gains kinetic energy (energy of motion).
   (*b*) gains gravitational potential energy (energy of position).
   (*c*) loses all of her original energy.
   (*d*) can't lose kinetic energy because energy remains constant.

5. A ball is thrown straight up. Neglecting air resistance, which statement is *not* true regarding the energy of the ball?
   (*a*) The potential energy decreases while the ball is going up.
   (*b*) The kinetic energy decreases while the ball is going up.
   (*c*) The sum of the kinetic energy and potential energy is constant.
   (*d*) The potential energy decreases when the ball is coming down.
   (*e*) The kinetic energy increases when the ball is coming down.

6. Two balls are thrown off a building with the same speed, one straight up and one at a 45° angle. Which statement is true if air resistance can be ignored?
   (*a*) Both hit the ground at the same time.
   (*b*) Both hit the ground with the same speed.
   (*c*) The one thrown at an angle hits the ground with a lower speed.
   (*d*) The one thrown at an angle hits the ground with a higher speed.
   (*e*) Both (*a*) and (*b*).

7. A skier starts from rest at the top of each of the hills shown in Fig. 8–31. On which hill will the skier have the highest speed at the bottom if we ignore friction: (*a*), (*b*), (*c*), (*d*), or (*e*) *c* and *d* equally?

(*a*) (*b*) (*c*) (*d*)

**FIGURE 8–31** MisConceptual Questions 7 and 8.

8. Answer MisConceptual Question 7 assuming a small amount of friction.
9. A child's swing is pulled back by an angle $\theta$ and released from rest. If the child on the swing remains motionless (relative to the swing seat), what is the maximum angle the swing can reach on the other side? Neglect air resistance and friction.
   (*a*) The angle depends on the length of the swing, which is not specified.
   (*b*) The exact same angle, $\theta$.
   (*c*) An angle less than $\theta$.
   (*d*) An angle greater than $\theta$.
10. Answer Question 9 taking into account air resistance and/or friction at the pivot point of the chain supporting the swing seat.
11. A person stands at the middle of a tall ladder, which is leaning against a wall. If the reference point $y = 0$ is taken to be at the top of the ladder, the person's gravitational potential energy is
   (*a*) positive.
   (*b*) negative.
   (*c*) zero.
12. What maximum work can a 250-W motor do?
   (*a*) Cannot tell—not enough information is given.
   (*b*) 250 J.
   (*c*) 0.335 hp.
   (*d*) 250 W.
   (*e*) Answers (*b*), (*c*), and (*d*) are all correct.
13. Is it possible for a system to have negative potential energy?
   (*a*) No, because the kinetic energy of a system must equal its potential energy.
   (*b*) No, because this would have no physical meaning.
   (*c*) Yes, since the choice of the zero of potential energy is arbitrary.
   (*d*) Yes, as long as the kinetic energy is positive.
   (*e*) Yes, as long as the total energy is positive.

# Problems

## 8–1 and 8–2 Conservative Forces and Potential Energy

1. (I) By how much does the gravitational potential energy of a 58-kg pole vaulter change if her center of mass rises 4.0 m during the jump?
2. (I) You drop a basketball from a height of 5.0 m, which rebounds to a new height of 3.0 m. How much energy is lost to nonconservative forces? Give your answer as percentage of the initial energy.
3. (I) A spring has a spring constant $k$ of 78.0 N/m. How much must this spring be compressed to store 45.0 J of potential energy?
4. (II) A 66.5-kg hiker starts at an elevation of 1150 m and climbs to the top of a peak 2660 m high. (*a*) What is the hiker's change in potential energy? (*b*) What is the minimum work the hiker must do? (*c*) Can the actual work done be greater than this? Explain.
5. (II) If it requries 7.5 J of work to stretch a particular spring by 2.0 cm from its equilibrium length, how much more work will be required to stretch it an additional 4.0 cm?
6. (II) A 1.60-m-tall person lifts a 1.65-kg book off the ground so it is 2.20 m above the ground. What is the potential energy of the book relative to (*a*) the ground, and (*b*) the top of the person's head? (*c*) How is the work done by the person related to the answers in parts (*a*) and (*b*)?
7. (II) A particle is constrained to move in one dimension along the $x$ axis and is acted upon by a force given by

$$\vec{\mathbf{F}}(x) = -\frac{k}{x^3}\,\hat{\mathbf{i}}$$

where $k$ is a constant with units appropriate to the SI system. Find the potential energy function $U(x)$, if $U$ is arbitrarily defined to be zero at $x = 2.0\,\text{m}$, so that $U(2.0\,\text{m}) = 0$.

*8. (II) If $U = 3x^2 + 2xy + 4y^2z$, what is the force, $\vec{\mathbf{F}}$?
9. (II) A particular spring obeys the force law $\vec{\mathbf{F}} = (-kx + ax^3 + bx^4)\,\hat{\mathbf{i}}$, where $k$, $a$ and $b$ are constants. (*a*) Is this force conservative? Explain why or why not. (*b*) If it is conservative, determine the form of the potential energy function.
10. (III) The spring in Problem 9 is stretched out to a postition $x_0$ from the equilibrium position. A mass $m$ is attached to the spring, and then released from rest. What is the speed of $m$ at (*a*) $x = x_0$, (*b*) $x = x_0/2$, and (*c*) $x = 0$? (*d*) How do these speeds compare to the "ideal" spring, with $a = 0$ and $b = 0$? Explain your answer.

## 8–3 and 8–4 Conservation of Mechanical Energy

11. (I) A novice skier, starting from rest, slides down an icy frictionless 8.0° incline whose vertical height is 115 m. How fast is she going when she reaches the bottom?
12. (I) Jane, looking for Tarzan, is running at top speed (5.0 m/s) and grabs a vine hanging vertically from a tall tree in the jungle. How high can she swing upward? Does the length of the vine affect your answer?
13. (II) A sled is initially given a shove up a frictionless 18.0° incline. It reaches a maximum vertical height 1.22 m higher than where it started at the bottom. What was its initial speed?
14. (II) In the *high jump*, the kinetic energy of an athlete is transformed into gravitational potential energy without the aid of a pole. With what minimum speed must the athlete leave the ground in order to lift his center of mass 2.10 m and cross the bar with a speed of 0.50 m/s?

**15.** (II) A spring with $k = 88\ \text{N/m}$ hangs vertically next to a vertical ruler. The end of the spring is next to the 15-cm mark on the ruler. If a 2.5-kg mass is now attached to the end of the spring, and the mass is allowed to fall freely, where will the end of the spring line up with the ruler marks when the mass is at its lowest position?

**16.** (II) A 0.40-kg ball is thrown with a speed of 7.8 m/s at an upward angle of 36°. (*a*) What is its speed at its highest point, and (*b*) how high does it go? Use conservation of energy for part *b*.

**17.** (II) A 1400-kg car moving on a horizontal surface has speed $v = 85\ \text{km/h}$ when it strikes a horizontal coiled spring and is brought to rest in a distance of 2.2 m. What is the spring constant of the spring? Ignore any thermal energy produced in the collision.

**18.** (II) A 62-kg trampoline artist jumps upward from the top of a platform with a vertical speed of 4.5 m/s. (*a*) How fast is he going as he lands on the trampoline, 2.0 m below (Fig. 8–32)? (*b*) If the trampoline behaves like a spring of spring constant $5.8 \times 10^4\ \text{N/m}$, how far does he depress it?

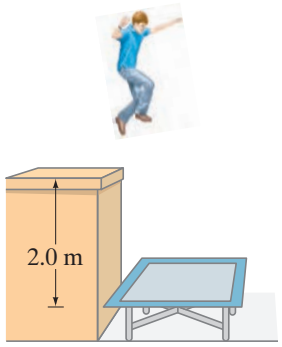


**FIGURE 8–32**
Problem 18.

**19.** (II) A vertical spring (ignore its mass), whose spring constant is 875 N/m, is attached to a table and is compressed down by 0.220 m. (*a*) What upward speed can it give to a 0.380-kg ball when released? (*b*) How high above its original position (spring compressed) will the ball fly?

**20.** (II) A roller-coaster car shown in Fig. 8–33 is pulled up to point 1 where it is released from rest. Assuming no friction, calculate the speed at points 2, 3, and 4.

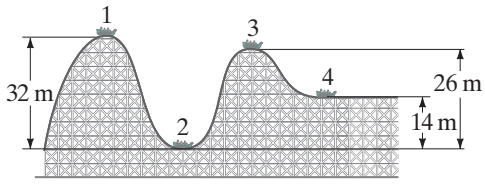

**FIGURE 8–33** Problems 20 and 31.

**21.** (II) When a mass *m* sits at rest on a spring, the spring is compressed by a distance *d* from its undeformed length (Fig. 8–34a). Suppose instead that the mass is released from rest when it barely touches the undeformed spring (Fig. 8–34b). Find the distance *D* that the spring is compressed before it is able to stop the mass. Does $D = d$? If not, why not?

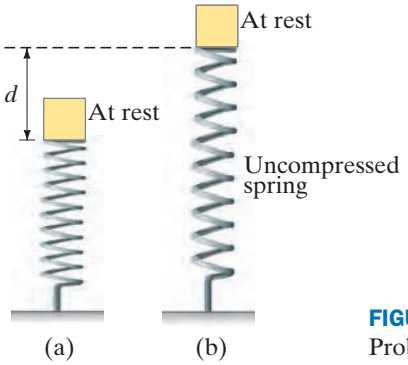

**FIGURE 8–34**
Problem 21.

**22.** (II) Two masses are connected by a string as shown in Fig. 8–35. Mass $m_A = 3.5\ \text{kg}$ rests on a frictionless inclined plane, while $m_B = 5.0\ \text{kg}$ is initially held at a height of $h = 0.75\ \text{m}$ above the floor. (*a*) If $m_B$ is allowed to fall, what will be the resulting acceleration of the masses? (*b*) If the masses were initially at rest, use the kinematic equations (Eqs. 2–12) to find their velocity just before $m_B$ hits the floor. (*c*) Use conservation of energy to find the velocity of the masses just before $m_B$ hits the floor. You should get the same answer as in part (*b*).

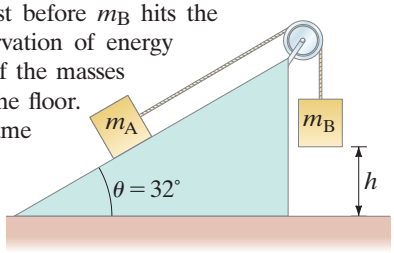

**FIGURE 8–35**
Problem 22.

**23.** (II) The 9.0-kg mass in Fig. 8–36 is held just barely in contact with a spring for which $k = 450\ \text{N/m}$. When that mass is released, it falls, compressing the spring and pulling the 3.0-kg mass up. How far does the 9.0-kg mass fall before momentarily coming to rest? Ignore friction in the pulley.

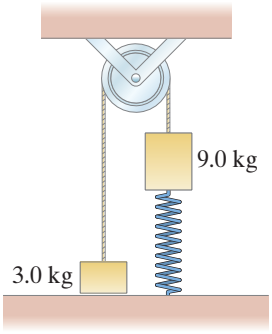

**FIGURE 8–36**
Problem 23.

**24.** (II) Chris jumps off a bridge with a 15-m-long *bungee cord* (a heavy stretchable cord) tied around his ankle, Fig. 8–37. He falls 15 m before the bungee cord begins to stretch. Chris's mass is 75 kg and we assume the cord obeys Hooke's law, $F = -kx$, with $k = 55\ \text{N/m}$. If we neglect air resistance, estimate what distance *d* below the bridge Chris's foot will be before coming to a stop. Ignore the mass of the cord (not realistic, however) and treat Chris as a particle.

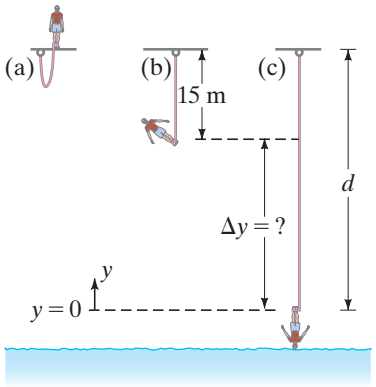

**FIGURE 8–37**
Problem 24. (a) Bungee jumper about to jump. (b) Bungee cord at its unstretched length. (c) Maximum stretch of cord.

**25.** (III) An engineer is designing a spring to be placed at the bottom of an elevator shaft. If the elevator cable breaks when the elevator is at a height *h* above the top of the spring, calculate the value that the spring constant *k* should have so that passengers undergo an acceleration of no more than 4.5 *g* when being brought to rest. Let *M* be the total mass of the elevator and passengers.

**26.** (III) A skier of mass $m$ starts from rest at the top of a solid sphere of radius $r$ and slides down its frictionless surface. ($a$) At what angle $\theta$ (Fig. 8–38) will the skier leave the sphere? ($b$) If friction is present, does the skier fly off at a greater or lesser angle?

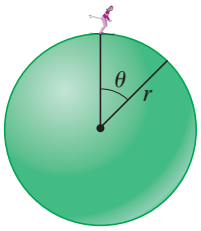

**FIGURE 8–38**
Problem 26.

## 8–5 and 8–6 Law of Conservation of Energy

**27.** (I) Two railroad cars, each of mass 72,000 kg, are traveling 85 km/h toward each other. They collide head-on and come to rest. How much thermal energy is produced in this collision?

**28.** (I) A 16.0-kg child descends a slide 2.20 m high and, starting from rest, reaches the bottom with a speed of 1.15 m/s. How much thermal energy due to friction was generated in this process?

**29.** (II) A ski starts from rest and slides down a 28° incline 85 m long. ($a$) If the coefficient of friction is 0.090, what is the ski's speed at the base of the incline? ($b$) If the snow is level at the foot of the incline and has the same coefficient of friction, how far will the ski travel along the level? Use energy methods.

**30.** (II) A 145-g baseball is dropped from a tree 14.0 m above the ground. ($a$) With what speed would it hit the ground if air resistance could be ignored? ($b$) If it actually hits the ground with a speed of 12.5 m/s, what is the average force of air resistance exerted on it?

**31.** (II) Suppose the roller-coaster car in Fig. 8–33 passes point 1 with a speed of 1.30 m/s. If the average force of friction is equal to 0.23 of its weight, with what speed will it reach point 2? The distance traveled is 45.0 m.

**32.** (II) An 18-kg sled starts up a 28° incline with a speed of 2.3 m/s. The coefficient of kinetic friction is $\mu_k = 0.25$. ($a$) How far up the incline does the sled travel? ($b$) What condition must you put on the coefficient of static friction if the sled is not to get stuck at the point determined in part ($a$)? ($c$) If the sled slides back down, what is its speed when it returns to its starting point?

**33.** (II) A projectile is fired at an upward angle of 34.0° from the top of a 135-m-high cliff with a speed of 165 m/s. What will be its speed when it strikes the ground below? (Use conservation of energy.)

**34.** (II) A *Lunar Module* could make a safe landing on the Moon if its vertical velocity at impact is 3.0 m/s or less. Suppose that you want to determine the greatest height $h$ at which the pilot could shut off the engine if the velocity of the lander relative to the surface is ($a$) zero; ($b$) 2.0 m/s downward; ($c$) 2.0 m/s upward. Use conservation of energy to determine $h$ in each case. The acceleration due to gravity at the surface of the Moon is 1.62 m/s$^2$.

**35.** (II) You slide down an 8.0-m-high icy hill ($\approx$ frictionless). At the bottom is a level stretch where the coefficient of kinetic friction is 0.30. How far would you travel across the level stretch?

**36.** (II) Consider the track shown in Fig. 8–39. The section AB is one quadrant of a circle of radius 2.0 m and is frictionless. B to C is a horizontal span 3.0 m long with a coefficient of kinetic friction $\mu_k = 0.25$. The section CD under the spring is frictionless. A block of mass 1.0 kg is released from rest at A. After sliding on the track, it compresses the spring by 0.20 m. Determine: ($a$) the velocity of the block at point B; ($b$) the thermal energy produced as the block slides from B to C; ($c$) the velocity of the block at point C; ($d$) the stiffness constant $k$ for the spring.

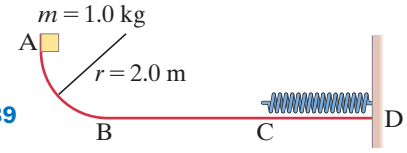

**FIGURE 8–39**
Problem 36.

**37.** (II) A 0.680-kg wood block is firmly attached to a very light horizontal spring ($k = 180$ N/m) as shown in Fig. 8–40. This block–spring system, when compressed 5.0 cm and released, stretches out 2.3 cm beyond the equilibrium position before stopping and turning back. What is the coefficient of kinetic friction between the block and the table?

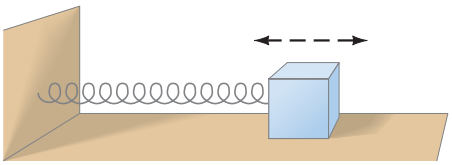

**FIGURE 8–40**
Problem 37.

**38.** (III) A spring ($k = 75$ N/m) has an equilibrium length of 1.00 m. The spring is compressed to a length of 0.50 m and a mass of 2.0 kg is placed at its free end on a frictionless slope which makes an angle of 41° with respect to the horizontal (Fig. 8–41). The spring is then released. ($a$) If the mass is *not* attached to the spring, how far up the slope will the mass move before coming to rest? ($b$) If the mass *is* attached to the spring, how far up the slope will the mass move before coming to rest? ($c$) Now the incline has a coefficient of kinetic friction $\mu_k$. If the block, attached to the spring, is observed to stop just as it reaches the spring's equilibrium position, what is the coefficient of friction $\mu_k$?

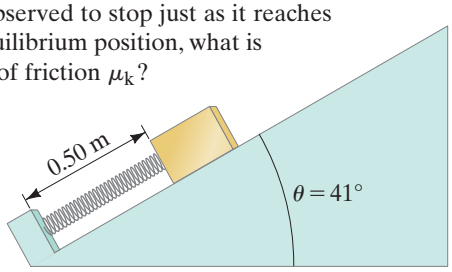

**FIGURE 8–41**
Problem 38.

**39.** (III) A 2.0-kg block slides along a horizontal surface with a coefficient of kinetic friction $\mu_k = 0.30$. The block has a speed $v = 1.6$ m/s when it strikes a massless spring head-on (as in Fig. 8–17). ($a$) If the spring has force constant $k = 120$ N/m, how far is the spring compressed? ($b$) What minimum value of the coefficient of static friction, $\mu_s$, will assure that the spring remains compressed at the maximum compressed position? ($c$) If $\mu_s$ is less than this, what is the speed of the block when it detaches from the decompressing spring? [*Hint*: Detachment occurs when the spring reaches its natural length ($x = 0$); explain why.]

**40.** (III) Early test flights for the space shuttle used a "glider" (mass of 980 kg including pilot). After a horizontal launch at 480 km/h at a height of 3200 m, the glider eventually landed at sea level with a speed of 210 km/h. (*a*) What would its landing speed have been in the absence of air resistance? (*b*) What was the average force of air resistance exerted on it if it came in at a constant glide angle of 12° to the Earth's surface?

## 8–7 Gravitational Potential Energy

**41.** (I) The escape velocity from planet A is double that for planet B. The two planets have the same mass. What is the ratio of their radii, $r_A/r_B$?

**42.** (II) For a satellite of mass $m_S$ in a circular orbit of radius $r_S$ around the Earth, determine (*a*) its kinetic energy $K$, (*b*) its potential energy $U$ ($U = 0$ at infinity), and (*c*) the ratio $K/U$.

**43.** (II) Show that Eq. 8–16 for gravitational potential energy reduces to Eq. 8–2, $\Delta U = mg(y_2 - y_1)$, for objects near the surface of the Earth. [*Hint*: set $r = r_E + y$, and assume $y \ll r_E$; see Eq. 6–4].

**44.** (II) Determine the *escape velocity from the Sun* for an object: (*a*) at the Sun's surface ($r = 7.0 \times 10^5$ km, $M = 2.0 \times 10^{30}$ kg); (*b*) at the average distance of the Earth ($1.50 \times 10^8$ km). Compare (give factor for each) to the speed of the Earth in its orbit.

**45.** (II) Two Earth *satellites*, A and B, each of mass $m = 950$ kg, are launched into circular orbits around the Earth's center. Satellite A orbits at an altitude of 4800 km, and satellite B orbits at an altitude of 12,600 km. (*a*) What are the potential energies of the two satellites? (*b*) What are the kinetic energies of the two satellites? (*c*) How much work would it require to change the orbit of satellite A to match that of satellite B?

**46.** (II) A NASA *satellite* is said to have observed an *asteroid* that is on a collision course with the Earth. The asteroid has an estimated mass, based on its size, of $4 \times 10^9$ kg. It is approaching the Earth on a head-on course with a velocity of 660 m/s relative to the Earth and is now $5.0 \times 10^6$ km away. With what speed will it hit the Earth's surface, neglecting friction with the atmosphere?

**47.** (II) Take into account the Earth's rotational speed (1 rev/day) and determine the necessary "escape velocity," with respect to the Earth, for a rocket to escape if fired from the Earth at the equator in a direction (*a*) eastward; (*b*) westward; (*c*) vertically upward.

**48.** (II) (*a*) Determine a formula for the maximum height $h$ that a rocket will reach if launched vertically from the Earth's surface with speed $v_0$ ($< v_{esc}$). Express in terms of $v_0$, $r_E$, $M_E$, and $G$. (*b*) How high does a rocket go if $v_0 = 8.35$ km/s? Ignore air resistance and the Earth's rotation.

**49.** (II) (*a*) Determine the rate at which the escape velocity from the Earth changes with distance $r$ ($> r_E$) from the center of the Earth, $dv_{esc}/dr$. (*b*) Use the approximation $\Delta v \approx (dv/dr)\Delta r$ to determine the escape velocity for a spacecraft orbiting the Earth at a height of 320 km.

**50.** (II) A *meteorite* has a speed of 90.0 m/s when 750 km above the Earth. It is falling vertically (ignore air resistance) and strikes a bed of sand in which it is brought to rest in 3.25 m. (*a*) What is its speed just before striking the sand? (*b*) How much work does the sand do to stop the meteorite (mass = 575 kg)? (*c*) What is the average force exerted by the sand on the meteorite? (*d*) How much thermal energy is produced?

**51.** (II) How much work would be required to move a satellite of mass $m$ from a circular orbit of radius $r_1 = 2r_E$ about the Earth to another circular orbit of radius $r_2 = 3r_E$? ($r_E$ is the radius of the Earth.)

**52.** (II) A sphere of radius $r_1$ has a concentric spherical cavity of radius $r_2$ (Fig. 8–42). Assume this spherical shell of thickness $r_1 - r_2$ is uniform and has a total mass $M$. Show that the gravitational potential energy of a mass $m$ at a distance $r$ from the center of the shell ($r > r_1$) is given by

$$U = -\frac{GmM}{r}.$$

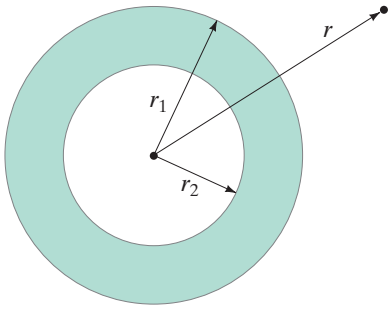

**FIGURE 8–42**
Problem 52.

**53.** (II) (*a*) Show that the total mechanical energy of a *satellite* (mass $m$) orbiting at a distance $r$ from the center of the Earth (mass $M_E$) is

$$E = -\frac{1}{2}\frac{GmM_E}{r},$$

if $U = 0$ at $r = \infty$. (*b*) What is the ratio of kinetic energy to potential energy? (*c*) Although friction causes the value of $E$ to decrease slowly, show that the orbit radius $r$ decreases and kinetic energy increases if the orbit remains a circle.

**54.** (III) To *escape the solar system*, an interstellar spacecraft launched from Earth must overcome the gravitational attraction of both the Earth and Sun. Ignore the effects of other bodies in the solar system. (*a*) Show that the *escape velocity from the Solar System* is

$$v = \sqrt{v_E^2 + (v_S - v_0)^2} = 16.7 \text{ km/s},$$

where: $v_E$ is the escape velocity from the Earth (Eq. 8–19); $v_S = \sqrt{2GM_S/r_{SE}}$ is the escape velocity from the gravitational field of the Sun (mass $M_S$) at the orbit of the Earth but far from the Earth's influence ($r_{SE}$ is the Sun–Earth distance); and $v_0$ is the Earth's orbital velocity about the Sun. (*b*) Show that the energy required is $1.40 \times 10^8$ J per kilogram of spacecraft mass. [*Hint*: Write the energy equation for escape from Earth with $v'$ as the spacecraft velocity, relative to Earth, but somewhat far from Earth (so its potential energy relative to Earth $\simeq 0$, but it is still $\simeq r_{SE}$ from the Sun). Then let $v' + v_0$ be the escape velocity from the Sun.]

## 8–8 Power

**55.** (I) What is the average power output of an elevator that lifts 845 kg a vertical height of 32.0 m in 11.0 s?

**56.** (I) How long will it take a 1750-W motor to lift a 335-kg piano to a sixth-story window 18.0 m above?

**57.** (I) An 85-kg football player traveling 5.0 m/s is stopped in 1.0 s by a tackler. (*a*) What is the original kinetic energy of the player? (*b*) What average power is required to stop him?

**58.** (II) If a car generates 18 hp when traveling at a steady 95 km/h, what must be the average force exerted on the car due to friction and air resistance?

**59.** (II) (*a*) Show that one British horsepower (550 ft · lb/s) is equal to 746 W. (*b*) What is the horsepower rating of a 75-W lightbulb? (*c*) How many kW is a 180-hp engine?

**60.** (II) An outboard motor for a boat is rated at 35 hp. If it can move a particular boat at a steady speed of 35 km/h, what is the total force resisting the motion of the boat?

**61.** (II) A shot-putter accelerates a 7.3-kg shot from rest to 14 m/s in 1.5 s. What average power was developed?

**62.** (II) A driver notices that her 950-kg car, when in neutral, slows down from 95 km/h to 65 km/h in about 7.0 s on a flat horizontal road. Approximately what power (watts and hp) is needed to keep the car traveling at a constant 80 km/h?

**63.** (II) A 975-kg sports car accelerates from rest to 95 km/h in 6.4 s. What is the average power delivered by the engine?

**64.** (II) During a workout, football players ran up the stadium stairs in 75 s. The distance along the stairs is 83 m and they are inclined at a 33° angle. If a player has a mass of 88 kg, estimate his average power output on the way up. Ignore friction and air resistance.

**65.** (II) A pump lifts 27.0 kg of water per minute through a height of 3.50 m. What minimum output rating (watts) must the pump motor have?

**66.** (II) A ski area claims that its lifts can move 45,000 people per hour. If the average lift carries people about 200 m (vertically) higher, estimate the maximum total power needed.

**67.** (II) A 65-kg skier grips a moving rope that is powered by an engine and is pulled at constant speed to the top of a 23° hill. The skier is pulled a distance $x = 250\,\text{m}$ along the incline and it takes 2.0 min to reach the top of the hill. If the coefficient of kinetic friction between the snow and skis is $\mu_k = 0.10$, what horsepower engine is required if 35 such skiers (max) are on the rope at one time?

**68.** (II) What minimum horsepower must a motor have to be able to drag a 370-kg box along a level floor at a speed of 1.20 m/s if the coefficient of friction is 0.45?

**69.** (III) The position of a 280-g object is given (in meters) by $x = 4.0t^3 - 8.0t^2 - 44t$, where $t$ is in seconds. Determine the net rate of work done on this object (*a*) at $t = 2.0\,\text{s}$ and (*b*) at $t = 4.0\,\text{s}$. (*c*) What is the average net power input during the interval from $t = 0\,\text{s}$ to $t = 2.0\,\text{s}$, and in the interval from $t = 2.0\,\text{s}$ to 4.0 s?

**70.** (III) A bicyclist coasts down a 6.0° hill at a steady speed of 4.0 m/s. Assuming a total mass of 75 kg (bicycle plus rider), what must be the cyclist's power output to climb the same hill at the same speed?

## 8–9 Potential Energy Diagrams

**71.** (II) Draw a potential energy diagram, $U$ vs. $x$, and analyze the motion of a mass $m$ resting on a frictionless horizontal table and connected to a horizontal spring with stiffness constant $k$. The mass is pulled a distance to the right so that the spring is initially stretched a distance $x_0$ from equilibrium $(x = 0)$, and then the mass is released from rest.

**72.** (II) The spring of Problem 71 has a stiffness constant $k = 160\,\text{N/m}$. The mass $m = 6.0\,\text{kg}$ is released from rest when the spring is stretched $x_0 = 1.0\,\text{m}$ from equilibrium. Determine (*a*) the total energy of the system; (*b*) the kinetic energy when $x = \frac{1}{2}x_0$; (*c*) the maximum kinetic energy; (*d*) the maximum speed and at what positions it occurs; (*e*) the maximum acceleration and where it occurs.

**73.** (II) The graph of Fig. 8–43 shows the potential energy curve of a particle moving along the $x$ axis under the influence of a conservative force. Note that the total energy $E > U(x)$, so that the particle's speed is never zero. (*a*) In which interval(s) of $x$ is the force on the particle to the right? (*b*) At what value(s) of $x$ is the magnitude of the force a minimum? (*c*) At what value of $x$ is the magnitude of the force a maximum?

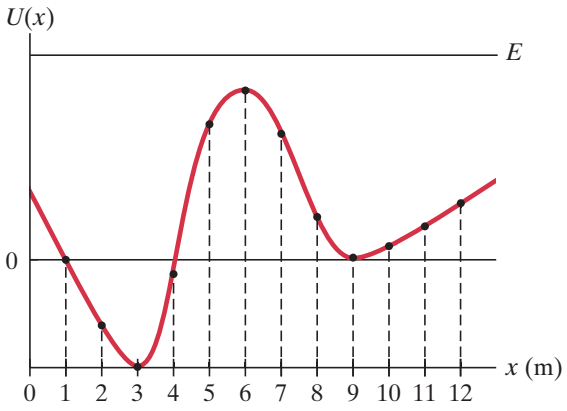

**FIGURE 8–43** Problem 73.

**74.** (III) The potential energy of the two atoms in a diatomic (two-atom) molecule can be approximated as (*Lennard-Jones* potential)

$$U(r) = -\frac{a}{r^6} + \frac{b}{r^{12}},$$

where $r$ is the distance between the two atoms and $a$ and $b$ are positive constants. (*a*) At what values of $r$ is $U(r)$ a minimum? A maximum? (*b*) At what values of $r$ is $U(r) = 0$? (*c*) Plot $U(r)$ as a function of $r$ from $r = 0$ to $r$ at a value large enough for all the features in (*a*) and (*b*) to show. (*d*) Describe the motion of one atom with respect to the second atom when $E < 0$, and when $E > 0$. (*e*) Let $F$ be the force one atom exerts on the other. For what values of $r$ is $F > 0$, $F < 0$, $F = 0$? (*f*) Determine $F$ as a function of $r$.

**75.** (III) The *binding energy* of a two-particle system is defined as the energy required to separate the two particles from their state of lowest energy to $r = \infty$. Determine the binding energy for the molecule discussed in Problem 74.

**76.** (III) A particle moves where its potential energy is given by $U(r) = U_0[(2/r^2) - (1/r)]$. (*a*) Plot $U(r)$ versus $r$. Where does the curve cross the $U(r) = 0$ axis? At what value of $r$ does the minimum value of $U(r)$ occur? (*b*) Suppose that the particle has an energy of $E = -0.050\,U_0$. Mark on your graph the approximate turning points of the motion of the particle. What is the maximum kinetic energy of the particle, and for what value of $r$ does this occur?

## *8–10 Gravitational Assist

***77.** (III) Show that to *slow down* a spacecraft (perhaps to put it into orbit around a planet or moon) $v_{0x}$ must be in the *same* direction as $\vec{\mathbf{u}}$ and have magnitude greater than $u$. Show that this means the spacecraft will then pass in *front* of Jupiter. Draw a new diagram to replace Fig. 8–25b for this situation.

# General Problems

**78.** (*a*) A 3.0-g locust reaches a speed of 3.0 m/s during its jump. What is its kinetic energy at this speed? (*b*) If the locust transforms energy with 35% efficiency, how much energy is required for the jump?

**79.** Water flows slowly over a dam at the rate of 320 kg/s and falls vertically 88 m before striking the turbine blades. Calculate (*a*) the speed of the water just before striking the turbine blades (neglect air resistance), and (*b*) the rate at which mechanical energy is transferred to the turbine blades, assuming 55% efficiency.

**80.** A bicyclist of mass 75 kg (including the bicycle) can coast down a 5.0° hill at a steady speed of 12 km/h. Pumping hard, the cyclist can descend the hill at a speed of 32 km/h. Using the same power, at what speed can the cyclist climb the same hill? Assume the force of friction is proportional to the square of the speed $v$; that is, $F_{fr} = bv^2$, where $b$ is a constant.

**81.** A 55-kg skier starts from rest at the top of a ski jump, point A in Fig. 8–44, and travels down the ramp. If friction and air resistance can be neglected, (*a*) determine her speed $v_B$ when she reaches the horizontal end of the ramp at B. (*b*) Determine the distance $s$ to where she strikes the ground at C.

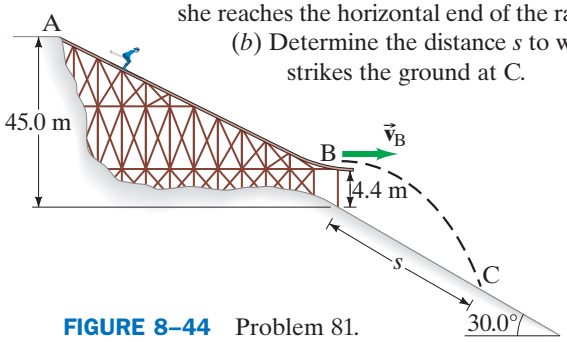

**FIGURE 8–44** Problem 81.

**82.** A ball is attached to a horizontal cord of length $\ell$ whose other end is fixed, Fig. 8–45. (*a*) If the ball is released, what will be its speed at the lowest point of its path? (*b*) A peg is located a distance $h$ directly below the point of attachment of the cord. If $h = 0.80\,\ell$, what will be the speed of the ball when it reaches the top of its circular path about the peg?

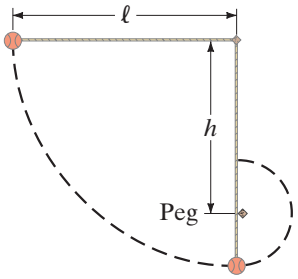

**FIGURE 8–45**
Problems 82 and 83.

**83.** Show that $h$ must be greater than $0.60\,\ell$ if the ball in Fig. 8–45 is to make a complete circle about the peg.

**84.** A cyclist intends to cycle up a 7.50° hill whose vertical height is 125 m. The pedals turn in a circle of diameter 36.0 cm. Assuming the mass of bicycle plus rider is 75.0 kg, (*a*) calculate how much work she must do against gravity. (*b*) If each complete revolution of the pedals moves the bike 5.10 m along its path, calculate the average force that must be exerted on the pedals tangent to their circular path. Neglect work done by friction and other losses.

**85.** If you stand on a bathroom scale, the spring inside the scale compresses 0.60 mm, and it tells you your weight is 760 N. Now if you jump on the scale from a height of 1.0 m, what does the scale read at its peak? Assume Hooke's law holds.

**86.** Show that on a roller coaster with a circular vertical loop (Fig. 8–46), the difference in your "apparent weight" (see Section 6–4) at the top of the loop and the bottom of the loop is 6.0 times your weight. Ignore friction. Show also that as long as your speed is above the minimum needed (so the car holds the track), this answer doesn't depend on the size of the loop or how fast you go through it.

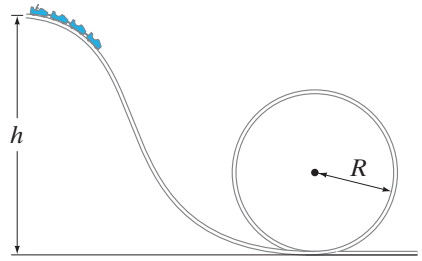

**FIGURE 8–46**
Problem 86.

**87.** A 65-kg hiker climbs to the top of a mountain 3900 m high. The climb is made in 4.6 h starting at an elevation of 2800 m. Calculate (*a*) the work done by the hiker against gravity, (*b*) the average power output in watts and in horsepower, and (*c*) assuming the body is 15% efficient, what rate of energy input was required.

**88.** Consider a force $F(x) = Ax^{3/2}$ acting on an object moving in a straight line. Assume that $A = 10.0\,\text{N/m}^z$. (*a*) What is the value of the exponent $z$? (*b*) Calculate the work done by this force as the object moves from $x = 0$ to $x = 3.0$ m.

**89.** The small mass $m$ sliding without friction along the looped track shown in Fig. 8–47 is to remain on the track at all times, even at the very top of the loop of radius $r$. (*a*) In terms of the given quantities, determine the minimum release height $h$. (*b*) If the actual release height is $2h$, calculate the normal force exerted by the track at the bottom of the loop, then (*c*) by the track at the top of the loop, and (*d*) by the track after the block exits the loop onto the flat section.

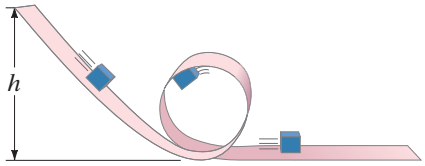

**FIGURE 8–47**
Problem 89.

**90.** Some electric power companies use placement of water to store energy. Water is pumped from a low reservoir to a high reservoir. To store the energy produced in 1.0 hour by a 180-MW electric power plant, how many cubic meters of water will have to be pumped from the lower to the upper reservoir? Assume the upper reservoir is 380 m above the lower one. Water has a mass of $1.00 \times 10^3$ kg for every 1.0 $\text{m}^3$ $(1\,\text{MW} = 10^6\,\text{W})$.

**91.** A film of Jesse Owens's famous long jump (Fig. 8–48) in the 1936 Olympics shows that his center of mass rose 1.1 m from launch point to the top of the arc. What minimum speed did he need at launch if he was traveling at 6.5 m/s at the top of the arc?

**FIGURE 8–48**
Problem 91.

**92.** The nuclear force between two neutrons in a nucleus is described roughly by the Yukawa potential

$$U(r) = -U_0 \frac{r_0}{r} e^{-r/r_0},$$

where $r$ is the distance between the neutrons and $U_0$ and $r_0$ ($\approx 10^{-15}$ m) are constants. (*a*) Determine the force $F(r)$. (*b*) What is the ratio $F(3r_0)/F(r_0)$? (*c*) Calculate this same ratio for the force between two electrically charged particles where $U(r) = -C/r$, with $C$ a constant. (*d*) Why is the Yukawa force referred to as a "short-range" force?

**93.** A 56-kg student runs at 6.0 m/s, grabs a hanging 10.0-m-long rope, and swings out over a lake (Fig. 8–49). He releases the rope when his velocity is zero. (*a*) What is the angle $\theta$ when he releases the rope? (*b*) What is the tension in the rope just before he releases it? (*c*) What is the maximum tension in the rope during the swing?

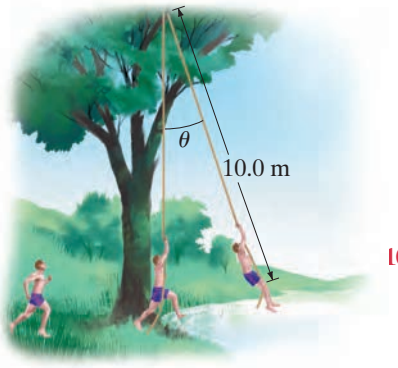

**FIGURE 8–49**
Problem 93.

**94.** A fire hose for use in urban areas must be able to shoot a stream of water to a maximum height of 33 m. The water leaves the hose at ground level as a circular stream 3.0 cm in diameter. What minimum power is required to create such a stream of water? Every cubic meter of water has a mass of $1.00 \times 10^3$ kg.

**95.** Proper design of automobile braking systems must account for heat buildup under heavy braking. Calculate the thermal energy dissipated from brakes in a 1500-kg car that descends a 17° hill. The car begins braking when its speed is 95 km/h and slows to a speed of 35 km/h in a distance of 0.30 km measured along the road.

**96.** (*a*) Suppose we have three masses, $m_1, m_2$, and $m_3$, that initially are extremely ($\approx$ infinitely) far apart from each other. Show that the work needed to bring them to the positions shown in Fig. 8–50 is

$$W = -G\left(\frac{m_1 m_2}{r_{12}} + \frac{m_1 m_3}{r_{13}} + \frac{m_2 m_3}{r_{23}}\right).$$

(*b*) Can we say that this formula also gives the potential energy of the system, or the potential energy of one or two of the objects? (*c*) Is $W$ equal to the binding energy of the system—that is, is $W$ equal to the energy required to separate the components by an infinite distance? Explain.

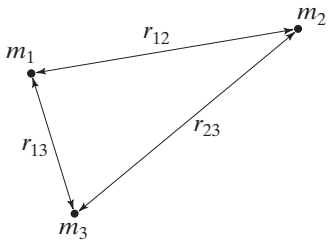

**FIGURE 8–50** Problem 96.

**97.** How much work can a 3.0-hp motor do in 1.0h?

**98.** Estimate the energy required from fuel to launch a 1225-kg satellite into orbit 1375 km above the Earth's surface. Consider two cases: (*a*) the satellite is launched into an equatorial orbit from a point on the Earth's equator, and (*b*) it is launched from the North Pole into a polar orbit.

**99.** A satellite is in an elliptic orbit around the Earth (Fig. 8–51). Its speed at the perigee A is 8650 m/s. (*a*) Use conservation of energy to determine its speed at B. (*b*) Use conservation of energy to determine the speed at the apogee C.

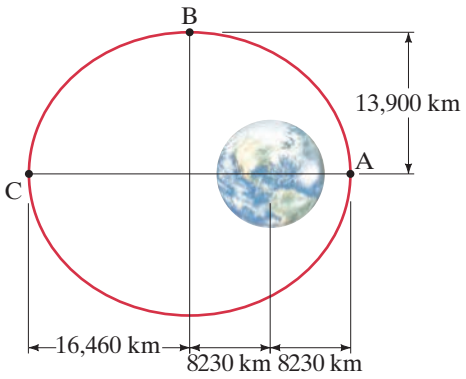

**FIGURE 8–51**
Problem 99.

**100.** Suppose the gravitational potential energy of an object of mass $m$ at a distance $r$ from the center of the Earth is given by

$$U(r) = -\frac{GMm}{r} e^{-\alpha r}$$

where $\alpha$ is a positive constant. (Newton's law of universal gravitation has $\alpha = 0$). (*a*) What would be the force on the object as a function of $r$? (*b*) What would be the object's escape velocity in terms of the Earth's radius $R_E$?

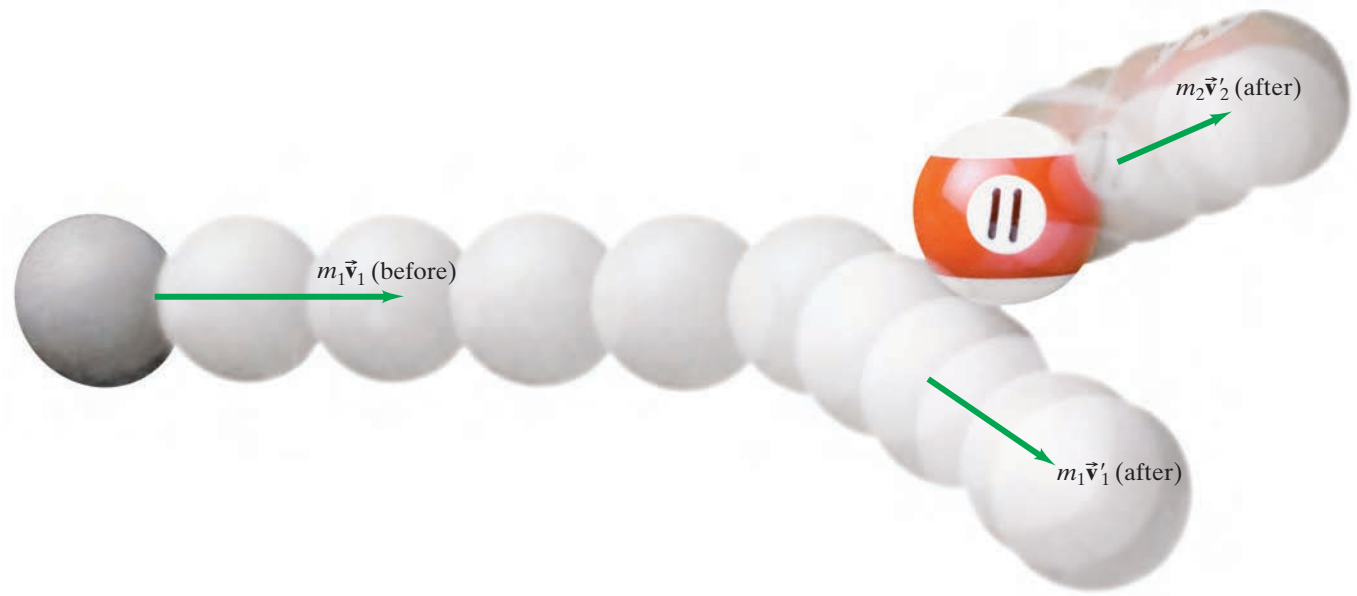
**101.** A particle of mass $m$ moves under the influence of a potential energy

$$U(x) = \frac{a}{x} + bx$$

where $a$ and $b$ are positive constants and the particle is restricted to the region $x > 0$. Find a point of equilibrium for the particle and demonstrate that it is stable.

**102.** An elevator cable breaks when a 975-kg elevator is 28.5 m above a huge spring ($k = 8.00 \times 10^4$ N/m) at the bottom of the shaft. Calculate (*a*) the work done by gravity on the elevator before it hits the spring; (*b*) the speed of the elevator just before striking the spring; and (*c*) the amount the spring compresses (use conservation of energy). Ignore any energy transformed to heat.

**103.** A 1600-kg spacecraft is launched from Earth and lands on the Moon. How does its total potential energy before launch compare with its total potential energy after landing?



**104.** The two atoms in a diatomic molecule exert an attractive force on each other at large distances and a repulsive force at short distances. The magnitude of the force between two atoms in a diatomic molecule can be approximated by the Lennard-Jones force, or $F(r) = F_0\left[2(\sigma/r)^{13} - (\sigma/r)^7\right]$, where $r$ is the separation between the two atoms, and $\sigma$ and $F_0$ are constants. For an oxygen molecule (which is diatomic) $F_0 = 9.60 \times 10^{-11}$ N and $\sigma = 3.50 \times 10^{-11}$ m. (*a*) Integrate the equation for $F(r)$ to determine the potential energy $U(r)$ of the oxygen molecule. (*b*) Find the equilibrium distance $r_0$ between the two atoms. (*c*) Graph $F(r)$ and $U(r)$ between $0.9\,r_0$ and $2.5\,r_0$.

## ANSWERS TO EXERCISES

**A:** (*b*).
**B:** (*c*).
**C:** Equal speeds.
**D:** (*e*), (*e*); (*e*), (*c*).

Conservation of linear momentum is another great conservation law of physics. Collisions, such as between billiard or pool balls, illustrate this law very nicely: the total vector momentum just before the collision equals the total vector momentum just after the collision. In this photo, the moving cue ball makes a glancing collision with the 11 ball which is initially at rest. After the collision, both balls move at angles, but the sum of their vector momenta equals the initial vector momentum of the incoming cue ball.

We will consider both elastic collisions (where kinetic energy is also conserved) and inelastic collisions. We also examine the concept of center of mass, and how it helps us in the study of complex motion.

CHAPTER 9

# Linear Momentum

## CHAPTER-OPENING QUESTIONS—Guess now!

**1.** A railroad car loaded with rocks coasts on a level track without friction. A worker at the back of the car starts throwing the rocks horizontally backward from the car. Then what happens?

**(a)** The car slows down.
**(b)** The car speeds up.
**(c)** First the car speeds up and then it slows down.
**(d)** The car's speed remains constant.
**(e)** None of these.

**2.** Which answer would you choose if the rocks fall out through a hole in the floor of the car, one at a time?

The law of conservation of energy, which we discussed in the previous Chapter, is one of several great conservation laws in physics. Among the other quantities found to be conserved are linear momentum, angular momentum, and electric charge. We will eventually discuss all of these because the conservation laws are among the most important ideas in science. In this Chapter we discuss linear momentum and its conservation. The law of conservation of momentum is essentially a reworking of Newton's laws that gives us tremendous physical insight and problem-solving power.

The law of conservation of momentum is particularly useful when dealing with a system of two or more objects that interact with each other, such as in collisions of ordinary objects or nuclear particles.

Our focus up to now has been mainly on the motion of a single object, often thought of as a "particle" in the sense that we have ignored any rotation or internal motion. In this Chapter we will deal with systems of two or more objects, and—toward the end of the Chapter—the concept of center of mass.

## 9–1 Momentum and Its Relation to Force

The **linear momentum** (or "momentum" for short) of an object is defined as the product of its mass and its velocity. Momentum (plural is *momenta*) is represented by the symbol $\vec{\mathbf{p}}$. If we let $m$ represent the mass of an object and $\vec{\mathbf{v}}$ represent its velocity, then its momentum $\vec{\mathbf{p}}$ is defined as

$$\vec{\mathbf{p}} = m\vec{\mathbf{v}}. \tag{9–1}$$

Velocity is a vector, so momentum too is a vector. The direction of the momentum is the direction of the velocity, and the magnitude of the momentum is $p = mv$. Because velocity depends on the reference frame, so does momentum; thus the reference frame must be specified. The unit of momentum is that of mass $\times$ velocity, which in SI units is kg · m/s. There is no special name for this unit.

Everyday usage of the term *momentum* is in accord with the definition above. According to Eq. 9–1, a fast-moving car has more momentum than a slow-moving car of the same mass; a heavy truck has more momentum than a small car moving with the same speed. The more momentum an object has, the harder it is to stop it, and the greater effect it will have on another object if it is brought to rest by striking that object. A football player is more likely to be stunned if tackled by a heavy opponent running at top speed than by a lighter or slower-moving tackler. A heavy, fast-moving truck can do more damage than a slow-moving motorcycle.

**EXERCISE A** Can a small sports car ever have the same momentum as a large sport-utility vehicle with three times the sports car's mass? Explain.

A force is required to change the momentum of an object, whether it is to increase the momentum, to decrease it, or to change its direction. Newton originally stated his second law of motion in terms of momentum (although he called the product $mv$ the "quantity of motion"). Newton's statement of the **second law of motion**, translated into modern language, is as follows:

> **The rate of change of momentum of an object is equal to the net force applied to it.**

We can write this as an equation,

*NEWTON'S SECOND LAW*

$$\Sigma\vec{\mathbf{F}} = \frac{d\vec{\mathbf{p}}}{dt}, \tag{9–2}$$

**⚠ CAUTION**

*The change in the momentum vector is in the direction of the net force*

where $\Sigma\vec{\mathbf{F}}$ is the net force applied to the object (the vector sum of all forces acting on it). We can readily derive the familiar form of the second law, $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$, from Eq. 9–2 for the case of constant mass. If $\vec{\mathbf{v}}$ is the velocity of an object at any moment, then Eq. 9–2 gives

$$\Sigma\vec{\mathbf{F}} = \frac{d\vec{\mathbf{p}}}{dt} = \frac{d(m\vec{\mathbf{v}})}{dt} = m\frac{d\vec{\mathbf{v}}}{dt} = m\vec{\mathbf{a}} \qquad \text{[constant mass]}$$

because, by definition, $\vec{\mathbf{a}} = d\vec{\mathbf{v}}/dt$ and we assume $m$ = constant. Newton's statement, Eq. 9–2, is actually more general than simply $\vec{\mathbf{F}} = m\vec{\mathbf{a}}$ because Eq. 9–2 is valid also in situations when the mass may change. For example, rockets lose mass as they burn fuel (Section 9–10).

**EXAMPLE 9–1** **ESTIMATE** **Force of a tennis serve.** For a top player, a tennis ball may leave the racket on the serve with a speed of 55 m/s (about 120 mi/h), Fig. 9–1. If the ball has a mass of 0.060 kg and is in contact with the racket for about 4 ms $(4 \times 10^{-3}\,\text{s})$, estimate the average force on the ball. Would this force be large enough to lift a 70-kg person?

**APPROACH** We write Newton's second law, Eq. 9–2, for the average force as

$$F_{\text{avg}} = \frac{\Delta p}{\Delta t} = \frac{mv_2 - mv_1}{\Delta t},$$

where $mv_1$ and $mv_2$ are the initial and final momenta. The tennis ball is hit when its initial velocity $v_1$ is very nearly zero at the top of the throw, so we set $v_1 = 0$, and we assume $v_2 = 55\,\text{m/s}$ is in the horizontal direction. We ignore all other forces on the ball during this brief time interval, such as gravity, in comparison to the force exerted by the tennis racket.

**SOLUTION** The force exerted on the ball by the racket is

$$F_{\text{avg}} = \frac{\Delta p}{\Delta t} = \frac{mv_2 - mv_1}{\Delta t} = \frac{(0.060\,\text{kg})(55\,\text{m/s}) - 0}{0.004\,\text{s}} \approx 800\,\text{N}.$$

This is a large force, larger than the weight of a 70-kg person, which would require a force $mg = (70\,\text{kg})(9.8\,\text{m/s}^2) \approx 700\,\text{N}$ to lift.

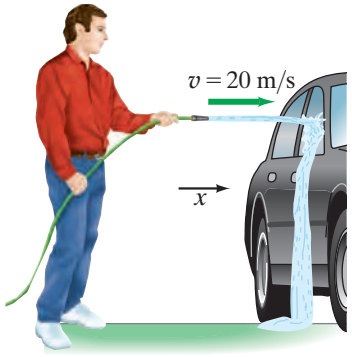
**NOTE** The force of gravity acting on the tennis ball is $mg = (0.060\,\text{kg})(9.8\,\text{m/s}^2) = 0.59\,\text{N}$, which justifies our ignoring it compared to the enormous force the racket exerts.

**NOTE** High-speed photography and radar can give us an estimate of the contact time and the velocity of the ball leaving the racket. But a direct measurement of the force is not practical. Our calculation shows a handy technique for determining an unknown force in the real world.

**FIGURE 9–1** Example 9–1.

**EXAMPLE 9–2** **Washing a car: momentum change and force.** Water leaves a hose at a rate of 1.5 kg/s with a speed of 20 m/s and is aimed at the side of a car, which stops it, Fig. 9–2. (That is, we ignore any splashing back.) What is the force exerted by the water on the car?

**APPROACH** The water leaving the hose has mass and velocity, so it has a momentum $p_{\text{initial}}$ in the horizontal ($x$) direction, and we assume gravity doesn't pull the water down significantly before it hits the car. When the water hits the car, the water loses this momentum $(p_{\text{final}} = 0)$. We use Newton's second law in the momentum form, Eq. 9–2, to find the force that the car exerts on the water to stop it. By Newton's third law, the force exerted by the water on the car is equal and opposite. We have a continuing process: 1.5 kg of water leaves the hose in each 1.0-s time interval. So let us write $F = \Delta p/\Delta t$ where $\Delta t = 1.0\,\text{s}$, and $mv_{\text{initial}} = (1.5\,\text{kg})(20\,\text{m/s}) = 30\,\text{kg}\cdot\text{m/s}$.



**SOLUTION** The force (assumed constant) that the car must exert to change the momentum of the water is

$$F = \frac{\Delta p}{\Delta t} = \frac{p_{\text{final}} - p_{\text{initial}}}{\Delta t} = \frac{0 - 30\,\text{kg}\cdot\text{m/s}}{1.0\,\text{s}} = -30\,\text{N}.$$

The minus sign indicates that the force exerted by the car on the water is opposite to the water's original velocity. The car exerts a force of 30 N to the left to stop the water, so by Newton's third law, the water exerts a force of 30 N to the right on the car.

**NOTE** Keep track of signs, although common sense helps too. The water is moving to the right, so common sense tells us the force on the car must be to the right.

**FIGURE 9–2** Example 9–2.

**EXERCISE B** If the water splashes back from the car in Example 9–2, would the force on the car be larger or smaller?

# 9–2 Conservation of Momentum

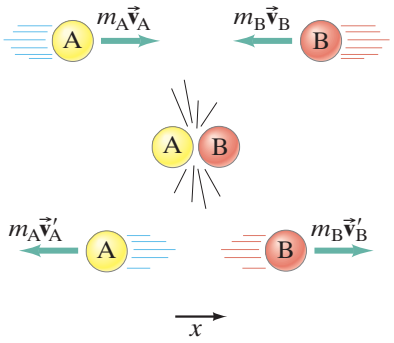


**FIGURE 9–3** Momentum is conserved in a collision of two balls, labeled A and B.

The concept of momentum is particularly important because, if no net external force acts on a system, the total momentum of the system is a conserved quantity. This was expressed in Eq. 9–2 for a single object, but it holds also for a system of objects, as we shall discuss.

Consider the head-on collision of two billiard balls, as shown in Fig. 9–3. We assume the net external force on this system of two balls is zero—that is, the only significant forces during the collision are the forces that each ball exerts on the other. Although the momentum of each of the two balls changes as a result of the collision, the *sum* of their momenta is found to be the same before as after the collision. If $m_A\vec{\mathbf{v}}_A$ is the momentum of ball A and $m_B\vec{\mathbf{v}}_B$ the momentum of ball B, both measured just before the collision, then the total momentum of the two balls before the collision is the vector sum $m_A\vec{\mathbf{v}}_A + m_B\vec{\mathbf{v}}_B$. Immediately after the collision, the balls each have a different velocity and momentum, which we designate by a "prime" on the velocity: $m_A\vec{\mathbf{v}}'_A$ and $m_B\vec{\mathbf{v}}'_B$. The total momentum after the collision is the vector sum $m_A\vec{\mathbf{v}}'_A + m_B\vec{\mathbf{v}}'_B$. No matter what the velocities and masses are, experiments show that the total momentum before the collision is the same as afterward, whether the collision is head-on or not, as long as no net external force acts:

*CONSERVATION OF MOMENTUM (two objects colliding)*

$$\text{momentum before} = \text{momentum after}$$

$$m_A\vec{\mathbf{v}}_A + m_B\vec{\mathbf{v}}_B = m_A\vec{\mathbf{v}}'_A + m_B\vec{\mathbf{v}}'_B. \qquad [\Sigma\vec{\mathbf{F}}_{\text{ext}} = 0] \quad \textbf{(9–3)}$$

That is, the total vector momentum of the system of two colliding balls is conserved: it stays constant. (We saw this result in this Chapter's opening photograph.)

Although the law of conservation of momentum was discovered experimentally, it can be derived from Newton's laws of motion, which we now show.

Let us consider two objects of mass $m_A$ and $m_B$ that have momenta $\vec{\mathbf{p}}_A$ $(= m_A\vec{\mathbf{v}}_A)$ and $\vec{\mathbf{p}}_B$ $(= m_B\vec{\mathbf{v}}_B)$ before they collide and $\vec{\mathbf{p}}'_A$ and $\vec{\mathbf{p}}'_B$ after they collide, as in Fig. 9–4. During the collision, suppose that the force exerted by object A on object B at any instant is $\vec{\mathbf{F}}$. Then, by Newton's third law, the force exerted by object B on object A is $-\vec{\mathbf{F}}$. During the brief collision time, we assume no other (external) forces are acting (or that $\vec{\mathbf{F}}$ is much greater than any other external forces acting). Thus we have

$$\vec{\mathbf{F}} = \frac{d\vec{\mathbf{p}}_B}{dt}$$

and

$$-\vec{\mathbf{F}} = \frac{d\vec{\mathbf{p}}_A}{dt}.$$

We add these two equations together and find

$$0 = \frac{d(\vec{\mathbf{p}}_A + \vec{\mathbf{p}}_B)}{dt}$$

which tells us that

$$\vec{\mathbf{p}}_A + \vec{\mathbf{p}}_B = \text{constant}.$$

This is Eq. 9–3. The total momentum is conserved.

We have put this derivation in the context of a collision. As long as no external forces act, it is valid over any time interval, and conservation of momentum is always valid as long as no external forces act on the chosen system. In the real world, external forces do act: friction on billiard balls, gravity acting on a tennis ball, and so on. So we often want our "observation time" (before and after) to be small. When a racket hits a tennis ball or a bat hits a baseball, both before and after the "collision" the ball moves as a projectile under the action of gravity and air resistance.

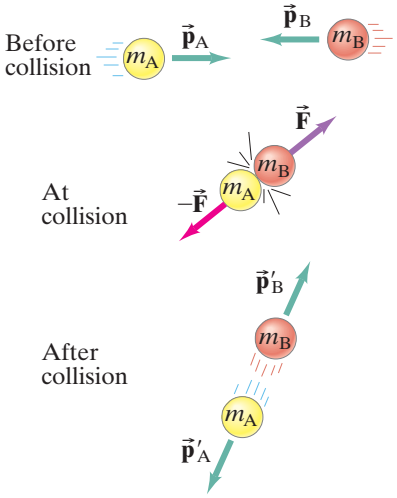

**FIGURE 9–4** Collision of two objects. Their momenta before collision are $\vec{\mathbf{p}}_A$ and $\vec{\mathbf{p}}_B$, and after collision are $\vec{\mathbf{p}}'_A$ and $\vec{\mathbf{p}}'_B$. At any moment during the collision each exerts a force on the other of equal magnitude but opposite direction.

However, when the bat or racket hits the ball, during the brief time of the collision those external forces are insignificant compared to the collision force the bat or racket exerts on the ball. Momentum is conserved (or very nearly so) as long as we measure $\vec{\mathbf{p}}_A$ and $\vec{\mathbf{p}}_B$ just before the collision and $\vec{\mathbf{p}}'_A$ and $\vec{\mathbf{p}}'_B$ immediately after the collision (Eq. 9–3). We can not wait for external forces to produce their effect before measuring $\vec{\mathbf{p}}'_A$ and $\vec{\mathbf{p}}'_B$.

Our derivation of the conservation of momentum can be extended to include any number of interacting objects. Let $\vec{\mathbf{P}}$ represent the total momentum of a system of $n$ interacting objects which we number from 1 to $n$:

$$\vec{\mathbf{P}} = m_1\vec{\mathbf{v}}_1 + m_2\vec{\mathbf{v}}_2 + \cdots + m_n\vec{\mathbf{v}}_n = \Sigma\vec{\mathbf{p}}_i.$$

We differentiate with respect to time:

$$\frac{d\vec{\mathbf{P}}}{dt} = \Sigma\frac{d\vec{\mathbf{p}}_i}{dt} = \Sigma\vec{\mathbf{F}}_i \qquad \textbf{(9–4)}$$

where $\vec{\mathbf{F}}_i$ represents the *net* force on the $i^{\text{th}}$ object. The forces can be of two types: (1) *external forces* on objects of the system, exerted by objects outside the system, and (2) *internal forces* that objects within the system exert on other objects in the system. By Newton's third law, the internal forces occur in pairs: if one object exerts a force on a second object, the second exerts an equal and opposite force on the first object. Thus, in the sum over all the forces in Eq. 9–4, all the internal forces cancel each other in pairs. So only external forces are left in Eq. 9–4:

$$\frac{d\vec{\mathbf{P}}}{dt} = \Sigma\vec{\mathbf{F}}_{\text{ext}}, \qquad \textbf{(9–5)}$$

*NEWTON'S SECOND LAW (for a system of objects)*

where $\Sigma\vec{\mathbf{F}}_{\text{ext}}$ is the sum of all external forces acting on our system. If the net external force is zero, then $d\vec{\mathbf{P}}/dt = 0$, so $\Delta\vec{\mathbf{P}} = 0$ or $\vec{\mathbf{P}} = \text{constant}$. Thus we see that

**when the net external force on a system of objects is zero, the total momentum of the system remains constant.**

*LAW OF CONSERVATION OF LINEAR MOMENTUM*

This is the **law of conservation of momentum**. It can also be stated as

**the total momentum of an isolated system of objects remains constant.**

By **system**, we simply mean a set of objects that we choose, and which may interact with each other. An **isolated system** is one in which the only (significant) forces are those between the objects in the system. The sum of all these "internal" forces within the system will be zero because of Newton's third law. If there are *external forces*—by which we mean forces exerted by objects *outside* the system—and they don't add up to zero, then the system is not isolated and the total momentum of the system won't be conserved. However, if the system can be redefined so as to include the other objects exerting these forces, then the conservation of momentum principle can apply. For example, if we take as our system a falling rock, it does not conserve momentum because an external force, the force of gravity exerted by the Earth, accelerates the rock and changes its momentum. However, if we include the Earth in the system, the total momentum of rock plus Earth is conserved. (This means that the Earth comes up to meet the rock. But the Earth's mass is so great, its upward velocity is tiny and unnoticeable.)

Although the law of conservation of momentum follows from Newton's second law, as we have seen, it is in fact more general than Newton's laws. In the tiny world of the atom, Newton's laws fail, but the great conservation laws—those of energy, momentum, angular momentum, and electric charge—have been found to hold in every experimental situation tested. It is for this reason that the conservation laws are considered more basic than Newton's laws.

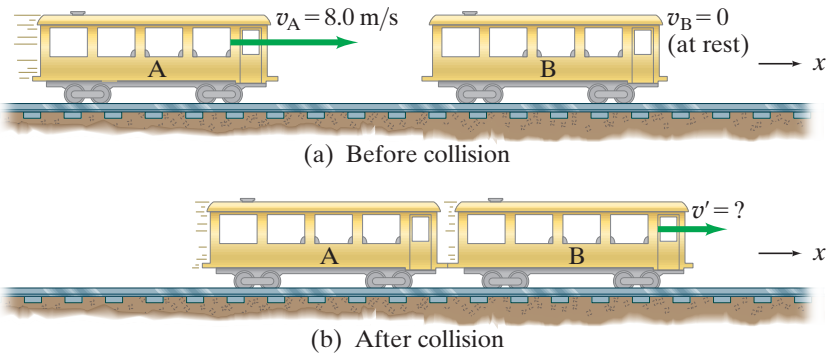

**FIGURE 9–5** Example 9–3.

**EXAMPLE 9–3** **Railroad cars collide: momentum conserved.** A 10,000-kg railroad car, A, traveling at a speed of 8.0 m/s strikes an identical car, B, at rest. If the cars lock together as a result of the collision, what is their common speed just afterward? See Fig. 9–5.

**APPROACH** We choose our system to be the two railroad cars. We consider a very brief time interval, from just before the collision until just after, so that external forces such as friction can be ignored. Then we apply conservation of momentum:

$$P_{\text{initial}} = P_{\text{final}}.$$

**SOLUTION** The initial total momentum is

$$P_{\text{initial}} = m_A v_A + m_B v_B = m_A v_A$$

because car B is at rest initially $(v_B = 0)$. The direction is to the right in the $+x$ direction. After the collision, the two cars become attached, so they will have the same speed, call it $v'$. Then the total momentum after the collision is

$$P_{\text{final}} = (m_A + m_B)\, v'.$$

We have assumed there are no external forces, so momentum is conserved:

$$P_{\text{initial}} = P_{\text{final}}$$

$$m_A v_A = (m_A + m_B)\, v'.$$

Solving for $v'$, we obtain

$$v' = \frac{m_A}{m_A + m_B} v_A = \left(\frac{10{,}000\text{ kg}}{10{,}000\text{ kg} + 10{,}000\text{ kg}}\right)(8.0\text{ m/s}) = 4.0\text{ m/s},$$

to the right. Their mutual speed after collision is half the initial speed of car A because their masses are equal.

**NOTE** We kept symbols until the very end, so we have an equation we can use in other (related) situations.

**NOTE** We haven't mentioned friction here. Why? Because we are examining speeds just before and just after the very brief time interval of the collision, and during that brief time friction can't do much—it is ignorable (but not for long: the cars will slow down because of friction).

**EXERCISE C** In Example 9–3, what result would you get if (*a*) $m_B = 3m_A$, (*b*) $m_B$ is much larger than $m_A$ $(m_B \gg m_A)$, and (*c*) $m_B \ll m_A$?

**EXERCISE D** A 50-kg child runs off a dock at 2.0 m/s (horizontally) and lands in a waiting rowboat of mass 150 kg. At what speed does the rowboat move away from the dock?

The law of conservation of momentum is particularly useful when we are dealing with fairly simple systems such as colliding objects and certain types of "explosions." For example, *rocket propulsion*, which we saw in Chapter 4 can be understood on the basis of action and reaction, can also be explained on the basis of the conservation of momentum. We can consider the rocket and fuel as an isolated system if it is far out in space (no external forces). In the reference frame of the rocket before any fuel is ejected, the total momentum of rocket plus fuel is zero. When the fuel burns, the total momentum remains unchanged: the backward momentum of the expelled gases is just balanced by the forward momentum gained by the rocket itself (see Fig. 9–6). Thus, a rocket can accelerate in empty space. There is no need for the expelled gases to push against the Earth or the air (as is sometimes erroneously thought). Similar examples of (nearly) isolated systems where momentum is conserved are the recoil of a gun when a bullet is fired (Example 9–4), and the movement of a rowboat just after a package is thrown from it.

**PHYSICS APPLIED**
*Rocket propulsion*

**CAUTION**
*Rockets accelerate by pushing out fuel gas they burn, not by pushing on Earth*

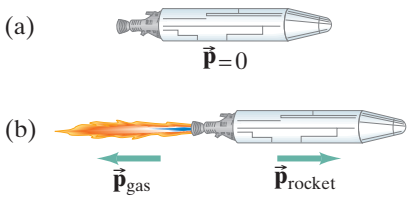

**FIGURE 9–6** (a) A rocket, containing fuel, at rest in some reference frame. (b) In the same reference frame, the rocket fires, and gases are expelled at high speed out the rear. The total vector momentum, $\vec{\mathbf{P}} = \vec{\mathbf{p}}_{\text{gas}} + \vec{\mathbf{p}}_{\text{rocket}}$, remains zero.

**EXAMPLE 9–4** **Rifle recoil.** Calculate the recoil velocity of a 5.0-kg rifle that shoots a 0.020-kg bullet at a speed of 620 m/s, Fig. 9–7.

**APPROACH** Our system is the rifle and the bullet, both at rest initially, just before the trigger is pulled. The trigger is pulled, an explosion occurs inside the bullet's shell, and we look at the rifle and bullet just as the bullet leaves the barrel (Fig. 9–7b). The bullet moves to the right $(+x)$, and the gun recoils to the left. During the very short time interval of the explosion, we can assume the external forces are small compared to the forces exerted by the exploding gunpowder. Thus we can apply conservation of momentum, at least approximately.

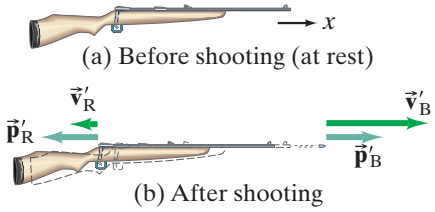
**SOLUTION** Let subscript B represent the bullet and R the rifle; the final velocities are indicated by primes. Then momentum conservation in the $x$ direction gives

$$\begin{aligned} \text{momentum before} &= \text{momentum after} \\ m_{\text{B}}v_{\text{B}} + m_{\text{R}}v_{\text{R}} &= m_{\text{B}}v'_{\text{B}} + m_{\text{R}}v'_{\text{R}} \\ 0 + 0 &= m_{\text{B}}v'_{\text{B}} + m_{\text{R}}v'_{\text{R}}. \end{aligned}$$

We solve for the unknown $v'_{\text{R}}$, and find

$$v'_{\text{R}} = -\frac{m_{\text{B}}v'_{\text{B}}}{m_{\text{R}}} = -\frac{(0.020\,\text{kg})\,(620\,\text{m/s})}{(5.0\,\text{kg})} = -2.5\,\text{m/s}.$$

Since the rifle has a much larger mass, its (recoil) velocity is much less than that of the bullet. The minus sign indicates that the velocity (and momentum) of the rifle is in the negative $x$ direction, opposite to that of the bullet.



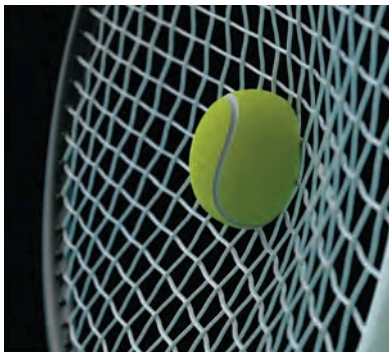


**FIGURE 9–7** Example 9–4.

**CONCEPTUAL EXAMPLE 9–5** **Falling on or off a sled.** (*a*) An empty sled is sliding on frictionless ice when Jeanne drops vertically from a tree down onto the sled. When she lands, does the sled speed up, slow down, or keep the same speed? (*b*) Later: Jeanne falls sideways off the sled. When she drops off, does the sled speed up, slow down, or keep the same speed?

**RESPONSE** (*a*) Because Jeanne falls vertically onto the sled, she has no initial horizontal momentum. Thus the total horizontal momentum afterward equals the momentum of the sled initially. Since the mass of the system (sled + person) has increased, the speed must decrease.

(*b*) At the instant Jeanne falls off, she is moving with the same horizontal speed as she was while on the sled. At the moment she leaves the sled (before hitting the ground), she has the same momentum she had an instant before. Because her momentum does not change, neither does the sled's (total momentum conserved); the sled keeps the same speed.

**EXERCISE E** Return to the Chapter-Opening Questions, page 227, and answer them again now. Try to explain why you may have answered differently the first time.

(a)

(b)

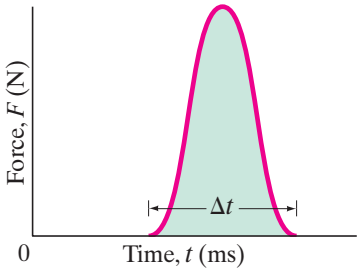

**FIGURE 9–8** (a) Tennis racket striking a ball. Both the ball and the racket strings are deformed due to the large force each exerts on the other. (b) Also for a baseball and bat.

# 9–3 Collisions and Impulse

Collisions are a common occurrence in everyday life: a tennis racket or a baseball bat striking a ball, billiard balls colliding, a hammer hitting a nail. When a collision occurs, the force that each object exerts on the other one is usually far stronger than any external forces. We can then ignore the effects of any other forces during the brief time interval of the collision.

During a collision of two ordinary objects, both objects are deformed, often considerably, because of the large forces involved (Fig. 9–8). When the collision occurs, the force each exerts on the other usually jumps from zero at the moment of contact to a very large force within a very short time, and then rapidly returns to zero again. A graph of the magnitude of the force that one object exerts on the other during a collision, as a function of time, is something like the red curve in Fig. 9–9. The time interval $\Delta t$ is usually very distinct and usually very small, typically milliseconds for a macroscopic collision.

**FIGURE 9–9** Force as a function of time during a typical collision. $F$ can become very large; $\Delta t$ is typically milliseconds for macroscopic collisions.

From Newton's second law, Eq. 9–2, the *net* force on an object is equal to the rate of change of its momentum:

$$\vec{\mathbf{F}} = \frac{d\vec{\mathbf{p}}}{dt}.$$

(We have written $\vec{\mathbf{F}}$ instead of $\Sigma\vec{\mathbf{F}}$ for the net force, which we assume is entirely due to the brief but large force that acts during the collision.) This equation applies to *each* of the objects in a collision. During the infinitesimal time interval $dt$, the momentum changes by

$$d\vec{\mathbf{p}} = \vec{\mathbf{F}}\,dt. \qquad \textbf{(9–6a)}$$

If we integrate this over the duration of a collision, we have

$$\int_{\text{i}}^{\text{f}} d\vec{\mathbf{p}} = \vec{\mathbf{p}}_{\text{f}} - \vec{\mathbf{p}}_{\text{i}} = \int_{t_{\text{i}}}^{t_{\text{f}}} \vec{\mathbf{F}}\,dt,$$

where $\vec{\mathbf{p}}_{\text{i}}$ and $\vec{\mathbf{p}}_{\text{f}}$ are the initial and final momenta of the object, just before and just after the collision. The integral of the net force over the time interval during which it acts is called the **impulse**, $\vec{\mathbf{J}}$:

$$\vec{\mathbf{J}} = \int_{t_{\text{i}}}^{t_{\text{f}}} \vec{\mathbf{F}}\,dt.$$

Thus the change in momentum of an object, $\Delta\vec{\mathbf{p}} = \vec{\mathbf{p}}_{\text{f}} - \vec{\mathbf{p}}_{\text{i}}$, is equal to the impulse acting on it:

$$\Delta\vec{\mathbf{p}} = \vec{\mathbf{p}}_{\text{f}} - \vec{\mathbf{p}}_{\text{i}} = \int_{t_{\text{i}}}^{t_{\text{f}}} \vec{\mathbf{F}}\,dt = \vec{\mathbf{J}}. \qquad \textbf{(9–6b)}$$

The units for impulse are the same as for momentum, kg · m/s (or N · s) in SI. Since $\vec{\mathbf{J}} = \int \vec{\mathbf{F}}\,dt$, we can state that the impulse $\vec{\mathbf{J}}$ of a force is equal to the area under the $F$ versus $t$ curve, as indicated by the shading in Fig. 9–9.

Equation 9–6b (also Eq. 9–6a) is true only if $\vec{\mathbf{F}}$ is the *net* force on the object. It is valid for *any* net force $\vec{\mathbf{F}}$ where $\vec{\mathbf{p}}_{\text{i}}$ and $\vec{\mathbf{p}}_{\text{f}}$ correspond precisely to the times $t_{\text{i}}$ and $t_{\text{f}}$.

But the impulse concept is really most useful for so-called *impulsive forces*—that is, for a force like that shown in Fig. 9–9, which has a very large magnitude over a very short time interval and is essentially zero outside this time interval. For most collision processes, the impulsive force is much larger than any other force acting, and the others can be neglected. For such an impulsive force, the time interval over which we take the integral in Eq. 9–6b is not critical as long as we start before $t_i$ and end after $t_f$, since $\vec{\mathbf{F}}$ is essentially zero outside this time interval. (Of course, if the chosen time interval is too large, the effect of the other (external) forces does become significant—such as the flight of a tennis ball which, after the impulsive force administered by the racket, begins to fall under gravity.)

It is sometimes useful to speak of the average force, $\vec{\mathbf{F}}_{\text{avg}}$, during a collision, defined as that constant force which, if acting over the same time interval $\Delta t = t_f - t_i$ as the actual force, would produce the same impulse and change in momentum. Thus

$$\vec{\mathbf{F}}_{\text{avg}}\,\Delta t = \int_{t_i}^{t_f} \vec{\mathbf{F}}\,dt.$$

Figure 9–10 shows the magnitude of the average force, $F_{\text{avg}}$, for the impulsive force of Fig. 9–9. The rectangular area $F_{\text{avg}}\,\Delta t$ equals the area under the impulsive force curve.

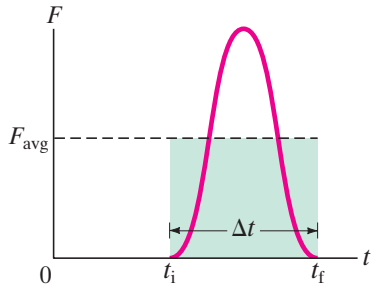

**FIGURE 9–10** The average force $F_{\text{avg}}$ acting over a very brief time interval $\Delta t$ gives the same impulse $(F_{\text{avg}}\,\Delta t)$ as the actual force.

**EXAMPLE 9–6** **ESTIMATE** **Karate blow.** Estimate the impulse and the average force delivered by a karate blow (Fig. 9–11) that breaks a board a few cm thick. Assume the hand moves at roughly 10 m/s when it hits the board.

**APPROACH** We use the momentum-impulse relation, Eq. 9–6b. The hand's speed changes from 10 m/s to zero over a distance of perhaps one cm (roughly how much your hand and the board compress before your hand comes to a stop, and the board begins to give way). The hand's mass should probably include part of the arm, and we take it to be roughly $m \approx 1\,\text{kg}$.

**SOLUTION** The impulse $J$ equals the change in momentum

$$J = \Delta p = (1\,\text{kg})(10\,\text{m/s} - 0) = 10\,\text{kg}\cdot\text{m/s}.$$

We obtain the force from the definition of impulse $F_{\text{avg}} = J/\Delta t$; but what is $\Delta t$? The hand is brought to rest over the distance of roughly a centimeter: $\Delta x \approx 1\,\text{cm}$. The average speed during the impact is $\bar{v} = (10\,\text{m/s} + 0)/2 = 5\,\text{m/s}$ and equals $\Delta x/\Delta t$. Thus $\Delta t = \Delta x/\bar{v} \approx (10^{-2}\,\text{m})/(5\,\text{m/s}) = 2\times10^{-3}\,\text{s}$ or about 2 ms. The force is thus (Eq. 9–6b) about

$$F_{\text{avg}} = \frac{J}{\Delta t} = \frac{10\,\text{kg}\cdot\text{m/s}}{2\times10^{-3}\,\text{s}} \approx 5000\,\text{N} = 5\,\text{kN}.$$

**FIGURE 9–11** Example 9–6.

## 9–4 Conservation of Energy and Momentum in Collisions

During most collisions, we usually don't know how the collision force varies over time, and so analysis using Newton's second law becomes difficult or impossible. But by making use of the conservation laws for momentum and energy, we can still determine a lot about the motion after a collision, given the motion before the collision. We saw in Section 9–2 that in the collision of two objects such as billiard balls, the total momentum is conserved. If the two objects are very hard and no heat or other form of energy is produced in the collision, then the total kinetic energy ($K$) of the two objects is the same after the collision as before. For the brief moment during which the two objects are in contact, some (or all) of the energy is stored momentarily in the form of elastic potential energy. But if we compare the total kinetic energy just before the collision with the total kinetic energy just after the collision, and they are found to be the same, then we say that the total kinetic energy is conserved. Such a collision is called an **elastic collision**.

**CAUTION**
*Elastic collision: total K conserved*

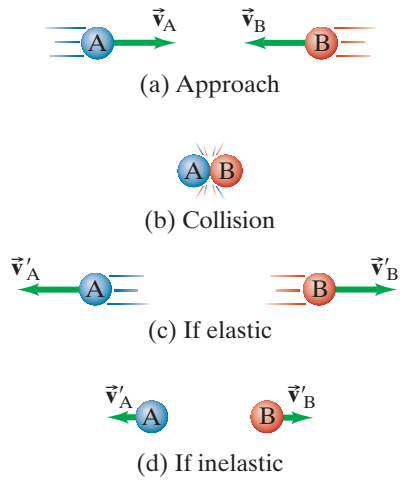

**FIGURE 9–12** Two equal-mass objects (a) approach each other with equal speeds, (b) collide, and then (c) bounce off with equal speeds in the opposite directions if the collision is elastic, or (d) bounce back much less or not at all if the collision is inelastic (some of the kinetic energy is transformed to other forms of energy such as sound and heat).

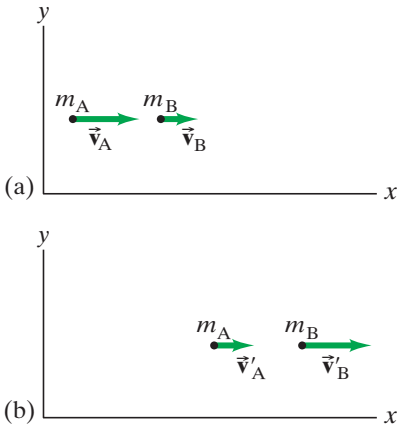

**FIGURE 9–13** Two small objects of masses $m_A$ and $m_B$, (a) before the collision and (b) after the collision.

If we use the subscripts A and B to represent the two objects, we can write the equation for conservation of total kinetic energy as

$$\text{total kinetic energy before} = \text{total kinetic energy after}$$

$$\tfrac{1}{2}m_A v_A^2 + \tfrac{1}{2}m_B v_B^2 = \tfrac{1}{2}m_A v_A'^2 + \tfrac{1}{2}m_B v_B'^2. \qquad \text{[elastic collision]} \quad \textbf{(9–7)}$$

Primed quantities ($'$) mean after the collision, and unprimed mean before the collision, just as in Eq. 9–3 for conservation of momentum.

At the atomic level the collisions of atoms and molecules are often elastic. But in the "macroscopic" world of ordinary objects, an elastic collision is an ideal that is never quite reached, because at least a little thermal energy (and perhaps sound and other forms of energy) is always produced during a collision. The collision of two hard elastic balls, such as billiard balls, however, is very close to being perfectly elastic, and we often treat it as such.

We do need to remember that even when the kinetic energy is not conserved, the *total* energy is always conserved.

Collisions in which kinetic energy is not conserved are said to be **inelastic collisions**. The kinetic energy that is lost is changed into other forms of energy, often thermal energy, so that the total energy (as always) is conserved. In this case,

$$K_A + K_B = K'_A + K'_B + \text{thermal and other forms of energy.}$$

See Fig. 9–12, and the details in its caption. We discuss inelastic collisions in Section 9–6.

# 9–5 Elastic Collisions in One Dimension

We now apply the conservation laws for momentum and kinetic energy to an elastic collision between two small objects that collide head-on, so all the motion is along a line. To be general, we assume that the two objects are moving, and their velocities $v_A$ and $v_B$ are along the $x$ axis before the collision, Fig. 9–13a. After the collision, their velocities are $v'_A$ and $v'_B$, Fig. 9–13b. For any $v > 0$, the object is moving to the right (increasing $x$), whereas for $v < 0$, the object is moving to the left (toward decreasing values of $x$).

From conservation of momentum, we have

$$m_A v_A + m_B v_B = m_A v'_A + m_B v'_B.$$

Because the collision is assumed to be elastic, kinetic energy is also conserved:

$$\tfrac{1}{2}m_A v_A^2 + \tfrac{1}{2}m_B v_B^2 = \tfrac{1}{2}m_A v_A'^2 + \tfrac{1}{2}m_B v_B'^2.$$

We have two equations, so we can solve for two unknowns. If we know the masses and velocities before the collision, then we can solve these two equations for the velocities after the collision, $v'_A$ and $v'_B$. We derive a helpful result by rewriting the momentum equation as

$$m_A(v_A - v'_A) = m_B(v'_B - v_B), \qquad \textbf{(i)}$$

and we rewrite the kinetic energy equation as

$$m_A(v_A^2 - v_A'^2) = m_B(v_B'^2 - v_B^2).$$

Noting that algebraically $a^2 - b^2 = (a - b)(a + b)$, we write this last equation as

$$m_A(v_A - v'_A)(v_A + v'_A) = m_B(v'_B - v_B)(v'_B + v_B). \qquad \textbf{(ii)}$$

We divide Eq. (ii) by Eq. (i), and (assuming $v_A \neq v'_A$ and $v_B \neq v'_B$)[†] obtain

$$v_A + v'_A = v'_B + v_B.$$

[†]Note that Eqs. (i) and (ii), which are the conservation laws for momentum and kinetic energy, are both satisfied by the solution $v'_A = v_A$ and $v'_B = v_B$. This is a valid solution, but not very interesting. It corresponds to no collision at all—when the two objects miss each other.

We can rewrite this equation as

$$v_A - v_B = v'_B - v'_A$$

or

$$v_A - v_B = -(v'_A - v'_B). \quad [\text{head-on (1-D) elastic collision}] \quad \textbf{(9–8)}$$

**CAUTION**
*Relative speeds (1-D only) (independent of masses)*

This is an interesting result: it tells us that for any elastic head-on collision, the relative speed of the two objects after the collision $(v'_A - v'_B)$ has the same magnitude (but opposite direction) as before the collision, no matter what the masses are.

Equation 9–8 was derived from conservation of kinetic energy for elastic collisions, and can be used in place of it. Because the $v$'s are not squared in Eq. 9–8, it is simpler to use in calculations than the conservation of kinetic energy equation (Eq. 9–7) directly.

**EXAMPLE 9–7** **Equal masses.** Billiard ball A of mass $m$ moving with speed $v_A$ collides head-on with ball B of equal mass. What are the speeds of the two balls after the collision, assuming it is elastic? Assume (*a*) both balls are moving initially ($v_A$ and $v_B$), (*b*) ball B is initially at rest $(v_B = 0)$.

**APPROACH** There are two unknowns, $v'_A$ and $v'_B$, so we need two independent equations. We focus on the time interval from just before the collision until just after. No net external force acts on our system of two balls ($mg$ and the normal force cancel), so momentum is conserved. Conservation of kinetic energy applies as well because we are told the collision is elastic.

**SOLUTION** (*a*) The masses are equal $(m_A = m_B = m)$ so conservation of momentum gives

$$v_A + v_B = v'_A + v'_B.$$

We need a second equation, because there are two unknowns. We could use the conservation of kinetic energy equation, or the simpler Eq. 9–8 derived from it:

$$v_A - v_B = v'_B - v'_A.$$

We add these two equations and obtain

$$v'_B = v_A$$

and then subtract the two equations to obtain

$$v'_A = v_B.$$

That is, the balls exchange velocities as a result of the collision: ball B acquires the velocity that ball A had before the collision, and vice versa.

(*b*) If ball B is at rest initially, so that $v_B = 0$, we have

$$v'_B = v_A \quad \text{and} \quad v'_A = 0.$$

That is, ball A is brought to rest by the collision, whereas ball B acquires the original velocity of ball A. See Fig. 9–14.

**NOTE** The result in part (*b*) is often observed by billiard and pool players, and is valid only if the two balls have equal masses (and no spin is given to the balls).

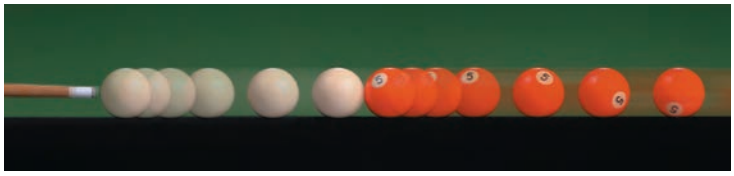

**FIGURE 9–14** In this multi-flash photo of a head-on collision between two balls of equal mass, the white cue ball is accelerated from rest by the cue stick and then strikes the red ball, initially at rest. The white ball stops in its tracks and the (equal mass) red ball moves off with the same speed as the white ball had before the collision. See Example 9–7. (Actually if you measure the distance between the equally-timed strobe photos of the red ball, they are slightly less than for the white cue ball; the red ball's speed is slightly less: a little kinetic energy was transformed to heat or sound energy.)

**EXAMPLE 9–8** **Unequal masses, target at rest.** A very common practical situation is for a moving object $(m_A)$ to strike a second object ($m_B$, the "target") at rest $(v_B = 0)$. Assume the objects have unequal masses, and that the collision is elastic and occurs along a line (head-on). (*a*) Derive equations for $v'_B$ and $v'_A$ in terms of the initial velocity $v_A$ of mass $m_A$ and the masses $m_A$ and $m_B$. (*b*) Determine the final velocities if the moving object $m_A$ is much more massive than the target $(m_A \gg m_B)$. (*c*) Determine the final velocities if the moving object is much less massive than the target $(m_A \ll m_B)$.

**APPROACH** The momentum equation (with $v_B = 0$) is

$$m_B v'_B = m_A(v_A - v'_A).$$

Kinetic energy is also conserved, and to use it we use Eq. 9–8 and rewrite it as

$$v'_A = v'_B - v_A.$$

**SOLUTION** (*a*) We substitute the above $v'_A$ equation into the momentum equation $(m_B v'_B = m_A v_A - m_A v'_B + m_A v_A)$ and rearrange to find

$$v'_B = v_A\left(\frac{2m_A}{m_A + m_B}\right).$$

We substitute this value for $v'_B$ back into the equation $v'_A = v'_B - v_A$ to obtain

$$v'_A = v_A\left(\frac{2m_A}{m_A + m_B}\right) - v_A = v_A\left(\frac{2m_A}{m_A + m_B} - 1\right),$$

or

$$v'_A = v_A\left(\frac{m_A - m_B}{m_A + m_B}\right).$$

To check these two equations we have derived, we let $m_A = m_B$, and we obtain

$$v'_B = v_A \quad \text{and} \quad v'_A = 0.$$

This is the same case treated in Example 9–7, and we get the same result: for objects of equal mass, one of which is initially at rest, the velocity of the one moving initially is completely transferred to the object originally at rest.

(*b*) We are given $v_B = 0$ and $m_A \gg m_B$. A very heavy moving object strikes a light object at rest, and we have, using the relations for $v'_B$ and $v'_A$ above,

$$v'_B \approx 2v_A \quad \text{and} \quad v'_A \approx v_A.$$

Thus the velocity of the heavy incoming object is practically unchanged, whereas the light object, originally at rest, takes off with twice the velocity of the heavy one. The velocity of a heavy bowling ball, for example, is hardly affected by striking a much lighter bowling pin.

(*c*) This time we have $v_B = 0$ and $m_A \ll m_B$. A moving light object strikes a very massive object at rest. In this case, using the equations in part (*a*)

$$v'_B \approx 0 \quad \text{and} \quad v'_A \approx -v_A.$$

The massive object at rest remains essentially at rest, and the very light incoming object rebounds with essentially its same speed but in the opposite direction. For example, a tennis ball colliding head-on with a stationary bowling ball will hardly affect the bowling ball, but will rebound with nearly the same speed it had initially, just as if it had struck a hard wall.

**NOTE** In nuclear reactors, neutrons are crucial to create a chain reaction of uranium fissions for producing energy release, as discussed in Chapter 42, Section 42–3. The neutrons (released in the fission reactions) must be slowed down in order to be effective in producing further fissions, and also not escape. The material that slows down neutrons by collisions, called the *moderator*, slows neutrons down faster if made up of material whose atoms have mass closer to that of a neutron, as we saw in Example 9–7 (also part (*a*) above): one collision with an equal mass particle can slow a neutron to zero. But if it collides with a much lighter or heavier particle (parts (*b*) and (*c*) above) its speed doesn't change much.

**PHYSICS APPLIED**
*Nuclear reactors: neutrons and moderator*

It can be shown (it is given as Problem 34) that for any elastic head-on collision the speeds after the collision are

$$v'_B = v_A\left(\frac{2m_A}{m_A + m_B}\right) + v_B\left(\frac{m_B - m_A}{m_A + m_B}\right)$$

and

$$v'_A = v_A\left(\frac{m_A - m_B}{m_A + m_B}\right) + v_B\left(\frac{2m_B}{m_A + m_B}\right).$$

These general equations should not be memorized. They can always be derived from the conservation laws: it is simplest to start a Problem from scratch, as we did above in Example 9–8, and as shown in the next Example.

**EXAMPLE 9–9** **A nuclear collision.** A proton (p) of mass 1.01 u (unified atomic mass units) traveling with a speed of $3.60 \times 10^4$ m/s has an elastic head-on collision with a helium (He) nucleus $(m_{He} = 4.00\,\text{u})$ initially at rest. What are the velocities of the proton and helium nucleus after the collision? (As mentioned in Chapter 1, $1\,\text{u} = 1.66 \times 10^{-27}$ kg, but we won't need this fact.) Assume this nuclear collision takes place in nearly empty space.

**APPROACH** Like Examples 9–7 and 9–8, this is an elastic head-on collision. The masses of our two particles are not equal. The only external force could be Earth's gravity, but it is insignificant compared to the powerful forces between the two particles at the moment of collision. So again we use the conservation laws of momentum and of kinetic energy, and apply them to our system of two particles.

**SOLUTION** We use the subscripts p for the proton and He for the helium nucleus. We are given $v_{He} = 0$ and $v_p = 3.60 \times 10^4$ m/s. We want to find the velocities $v'_p$ and $v'_{He}$ after the collision. From conservation of momentum,

$$m_p v_p + 0 = m_p v'_p + m_{He} v'_{He}.$$

Because the collision is elastic, the kinetic energy of our system of two particles is conserved and we can use Eq. 9–8, which becomes

$$v_p - 0 = v'_{He} - v'_p.$$

Thus

$$v'_p = v'_{He} - v_p,$$

and substituting this into our momentum equation displayed above, we get

$$m_p v_p = m_p v'_{He} - m_p v_p + m_{He} v'_{He}.$$

Solving for $v'_{He}$, the only unknown in this equation, we obtain

$$v'_{He} = \frac{2m_p v_p}{m_p + m_{He}} = \frac{2(1.01\,\text{u})(3.60 \times 10^4\,\text{m/s})}{(4.00\,\text{u} + 1.01\,\text{u})} = 1.45 \times 10^4\,\text{m/s}.$$

The other unknown is $v'_p$, which we can now obtain from

$$v'_p = v'_{He} - v_p = (1.45 \times 10^4\,\text{m/s}) - (3.60 \times 10^4\,\text{m/s}) = -2.15 \times 10^4\,\text{m/s}.$$

The minus sign for $v'_p$ tells us that the proton reverses direction upon collision, and we see that its speed is less than its initial speed (see Fig. 9–15).

**NOTE** This result makes sense: the lighter proton would be expected to "bounce back" from the more massive helium nucleus, but not with its full original velocity as from a rigid wall (which corresponds to extremely large, or infinite, mass).

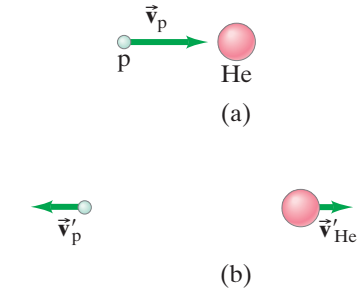

**FIGURE 9–15** Example 9–9: (a) before collision, (b) after collision.

# 9–6 Inelastic Collisions

Collisions in which kinetic energy is not conserved are called **inelastic collisions**. Some of the initial kinetic energy is transformed into other types of energy, such as thermal or potential energy, so the total kinetic energy after the collision is less than the total kinetic energy before the collision. The inverse can also happen when potential energy (such as chemical or nuclear) is released, in which case the total kinetic energy after the interaction can be greater than the initial kinetic energy. Explosions are examples of this type.

Typical macroscopic collisions are inelastic, at least to some extent, and often to a large extent. If two objects stick together as a result of a collision, the collision is said to be **completely inelastic**. Two colliding balls of putty that stick together or two railroad cars that couple together when they collide are examples of completely inelastic collisions. The kinetic energy in some cases is all transformed to other forms of energy in an inelastic collision, but in other cases only part of it is. In Example 9–3, for instance, we saw that when a traveling railroad car collided with a stationary one, the coupled cars traveled off with some kinetic energy. In a completely inelastic collision, the maximum amount of kinetic energy is transformed to other forms consistent with conservation of momentum. Even though kinetic energy is not conserved in inelastic collisions, the total energy is always conserved, and the total vector momentum is also conserved.

**PHYSICS APPLIED**
*Ballistic pendulum*

**EXAMPLE 9–10** **Ballistic pendulum.** The *ballistic pendulum* is a device used to measure the speed of a projectile, such as a bullet. The projectile, of mass $m$, is fired into a large block (of wood or other material) of mass $M$, which is suspended like a pendulum. (Usually, $M$ is somewhat greater than $m$.) As a result of the collision, the pendulum and projectile together swing up to a maximum height $h$, Fig. 9–16. Determine the relationship between the initial horizontal speed of the projectile, $v$, and the maximum height $h$.

**APPROACH** We can analyze the process by dividing it into two parts or two time intervals: (1) the time interval from just before to just after the collision itself, and (2) the subsequent time interval in which the pendulum moves from the vertical hanging position to the maximum height $h$.

In part (1), Fig. 9–16a, we assume the collision time is very short, so that the projectile is embedded in the block before the block has moved significantly from its rest position directly below its support. Thus there is effectively no net external force, and we can apply conservation of momentum to this completely inelastic collision.

In part (2), Fig. 9–16b, the pendulum begins to move, although gravity is acting, tending to pull it back toward the vertical position.† So for part (2), we cannot use conservation of momentum. But we can use conservation of mechanical energy because gravity is a conservative force (Chapter 8). The kinetic energy immediately after the collision is changed entirely to gravitational potential energy when the pendulum reaches its maximum height, $h$.

**SOLUTION** In part (1) momentum is conserved:

$$\begin{aligned} \text{total } P \text{ before} &= \text{total } P \text{ after} \\ mv &= (m + M)\,v', \end{aligned} \qquad \textbf{(i)}$$

where $v'$ is the speed of the block and embedded projectile just after the collision, before they have moved significantly.

In part (2), mechanical energy is conserved. We choose $y = 0$ when the pendulum hangs vertically, and then $y = h$ when the pendulum–projectile system reaches its maximum height. Thus we write

$$(K + U) \text{ just after collision} = (K + U) \text{ at pendulum's maximum height}$$

or

$$\tfrac{1}{2}(m + M)\,v'^2 + 0 = 0 + (m + M)\,gh. \qquad \textbf{(ii)}$$

We solve for $v'$:

$$v' = \sqrt{2gh}.$$

Inserting this result for $v'$ into Eq. (i) above, and solving for $v$, gives

$$v = \frac{m + M}{m} v' = \frac{m + M}{m} \sqrt{2gh},$$

which is our final result.

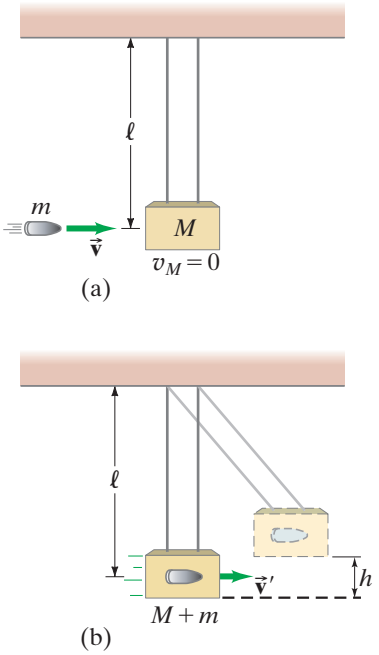

**FIGURE 9–16** Ballistic pendulum. Example 9–10.

†The force due to tension in the cords is perpendicular to the motion and so does no work—see Fig. 8–14.

**NOTE** The separation of the process into two parts was crucial. Such an analysis is a powerful problem-solving tool. But how do you decide how to make such a division? Think about the conservation laws. They are your *tools*. Start a problem by asking yourself whether the conservation laws apply in the given situation. Here, we determined that momentum is conserved only during the brief collision, which we called part (1). But in part (1), because the collision is inelastic, the conservation of mechanical energy is not valid. Then in part (2), conservation of mechanical energy is valid, but not conservation of momentum.

Note, however, that if there had been significant motion of the pendulum during the deceleration of the projectile in the block, then there *would* have been an external force (gravity) during the collision, so conservation of momentum would not have been valid in part (1).

**PROBLEM SOLVING**
*Use the conservation laws to analyze a problem*

**EXAMPLE 9–11** **Railroad cars again.** For the completely inelastic collision of the two railroad cars that we considered in Example 9–3, calculate how much of the initial kinetic energy is transformed to thermal or other forms of energy.

**APPROACH** The railroad cars stick together after the collision, so this is a completely inelastic collision. By subtracting the total kinetic energy after the collision from the total initial kinetic energy, we can find how much energy is transformed to other types of energy.

**SOLUTION** Before the collision, only car A is moving, so the total initial kinetic energy is $\frac{1}{2}m_A v_A^2 = \frac{1}{2}(10{,}000\,\text{kg})\,(8.0\,\text{m/s})^2 = 3.20 \times 10^5\,\text{J}$. After the collision, both cars are moving with half the speed, $v' = 4.0\,\text{m/s}$, by conservation of momentum (Example 9–3). So the total kinetic energy afterward is $K' = \frac{1}{2}(m_A + m_B)v'^2 = \frac{1}{2}(20{,}000\,\text{kg})\,(4.0\,\text{m/s})^2 = 1.60 \times 10^5\,\text{J}$. Hence the energy transformed to other forms is

$$(3.20 \times 10^5\,\text{J}) - (1.60 \times 10^5\,\text{J}) \;=\; 1.60 \times 10^5\,\text{J},$$

which is half the original kinetic energy.

# 9–7 Collisions in 2 or 3 Dimensions

Conservation of momentum and energy can also be applied to collisions in two or three dimensions, where the vector nature of momentum is especially important. One common type of non-head-on collision is that in which a moving object (called the "projectile") strikes a second object initially at rest (the "target"). This is the common situation in games such as billiards and pool, and for experiments in atomic and nuclear physics (the projectiles, from radioactive decay or a high-energy accelerator, strike a stationary target nucleus, Fig. 9–17).

Figure 9–18 shows the incoming projectile, $m_A$, heading along the $x$ axis toward the target object, $m_B$, which is initially at rest. If these are billiard balls, $m_A$ strikes $m_B$ not quite head-on and they go off at the angles $\theta'_A$ and $\theta'_B$, respectively, which are measured relative to $m_A$'s initial direction (the $x$ axis).†

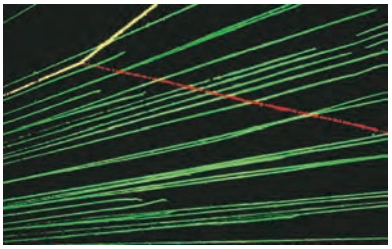

**FIGURE 9–17** A recent color-enhanced version of a cloud-chamber photograph made in the early days (1920s) of nuclear physics. Green lines are paths of helium nuclei (He) coming from the left. One He, highlighted in yellow, strikes a proton of the hydrogen gas in the chamber, and both scatter at an angle; the scattered proton's path is shown in red.

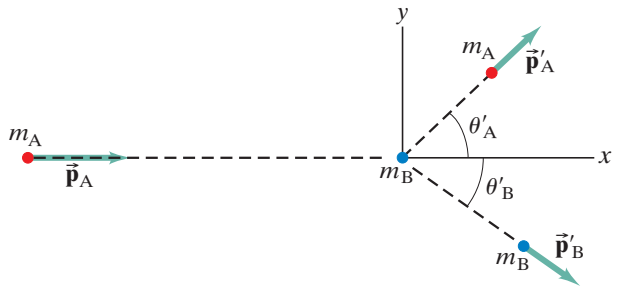

**FIGURE 9–18** Object A, the projectile, collides with object B, the target. After the collision, they move off with momenta $\vec{p}'_A$ and $\vec{p}'_B$ at angles $\theta'_A$ and $\theta'_B$.

†The objects may begin to deflect even before they touch if electric, magnetic, or nuclear forces act between them. You might think, for example, of two magnets oriented so that they repel each other: when one moves toward the other, the second moves away before the first one touches it.

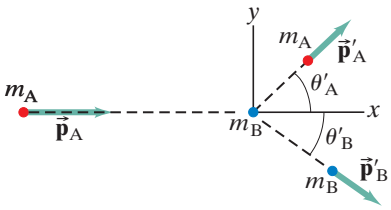

**FIGURE 9–18** (Repeated.) Projectile A hits target B; A and B move off at angles $\theta'_A$, $\theta'_B$.

Let us apply the law of conservation of momentum to a collision like that of Fig. 9–18. We choose the $xy$ plane to be the plane in which the initial and final momenta lie. Momentum is a vector, and because the total momentum is conserved, its components in the $x$ and $y$ directions also are conserved. The $x$ component of momentum conservation gives

$$p_{Ax} + p_{Bx} = p'_{Ax} + p'_{Bx}$$

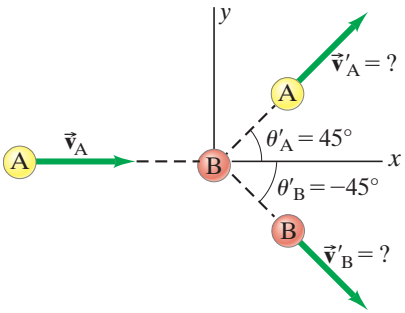
or, with $p_{Bx} = m_B v_{Bx} = 0$,

*$p_x$ conserved*

$$m_A v_A = m_A v'_A \cos\theta'_A + m_B v'_B \cos\theta'_B, \qquad \textbf{(9–9a)}$$

where the primes ($'$) refer to quantities *after* the collision. There is no motion in the $y$ direction initially, so the $y$ component of the total momentum is zero before the collision. The $y$ component equation of momentum conservation is then

$$p_{Ay} + p_{By} = p'_{Ay} + p'_{By}$$



or

*$p_y$ conserved*

$$0 = m_A v'_A \sin\theta'_A + m_B v'_B \sin\theta'_B. \qquad \textbf{(9–9b)}$$

When we have two independent equations, we can solve for two unknowns at most.

**FIGURE 9–19** Example 9–12.

**EXAMPLE 9–12 Billiard ball collision in 2-D.** Billiard ball A moving with speed $v_A = 3.0\,\text{m/s}$ in the $+x$ direction (Fig. 9–19) strikes an equal-mass ball B initially at rest. The two balls are observed to move off at 45° to the $x$ axis, ball A above the $x$ axis and ball B below. That is, $\theta'_A = 45°$ and $\theta'_B = -45°$ in Fig. 9–19. What are the speeds of the two balls after the collision?

**APPROACH** There is no net external force on our system of two balls, assuming the table is level (the normal force balances gravity). Thus momentum conservation applies, and we apply it to both the $x$ and $y$ components using the $xy$ coordinate system shown in Fig. 9–19. We get two equations, and we have two unknowns, $v'_A$ and $v'_B$. From *symmetry* we might guess that the two balls have the same speed. But let us not assume that now. Even though we are not told whether the collision is elastic or inelastic, we can still use conservation of momentum.

**SOLUTION** We apply conservation of momentum for the $x$ and $y$ components, Eqs. 9–9a and b, and we solve for $v'_A$ and $v'_B$. We are given $m_A = m_B (= m)$, so

$$\text{(for } x\text{)} \qquad mv_A = mv'_A \cos(45°) + mv'_B \cos(-45°)$$

and

$$\text{(for } y\text{)} \qquad 0 = mv'_A \sin(45°) + mv'_B \sin(-45°).$$

The $m$'s cancel out in both equations (the masses are equal). The second equation yields [recall from trigonometry that $\sin(-\theta) = -\sin\theta$]:

$$v'_B = -v'_A \frac{\sin(45°)}{\sin(-45°)} = -v'_A\left(\frac{\sin 45°}{-\sin 45°}\right) = v'_A.$$

So they do have equal speeds as we guessed at first. The $x$ component equation gives [recall that $\cos(-\theta) = \cos\theta$]:

$$v_A = v'_A \cos(45°) + v'_B \cos(45°) = 2v'_A \cos(45°);$$

solving for $v'_A$ (which also equals $v'_B$) gives

$$v'_A = \frac{v_A}{2\cos(45°)} = \frac{3.0\,\text{m/s}}{2(0.707)} = 2.1\,\text{m/s}.$$

If we know that a collision is elastic, we can also apply conservation of kinetic energy and obtain a third equation in addition to Eqs. 9–9a and b:

$$K_A + K_B = K'_A + K'_B$$

or, for the collision shown in Fig. 9–18 or 9–19 (where $K_B = 0$),

$$\tfrac{1}{2}m_A v_A^2 = \tfrac{1}{2}m_A v_A'^2 + \tfrac{1}{2}m_B v_B'^2. \quad \text{[elastic collision]} \quad \textbf{(9–9c)}$$

*Total K conserved, if elastic*

If the collision is elastic, we have three independent equations and can solve for three unknowns. If we are given $m_A$, $m_B$, $v_A$ (and $v_B$, if it is not zero), we cannot, for example, predict the final variables, $v'_A$, $v'_B$, $\theta'_A$, and $\theta'_B$, because there are four of them. However, if we measure one of these variables, say $\theta'_A$, then the other three variables ($v'_A$, $v'_B$, and $\theta'_B$) are uniquely determined, and we can determine them using Eqs. 9–9a, b, and c.

A note of caution: Eq. 9–8 (page 237) does *not* apply for two-dimensional collisions. It works only when a collision occurs along a line.

**⚠ CAUTION**

*Equation 9–8 applies only in 1-D*

**EXAMPLE 9–13** **Proton–proton collision.** A proton traveling with speed $8.2 \times 10^5$ m/s collides elastically with a stationary proton in a hydrogen target as in Fig. 9–18. One of the protons is observed to be scattered at a 60° angle. At what angle will the second proton be observed, and what will be the velocities of the two protons after the collision?

**APPROACH** We saw a two-dimensional collision in Example 9–12, where we needed to use only conservation of momentum. Now we are given less information: we have three unknowns instead of two. Because the collision is elastic, we can use the kinetic energy equation as well as the two momentum equations.

**SOLUTION** Since $m_A = m_B$, Eqs. 9–9a, b, and c become

$$v_A = v'_A \cos\theta'_A + v'_B \cos\theta'_B \quad \textbf{(i)}$$

$$0 = v'_A \sin\theta'_A + v'_B \sin\theta'_B \quad \textbf{(ii)}$$

$$v_A^2 = v_A'^2 + v_B'^2, \quad \textbf{(iii)}$$

where $v_A = 8.2 \times 10^5$ m/s and $\theta'_A = 60°$ are given. In the first and second equations, we move the $v'_A$ terms to the left side and square both sides of the equations:

$$v_A^2 - 2v_A v'_A \cos\theta'_A + v_A'^2 \cos^2\theta'_A = v_B'^2 \cos^2\theta'_B$$

$$v_A'^2 \sin^2\theta'_A = v_B'^2 \sin^2\theta'_B.$$

We add these two equations and use $\sin^2\theta + \cos^2\theta = 1$ to get:

$$v_A^2 - 2v_A v'_A \cos\theta'_A + v_A'^2 = v_B'^2.$$

Into this equation we substitute $v_B'^2 = v_A^2 - v_A'^2$, from equation (iii) above, and get

$$2v_A'^2 = 2v_A v'_A \cos\theta'_A$$

or

$$v'_A = v_A \cos\theta'_A = (8.2 \times 10^5 \text{ m/s})(\cos 60°) = 4.1 \times 10^5 \text{ m/s}.$$

To obtain $v'_B$, we use equation (iii) above (conservation of kinetic energy):

$$v'_B = \sqrt{v_A^2 - v_A'^2} = 7.1 \times 10^5 \text{ m/s}.$$

Finally, from equation (ii), we have

$$\sin\theta'_B = -\frac{v'_A}{v'_B}\sin\theta'_A = -\left(\frac{4.1 \times 10^5 \text{ m/s}}{7.1 \times 10^5 \text{ m/s}}\right)(0.866) = -0.50,$$

so $\theta'_B = -30°$. The minus sign means particle B moves at an angle below the $x$ axis if particle A is above the axis, as in Fig. 9–18. (See Fig. 9–20 for an example of such a collision.) The two trajectories are at right angles to each other after the collision. This can be shown to be true in general for 2-D collisions of equal mass particles, one of which is at rest initially: see Problem 51.

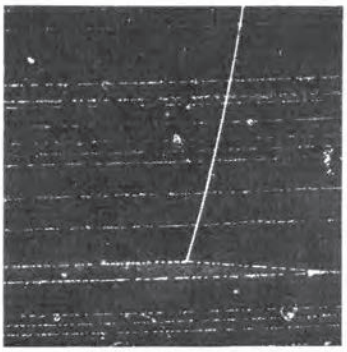


**FIGURE 9–20** Photo of a proton–proton collision in a hydrogen bubble chamber (a device that makes visible the paths of elementary particles). The many horizontal lines represent incoming protons which can strike the protons of the hydrogen in the chamber.

PROBLEM SOLVING

## Momentum Conservation and Collisions

1. Choose your **system**. If the situation is complex, think about how you might break it up into separate parts when one or more conservation laws apply.
2. If a significant **net external force** acts on your chosen system, be sure the time interval $\Delta t$ is so short that the effect on momentum is negligible. That is, the forces that act between the interacting objects must be the only significant ones if momentum conservation is to be used. [Note: If this is valid for a portion of the problem, you can use momentum conservation only for that portion.]
3. Draw a **diagram** of the initial situation, just before the interaction (collision, explosion) takes place, and represent the momentum of each object with an arrow and a label. Do the same for the final situation, just after the interaction.
4. Choose a **coordinate system** and "+" and "−" directions. (For a head-on collision, you will need only an $x$ axis.) It is often convenient to choose the $+x$ axis in the direction of one object's initial velocity.
5. Apply the **momentum conservation** equation(s):

   total initial momentum = total final momentum.

   You have one equation for each component ($x$, $y$, $z$): only one equation for a head-on collision.
6. If the collision is elastic, you can also write down a **conservation of kinetic energy** equation:

   total initial kinetic energy = total final kinetic energy.

   Alternately, for 1-D collisions, you can use Eq. 9–8:

   $$v_A - v_B = v'_B - v'_A.$$
7. Solve for the **unknown(s)**.
8. **Check** your work, check the units, and ask yourself whether the results are reasonable.

(a) (b)

**FIGURE 9–21** The motion of the diver is pure translation in (a), but is translation plus rotation in (b). The black dots represent the diver's CM at each moment.

# 9–8 Center of Mass (CM)

Momentum is a powerful concept not only for analyzing collisions but also for analyzing the translational motion of real extended objects. Until now, whenever we have dealt with the motion of an extended object (that is, an object that has size), we have assumed that it could be approximated as a point particle or that it undergoes only translational motion. Real extended objects, however, can undergo rotational and other types of motion as well. For example, the diver in Fig. 9–21a undergoes only translational motion (all parts of the object follow the same path), whereas the diver in Fig. 9–21b undergoes both translational and rotational motion. We will refer to motion that is not pure translation as *general motion*.

Observations indicate that even if an object rotates, or several parts of a system of objects move relative to one another, there is one point that moves in the same path that a particle would move if subjected to the same net force. This point is called the **center of mass** (abbreviated CM). The general motion of an extended object (or system of objects) can be considered as *the sum of the translational motion of the CM, plus rotational, vibrational, or other types of motion about the CM*.

As an example, consider the motion of the center of mass of the diver in Fig. 9–21; the CM follows a parabolic path even when the diver rotates, as shown in Fig. 9–21b. This is the same parabolic path that a projected particle follows when acted on only by the force of gravity (projectile motion, Section 3–7). Other points in the rotating diver's body, such as her feet or head, follow more complicated paths.

Figure 9–22 shows a wrench acted on by zero net force, translating and rotating along a horizontal surface. Note that its CM, marked by a red cross, moves in a straight line, as shown by the dashed white line.

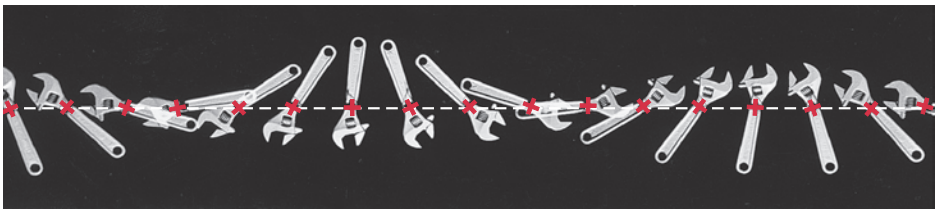

**FIGURE 9–22** Translation plus rotation: a wrench moving over a smooth horizontal surface. The CM, marked with a red cross, moves in a straight line because no net force acts on the wrench.

We will show in Section 9–9 that the important properties of the CM follow from Newton's laws if the CM is defined in the following way. We can consider any extended object as being made up of many tiny particles. But first we consider a system made up of only two particles (or small objects), of masses $m_A$ and $m_B$. We choose a coordinate system so that both particles lie on the $x$ axis at positions $x_A$ and $x_B$, Fig. 9–23. The center of mass of this system is defined to be at the position $x_{CM}$, given by

$$x_{CM} = \frac{m_A x_A + m_B x_B}{m_A + m_B} = \frac{m_A x_A + m_B x_B}{M},$$

where $M = m_A + m_B$ is the total mass of the system. The center of mass lies on the line joining $m_A$ and $m_B$. If the two masses are equal $(m_A = m_B = m)$, then $x_{CM}$ is midway between them, since in this case

$$x_{CM} = \frac{m(x_A + x_B)}{2m} = \frac{(x_A + x_B)}{2}.$$

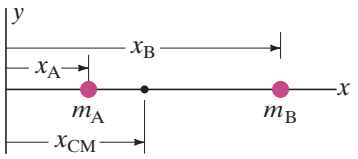

**FIGURE 9–23** The center of mass of a two-particle system lies on the line joining the two masses. Here $m_A > m_B$, so the CM is closer to $m_A$ than to $m_B$.

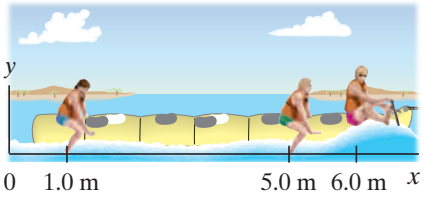
If one mass is greater than the other, say, $m_A > m_B$, then the CM is closer to the larger mass. If all the mass is concentrated at $x_B$, so $m_A = 0$, then $x_{CM} = (0x_A + m_B x_B)/(0 + m_B) = x_B$, as we would expect.

Now let us consider a system consisting of $n$ particles, where $n$ could be very large. This system could be an extended object which we consider as being made up of $n$ tiny particles. If these $n$ particles are all along a straight line (call it the $x$ axis), we define the CM of the system to be located at

$$x_{CM} = \frac{m_1 x_1 + m_2 x_2 + \cdots + m_n x_n}{m_1 + m_2 + \cdots + m_n} = \frac{\sum_{i=1}^{n} m_i x_i}{M}, \qquad \textbf{(9–10)}$$

where $m_1, m_2, \ldots m_n$ are the masses of each particle and $x_1, x_2, \ldots x_n$ are their positions. The symbol $\sum_{i=1}^{n}$ is the summation sign meaning to sum over all the particles, where $i$ takes on integer values from 1 to $n$. (Often we simply write $\Sigma m_i x_i$, leaving out the $i = 1$ to $n$.) The total mass of the system is $M = \Sigma m_i$.

**EXAMPLE 9–14** **CM of three guys on a raft.** Three people of roughly equal masses $m$ on a lightweight (air-filled) banana boat sit along the $x$ axis at positions $x_A = 1.0\,\text{m}$, $x_B = 5.0\,\text{m}$, and $x_C = 6.0\,\text{m}$, measured from the left-hand end as shown in Fig. 9–24. Find the position of the CM. Ignore the boat's mass.



**APPROACH** We are given the mass and location of the three people, so we use three terms in Eq. 9–10. We approximate each person as a point particle. Equivalently, the location of each person is the position of that person's own CM.

**SOLUTION** We use Eq. 9–10 with three terms:

$$x_{CM} = \frac{mx_A + mx_B + mx_C}{m + m + m} = \frac{m(x_A + x_B + x_C)}{3m}$$
$$= \frac{(1.0\,\text{m} + 5.0\,\text{m} + 6.0\,\text{m})}{3} = \frac{12.0\,\text{m}}{3} = 4.0\,\text{m}.$$

The CM is 4.0 m from the left-hand end of the boat.

**FIGURE 9–24** Example 9–14.

Note that the coordinates of the CM depend on the reference frame or coordinate system chosen. But the physical location of the CM is independent of that choice.

**EXERCISE F** Calculate the CM of the three people in Example 9–14 taking the origin at the driver $(x_C = 0)$ on the right. Is the physical location of the CM the same?

If the particles are spread out in two or three dimensions, as for a typical extended object, then we define the coordinates of the CM as

$$x_{CM} = \frac{\Sigma m_i x_i}{M}, \quad y_{CM} = \frac{\Sigma m_i y_i}{M}, \quad z_{CM} = \frac{\Sigma m_i z_i}{M}, \tag{9–11}$$

where $x_i$, $y_i$, $z_i$ are the coordinates of the particle of mass $m_i$ and again $M = \Sigma m_i$ is the total mass.

Although we usually calculate the components of the CM (Eq. 9–11), it is sometimes convenient (for example, for derivations) to write Eq. 9–11 in vector form. If $\vec{\mathbf{r}}_i = x_i\hat{\mathbf{i}} + y_i\hat{\mathbf{j}} + z_i\hat{\mathbf{k}}$ is the position vector of the $i^{\text{th}}$ particle, and $\vec{\mathbf{r}}_{CM} = x_{CM}\hat{\mathbf{i}} + y_{CM}\hat{\mathbf{j}} + z_{CM}\hat{\mathbf{k}}$ is the position vector of the center of mass, then

$$\vec{\mathbf{r}}_{CM} = \frac{\Sigma m_i \vec{\mathbf{r}}_i}{M}. \tag{9–12}$$

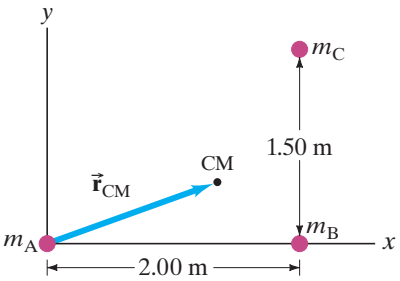


**FIGURE 9–25** Example 9–15.

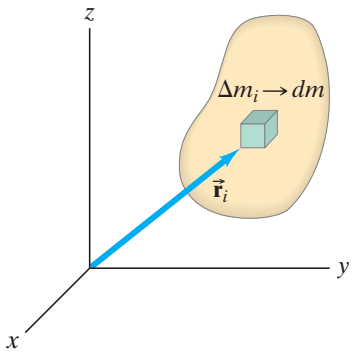
**EXAMPLE 9–15** **Three particles in 2-D.** Three particles, each of mass 2.50 kg, are located at the corners of a right triangle whose sides are 2.00 m and 1.50 m long, as shown in Fig. 9–25. Locate the center of mass.

**APPROACH** We choose our coordinate system as shown (to simplify calculations) with $m_A$ at the origin and $m_B$ on the $x$ axis. Then $m_A$ has coordinates $x_A = y_A = 0$; $m_B$ has coordinates $x_B = 2.0\,\text{m}$, $y_B = 0$; and $m_C$ has coordinates $x_C = 2.0\,\text{m}$, $y_C = 1.5\,\text{m}$.

**SOLUTION** From Eqs. 9–11,



$$x_{CM} = \frac{(2.50\,\text{kg})(0) + (2.50\,\text{kg})(2.00\,\text{m}) + (2.50\,\text{kg})(2.00\,\text{m})}{3(2.50\,\text{kg})} = 1.33\,\text{m}$$

$$y_{CM} = \frac{(2.50\,\text{kg})(0) + (2.50\,\text{kg})(0) + (2.50\,\text{kg})(1.50\,\text{m})}{7.50\,\text{kg}} = 0.50\,\text{m}.$$

The CM and the position vector $\vec{\mathbf{r}}_{CM}$ are shown in Fig. 9–25, inside the "triangle" as we should expect.

**EXERCISE G** A diver does a high dive involving a flip and a half-pike (legs and arms straight, but body bent in half). What can you say about the diver's center of mass? (*a*) It accelerates with a magnitude of $9.8\,\text{m/s}^2$ (ignoring air friction). (*b*) It moves in a circular path because of the rotation of the diver. (*c*) It must always be roughly located inside the diver's body, somewhere in the geometric center. (*d*) All of the above are true.

**FIGURE 9–26** An extended object, here shown in only two dimensions, can be considered to be made up of many tiny particles ($n$), each having a mass $\Delta m_i$. One such particle is shown located at a point $\vec{\mathbf{r}}_i = x_i\hat{\mathbf{i}} + y_i\hat{\mathbf{j}} + z_i\hat{\mathbf{k}}$. We take the limit of $n \to \infty$ so $\Delta m_i$ becomes the infinitesimal $dm$.

It is often convenient to think of an extended object as made up of a continuous distribution of matter. In other words, we consider the object to be made up of $n$ particles, each of mass $\Delta m_i$ in a tiny volume around a point $x_i$, $y_i$, $z_i$, and we take the limit of $n$ approaching infinity (Fig. 9–26). Then $\Delta m_i$ becomes the infinitesimal mass $dm$ at points $x$, $y$, $z$. The summations in Eqs. 9–11 and 9–12 become integrals:

$$x_{CM} = \frac{1}{M}\int x\,dm, \quad y_{CM} = \frac{1}{M}\int y\,dm, \quad z_{CM} = \frac{1}{M}\int z\,dm, \tag{9–13}$$

where the sum over all the mass elements is $\int dm = M$, the total mass of the object. In vector notation, this becomes

$$\vec{\mathbf{r}}_{CM} = \frac{1}{M}\int \vec{\mathbf{r}}\,dm. \tag{9–14}$$

A concept similar to *center of mass* is **center of gravity** (CG). The CG of an object is that point at which the force of gravity can be considered to act. The force of gravity actually acts on *all* the different parts or particles of an object, but for purposes of the translational motion of an object as a whole, we can assume that the entire weight of the object (the sum of the weights of all its parts) acts at the CG. There is a conceptual difference between the center of gravity and the center of mass, but for nearly all practical purposes, they are at the same point.†

†There would be a difference between the CM and CG only in the unusual case of an object so large that the acceleration due to gravity, $g$, was different at different parts of the object.

**EXAMPLE 9–16** **CM of a thin rod.** (*a*) Show that the CM of a uniform thin rod of length $\ell$ and mass $M$ is at its center. (*b*) Determine the CM of the rod assuming its linear mass density $\lambda$ (its mass per unit length) varies linearly from $\lambda = \lambda_0$ at the left end to double that value, $\lambda = 2\lambda_0$, at the right end.

**APPROACH** We choose a coordinate system so that the rod lies on the $x$ axis with the left end at $x = 0$, Fig. 9–27. Then $y_{CM} = 0$ and $z_{CM} = 0$.

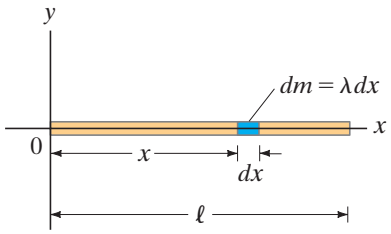


**FIGURE 9–27** Example 9–16.

**SOLUTION** (*a*) The rod is uniform, so its mass per unit length (linear mass density $\lambda$) is constant and we write it as $\lambda = M/\ell$. We now imagine the rod as divided into infinitesimal elements of length $dx$, each of which has mass $dm = \lambda\, dx$. We use Eq. 9–13:

$$x_{CM} = \frac{1}{M}\int_{x=0}^{\ell} x\, dm = \frac{1}{M}\int_0^{\ell} \lambda x\, dx = \frac{\lambda}{M}\frac{x^2}{2}\bigg|_0^{\ell} = \frac{\lambda \ell^2}{2M} = \frac{\ell}{2}$$

where we used $\lambda = M/\ell$. This result, $x_{CM}$ at the center, is what we expected.
(*b*) Now we have $\lambda = \lambda_0$ at $x = 0$ and we are told that $\lambda$ increases linearly to $\lambda = 2\lambda_0$ at $x = \ell$. So we write (let $\alpha$ be a constant)

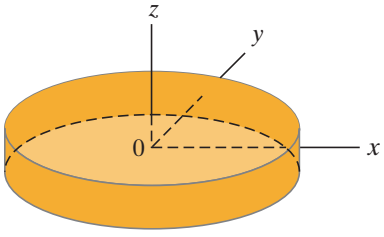
$$\lambda = \lambda_0(1 + \alpha x)$$

which satisfies $\lambda = \lambda_0$ at $x = 0$, increases linearly, and gives $\lambda = 2\lambda_0$ at $x = \ell$ if $(1 + \alpha\ell) = 2$. In other words, $\alpha = 1/\ell$. Again we use Eq. 9–13, with $\lambda = \lambda_0(1 + x/\ell)$:

$$x_{CM} = \frac{1}{M}\int_{x=0}^{\ell} \lambda x\, dx = \frac{1}{M}\lambda_0\int_0^{\ell}\left(1 + \frac{x}{\ell}\right)x\, dx = \frac{\lambda_0}{M}\left(\frac{x^2}{2} + \frac{x^3}{3\ell}\right)\bigg|_0^{\ell} = \frac{5}{6}\frac{\lambda_0}{M}\ell^2.$$

Now let us write $M$ in terms of $\lambda_0$ and $\ell$. We can write

$$M = \int_{x=0}^{\ell} dm = \int_0^{\ell} \lambda\, dx = \lambda_0\int_0^{\ell}\left(1 + \frac{x}{\ell}\right)dx = \lambda_0\left(x + \frac{x^2}{2\ell}\right)\bigg|_0^{\ell} = \frac{3}{2}\lambda_0\ell.$$



Then

$$x_{CM} = \frac{5}{6}\frac{\lambda_0}{M}\ell^2 = \frac{5}{9}\ell,$$

which is more than halfway along the rod, as we would expect since there is more mass to the right.

For symmetrically shaped objects of uniform composition, such as spheres, cylinders, and rectangular solids, the CM is located at the geometric center of the object. Consider a uniform circular cylinder, such as a solid circular disk. We expect the CM to be at the center of the circle. To show that it is, we first choose a coordinate system whose origin is at the center of the circle with the $z$ axis perpendicular to the disk (Fig. 9–28). When we take the sum $\Sigma m_i x_i$ in Eqs. 9–11, there is as much mass at any $+x_i$ as there is at $-x_i$. So all terms cancel out in pairs and $x_{CM} = 0$. The same is true for $y_{CM}$. In the vertical ($z$) direction, the CM must lie halfway between the circular faces: if we choose our origin of coordinates at that point, there is as much mass at any $+z_i$ as at $-z_i$, so $z_{CM} = 0$. For other uniform, symmetrically shaped objects, we can make similar arguments to show that the CM must lie on a line of *symmetry*. If a symmetric body is *not* uniform, then these arguments do not hold. For example, the CM of a wheel or disk weighted on one side is not at the geometric center but closer to the weighted side.

**FIGURE 9–28** Cylindrical disk with origin of coordinates at geometric center.

To locate the center of mass of a group of extended objects, we can use Eqs. 9–11, where the $m_i$ are the masses of these objects and $x_i$, $y_i$, and $z_i$ are the coordinates of the CM of each of the objects.

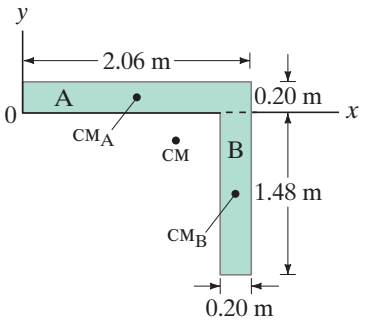


**FIGURE 9–29** Example 9–17. This L-shaped object has thickness $t$ (not shown on diagram).

**EXAMPLE 9–17** **CM of L-shaped flat object.** Determine the CM of the uniform thin L-shaped construction brace shown in Fig. 9–29.

**APPROACH** We can consider the object as two rectangles: rectangle A, which is $2.06\,\text{m} \times 0.20\,\text{m}$, and rectangle B, which is $1.48\,\text{m} \times 0.20\,\text{m}$. We choose the origin at 0 as shown. We assume a uniform thickness $t$.

**SOLUTION** The CM of rectangle A is at

$$x_A = 1.03\,\text{m},$$
$$y_A = 0.10\,\text{m}.$$

The CM of B is at

$$x_B = 2.06\,\text{m} - \tfrac{1}{2}(0.20\,\text{m}) = 1.96\,\text{m},$$
$$y_B = -0.74\,\text{m}.$$

The mass of A, whose thickness is $t$, is $\rho V$ where volume $V = (\text{length}) \times (\text{width}) \times (\text{thickness})$ is

$$M_A = (2.06\,\text{m})(0.20\,\text{m})(t)(\rho) = (0.412\,\text{m}^2)(\rho t),$$

where $\rho$ is the uniform density (mass per unit volume). The mass of B is

$$M_B = (1.48\,\text{m})(0.20\,\text{m})(\rho t) = (0.296\,\text{m}^2)(\rho t),$$

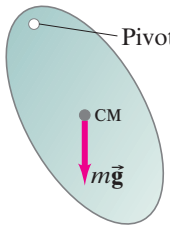
and the total mass is $M = M_A + M_B = (0.708\,\text{m}^2)(\rho t)$. Thus

$$x_{CM} = \frac{M_A x_A + M_B x_B}{M} = \frac{(0.412\,\text{m}^2)(1.03\,\text{m}) + (0.296\,\text{m}^2)(1.96\,\text{m})}{(0.708\,\text{m}^2)} = 1.42\,\text{m},$$

where $\rho t$ was canceled out in numerator and denominator. Similarly,

$$y_{CM} = \frac{(0.412\,\text{m}^2)(0.10\,\text{m}) + (0.296\,\text{m}^2)(-0.74\,\text{m})}{(0.708\,\text{m}^2)} = -0.25\,\text{m},$$

which puts the CM approximately at the point so labeled in Fig. 9–29. In thickness, $z_{CM} = t/2$, since the object is assumed to be uniform.



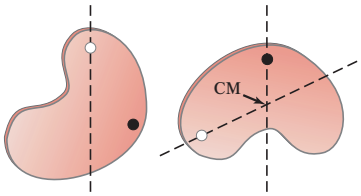


**FIGURE 9–30** Determining the CM of a flat uniform body.

**FIGURE 9–31** Finding the CM.

Note in this last Example that the CM can actually lie *outside* the object. Another example is a doughnut whose CM is at the center of the hole.

It is often easier to determine the CM or CG of an extended object experimentally rather than analytically. If an object is suspended from any point, it will swing (Fig. 9–30) due to the force of gravity on it, unless it is placed so its CM lies on a vertical line directly below the point from which it is suspended. If the object is two-dimensional, or has a plane of symmetry, it need only be hung from two different pivot points and the respective vertical (plumb) lines drawn. Then the center of mass will be at the intersection of the two lines, as in Fig. 9–31. If the object doesn't have a plane of symmetry, the CM with respect to the third dimension is found by suspending the object from at least three points whose plumb lines do not lie in the same plane. For symmetrically shaped objects, the CM is located at the geometric center of the object.

## 9–9 Center of Mass and Translational Motion

As mentioned in Section 9–8, a major reason for the importance of the concept of center of mass is that the translational motion of the CM for a system of particles (or an extended object) is directly related to the net force acting on the system as a whole. We now show this, by examining the motion of a system of $n$ particles

of total mass $M$, and we assume all the masses $m_i$ remain constant. We begin by rewriting Eq. 9–12 as

$$M\vec{\mathbf{r}}_{\text{CM}} = \Sigma m_i \vec{\mathbf{r}}_i.$$

We differentiate this equation with respect to time:

$$M\frac{d\vec{\mathbf{r}}_{\text{CM}}}{dt} = \Sigma m_i \frac{d\vec{\mathbf{r}}_i}{dt}$$

or

$$M\vec{\mathbf{v}}_{\text{CM}} = \Sigma m_i \vec{\mathbf{v}}_i, \qquad \textbf{(9–15)}$$

where $\vec{\mathbf{v}}_i = d\vec{\mathbf{r}}_i/dt$ is the velocity of the $i^{\text{th}}$ particle of mass $m_i$, and $\vec{\mathbf{v}}_{\text{CM}}$ is the velocity of the CM. We take the derivative with respect to time again and obtain

$$M\frac{d\vec{\mathbf{v}}_{\text{CM}}}{dt} = \Sigma m_i \vec{\mathbf{a}}_i,$$

where $\vec{\mathbf{a}}_i = d\vec{\mathbf{v}}_i/dt$ is the acceleration of the $i^{\text{th}}$ particle. Now $d\vec{\mathbf{v}}_{\text{CM}}/dt$ is the acceleration of the CM, $\vec{\mathbf{a}}_{\text{CM}}$. By Newton's second law, $m_i\vec{\mathbf{a}}_i = \vec{\mathbf{F}}_i$ where $\vec{\mathbf{F}}_i$ is the net force on the $i^{\text{th}}$ particle. Therefore

$$M\vec{\mathbf{a}}_{\text{CM}} = \vec{\mathbf{F}}_1 + \vec{\mathbf{F}}_2 + \cdots + \vec{\mathbf{F}}_n = \Sigma\vec{\mathbf{F}}_i. \qquad \textbf{(9–16)}$$

That is, the vector sum of all the forces acting on the system is equal to the total mass of the system times the acceleration of its center of mass. Note that our system of $n$ particles could be the $n$ particles that make up one or more extended objects.

The forces $\vec{\mathbf{F}}_i$ exerted on the particles of the system can be divided into two types: (1) *external forces* exerted by objects outside the system and (2) *internal forces* that particles within the system exert on one another. By Newton's third law, the internal forces occur in pairs: if one particle exerts a force on a second particle in our system, the second must exert an equal and opposite force on the first. Thus, in the sum over all the forces in Eq. 9–16, these internal forces cancel each other in pairs. We are left, then, with only the external forces on the right side of Eq. 9–16:

$$M\vec{\mathbf{a}}_{\text{CM}} = \Sigma\vec{\mathbf{F}}_{\text{ext}}, \qquad [\text{constant } M] \quad \textbf{(9–17)}$$

*NEWTON'S SECOND LAW (for a system)*

where $\Sigma\vec{\mathbf{F}}_{\text{ext}}$ is the sum of all the external forces acting on our system, which is the *net force* acting on the system. Thus

**the sum of all the forces acting on the system is equal to the total mass of the system times the acceleration of its center of mass.**

This is **Newton's second law** for a system of particles. It also applies to an extended object (which can be thought of as a collection of particles), and to a system of objects. Thus we conclude that

**the center of mass of a system of particles (or objects) with total mass $M$ moves like a single particle of mass $M$ acted upon by the same net external force.**

*TRANSLATIONAL MOTION OF CM*

That is, the system translates as if all its mass were concentrated at the CM and all the external forces acted at that point. We can thus treat the *translational motion* of any object or system of objects as the motion of a particle (see Figs. 9–21 and 9–22) at the position of the CM. This result simplifies our analysis of the motion of complex systems and extended objects. Although the motion of various parts of the system may be complicated, we may often be satisfied with knowing the motion of the center of mass. This result also allows us to solve certain types of problems very easily, as illustrated by the following Example.

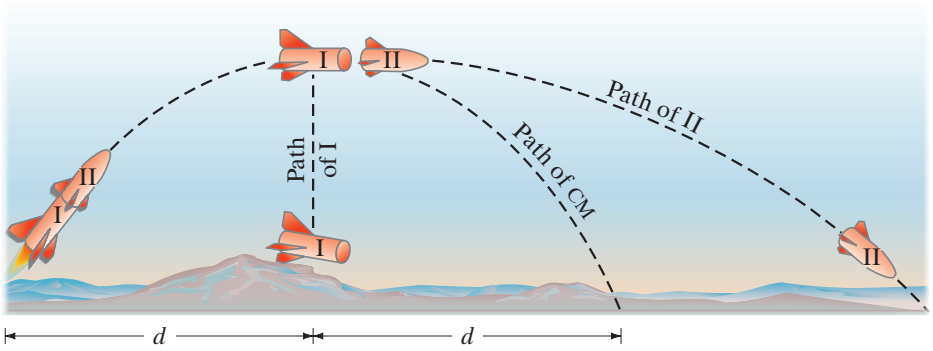

**FIGURE 9–32** Example 9–18.

**CONCEPTUAL EXAMPLE 9–18** **A two-stage rocket.** A rocket is shot into the air as shown in Fig. 9–32. At the moment the rocket reaches its highest point, a horizontal distance $d$ from its starting point, a prearranged explosion separates it into two parts of equal mass. Part I is stopped in midair by the explosion and falls vertically to Earth. Where does part II land? Assume $\vec{\mathbf{g}}$ = constant.

**RESPONSE** After the rocket is fired, the path of the CM of the system continues to follow the parabolic trajectory of a projectile acted on only by a constant gravitational force. The CM will thus land at a point $2d$ from the starting point. Since the masses of I and II are equal, the CM must be midway between them at any time. Therefore, part II lands a distance $3d$ from the starting point.

**NOTE** If part I had been given a kick up or down, instead of merely falling, the solution would have been somewhat more complicated.

**EXERCISE H** A woman stands up in a rowboat and walks from one end of the boat to the other. How does the boat move, as seen from the shore?

We can write Eq. 9–17, $M\vec{\mathbf{a}}_{\text{CM}} = \Sigma\vec{\mathbf{F}}_{\text{ext}}$, in terms of the total momentum $\vec{\mathbf{P}}$ of a system of particles: $\vec{\mathbf{P}} = m_1\vec{\mathbf{v}}_1 + m_2\vec{\mathbf{v}}_2 + \cdots + m_n\vec{\mathbf{v}}_n = \Sigma\vec{\mathbf{p}}_i$, as we saw in Section 9–2. From Eq. 9–15 $\left(M\vec{\mathbf{v}}_{\text{CM}} = \Sigma m_i\vec{\mathbf{v}}_i\right)$ we have

$$\vec{\mathbf{P}} = M\vec{\mathbf{v}}_{\text{CM}}. \qquad \textbf{(9–18)}$$

Thus, *the total linear momentum of a system of particles is equal to the product of the total mass* M *and the velocity of the center of mass of the system.* Or, *the linear momentum of an extended object is the product of the object's mass and the velocity of its* CM.

If we differentiate Eq. 9–18 with respect to time, we obtain (assuming the total mass $M$ is constant)

$$\frac{d\vec{\mathbf{P}}}{dt} = M\frac{d\vec{\mathbf{v}}_{\text{CM}}}{dt} = M\vec{\mathbf{a}}_{\text{CM}}.$$

From Eq. 9–17, we see that

*NEWTON'S SECOND LAW (for a system)*

$$\frac{d\vec{\mathbf{P}}}{dt} = \Sigma\vec{\mathbf{F}}_{\text{ext}}, \qquad \text{[same as Eq. 9–5]}$$

where $\Sigma\vec{\mathbf{F}}_{\text{ext}}$ is the net external force on the system. This is just Eq. 9–5 obtained earlier: **Newton's second law for a system of objects**. It is valid for any definite fixed system of particles or objects. If we know $\Sigma\vec{\mathbf{F}}_{\text{ext}}$, we can determine how the total momentum changes.

**PHYSICS APPLIED**
*Distant planets discovered*

An interesting application is the discovery of nearby stars (see Section 6–5) that seem to "wobble." What could cause such a wobble? It could be that a planet orbits the star, and each exerts a gravitational force on the other. The planets may be too small and too far away to be observed directly by telescopes. But the slight wobble in the motion of the star suggests that both the planet and the star (its sun) orbit about their mutual center of mass, and hence the star appears to have a wobble. Irregularities in the star's motion can be measured to high accuracy, yielding information on the size of the planets' orbits and their masses. See Fig. 6–19 in Chapter 6.

# *9–10 Systems of Variable Mass; Rocket Propulsion

We now treat objects or systems whose mass varies. Such systems could be treated as a type of inelastic collision, but it is simpler to use Eq. 9–5, $d\vec{\mathbf{P}}/dt = \Sigma\vec{\mathbf{F}}_{\text{ext}}$, where $\vec{\mathbf{P}}$ is the total momentum of the system and $\Sigma\vec{\mathbf{F}}_{\text{ext}}$ is the net external force exerted on it. Great care must be taken to define the *system*, and to include all changes in momentum. An important application is to rockets, which propel themselves forward by the ejection of burned gases: the force exerted by the gases on the rocket accelerates the rocket. The mass $M$ of the rocket decreases as it ejects gas, so for the rocket $dM/dt < 0$. Another application of changing mass is the dropping of material (gravel, packaged goods) onto a conveyor belt. In this situation, the mass $M$ of the loaded conveyor belt increases and $dM/dt > 0$.

To treat the general case of variable mass, let us consider the system shown in Fig. 9–33. At some time $t$, we have a mass $M$ with momentum $M\vec{\mathbf{v}}$. We also have a tiny (infinitesimal) mass $dM$ traveling with velocity $\vec{\mathbf{u}}$ which is about to enter mass $M$ (Fig. 9–33a). An infinitesimal time $dt$ later, the mass $dM$ combines with mass $M$ (Fig. 9–33b). For simplicity we will refer to this as a "collision." So our large mass has changed in mass from $M$ to $M + dM$ in the time $dt$. Note that $dM$ can be less than zero, as for a rocket propelled by ejected gases whose mass $M$ thus decreases.

In order to apply Eq. 9–5, $d\vec{\mathbf{P}}/dt = \Sigma\vec{\mathbf{F}}_{\text{ext}}$, we must consider a definite fixed system of particles. That is, in considering the change in momentum, $d\vec{\mathbf{P}}$, we must consider the momentum of the same particles initially and finally. We will thus define our *system* as including $M$ plus $dM$. Then initially, at time $t$, the total momentum is $M\vec{\mathbf{v}} + \vec{\mathbf{u}}\,dM$ (Fig. 9–33). At time $t + dt$, after $dM$ has combined with $M$, the velocity of the whole is now $\vec{\mathbf{v}} + d\vec{\mathbf{v}}$ and the total momentum is $(M + dM)(\vec{\mathbf{v}} + d\vec{\mathbf{v}})$. So the change in momentum $d\vec{\mathbf{P}}$ is

$$\begin{aligned} d\vec{\mathbf{P}} &= (M + dM)(\vec{\mathbf{v}} + d\vec{\mathbf{v}}) - (M\vec{\mathbf{v}} + \vec{\mathbf{u}}\,dM) \\ &= M\,d\vec{\mathbf{v}} + \vec{\mathbf{v}}\,dM + dM\,d\vec{\mathbf{v}} - \vec{\mathbf{u}}\,dM. \end{aligned}$$

The term $dM\,d\vec{\mathbf{v}}$ is the product of two differentials and is zero even after we "divide by $dt$," which we do, and apply Eq. 9–5 to obtain

$$\Sigma\vec{\mathbf{F}}_{\text{ext}} = \frac{d\vec{\mathbf{P}}}{dt} = \frac{M\,d\vec{\mathbf{v}} + \vec{\mathbf{v}}\,dM - \vec{\mathbf{u}}\,dM}{dt}.$$

Thus we get

$$\Sigma\vec{\mathbf{F}}_{\text{ext}} = M\frac{d\vec{\mathbf{v}}}{dt} - (\vec{\mathbf{u}} - \vec{\mathbf{v}})\frac{dM}{dt}. \qquad \textbf{(9–19a)}$$

Note that the quantity $(\vec{\mathbf{u}} - \vec{\mathbf{v}})$ is the relative velocity, $\vec{\mathbf{v}}_{\text{rel}}$, of $dM$ with respect to $M$. That is,

$$\vec{\mathbf{v}}_{\text{rel}} = \vec{\mathbf{u}} - \vec{\mathbf{v}}$$

is the velocity of the entering mass $dM$ as seen by an observer on $M$. We can rearrange Eq. 9–19a:

$$M\frac{d\vec{\mathbf{v}}}{dt} = \Sigma\vec{\mathbf{F}}_{\text{ext}} + \vec{\mathbf{v}}_{\text{rel}}\frac{dM}{dt}. \qquad \textbf{(9–19b)}$$

We can interpret this equation as follows. $Md\vec{\mathbf{v}}/dt$ is the mass times the acceleration of $M$. The first term on the right, $\Sigma\vec{\mathbf{F}}_{\text{ext}}$, refers to the external force on the mass $M$ (for a rocket, it would include the force of gravity and air resistance). It does *not* include the force that $dM$ exerts on $M$ as a result of their collision. This is taken care of by the second term on the right, $\vec{\mathbf{v}}_{\text{rel}}\,(dM/dt)$, which represents the rate at which momentum is being transferred into (or out of) the mass $M$ because of the mass that is added to (or leaves) it. It can thus be interpreted as the force exerted on the mass $M$ due to the addition (or ejection) of mass.

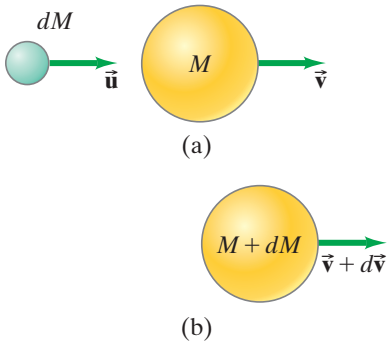

**FIGURE 9–33** (a) At time $t$, a mass $dM$ is about to be added to an object of mass $M$. (b) At time $t + dt$, the mass $dM$ has been added to our mass which now has mass $M + dM$.

For a rocket this term $\vec{\mathbf{v}}_{\text{rel}}\,(dM/dt)$ is called the **thrust**, since it represents the force exerted on the rocket by the expelled gases. For a rocket ejecting burned fuel, $dM/dt < 0$, but so is $\vec{\mathbf{v}}_{\text{rel}}$ (gases are forced out the back), so the second term in Eq. 9–19b acts to increase $\vec{\mathbf{v}}$.

**PHYSICS APPLIED**
*Rocket propulsion*

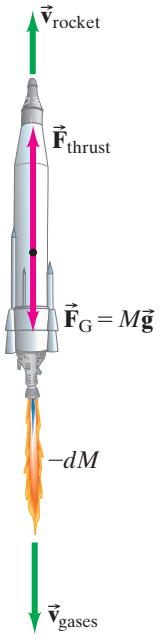

**FIGURE 9–34** Example 9–19; $\vec{\mathbf{v}}_{\text{rel}} = \vec{\mathbf{v}}_{\text{gases}} - \vec{\mathbf{v}}_{\text{rocket}}$. $M$ is the mass of the rocket at any instant and is decreasing until burnout.

**EXAMPLE 9–19** **Rocket propulsion.** A fully fueled rocket has a mass of 21,000 kg, of which 15,000 kg is fuel. The burned fuel is spewed out the rear at a rate of 190 kg/s with a speed of 2800 m/s relative to the rocket. If the rocket is fired vertically upward (Fig. 9–34) calculate: (*a*) the thrust of the rocket; (*b*) the net force on the rocket at blastoff, and just before burnout (when all the fuel has been used up); (*c*) the rocket's velocity as a function of time, and (*d*) its final velocity at burnout. Ignore air resistance and assume the acceleration due to gravity is constant at $g = 9.80\,\text{m/s}^2$.

**APPROACH** In part (*a*), the thrust is defined (see above) as the last term in Eq. 9–19b, $v_{\text{rel}}(dM/dt)$. The net force [for (*b*)] is the vector sum of the thrust and gravity. The velocity is found from Eq. 9–19b. The mass $M$ of the rocket varies in time, decreasing as burnt fuel is forced out (most of the rocket's initial mass is fuel).

**SOLUTION** (*a*) The thrust is:

$$F_{\text{thrust}} = v_{\text{rel}}\frac{dM}{dt} = (-2800\,\text{m/s})(-190\,\text{kg/s}) = 5.3\times10^5\,\text{N},$$

where we have taken upward as positive so $v_{\text{rel}}$ is negative because it is downward, and $dM/dt$ is negative because the rocket's mass is diminishing.

(*b*) $F_{\text{ext}} = Mg = (2.1\times10^4\,\text{kg})(9.80\,\text{m/s}^2) = 2.1\times10^5\,\text{N}$ initially, when $M = 21{,}000\,\text{kg}$; then at burnout, when $M = 21{,}000\,\text{kg} - 15{,}000\,\text{kg} = 6{,}000\,\text{kg}$, $F_{\text{ext}} = (6.0\times10^3\,\text{kg})(9.80\,\text{m/s}^2) = 5.9\times10^4\,\text{N}$. The net force on the rocket at blastoff is the thrust minus the rocket's weight (the "external force") as shown in Fig. 9–34:

$$F_{\text{net}} = 5.3\times10^5\,\text{N} - 2.1\times10^5\,\text{N} = 3.2\times10^5\,\text{N}, \quad [\text{blastoff}]$$

and just before burnout it is

$$F_{\text{net}} = 5.3\times10^5\,\text{N} - 5.9\times10^4\,\text{N} = 4.7\times10^5\,\text{N}. \quad [\text{burnout}]$$

*After* burnout, the net force on the rocket is only that of gravity, $-5.9\times10^4\,\text{N}$, slowing it down.

(*c*) From Eq. 9–19b we have

$$dv = \frac{F_{\text{ext}}}{M}\,dt + v_{\text{rel}}\frac{dM}{M},$$

where $F_{\text{ext}} = -Mg$, and $M$ is the mass of the rocket and is a function of time. Since $v_{\text{rel}}$ is constant, we can integrate this easily:

$$\int_{v_0}^{v} dv = -\int_0^t g\,dt + v_{\text{rel}}\int_{M_0}^{M}\frac{dM}{M}$$

or

$$v(t) = v_0 - gt + v_{\text{rel}}\ln\frac{M}{M_0},$$

where $v(t)$ is the rocket's velocity and $M$ its mass at any time $t$. Note that $v_{\text{rel}}$ is negative ($-2800\,\text{m/s}$ in our case) because it is opposite to the motion, and that $\ln(M/M_0)$ is also negative because $M_0 > M$. Hence the last term, which represents the thrust, is positive and acts to increase the velocity.

(*d*) The time required to reach burnout is the time needed to use up all the fuel (15,000 kg) at a rate of 190 kg/s; so at burnout,

$$t = \frac{1.50\times10^4\,\text{kg}}{190\,\text{kg/s}} = 79\,\text{s}.$$

If we take $v_0 = 0$, then using the result of part (*c*):

$$v = 0 - (9.80\,\text{m/s}^2)(79\,\text{s}) + (-2800\,\text{m/s})\left(\ln\frac{6000\,\text{kg}}{21{,}000\,\text{kg}}\right) = 2700\,\text{m/s}.$$

**EXAMPLE 9–20** **Conveyor belt.** You are designing a conveyor system for a gravel yard. A hopper drops gravel gently at a rate of 75.0 kg/s onto a conveyor belt that moves at a constant speed $v = 2.20\,\text{m/s}$ (Fig. 9–35). (*a*) Determine the additional force (over and above its own internal friction) needed to keep the conveyor belt moving as gravel falls on it. (*b*) What power output would be needed from the motor that drives the conveyor belt?

**PHYSICS APPLIED**
*Moving conveyor belt*

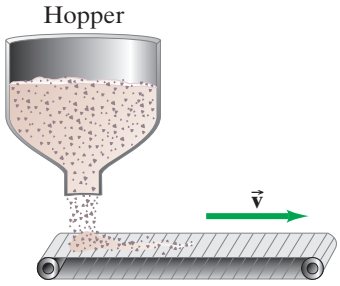

**FIGURE 9–35** Example 9–20. Gravel dropped from hopper onto conveyor belt.

**APPROACH** We assume that the hopper is at rest so $u = 0$ in Eq. 9–19a, and that the hopper has just begun dropping gravel so $dM/dt = 75.0\,\text{kg/s}$.

**SOLUTION** (*a*) The belt needs to move at a constant speed $(dv/dt = 0)$, so Eq. 9–19a, written for one dimension, gives:

$$\begin{aligned} F_{\text{ext}} &= M\frac{dv}{dt} - (u - v)\frac{dM}{dt} \\ &= 0 - (0 - v)\frac{dM}{dt} \\ &= v\frac{dM}{dt} = (2.20\,\text{m/s})(75.0\,\text{kg/s}) = 165\,\text{N}. \end{aligned}$$

(*b*) This force does work at the rate (Eq. 8–21)

$$\begin{aligned} \frac{dW}{dt} &= \vec{\mathbf{F}}_{\text{ext}} \cdot \vec{\mathbf{v}} = v^2\frac{dM}{dt} \\ &= 363\,\text{W}, \end{aligned}$$

which is the minimum power output required of the motor.

**NOTE** This work does not all go into kinetic energy of the gravel, since

$$\frac{dK}{dt} = \frac{d}{dt}\left(\frac{1}{2}Mv^2\right) = \frac{1}{2}\frac{dM}{dt}v^2,$$

which is only half the rate at which work is done by $\vec{\mathbf{F}}_{\text{ext}}$. The other half of the external work done goes into thermal energy produced by friction between the gravel and the belt (the same friction force that accelerates the gravel).

**NOTE** When gravel reaches the far end of the conveyor belt and falls off, there is no effect or force on the conveyor belt. The difference here is that the gravel falling *onto* the belt from the hopper at the left must be accelerated.

**CAUTION**
*Note difference between gravel falling* on *and* off *belt*

# Summary

The **linear momentum**, $\vec{\mathbf{p}}$, of an object is defined as the product of its mass times its velocity,

$$\vec{\mathbf{p}} = m\vec{\mathbf{v}}. \qquad \textbf{(9–1)}$$

In terms of momentum, **Newton's second law** can be written as

$$\Sigma\vec{\mathbf{F}} = \frac{d\vec{\mathbf{p}}}{dt}. \qquad \textbf{(9–2)}$$

That is, the rate of change of momentum of an object equals the net force exerted on it.

When the net external force on a system of objects is zero, the total momentum remains constant. This is the **law of conservation of momentum**. Stated another way, the total momentum of an isolated system of objects remains constant.

The law of conservation of momentum is very useful in dealing with **collisions**. In a collision, two (or more) objects interact with each other over a very short time interval, and the force each exerts on the other during this time interval is very large compared to any other forces acting.

The **impulse** delivered by a force on an object is defined as

$$\vec{\mathbf{J}} = \int \vec{\mathbf{F}}\,dt$$

and is equal to the change in momentum of the object as long as $\vec{\mathbf{F}}$ is the net force on the object:

$$\Delta\vec{\mathbf{p}} = \vec{\mathbf{p}}_{\text{f}} - \vec{\mathbf{p}}_{\text{i}} = \int_{t_{\text{i}}}^{t_{\text{f}}} \vec{\mathbf{F}}\,dt = \vec{\mathbf{J}}. \qquad \textbf{(9–6b)}$$

Total momentum is conserved in *any* collision as long as any net external force is zero or negligible. If $m_{\text{A}}\vec{\mathbf{v}}_{\text{A}}$ and $m_{\text{B}}\vec{\mathbf{v}}_{\text{B}}$ are the momenta of two objects before the collision and $m_{\text{A}}\vec{\mathbf{v}}'_{\text{A}}$ and $m_{\text{B}}\vec{\mathbf{v}}'_{\text{B}}$ are their momenta after, then momentum conservation tells us that

$$m_{\text{A}}\vec{\mathbf{v}}_{\text{A}} + m_{\text{B}}\vec{\mathbf{v}}_{\text{B}} = m_{\text{A}}\vec{\mathbf{v}}'_{\text{A}} + m_{\text{B}}\vec{\mathbf{v}}'_{\text{B}} \qquad \textbf{(9–3)}$$

for this two-object system.

Total energy is also conserved. But this may not be helpful unless kinetic energy is conserved, in which case the collision is called an **elastic collision** and we can write

$$\tfrac{1}{2}m_A v_A^2 + \tfrac{1}{2}m_B v_B^2 = \tfrac{1}{2}m_A v_A'^2 + \tfrac{1}{2}m_B v_B'^2. \quad \textbf{(9–7)}$$

If kinetic energy is not conserved, the collision is called **inelastic**. Macroscopic collisions are generally inelastic. If two colliding objects stick together as the result of a collision, the collision is said to be **completely inelastic**.

For a system of particles, or for an extended object that can be considered as having a continuous distribution of matter, the **center of mass** (CM) is defined as

$$x_{CM} = \frac{\Sigma m_i x_i}{M}, \quad y_{CM} = \frac{\Sigma m_i y_i}{M}, \quad z_{CM} = \frac{\Sigma m_i z_i}{M} \quad \textbf{(9–11)}$$

or

$$x_{CM} = \frac{1}{M}\int x\,dm, \quad y_{CM} = \frac{1}{M}\int y\,dm, \quad z_{CM} = \frac{1}{M}\int z\,dm, \quad \textbf{(9–13)}$$

where $M$ is the total mass of the system.

The center of mass of a system is important because this point moves like a single particle of mass $M$ acted on by the same net external force, $\Sigma\vec{\mathbf{F}}_{ext}$. In equation form, this is just Newton's second law for a system of particles (or extended objects):

$$M\vec{\mathbf{a}}_{CM} = \Sigma\vec{\mathbf{F}}_{ext}, \quad \textbf{(9–17)}$$

where $M$ is the total mass of the system, $\vec{\mathbf{a}}_{CM}$ is the acceleration of the CM of the system, and $\Sigma\vec{\mathbf{F}}_{ext}$ is the total (net) external force acting on all parts of the system.

For a system of particles of total linear momentum $\vec{\mathbf{P}} = \Sigma m_i\vec{\mathbf{v}}_i = M\vec{\mathbf{v}}_{CM}$, Newton's second law is

$$\frac{d\vec{\mathbf{P}}}{dt} = \Sigma\vec{\mathbf{F}}_{ext}. \quad \textbf{(9–5)}$$

[*If the mass $M$ of an object is not constant, then

$$M\frac{d\vec{\mathbf{v}}}{dt} = \Sigma\vec{\mathbf{F}}_{ext} + \vec{\mathbf{v}}_{rel}\frac{dM}{dt} \quad \textbf{(9–19b)}$$

where $\vec{\mathbf{v}}$ is the velocity of the object at any instant and $\vec{\mathbf{v}}_{rel}$ is the relative velocity at which mass enters (or leaves) the object.]

# Questions

1. We claim that momentum is conserved. Yet most moving objects eventually slow down and stop. Explain.
2. A light object and a heavy object have the same kinetic energy. Which has the greater momentum? Explain.
3. When a person jumps from a tree to the ground, what happens to the momentum of the person upon striking the ground?
4. When you release an inflated but untied balloon, why does it fly across the room?
5. Explain, on the basis of conservation of momentum, how a fish propels itself forward by swishing its tail back and forth.
6. According to Eq. 9–6a (also Eq. 9–6b), the longer the impact time $t$ of an impulse, the smaller the force $\vec{\mathbf{F}}$ needs to be for the same momentum change, and hence the smaller the deformation of the object on which the force acts. On this basis, explain the value of *air bags*, which are intended to inflate during an automobile collision and reduce the possibility of fracture or death.
7. If a falling ball made a perfectly elastic collision with the floor, would it rebound to its original height? Explain.
8. A boy stands on the back of a rowboat and dives into the water. What happens to the boat as the boy leaves it? Explain.
9. It is said that in ancient times a rich man with a bag of gold coins was stranded on the surface of a frozen lake. Because the ice was frictionless, he could not push himself to shore and froze to death. What could he have done to save himself had he not been so miserly?
10. The speed of a tennis ball on the return of a serve can be just as fast as the serve, even though the racket isn't swung very fast. How can this be?
11. Is it possible for an object to receive a larger impulse from a small force than from a large force? Explain.
12. How could a force give zero impulse over a nonzero time interval even though the force is not zero for at least a part of that time interval?
13. In a collision between two cars, which would you expect to be more damaging to the occupants: if the cars collide and remain together, or if the two cars collide and rebound backward? Explain.
14. A very elastic ball is dropped from a height $h$ onto a hard steel plate (fixed to the Earth), from which it rebounds at very nearly the same speed. (*a*) Is the momentum of the ball conserved during any part of this process? (*b*) If we consider the ball and the Earth as our system, during what parts of the process is momentum conserved? (*c*) Answer part (*b*) for a piece of putty that falls and sticks to the steel plate.
15. Cars used to be built as rigid as possible to withstand collisions. Today, though, cars are designed to have "crumple zones" that collapse upon impact. What is the advantage of this new design?
16. At a hydroelectric power plant, water is directed at high speed against turbine blades on an axle that turns an electric generator. For maximum power generation, should the turbine blades be designed so that the water is brought to a dead stop, or so that the water rebounds? Explain.
17. A squash ball hits a wall at a 45° angle as shown in Fig. 9–36. What is the direction (*a*) of the change in momentum of the ball, (*b*) of the force on the wall?

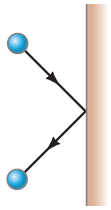

**FIGURE 9–36**
Question 17.

18. Two blocks of mass $m_1$ and $m_2$ rest on a frictionless table and are connected by a spring. The blocks are pulled apart, stretching the spring, and then released. Describe the subsequent motion of the two blocks.
19. Why can a batter hit a pitched baseball farther than a ball he himself has tossed up in the air?
20. If a small 20-passenger plane is not full, sometimes passengers are told they must sit in certain seats and may not move to empty seats. Why might this be?
21. Why do you tend to lean backward when carrying a heavy load in your arms?
22. Why is the CM of a 1-m length of pipe at its midpoint, whereas this is not true for your arm or leg?

**23.** Describe an analytic way of determining the CM of any thin, triangular-shaped, uniform plate.

**24.** How can a rocket change direction when it is far out in space and essentially in a vacuum?

**25.** Bob and Jim decide to play *tug-of-war* on a frictionless (icy) surface. Jim is considerably stronger than Bob, but Bob weighs 160 lb whereas Jim weighs 145 lb. Who loses by crossing over the midline first? Explain.

**26.** In one type of nuclear radioactive decay, an electron and a recoil nucleus are emitted but often do not separate along the same line. Use conservation of momentum in two dimensions to explain why this implies the emission of at least one other particle (it came to be called a "neutrino").

**27.** Show on a diagram how your CM shifts when you move from a lying position to a sitting position.

**28.** Place yourself facing the edge of an open door. Position your feet astride the door with your nose and abdomen touching the door's edge. Try to rise on your tiptoes. Why can't this be done?

**29.** If only an external force can change the momentum of the center of mass of an object, how can the internal force of the engine accelerate a car?

**30.** A rocket following a parabolic path through the air suddenly explodes into many pieces. What can you say about the motion of this system of pieces?

**31.** At a carnival game you try to knock over a heavy cylinder by throwing a small ball at it. You have a choice of throwing either a ball that will stick to the cylinder, or a second ball of equal mass and speed that will bounce backward off the cylinder. Which ball is more likely to make the cylinder move, and why?

# MisConceptual Questions

**1.** Two children float motionlessly in a space station. The 20-kg girl pushes on the 40-kg boy and he sails away at 1.0 m/s. The girl
(*a*) remains motionless.
(*b*) moves in the same direction at 1.0 m/s.
(*c*) moves in the opposite direction at 1.0 m/s.
(*d*) moves in the opposite direction at 2.0 m/s.
(*e*) none of these.

**2.** A small boat coasts at constant speed under a bridge. A heavy sack of sand is dropped from the bridge onto the boat. The speed of the boat
(*a*) increases.
(*b*) decreases.
(*c*) does not change.
(*d*) Without knowing the mass of the boat and the sand, we can't tell.

**3.** An astronaut is a short distance away from her space station without a tether rope. She has a large wrench. What should she do with the wrench to move toward the space station?
(*a*) Throw it directly away from the space station.
(*b*) Throw it directly toward the space station.
(*c*) Throw it toward the station without letting go of it.
(*d*) Throw it parallel to the direction of the station's orbit.
(*e*) Throw it opposite to the direction of the station's orbit.

**4.** A space vehicle, in circular orbit around the Earth, collides with a small asteroid which ends up in the vehicle's storage bay. For this collision,
(*a*) only momentum is conserved.
(*b*) only kinetic energy is conserved.
(*c*) both momentum and kinetic energy are conserved.
(*d*) neither momentum nor kinetic energy is conserved.

**5.** A baseball is pitched horizontally toward home plate with a velocity of 110 km/h. In which of the following scenarios does the change in momentum of the baseball have the largest magnitude?
(*a*) The catcher catches the ball.
(*b*) The ball is popped straight up at a speed of 110 km/h.
(*c*) The baseball is hit straight back to the pitcher at a speed of 110 km/h.
(*d*) Scenarios (*a*) and (*b*) have the same change in momentum.
(*e*) Scenarios (*a*), (*b*), and (*c*) have the same change in momentum.

**6.** You are lying in bed and want to shut your bedroom door. You have a bouncy ball and a blob of clay, both with the same mass. Which one would be more effective to throw at your door to close it?
(*a*) The ball. (*c*) Both the same.
(*b*) The blob of clay. (*d*) Neither will work.

**7.** A small car and a heavy pickup truck are both out of gas. The truck has twice the mass of the car. After you push first the car and then the truck for the *same amount of time* with the same force, what can you say about the momentum and kinetic energy of the car and the truck? Ignore friction.
(*a*) They have the same momentum and the same kinetic energy.
(*b*) The car has more momentum and more kinetic energy than the truck.
(*c*) The truck has more momentum and more kinetic energy than the car.
(*d*) They have the same momentum, but the car has more kinetic energy than the truck.
(*e*) They have the same kinetic energy, but the truck has more momentum than the car.

**8.** Answer the previous Question (#7) but now assume that you push both the car and the truck for the *same distance* with the same force. [*Hint*: See also Chapter 7.]

**9.** A railroad tank car contains milk and moves at a constant speed along a level track. The milk begins to leak out the bottom. The car then
(*a*) slows down.
(*b*) speeds up.
(*c*) maintains a constant speed.
(*d*) Need more information about the rate of the leak.

**10.** A truck going 15 km/h has a head-on collision with a small car going 30 km/h. Which statement best describes the situation?
(*a*) The truck has the greater change of momentum because it has the greater mass.
(*b*) The car has the greater change of momentum because it has the greater speed.
(*c*) Neither the car nor the truck changes its momentum in the collision because momentum is conserved.
(*d*) They both have the same change in magnitude of momentum because momentum is conserved.
(*e*) None of the above is necessarily true.

**11.** A bowling ball hangs from a 1.0-m-long cord, Fig. 9–37: (i) A 200-gram putty ball moving 5.0 m/s hits the bowling ball and sticks to it, causing the bowling ball to swing up; (ii) a 200-gram rubber ball moving 5.0 m/s hits the bowling ball and bounces straight back at nearly 5.0 m/s, causing the bowling ball to swing up. Describe what happens.
(*a*) The bowling ball swings up by the same amount in both (i) and (ii).
(*b*) The ball swings up farther in (i) than in (ii).
(*c*) The ball swings up farther in (ii) than in (i).
(*d*) Not enough information is given; we need the contact time between the rubber ball and the bowling ball.

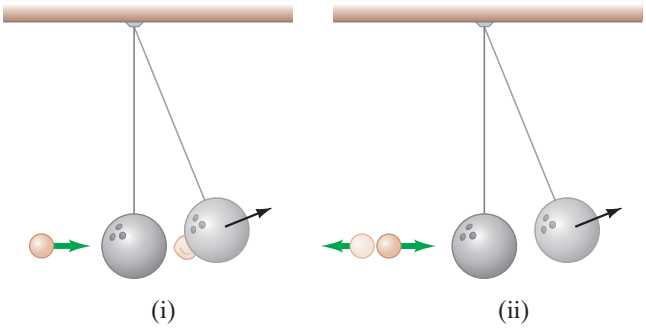

**FIGURE 9–37** MisConceptual Question 11.

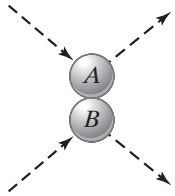
**12.** Inelastic and elastic collisions are similar in that
(*a*) momentum and kinetic energy are conserved in both.
(*b*) momentum is conserved in both.
(*c*) momentum and potential energy are conserved in both.
(*d*) kinetic energy is conserved in both.

**13.** Figure 9–38 shows the paths of two colliding steel balls, *A* and *B*. Which set of arrows below best represents the direction of the *change* in momentum of each ball?



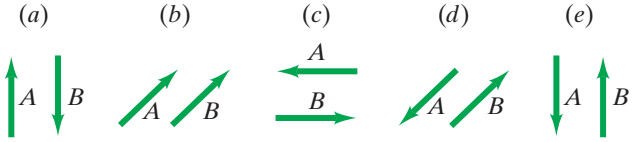


**FIGURE 9–38** (Above.)

# Problems

## 9–1 and 9–2 Momentum and Its Conservation

**1.** (I) What is the magnitude of the momentum of a 32-g sparrow flying with a speed of 8.4 m/s?

**2.** (I) A 7150-kg railroad car travels alone on a level frictionless track with a constant speed of 15.0 m/s. A 3650-kg load, initially at rest, is dropped onto the car. What will be the car's new speed?

**3.** (I) A 110-kg tackler moving at 2.5 m/s meets head-on (and holds on to) an 82-kg halfback moving at 4.4 m/s. What will be their mutual speed immediately after the collision?

**4.** (I) Calculate the force exerted on a rocket when the propelling gases are being expelled at a rate of 1200 kg/s with a speed of $4.5 \times 10^4$ m/s.

**5.** (II) The momentum of a particle, in SI units, is given by $\vec{\mathbf{p}} = 4.8t^2\hat{\mathbf{i}} - 8.0\hat{\mathbf{j}} - 9.4t\hat{\mathbf{k}}$. What is the force exerted on the particle as a function of time?

**6.** (II) A child in a boat throws a 5.30-kg package out horizontally with a speed of 10.0 m/s, Fig. 9–39. Calculate the velocity of the boat immediately after, assuming it was initially at rest. The mass of the child is 24.0 kg and that of the boat is 42.0 kg.

**FIGURE 9–39** Problem 6.

**7.** (II) An atomic nucleus initially moving at 320 m/s emits an alpha particle in the direction of its velocity, and the remaining nucleus slows to 280 m/s. If the alpha particle has a mass of 4.0 u and the original nucleus has a mass of 222 u, what speed does the alpha particle have when it is emitted?

**8.** (II) The force on a particle of mass $m$ is given by $\vec{\mathbf{F}} = 26\hat{\mathbf{i}} - 12t^2\hat{\mathbf{j}}$ where $F$ is in N and $t$ in s. What will be the change in the particle's momentum between $t = 1.0$ s and $t = 2.0$ s?

**9.** (II) An object at rest is suddenly broken apart into two fragments by an explosion. One fragment acquires twice the kinetic energy of the other. What is the ratio of their masses?

**10.** (II) A 22-g bullet traveling 240 m/s penetrates a 2.0-kg block of wood and emerges going 130 m/s. If the block is stationary on a frictionless surface when hit, how fast does it move after the bullet emerges?

**11.** (II) A 0.145-kg baseball pitched horizontally at 35.0 m/s strikes a bat and pops straight up to a height of 31.5 m. If the contact time between bat and ball is 2.5 ms, calculate the average force between the ball and bat during contact.

**12.** (II) A rocket of total mass 3180 kg is traveling in outer space with a velocity of 125 m/s. To alter its course by 35.0°, its rockets can be fired briefly in a direction perpendicular to its original motion. If the rocket gases are expelled at a speed of 1750 m/s, how much mass must be expelled?

**13.** (II) A rocket of mass $m$ traveling with speed $v_0$ along the $x$ axis suddenly shoots out fuel equal to one-third its mass, perpendicular to the $x$ axis (along the $y$ axis) with speed $2v_0$. Express the final velocity of the rocket in $\hat{\mathbf{i}}, \hat{\mathbf{j}}, \hat{\mathbf{k}}$ notation.

**14.** (II) The *radioactive decay* of a neutron into a proton, an electron, and a neutrino is an example of a three-particle decay process. Use the vector nature of momentum to show that if the neutron is initially at rest, the velocity vectors of the three must be coplanar (that is, all in the same plane). The result is not true for numbers greater than three.

**15.** (II) A mass $m_A = 2.0\,\text{kg}$, moving with velocity $\vec{\mathbf{v}}_A = (4.0\,\hat{\mathbf{i}} + 5.0\,\hat{\mathbf{j}} - 2.0\,\hat{\mathbf{k}})\,\text{m/s}$, collides with mass $m_B = 3.0\,\text{kg}$, which is initially at rest. Immediately after the collision, mass $m_A$ is observed traveling at velocity $\vec{\mathbf{v}}'_A = (-2.0\,\hat{\mathbf{i}} + 3.0\,\hat{\mathbf{k}})\,\text{m/s}$. Find the velocity of mass $m_B$ after the collision. Assume no outside force acts on the two masses during the collision.

**16.** (III) Air in a 120-km/h wind strikes head-on the face of a building 45 m wide by 75 m high and is brought to rest. If air has a mass of 1.3 kg per cubic meter, determine the average force of the wind on the building.

**17.** (III) A 195-kg projectile, fired with a speed of 116 m/s at a 60.0° angle, breaks into three pieces of equal mass at the highest point of its arc (where its velocity is horizontal). Two of the fragments move with the same speed right after the explosion as the entire projectile had just before the explosion; one of these moves vertically downward and the other horizontally. Determine (*a*) the velocity of the third fragment immediately after the explosion and (*b*) the energy released in the explosion.

## 9–3 Collisions and Impulse

**18.** (I) A 0.145-kg baseball pitched at 31.0 m/s is hit on a horizontal line drive straight back at the pitcher at 46.0 m/s. If the contact time between bat and ball is $5.00 \times 10^{-3}\,\text{s}$, calculate the force (assumed to be constant) between the ball and bat.

**19.** (II) A golf ball of mass 0.045 kg is hit off the tee at a speed of 38 m/s. The golf club was in contact with the ball for $3.5 \times 10^{-3}\,\text{s}$. Find (*a*) the impulse imparted to the golf ball, and (*b*) the average force exerted on the ball by the golf club.

**20.** (II) A tennis ball of mass $m = 0.060\,\text{kg}$ and speed $v = 28\,\text{m/s}$ strikes a wall at a 45° angle and rebounds with the same speed at 45° (Fig. 9–40). What is the impulse (magnitude and direction) given to the ball?

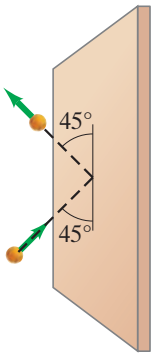

**FIGURE 9–40**
Problem 20.

**21.** (II) A 125-kg astronaut (including space suit) acquires a speed of 2.50 m/s by pushing off with her legs from a 2200-kg space capsule. (*a*) What is the change in speed of the space capsule? (*b*) If the push lasts 0.600 s, what is the average force exerted by each on the other? As the reference frame, use the position of the capsule before the push. (*c*) What is the kinetic energy of each after the push?

**22.** (II) A 95-kg fullback is running at 3.0 m/s to the east and is stopped in 0.75 s by a head-on tackle by a tackler running due west. Calculate (*a*) the original momentum of the fullback, (*b*) the impulse exerted on the fullback, (*c*) the impulse exerted on the tackler, and (*d*) the average force exerted on the tackler.

**23.** (II) Suppose the force acting on a tennis ball (mass 0.060 kg) points in the $+x$ direction and is given by the graph of Fig. 9–41 as a function of time. (*a*) Use graphical methods (count squares) to estimate the total impulse given the ball. (*b*) Estimate the velocity of the ball after being struck, assuming the tennis ball is being served so it is nearly at rest initially.

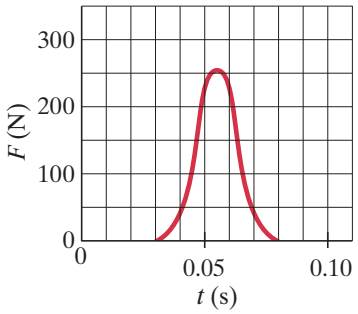

**FIGURE 9–41**
Problem 23.

**24.** (II) The force on a bullet along the barrel of a firearm is given by the formula $F = [740 - (2.3 \times 10^5\,\text{s}^{-1})\,t]\,\text{N}$ over the time interval $t = 0$ to $t = 3.0 \times 10^{-3}\,\text{s}$. (*a*) Plot a graph of $F$ versus $t$ for $t = 0$ to $t = 3.0\,\text{ms}$. (*b*) Use the graph to estimate the impulse given the bullet. (*c*) Determine the impulse by integration. (*d*) If the bullet achieves a speed of 260 m/s as a result of this impulse, given to it in the barrel of a gun, what must the bullet's mass be? (*e*) What is the recoil speed of the 4.5-kg gun?

**25.** (II) (*a*) A molecule of mass $m$ and speed $v$ strikes a wall at right angles and rebounds back with the same speed. If the collision time is $\Delta t$, what is the average force on the wall during the collision? (*b*) If molecules, all of this type, strike the wall at intervals a time $t$ apart (on the average) what is the average force on the wall averaged over a long time?

**26.** (III) (*a*) Calculate the impulse experienced when a 68-kg person lands on firm ground after jumping from a height of 2.8 m. (*b*) Estimate the average force exerted on the person's feet by the ground if the landing is stiff-legged, and again (*c*) with bent legs. With stiff legs, assume the body moves 1.0 cm during impact, and when the legs are bent, about 50 cm. [*Hint*: The average net force on him, which is related to impulse, is the vector sum of gravity and the force exerted by the ground. See Fig. 9–42.] We will see in Chapter 12 that the force in (*b*) exceeds the ultimate strength of bone (Table 12–2).

**FIGURE 9–42**
Problem 26.

**27.** (III) A scale is adjusted so that when a large, shallow pan is placed on it, it reads zero. A water faucet at height $h = 2.35\,\text{m}$ above is turned on and water falls into the pan at a rate $R = 0.142\,\text{kg/s}$. Determine (*a*) a formula for the scale reading as a function of time $t$ and (*b*) the reading for $t = 11.8\,\text{s}$. (*c*) Repeat (*a*) and (*b*), but replace the shallow pan with a tall, narrow cylindrical container of area $A = 18.5\,\text{cm}^2$ (the level rises in this case).

## 9–4 and 9–5 Elastic Collisions

**28.** (II) A 0.450-kg hockey puck, moving east (+ $x$ direction) with a speed of 7.40 m/s, has a head-on collision with a 0.900-kg puck initially at rest. Assuming a perfectly elastic collision, what will be the speed and direction of each puck after the collision?

**29.** (II) Two billiard balls of equal mass undergo a perfectly elastic head-on collision. If one ball's initial speed was 2.00 m/s, and the other's was 3.60 m/s in the opposite direction, what will be their speeds and directions after the collision?

**30.** (II) A 0.280-kg croquet ball makes an elastic head-on collision with a second ball initially at rest. The second ball moves off with half the original speed of the first ball. (*a*) What is the mass of the second ball? (*b*) What fraction of the original kinetic energy ($\Delta K/K$) gets transferred to the second ball?

**31.** (II) A block of mass $m_2$ is at rest on a long frictionless table. A block of mass $m_1$ is projected toward the first block, and makes a perfectly elastic head-on collision with block $m_2$. Determine the value of $m_2$ (in terms of $m_1$) for which both blocks move with the same speed but in opposite directions after the collision.

**32.** (II) A ball of mass 0.320 kg that is moving with a speed of 5.5 m/s collides head-on and elastically with another ball initially at rest. Immediately after the collision, the incoming ball bounces backward with a speed of 3.8 m/s. Calculate (*a*) the velocity of the target ball after the collision, and (*b*) the mass of the target ball.

**33.** (II) Determine the fraction of kinetic energy lost by a neutron $(m_1 = 1.01\text{ u})$ when it collides head-on and elastically with a target particle at rest which is (*a*) ${}^{1}_{1}\text{H}$ ($m = 1.01$ u); (*b*) ${}^{2}_{1}\text{H}$ (heavy hydrogen, $m = 2.01$ u); (*c*) ${}^{12}_{6}\text{C}$ ($m = 12.00$ u); (*d*) ${}^{208}_{82}\text{Pb}$ (lead, $m = 208$ u).

**34.** (II) Show that, in general, for any head-on one-dimensional elastic collision, the speeds after collision are

$$v'_B = v_A\left(\frac{2m_A}{m_A + m_B}\right) + v_B\left(\frac{m_B - m_A}{m_A + m_B}\right)$$

and

$$v'_A = v_A\left(\frac{m_A - m_B}{m_A + m_B}\right) + v_B\left(\frac{2m_B}{m_A + m_B}\right),$$

where $v_A$ and $v_B$ are the initial speeds of the two objects of mass $m_A$ and $m_B$.

**35.** (III) Two objects, one initially at rest, undergo a 1-D elastic collision. If one-fourth of the initial kinetic energy is transferred to the target, what is the ratio of their masses?

**36.** (III) A 3.0-kg block slides along a frictionless tabletop at 8.0 m/s toward a second block (at rest) of mass 4.5 kg. A coil spring, which obeys Hooke's law and has spring constant $k = 850$ N/m, is attached to the second block in such a way that it will be compressed when struck by the moving block, Fig. 9–43. (*a*) What will be the maximum compression of the spring? (*b*) What will be the final velocities of the blocks after the collision? (*c*) Is the collision elastic? Ignore the mass of the spring.

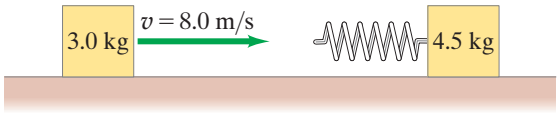

**FIGURE 9–43** Problem 36.

## 9–6 Inelastic Collisions

**37.** (I) In a ballistic pendulum experiment, projectile 1 results in a maximum height $h$ of the pendulum equal to 2.6 cm. A second projectile (of the same mass) causes the pendulum to swing twice as high, $h_2 = 5.2$ cm. The second projectile was how many times faster than the first?

**38.** (II) A 28-g rifle bullet traveling 190 m/s embeds itself in a 3.1-kg pendulum hanging on a 2.4-m-long string, which makes the pendulum swing upward in an arc. Determine the vertical and horizontal components of the pendulum's maximum displacement.

**39.** (II) An internal explosion breaks an object, initially at rest, into two pieces, one of which has 1.5 times the mass of the other. If 4600 J is released in the explosion, how much kinetic energy does each piece acquire?

**40.** (II) You drop a 21-g ball from a height of 1.5 m and it only bounces back to a height of 0.85 m. What was the total impulse on the ball when it hit the floor? (Ignore air resistance.)

**41.** (II) Croquet ball A moving at 4.3 m/s makes a head-on collision with ball B of equal mass initially at rest. Immediately after the collision, ball B moves forward at 3.0 m/s. What fraction of the initial kinetic energy is lost in the collision?

**42.** (II) A 144-g baseball moving 28.0 m/s strikes a stationary 4.85-kg brick resting on small rollers so it moves without significant friction. After hitting the brick, the baseball bounces straight back, and the brick moves forward at 1.10 m/s. (*a*) What is the baseball's speed after the collision? (*b*) Find the total kinetic energy before and after the collision.

**43.** (II) A 2.0-kg ball moving 3.5 m/s strikes a 3.0-kg ball at rest head-on. If the total kinetic energy after the collision is 75% of that before the collision, what are the speeds and directions of both balls after the collision?

**44.** (II) A pendulum consists of a mass $M$ hanging at the bottom end of a massless rod of length $\ell$, which has a frictionless pivot at its top end. A mass $m$, moving horizontally as shown in Fig. 9–44 with velocity $v$, impacts $M$ and becomes embedded. What is the smallest value of $v$ sufficient to cause the pendulum (with embedded mass $m$) to swing clear over the top of its arc?

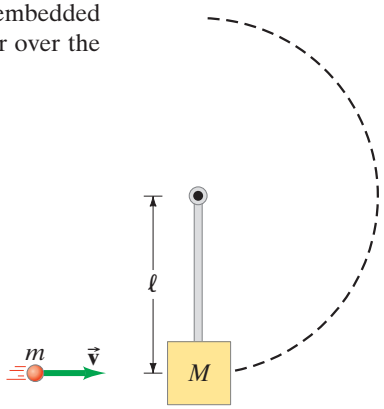

**FIGURE 9–44**
Problem 44.

**45.** (II) A bullet of mass $m = 0.0010$ kg embeds itself in a wooden block with mass $M = 0.999$ kg, which then compresses a spring ($k = 140$ N/m) by a distance $x = 0.050$ m before coming to rest. The coefficient of kinetic friction between the block and table is $\mu = 0.50$. (*a*) What is the initial velocity (assumed horizontal) of the bullet? (*b*) What fraction of the bullet's initial kinetic energy is dissipated (in damage to the wooden block, rising temperature, etc.) in the collision between the bullet and the block?

**46.** (II) A measure of inelasticity in a head-on collision of two objects is the **coefficient of restitution**, defined as

$$e = \frac{v'_A - v'_B}{v_B - v_A},$$

where $v'_A - v'_B$ is the relative velocity of the two objects after the collision and $v_B - v_A$ is their relative velocity before it. (*a*) Show that $e = 1$ for a perfectly elastic collision, and $e = 0$ for a completely inelastic collision. (*b*) A simple method for measuring the coefficient of restitution for an object colliding with a very hard surface like steel is to drop the object onto a heavy steel plate, as shown in Fig. 9–45. Determine a formula for $e$ in terms of the original height $h$ and the maximum height $h'$ reached after collision.

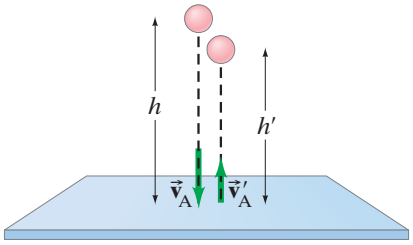

**FIGURE 9–45** Problem 46.
Measurement of coefficient of restitution.

## 9–7 Collisions in 2 or 3 Dimensions

**47.** (II) Billiard ball A of mass $m_A = 0.120\,\text{kg}$ moving with speed $v_A = 2.80\,\text{m/s}$ strikes ball B, initially at rest, of mass $m_B = 0.140\,\text{kg}$. As a result of the collision, ball A is deflected off at an angle of 35.0° with a speed $v'_A = 2.10\,\text{m/s}$. (*a*) Taking the $x$ axis to be the original direction of motion of ball A, write down the equations expressing the conservation of momentum for the components in the $x$ and $y$ directions separately. (*b*) Solve these equations for the speed, $v'_B$, and angle, $\theta'_B$, of ball B after the collision. Do not assume the collision is elastic.

**48.** (II) A radioactive nucleus at rest decays into a second nucleus, an electron, and a neutrino. The electron and neutrino are emitted at right angles and have momenta of $9.6 \times 10^{-23}\,\text{kg}\cdot\text{m/s}$ and $6.2 \times 10^{-23}\,\text{kg}\cdot\text{m/s}$, respectively. Determine the magnitude and the direction of the momentum of the second (recoiling) nucleus.

**49.** (II) An atomic nucleus of mass $m$ traveling with speed $v$ collides elastically with a target particle of mass $2m$ (initially at rest) and is scattered at 90°. (*a*) At what angle does the target particle move after the collision? (*b*) What are the final speeds of the two particles? (*c*) What fraction of the initial kinetic energy is transferred to the target particle?

**50.** (II) A neutron collides elastically with a helium nucleus (at rest initially) whose mass is 4.0 times that of the neutron. The helium nucleus is observed to move off at an angle $\theta'_{He} = 45°$. Determine the angle of the neutron, $\theta'_n$, and the speeds of the two particles, $v'_n$ and $v'_{He}$, after the collision. The neutron's initial speed is $6.2 \times 10^5\,\text{m/s}$.

**51.** (III) Prove that in a non-head-on elastic collision of two objects of identical mass, with one being a target initially at rest, the angle between their velocity vectors after collision is always 90°.

**52.** (III) A neon atom ($m = 20.0\,\text{u}$) makes a perfectly elastic collision with another atom at rest. After the impact, the neon atom travels away at a 55.6° angle from its original direction and the unknown atom travels away at a −50.0° angle. What is the mass (in u) of the unknown atom? [*Hint*: You could use the law of sines.]

**53.** (III) Two billiard balls in contact with each other are struck by a third ball moving at 5.5 m/s as shown in Fig. 9–46a. If both of the first two balls move after the collision at an angle of 32° to the initial path of the third ball (Fig. 9–46b), find the velocities of all three balls after the collision. Assume all balls have the same mass, and the collision is elastic.

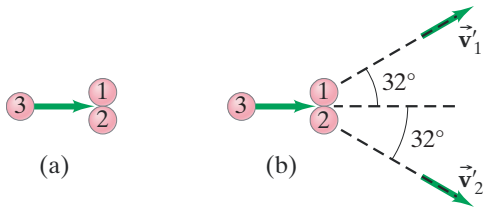

**FIGURE 9–46** Problem 53.

## 9–8 Center of Mass (CM)

**54.** (I) The distance between a carbon atom ($m = 12\,\text{u}$) and an oxygen atom ($m = 16\,\text{u}$) in the CO molecule is $1.13 \times 10^{-10}\,\text{m}$. How far from the carbon atom is the center of mass of the molecule?

**55.** (I) Find the center of mass of the three-mass system shown in Fig. 9–47 relative to the 1.00-kg mass.

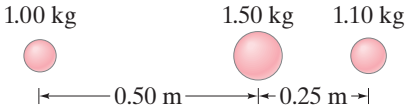

**FIGURE 9–47** Problem 55.

**56.** (I) The CM of an empty 1750-kg Jeep is 2.40 m behind the front of the Jeep. How far from the front of the Jeep will the CM be when two people sit in the front seat 2.80 m from the front of the Jeep, and three people sit in the back seat 3.90 m from the front? Assume that each person has a mass of 65.0 kg.

**57.** (II) Three cubes, of side $\ell_0$, $2\ell_0$, and $3\ell_0$, are placed next to one another (in contact) with their centers along a straight line as shown in Fig. 9–48. What is the position, along this line, of the CM of this system? Assume the cubes are made of the same uniform material.

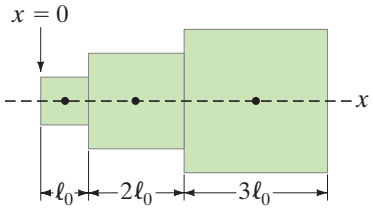

**FIGURE 9–48** Problem 57

**58.** (II) Find the center of mass of the ammonia molecule. The chemical formula is $NH_3$. The hydrogens are at the corners of an equilateral triangle (with sides 0.16 nm) that forms the base of a pyramid, with nitrogen at the apex (0.037 nm vertically above the plane of the triangle).

**59.** (II) A (lightweight) pallet has a load of ten identical cases of tomato paste (see Fig. 9–49), each of which is a cube of length $\ell$. Find the center of gravity in the horizontal plane, so that the crane operator can pick up the load without tipping it.

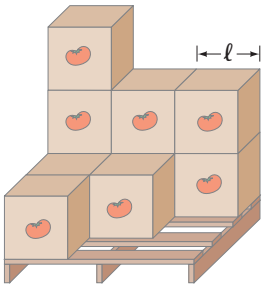

**FIGURE 9–49**
Problem 59.

**60.** (II) A uniform circular plate of radius $2R$ has a circular hole of radius $R$ cut out of it. The center C′ of the smaller circle is a distance $0.80R$ from the center C of the larger circle, Fig. 9–50. What is the position of the center of mass of the plate? [*Hint*: Try subtraction.]

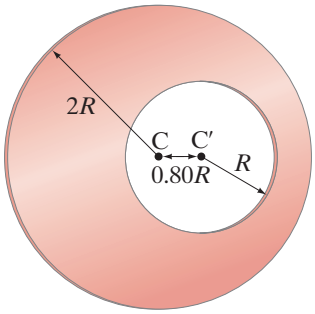

**FIGURE 9–50** Problem 60.

**61.** (II) A square uniform raft, 18 m by 18 m, of mass 5800 kg, is used as a ferryboat. If three cars, each of mass 1350 kg and pointing east, occupy the NE, SE, and SW corners, determine the CM of the loaded ferryboat relative to the center of the raft. Each car is 5.0 m long and 2.0 m wide, with the CM at the center.

**62.** (II) A uniform thin wire is bent into a semicircle of radius $R$. Determine the coordinates of its center of mass with respect to an origin of coordinates at the center of the "full" circle.

**63.** (III) Determine the CM of a machine part that is a uniform cone of height $h$ and radius $R$, Fig. 9–51. [*Hint*: Divide the cone into an infinite number of circular disks of thickness $dz$, one of which is shown.]

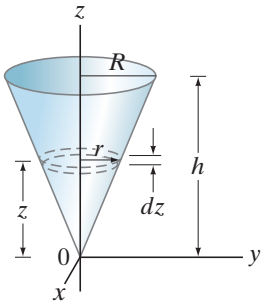

**FIGURE 9–51** Problem 63.

**64.** (III) Determine the CM of a uniform pyramid that has four triangular faces and a square base with equal sides all of length $s$. [*Hint*: See Problem 63.]

## 9–9 CM and Translational Motion

**65.** (II) The masses of the Earth and Moon are $5.98 \times 10^{24}$ kg and $7.35 \times 10^{22}$ kg, respectively, and their centers are separated by $3.84 \times 10^{8}$ m. (*a*) Where is the CM of the Earth–Moon system located? (*b*) What can you say about the motion of the Earth–Moon system about the Sun, and of the Earth and Moon separately about the Sun?

**66.** (II) A mallet consists of a uniform cylindrical head of mass 2.60 kg and diameter 0.0800 m attached at its center to a uniform cylindrical handle of mass 0.500 kg and length 0.240 m, as shown in Fig. 9–52. If this mallet is tossed, spinning, into the air, how far above the bottom of the handle is the point that will follow a parabolic trajectory?

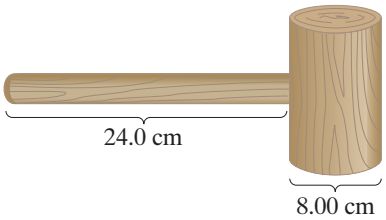

**FIGURE 9–52**
Problem 66.

**67.** (II) A 52-kg woman and a 72-kg man stand 8.6 m apart on nearly frictionless ice. (*a*) How far from the woman is their CM? (*b*) If each holds one end of a rope, and the man pulls on the rope so that he moves 2.5 m, how far from the woman will he be now? (*c*) How far will the man have moved from his original position when he collides with the woman?

**68.** (II) Suppose that in Example 9–18 (Fig. 9–32), $m_{II} = 3m_I$. (*a*) Where then would $m_{II}$ land? (*b*) What if $m_I = 3m_{II}$?

**69.** (II) Mass $M_A = 35$ kg and mass $M_B = 25$ kg. They have velocities (in m/s) $\vec{\mathbf{v}}_A = 14\hat{\mathbf{i}} - 16\hat{\mathbf{j}}$ and $\vec{\mathbf{v}}_B = -25\hat{\mathbf{i}} + 14\hat{\mathbf{j}}$. Determine the velocity of the center of mass of the system.

**70.** (III) A huge balloon and its gondola, of mass $M$, are in the air and stationary with respect to the ground. A passenger, of mass $m$, then climbs out and slides down a rope with speed $v$, measured with respect to the balloon. With what speed and direction (relative to Earth) does the balloon then move? What happens if the passenger stops?

**71.** (III) A 360-kg four-wheel flat cart 15 m long is moving horizontally with a speed of 6.0 m/s. A 110-kg worker starts walking from one end of the cart to the other in the direction of motion, with speed 2.0 m/s with respect to the cart. In the time it takes for him to reach the other end, how far has the cart moved?

## *9–10 Variable Mass

***72.** (II) A 3500-kg rocket is to be accelerated at $3.5\,g$ at take-off from the Earth. If the gases can be ejected at a rate of 27 kg/s, what must be their exhaust speed?

***73.** (II) A rocket traveling 1950 m/s away from the Earth at an altitude of 6400 km fires its rockets, which eject gas at a speed of 1200 m/s (relative to the rocket). If the mass of the rocket at this moment is 25,000 kg and an acceleration of $1.5\ \text{m/s}^2$ is desired, at what rate must the gases be ejected?

***74.** (II) The jet engine of an airplane takes in 120 kg of air per second, which is burned with 4.2 kg of fuel per second. The burned gases leave the plane at a speed of 550 m/s (relative to the plane). If the plane is traveling 270 m/s (600 mi/h), determine: (*a*) the thrust due to ejected fuel; (*b*) the thrust due to accelerated air passing through the engine; and (*c*) the power (hp) delivered.

*75. (II) Suppose the conveyor belt of Example 9–20 is retarded by a friction force of 150 N. Determine the required output power (hp) of the motor as a function of time from the moment gravel first starts falling ($t = 0$) until 3.0 s after the gravel begins to be dumped off the end of the 22-m-long conveyor belt.

*76. (III) A sled filled with sand slides without friction down a 32° slope. Sand leaks out a hole in the sled at a rate of 2.0 kg/s. If the sled starts from rest with an initial total mass of 45.0 kg, how long does it take the sled to travel 120 m along the slope?

# General Problems

77. Two astronauts, one of mass 195 kg and the other 235 kg, including their space suits, are initially at rest together in outer space. They then push each other apart. How far apart are they when the lighter astronaut has moved 12 m from their starting point?

78. A 4800-kg open truck coasts at a constant speed of 6.70 m/s. Snow begins to fall vertically and fills the truck at a rate of 3.80 kg/min. Ignoring friction, what is the truck's speed after 60.0 min?

79. Two bumper cars in an amusement park ride collide elastically as one approaches the other directly from the rear (Fig. 9–53). Car A has a mass of 435 kg and car B 495 kg, owing to differences in passenger mass. If car A approaches at 4.50 m/s and car B is moving at 3.70 m/s, calculate (*a*) their velocities after the collision, and (*b*) the change in momentum of each.

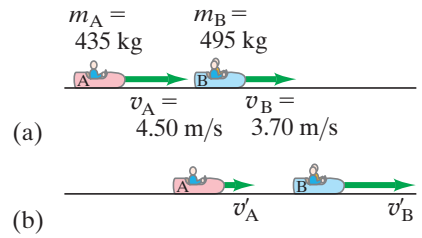

**FIGURE 9–53** Problem 79: (a) before collision, (b) after collision.

80. A gun fires a bullet vertically into a 1.40-kg block of wood at rest on a thin horizontal sheet, Fig. 9–54. If the bullet has a mass of 15.0 g and a speed of 230 m/s, how high will the block rise into the air after the bullet becomes embedded in it?

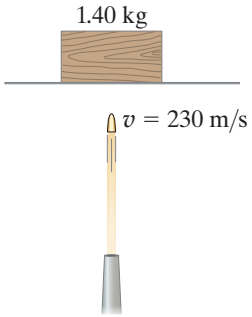

**FIGURE 9–54** Problem 80.

81. A 145-g baseball, moving along the $x$ axis with speed 30.0 m/s, strikes a fence at a 45° angle and rebounds along the $y$ axis with unchanged speed. Give its change in momentum using unit vector notation.

82. A meteor whose mass was about $1.5 \times 10^8$ kg struck the Earth ($m_E = 6.0 \times 10^{24}$ kg) with a speed of about 25 km/s and came to rest in the Earth. (*a*) What was the Earth's recoil speed (relative to Earth at rest before the collision)? (*b*) What fraction of the meteor's kinetic energy was transformed to kinetic energy of the Earth? (*c*) By how much did the Earth's kinetic energy change as a result of this collision?

83. You are the design engineer in charge of the *crashworthiness* of new automobile models. Cars are tested by smashing them into fixed, massive barriers at 45 km/h. A new model of mass 1500 kg takes 0.15 s from the time of impact until it is brought to rest. (*a*) Calculate the average force exerted on the car by the barrier. (*b*) Calculate the average deceleration of the car in $g$'s.

84. After a completely inelastic collision between two objects of equal mass, each having initial speed, $v$, the two move off together with speed $v/3$. What was the angle between their initial directions?

85. A 5.5-kg object moving in the $+x$ direction at 6.5 m/s collides head-on with an 8.0-kg object moving in the $-x$ direction at 4.0 m/s. Determine the final velocity of each object if: (*a*) the objects stick together; (*b*) the collision is elastic; (*c*) the 5.5-kg object is at rest after the collision; (*d*) the 8.0-kg object is at rest after the collision; (*e*) the 5.5-kg object has a velocity of 4.0 m/s in the $-x$ direction after the collision. Finally, (*f*) are the results in (*c*), (*d*), and (*e*) "reasonable"? Explain.

86. Two balls, of masses $m_A = 42$ g and $m_B = 96$ g, are suspended as shown in Fig. 9–55. The lighter ball is pulled away to a 66° angle with the vertical and released. (*a*) What is the velocity of the lighter ball before impact? (*b*) What is the velocity of each ball after the elastic collision? (*c*) What will be the maximum height of each ball after the elastic collision?

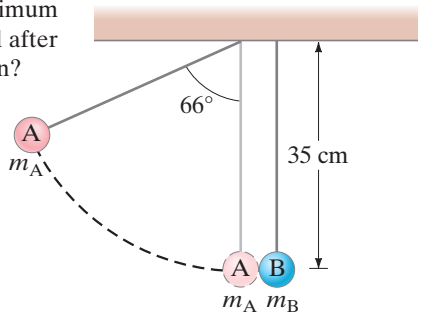

**FIGURE 9–55** Problem 86.

87. A block of mass $m = 2.20$ kg slides down a 30.0° incline which is 3.60 m high. At the bottom, it strikes a block of mass $M = 7.70$ kg which is at rest on a horizontal surface, Fig. 9–56. (Assume a smooth transition at the bottom of the incline.) If the collision is elastic, and friction can be ignored, determine (*a*) the speeds of the two blocks after the collision, and (*b*) how far back up along the incline will the smaller mass go.

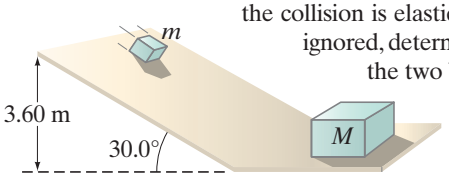

**FIGURE 9–56** Problems 87 and 88.

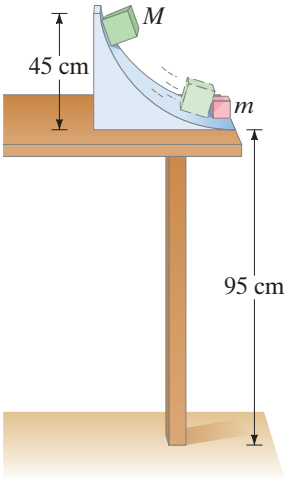
88. In Problem 87 (Fig. 9–56), what is the upper limit on mass $m$ if it is to rebound from $M$, slide up the incline, stop, slide down the incline, and collide with $M$ again?

**89.** An *extrasolar planet* can be detected by observing the *wobble* it produces on the star around which it orbits. Suppose an extrasolar planet of mass $m_B$ orbits around its star of mass $m_A$. If no external force acts on this simple two-object system, then its CM is stationary. Assume $m_A$ and $m_B$ are in circular orbits with radii $r_A$ and $r_B$ about the system's CM. (*a*) Show that

$$r_A = \frac{m_B}{m_A} r_B.$$

(*b*) Now consider a Sun-like star and a single planet with the same characteristics as Jupiter. That is, $m_B = 1.0 \times 10^{-3} m_A$ and the planet has an orbital radius of $8.0 \times 10^{11}$ m. Determine the radius $r_A$ of the star's orbit about the system's CM. (*c*) When viewed from Earth, the distant system appears to wobble over a distance of $2r_A$. If astronomers are able to detect angular displacements $\theta$ of about 1 *milliarcsec* (1 arcsec $= \frac{1}{3600}$ of a degree), from what distance $d$ (in light-years) can the star's wobble be detected (1 ly $= 9.46 \times 10^{15}$ m)? (*d*) The star nearest to our Sun is about 4 ly away. Assuming stars are uniformly distributed throughout our region of the Milky Way Galaxy, about how many stars can this technique be applied to in the search for extrasolar planetary systems?

**90.** In a physics lab, a cube slides down a frictionless incline as shown in Fig. 9–57 and elastically strikes another cube at the bottom that is only one-half its mass. If the incline is 45 cm high and the table is 95 cm off the floor, where does each cube land? [*Hint*: Both leave the incline moving horizontally.]



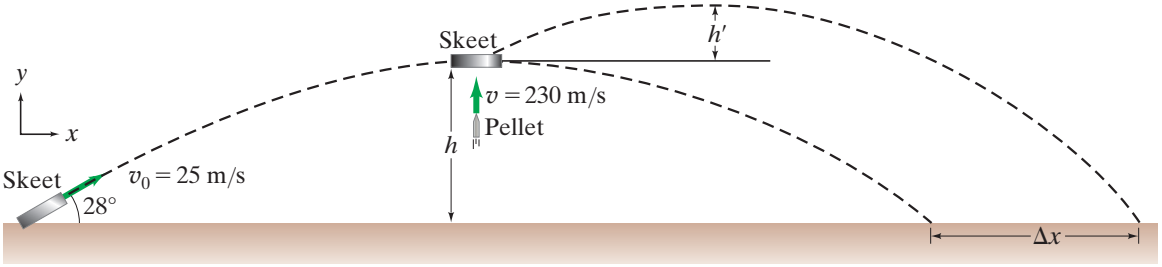


**FIGURE 9–57** Problem 90.

**91.** A 0.20-kg *skeet* (clay target) is fired at an angle of 28° to the horizontal with a speed of 25 m/s (Fig. 9–58). When it reaches the maximum height, $h$, it is hit from below by a 15-g pellet traveling vertically upward at a speed of 230 m/s. The pellet is embedded in the skeet. (*a*) How much higher, $h'$, does the skeet go up? (*b*) How much extra distance, $\Delta x$, does the skeet travel because of the collision?

**FIGURE 9–58** Problem 91.

**92.** A rifle is aimed at a 2.0-kg block of wood along an inclined plane making an angle of 25°, as shown in Fig. 9–59. A 9.5-g bullet is fired at 760 m/s and becomes embedded in the block. How far up the incline does the block/bullet slide? (*a*) Ignore the friction. (*b*) Assume $\mu_k = 0.33$.

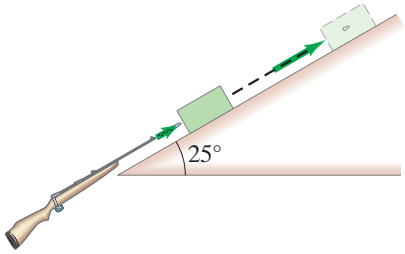

**FIGURE 9–59** Problem 92.

**93.** Astronomers estimate that a 2.0-km-diameter *asteroid* collides with the Earth once every million years. The collision could pose a threat to life on Earth. (*a*) Assume a spherical asteroid has a mass of 3200 kg for each cubic meter of volume and moves toward the Earth at 15 km/s. How much destructive energy could be released when it embeds itself in the Earth? (*b*) For comparison, a nuclear bomb could release about $5.0 \times 10^{16}$ J. How many such bombs would have to explode simultaneously to release the destructive energy of the asteroid collision with the Earth?

**94.** An astronaut of mass 210 kg including his suit and jet pack wants to acquire a velocity of 2.0 m/s to move back toward his space shuttle. Assuming the jet pack can eject gas with a velocity of 35 m/s, what mass of gas will need to be ejected?

**95.** Two blocks of mass $m_A$ and $m_B$, resting on a frictionless table, are connected by a stretched spring and then released (Fig. 9–60). (*a*) Is there a net external force on the system before release? (*b*) Determine the ratio of their speeds, $v_A/v_B$. (*c*) What is the ratio of their kinetic energies? (*d*) Describe the motion of the CM of this system. Ignore mass of spring.

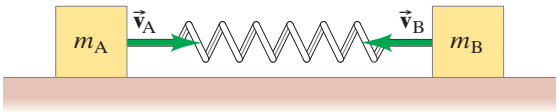

**FIGURE 9–60** Problem 95.

**96.** A fake hockey puck of mass $4m$ has been rigged to explode. Initially the puck is at rest on a frictionless ice rink. Then it bursts into three pieces. One chunk, of mass $m$, slides across the ice at velocity $v\hat{\mathbf{i}}$. Another chunk, of mass $2m$, slides across the ice at velocity $2v\hat{\mathbf{j}}$. Determine the velocity of the third chunk.

**97.** Determine the CM of a thin, uniform, semicircular plate, Fig. 9–61. [*Hint*: Integrate; see Problem 63.]

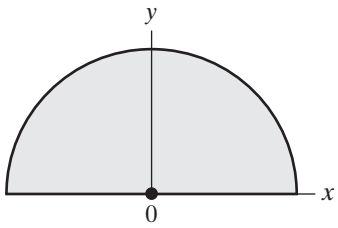

**FIGURE 9–61** Problem 97.

**98.** A massless spring with spring constant $k$ is placed between a block of mass $m$ and a block of mass $3m$. Initially the blocks are at rest on a frictionless surface and they are held together so that the spring between them is compressed by an amount $D$ from its equilibrium length. The blocks are then released and the spring pushes them off in opposite directions. Find the speeds of the two blocks when they detach from the spring.

***99.** Consider the truck of Problem 78, which is slowly filling with snow. (*a*) Determine the speed of the truck as a function of time using Eqs. 9–19. (*b*) What is the speed of the truck after 60.0 min? Does this agree with the simpler calculation (Problem 78)?

**100.** **The gravitational slingshot effect**. Figure 9–62 shows the planet Saturn moving in the negative $x$ direction at its orbital speed (with respect to the Sun) of 9.6 km/s. The mass of Saturn is $5.69 \times 10^{26}$ kg. A spacecraft with mass 825 kg approaches Saturn. When far from Saturn, it moves in the $+x$ direction at 10.4 km/s. The gravitational attraction of Saturn (a conservative force) acting on the spacecraft causes it to swing around the planet (orbit shown as dashed line) and head off in the opposite direction. Using momentum conservation in one dimension, estimate the final speed of the spacecraft after it is far enough away to be considered free of Saturn's gravitational pull. Assume the spacecraft does not affect the orbit of Saturn whose mass is so much larger.

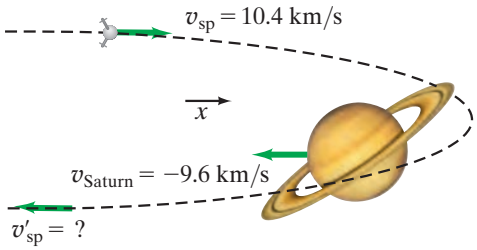

**FIGURE 9–62** Problem 100.

**101.** During a Chicago storm, winds can whip at speeds of 110 km/h. (*a*) Show that the air strikes a person horizontally at the rate of 40 kg/s per square meter and assume it is brought to rest. (Air has a mass of 1.29 kg per $m^3$ of volume.) (*b*) Calculate the *force of the wind* on a person. Assume the person is 1.60 m high and 0.50 m wide. Compare to the typical maximum force of friction ($\mu \approx 1.0$) between the person and the ground, if the person has a mass of 70 kg.

**102.** A novice pool player is faced with the corner pocket shot shown in Fig. 9–63. Relative dimensions are also shown. Should the player worry that this might be a "*scratch shot*," in which the cue ball will also fall into a pocket? Give details. Assume equal-mass balls and an elastic collision. Ignore spin.

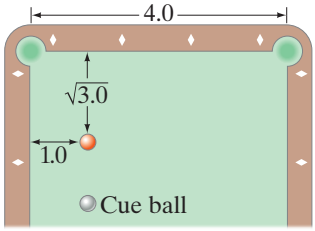

**FIGURE 9–63** Problem 102.

**103.** In order to convert a tough split in *bowling*, it is necessary to strike the pin a glancing blow as shown in Fig. 9–64. Assume that the bowling ball, traveling at 14.0 m/s just before it strikes the pin, has five times the mass of a pin and that the pin goes off at 75° from the original direction of the ball. Calculate the speed (*a*) of the pin and (*b*) of the ball just after collision, and (*c*) calculate the angle $\theta$ through which the ball was deflected. Assume the collision is elastic and ignore any spin of the ball.

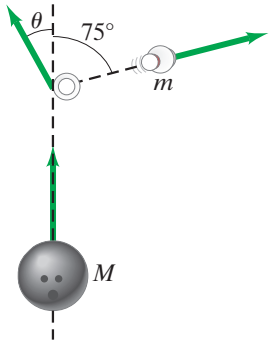

**FIGURE 9–64** Problem 103.

**104.** A small ball of mass $m$ and a large ball of mass $M$, with $M \gg m$, are dropped from a height $h$ above the floor. Ball $m$ is dropped a very short time after ball $M$, and directly above it. Ball $M$ collides elastically with the floor, rebounds, and then collides elastically with ball $m$ (which is still falling) just after it rebounds off the floor. Show that the smaller ball rebounds to a height $9h$.

## ANSWERS TO EXERCISES

**A:** Yes, if the sports car's speed is three times greater.
**B:** Larger ($\Delta p$ is greater).
**C:** (*a*) 2.0 m/s; (*b*) almost zero; (*c*) almost 8.0 m/s.
**D:** 0.50 m/s.
**E:** (*b*); (*d*).
**F:** $x_{CM} = -2.0$ m; yes.
**G:** (*a*).
**H:** The boat moves in the opposite direction.

You too can experience rapid rotation—if your stomach can take the high angular velocity and centripetal acceleration of some of the faster amusement park rides. If not, try the slower merry-go-round or Ferris wheel. Rotating carnival rides have rotational kinetic energy as well as angular momentum. Angular acceleration is produced by a net torque, and rotating objects have rotational kinetic energy.

10 – 7 Determining Moments of Inertia
10 – 8 Rotational Kinetic Energy
10 – 9 Rotational Plus Translational Motion; Rolling
*10–10 Why Does a Rolling Sphere Slow Down?

**CHAPTER-OPENING QUESTION—Guess now!**

A solid ball and a solid cylinder roll down a ramp. They both start from rest at the same time. Which gets to the bottom first?

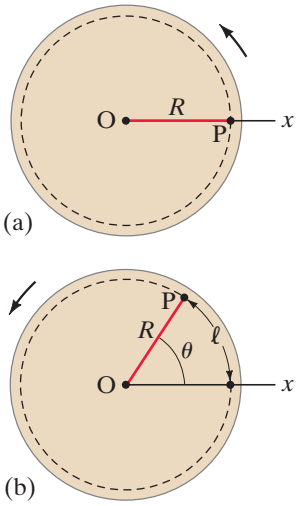
**(a)** They get there at the same time.
**(b)** They get there at almost exactly the same time except for frictional differences.
**(c)** The ball gets there first.
**(d)** The cylinder gets there first.
**(e)** Can't tell without knowing the mass of each.
**(f)** Can't tell without knowing the radius of each.

Until now, we have been concerned mainly with translational motion. We discussed the kinematics and dynamics of translational motion (the role of force). We also discussed energy and momentum for translational motion. In this Chapter and the next we will deal with rotational motion. We first discuss the kinematics of rotational motion and then rotational dynamics (involving torque), as well as rotational kinetic energy and angular momentum (the rotational analog of linear momentum). Our understanding of the world around us will be increased significantly—from rotating bicycle wheels and CDs (or vinyl) to amusement park rides, a spinning skater, the rotating Earth, and a centrifuge—and there may be a few surprises.

We will consider mainly the rotation of rigid objects about a fixed axis. A **rigid object** is an object with a definite shape that doesn't change, so that the particles composing it stay in fixed positions relative to one another. Any real object is capable of vibrating or deforming when a force is exerted on it. But these effects are often very small, so the concept of an ideal rigid object is very useful as a good approximation.

# 10–1 Angular Quantities

The motion of a rigid object can be analyzed as the translational motion of its center of mass plus rotational motion *about* its center of mass (Sections 9–8 and 9–9). We have already discussed translational motion in detail, so now we focus our attention on purely rotational motion. By *purely rotational motion* of an object about a fixed axis, we mean that all points in the object move in circles, such as the point P on the rotating wheel of Fig. 10–1, and that the centers of these circles all lie on one line called the **axis of rotation**. In Fig. 10–1 the axis of rotation is perpendicular to the page and passes through point O. We assume the axis is fixed in an inertial reference frame, but we will not always insist that the axis pass through the center of mass.



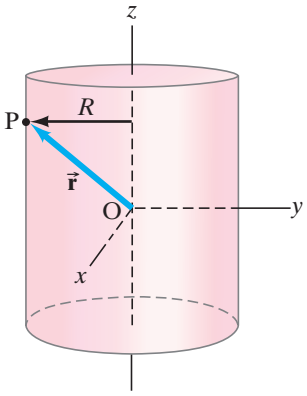


**FIGURE 10–1** Looking at a wheel that is rotating counterclockwise about an axis through the wheel's center at O (axis perpendicular to the page). Each point, such as point P, moves in a circular path; $\ell$ is the distance P travels as the wheel rotates through the angle $\theta$.

For a three-dimensional rigid object rotating about a fixed axis, we will use the symbol $R$ to represent the perpendicular distance of a point or particle from the axis of rotation. We do this to distinguish $R$ from $r$, which will continue to represent the position of a particle with reference to the origin (point) of some coordinate system. This distinction is illustrated in Fig. 10–2. This distinction may seem like a small point, but not being fully aware of it can cause huge errors when working with rotational motion.

**CAUTION**
*Distinguish R from r*

Every point in an object rotating about a fixed axis moves in a circle (shown dashed in Fig. 10–1 for point P) whose center is on the axis of rotation and whose radius is $R$, the distance of that point from the axis of rotation. A straight line drawn from the axis to any point in the object sweeps out the same angle $\theta$ in the same time interval.

**FIGURE 10–2** Showing the distinction between $\vec{\mathbf{r}}$ (the position vector) and $R$ (the distance from the rotation axis) for a point P on the edge of a cylinder rotating about the $z$ axis.

To indicate the **angular position** of a rotating object, or how far it has rotated, we specify the angle $\theta$ of some particular line in the object (red in Fig. 10–1) with respect to some reference line, such as the $x$ axis in Fig. 10–1. A point in the object, such as P in Fig. 10–1b, moves through an angle $\theta$ when it travels the distance $\ell$ measured along the circumference of its circular path. Angles are commonly specified in degrees, but the mathematics of circular motion is much simpler if we use the *radian* for angular measure. One **radian** (abbreviated rad) is defined as the angle subtended by an arc whose length is equal to the radius. For example, in Fig. 10–1, point P is a distance $R$ from the axis of rotation, and it has moved a distance $\ell$ along the arc of a circle. The arc length $\ell$ is said to "subtend" the angle $\theta$. In general, any angle $\theta$, in radians, is given by

$$\theta = \frac{\ell}{R}, \qquad [\theta \text{ in radians}] \quad \textbf{(10–1a)}$$

If $\ell = R$, then $\theta = 1$ rad. Equation 10–1a does not hold if $\theta$ is in degrees.

**CAUTION**
*Use radians in calculating, not degrees*

The radian is dimensionless since it is the ratio of two lengths. Nonetheless when giving an angle in radians, we always write "rad" to remind us it is not degrees. It is often useful to rewrite Eq. 10–1a in terms of arc length $\ell$:

$$\ell = R\theta. \qquad \textbf{(10–1b)}$$

Radians can be related to degrees in the following way. In a complete circle there are 360°, which must correspond to an arc length equal to the circumference of the circle, $\ell = 2\pi R$. For a full circle, $\theta = \ell/R = 2\pi R/R = 2\pi$ rad. Thus

$$360^\circ = 2\pi \text{ rad}.$$

One radian is then $360^\circ/2\pi \approx 360^\circ/6.28 \approx 57.3^\circ$. An object that makes one complete revolution (rev) has rotated through 360°, or $2\pi$ radians:

$$1 \text{ rev} = 360^\circ = 2\pi \text{ rad}.$$

1 rad ≈ 57.3°

**EXAMPLE 10–1** **Bike wheel.** A bike wheel rotates 4.50 revolutions. How many radians has it rotated?

**APPROACH** All we need is a conversion of units using

$$1\text{ revolution} = 360^\circ = 2\pi\text{ rad} = 6.28\text{ rad}.$$

**SOLUTION**

$$4.50\text{ revolutions} = (4.50\text{ rev})\left(2\pi\frac{\text{rad}}{\text{rev}}\right) = 9.00\pi\text{ rad} = 28.3\text{ rad}.$$

**EXAMPLE 10–2** **Birds of prey—in radians.** A particular bird's eye can just distinguish objects that subtend an angle no smaller than about $3\times10^{-4}$ rad. (*a*) How many degrees is this? (*b*) How small an object can the bird just distinguish when flying at a height of 100 m (Fig. 10–3a)?

**APPROACH** For (*a*) we use the relation $360^\circ = 2\pi$ rad. For (*b*) we use Eq. 10–1b, $\ell = R\theta$, to find the arc length.

**SOLUTION** (*a*) We convert $3\times10^{-4}$ rad to degrees:

$$(3\times10^{-4}\text{ rad})\left(\frac{360^\circ}{2\pi\text{ rad}}\right) = 0.017^\circ,$$

or about 0.02°.

(*b*) We use Eq. 10–1b, $\ell = R\theta$. For small angles, the arc length $\ell$ and the chord length are approximately the same (Fig. 10–3b). Since $R = 100$ m and $\theta = 3\times10^{-4}$ rad, we find

$$\ell = (100\text{ m})(3\times10^{-4}\text{ rad}) = 3\times10^{-2}\text{ m} = 3\text{ cm}.$$

A bird can distinguish a small mouse (about 3 cm long) from a height of 100 m. That is good eyesight.

**NOTE** Had the angle been given in degrees, we would first have had to convert it to radians to make this calculation. Equation 10–1 is valid *only* if the angle is specified in radians. Degrees (or revolutions) won't work.

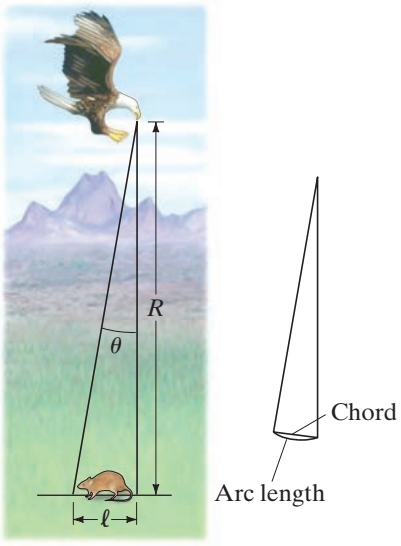

**FIGURE 10–3** (a) Example 10–2. (b) For small angles, arc length and the chord length (straight line) are nearly equal. For an angle as large as 15°, the error in making this estimate is only 1%. For larger angles the error increases rapidly. (The **chord** is the straight-line distance between the ends of the arc.)

To describe rotational motion, we use angular quantities, such as angular velocity and angular acceleration. These quantities are defined in analogy to the corresponding quantities in linear motion; they describe the rotating object as a whole, so they each have the same value for every point in a rotating rigid object. Each point in a rotating object also has translational velocity and acceleration, but they have different values for different points in the object.

When an object, such as the bicycle wheel in Fig. 10–4, rotates from some initial position, specified by $\theta_1$, to some final position, $\theta_2$, its **angular displacement** is

$$\Delta\theta = \theta_2 - \theta_1.$$

The *angular velocity* (denoted by $\omega$, the Greek lowercase letter omega) is defined in analogy with linear (translational) velocity that was discussed in Chapter 2. Instead of linear displacement, we use the angular displacement. Thus the **average angular velocity** of an object rotating about a fixed axis is defined as the time rate of change of angular position:

$$\overline{\omega} = \frac{\Delta\theta}{\Delta t}, \qquad \textbf{(10–2a)}$$

where $\Delta\theta$ is the angle through which the object has rotated in the time interval $\Delta t$. The **instantaneous angular velocity** is the limit of this ratio as $\Delta t$ approaches zero:

$$\omega = \lim_{\Delta t\to0}\frac{\Delta\theta}{\Delta t} = \frac{d\theta}{dt}. \qquad \textbf{(10–2b)}$$

Angular velocity has units of radians per second (rad/s). Note that *all points in a rigid object rotate with the same angular velocity*, since every position in the object moves through the same angle in the same time interval.

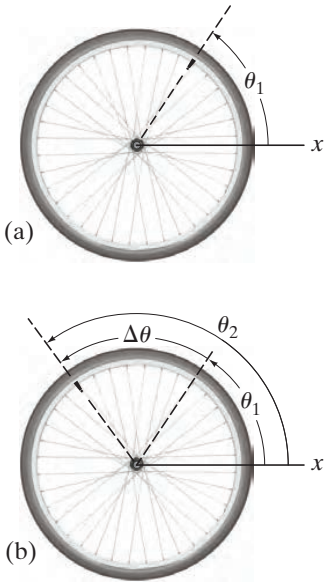

**FIGURE 10–4** A wheel rotates from (a) initial position $\theta_1$ to (b) final position $\theta_2$. The angular displacement is $\Delta\theta = \theta_2 - \theta_1$.

An object such as the wheel in Fig. 10–4 can rotate about a fixed axis either clockwise or counterclockwise. The direction can be specified with a + or − sign. The usual convention is to choose the angular displacement $\Delta\theta$ and angular velocity $\omega$ as positive when the wheel rotates counterclockwise. If the rotation is clockwise, then $\theta$ would decrease, so $\Delta\theta$ and $\omega$ would be negative.

*Angular acceleration* (denoted by $\alpha$, the Greek lowercase letter alpha), in analogy to linear acceleration, is defined as the change in angular velocity divided by the time required to make this change. The **average angular acceleration** is defined as

$$\bar{\alpha} = \frac{\omega_2 - \omega_1}{\Delta t} = \frac{\Delta\omega}{\Delta t}, \qquad \textbf{(10–3a)}$$

where $\omega_1$ is the angular velocity initially, and $\omega_2$ is the angular velocity after a time interval $\Delta t$. **Instantaneous angular acceleration** is defined as the limit of this ratio as $\Delta t$ approaches zero:

$$\alpha = \lim_{\Delta t \to 0} \frac{\Delta\omega}{\Delta t} = \frac{d\omega}{dt}. \qquad \textbf{(10–3b)}$$

Since $\omega$ is the same for all points of a rotating object, Eq. 10–3 tells us that $\alpha$ also will be the same for all points. Thus, $\omega$ and $\alpha$ are properties of the rotating object as a whole. With $\omega$ measured in radians per second and $t$ in seconds, $\alpha$ has units of radians per second squared $(\text{rad/s}^2)$.

Each point or particle of a rotating object has, at any instant, a linear velocity $v$ and a linear acceleration $a$. We can relate the linear quantities at each point, $v$ and $a$, to the angular quantities, $\omega$ and $\alpha$, for a rigid object rotating around a fixed axis. Consider a point P located a distance $R$ from the axis of rotation, as in Fig. 10–5. If the object rotates with angular velocity $\omega$, any point will have a linear velocity whose direction is tangent to its circular path. The magnitude of that point's linear velocity is $v = d\ell/dt$. From Eq. 10–1b, a change in rotation angle $d\theta$ (in radians) is related to the linear distance traveled by $d\ell = R\,d\theta$. Hence

$$v = \frac{d\ell}{dt} = R\frac{d\theta}{dt}$$

or, since $d\theta/dt = \omega$,

$$v = R\omega. \qquad \textbf{(10–4)}$$

In this very useful Eq. 10–4, $R$ is the distance of a point from the rotation axis and $\omega$ is given in rad/s. We see that although $\omega$ is the same for every point in the rotating object at any instant, the linear velocity $v$ is greater for points farther from the axis (Fig. 10–6). Note that Eq. 10–4 is valid both instantaneously and on the average.

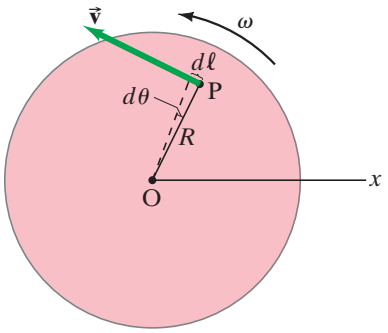

**FIGURE 10–5** A point P on a rotating wheel has a linear velocity $\vec{\mathbf{v}}$ at any moment.

**CONCEPTUAL EXAMPLE 10–3** **Is the lion faster than the horse?** On a rotating carousel or merry-go-round, one child sits on a horse near the outer edge and another child sits on a lion halfway out from the center. (*a*) Which child has the greater linear velocity? (*b*) Which child has the greater angular velocity?

**RESPONSE** (*a*) The *linear* velocity is the distance traveled divided by the time interval. In one rotation the child on the outer edge travels a longer distance than the child near the center, but the time interval is the same for both. Thus the child at the outer edge, on the horse, has the greater linear velocity.

(*b*) The *angular* velocity is the angle of rotation of the carousel as a whole divided by the time interval. For example, in one rotation both children rotate through the same angle. The two children have the same angular velocity.

If the angular velocity of a rotating object changes, the object as a whole—and each point in it—has an angular acceleration. Each point then also has a component of linear acceleration tangent to that point's circular path.

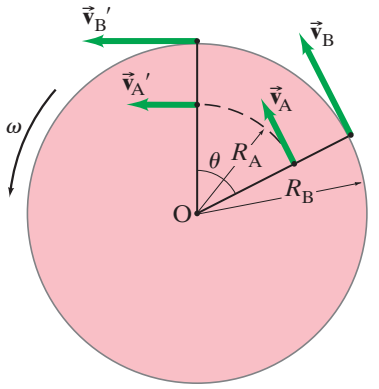

**FIGURE 10–6** A wheel rotating uniformly counterclockwise. Two points on the wheel, at distances $R_A$ and $R_B$ from the center, have the same angular velocity $\omega$ because they travel through the same angle $\theta$ in the same time interval. But the two points have different linear velocities because they travel different distances in the same time interval. Since $R_B > R_A$, then $v_B > v_A$ (because $v = R\omega$).

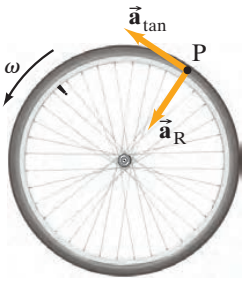

**FIGURE 10–7** On a rotating wheel whose angular speed is increasing, a point P has both tangential and radial (centripetal) components of linear acceleration. (See also Chapter 5.)

We use Eq. 10–4 ($v = R\omega$) to see that the angular acceleration $\alpha$ is related to the tangential linear acceleration $a_{\tan}$ of a point in the rotating object by

$$a_{\tan} = \frac{dv}{dt} = R\frac{d\omega}{dt}$$

or

$$a_{\tan} = R\alpha. \qquad \textbf{(10–5)}$$

In this equation, $R$ is the radius of the circle in which the particle is moving (its distance from the rotation axis), and the subscript "tan" in $a_{\tan}$ stands for "tangential."

The total linear acceleration of a point in the rotating object at any instant is the vector sum of two components:

$$\vec{\mathbf{a}} = \vec{\mathbf{a}}_{\tan} + \vec{\mathbf{a}}_{\mathrm{R}},$$

where the radial component, $\vec{\mathbf{a}}_{\mathrm{R}}$, is the radial or "centripetal" acceleration and its direction is toward the center of the point's circular path; see Fig. 10–7. We saw in Chapter 5 (Eq. 5–1) that a particle moving in a circle of radius $R$ with linear speed $v$ has a radial acceleration $a_{\mathrm{R}} = v^2/R$; we can rewrite this in terms of $\omega$ using Eq. 10–4:

$$a_{\mathrm{R}} = \frac{v^2}{R} = \frac{(R\omega)^2}{R} = \omega^2 R. \qquad \textbf{(10–6)}$$

Thus the centripetal acceleration is greater the farther you are from the axis of rotation: the children farthest out on a carousel experience the greatest radial acceleration.

Table 10–1 summarizes the relationships between the angular quantities describing the rotation of an object to the linear quantities for each point of the object.

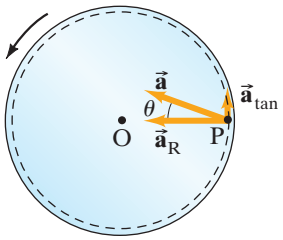

**TABLE 10–1**
**Linear and Rotational Quantities**

| Linear | Type | Rotational | Relation ($\theta$ in radians) |
|---|---|---|---|
| $x$ | displacement | $\theta$ | $x = R\theta$ |
| $v$ | velocity | $\omega$ | $v = R\omega$ |
| $a_{\tan}$ | acceleration | $\alpha$ | $a_{\tan} = R\alpha$ |

**FIGURE 10–8** Example 10–4. The total acceleration vector $\vec{\mathbf{a}} = \vec{\mathbf{a}}_{\tan} + \vec{\mathbf{a}}_{\mathrm{R}}$, at $t = 8.0$ s.

(a)

(b)

**EXAMPLE 10–4** **Angular and linear velocities and accelerations.** A carousel is initially at rest. At $t = 0$ it is given a constant angular acceleration $\alpha = 0.060\ \mathrm{rad/s^2}$, which increases its angular velocity for 8.0 s. At $t = 8.0$ s, determine the magnitude of the following quantities: (*a*) the angular velocity of the carousel; (*b*) the linear velocity of a child (Fig. 10–8a) located 5.5 m from the center, point P in Fig. 10–8b; (*c*) the tangential (linear) acceleration of that child; (*d*) the centripetal acceleration of the child; and (*e*) the total linear acceleration of the child.

**APPROACH** The angular acceleration $\alpha$ is constant, so we can use Eq. 10–3a, $\alpha = \bar{\alpha} = \Delta\omega/\Delta t$ to solve for $\omega$ after a time $t = 8.0$ s. With this $\omega$ and the given $\alpha$, we determine the other quantities using the relations we just developed, Eqs. 10–4, 10–5, and 10–6.

**SOLUTION** (*a*) In Equation 10–3a, $\bar{\alpha} = (\omega_2 - \omega_1)/\Delta t$, we put $\Delta t = 8.0$ s, $\bar{\alpha} = 0.060\ \mathrm{rad/s^2}$, and $\omega_1 = 0$. Solving for $\omega_2$, we get

$$\omega_2 = \omega_1 + \bar{\alpha}\,\Delta t = 0 + (0.060\ \mathrm{rad/s^2})(8.0\ \mathrm{s}) = 0.48\ \mathrm{rad/s}.$$

During the 8.0-s interval, the carousel has accelerated from $\omega_1 = 0$ (rest) to $\omega_2 = 0.48$ rad/s.

(*b*) The linear velocity of the child, with $R = 5.5$ m at time $t = 8.0$ s, is found using Eq. 10–4:

$$v = R\omega = (5.5\ \mathrm{m})(0.48\ \mathrm{rad/s}) = 2.6\ \mathrm{m/s}.$$

Note that the "rad" has been dropped here because it is dimensionless (and only a reminder)—it is a ratio of two distances, Eq. 10–1a.

(*c*) The child's tangential acceleration is given by Eq. 10–5:

$$a_{\tan} = R\alpha = (5.5\ \mathrm{m})(0.060\ \mathrm{rad/s^2}) = 0.33\ \mathrm{m/s^2},$$

and it is the same throughout the 8.0-s acceleration interval.

(*d*) The child's centripetal acceleration at $t = 8.0$ s is given by Eq. 10–6:

$$a_{\mathrm{R}} = \omega^2 \mathrm{R} = (0.48\ \mathrm{s^{-1}})^2(5.5\ \mathrm{m}) = 1.27\ \mathrm{m/s^2}.$$

(*e*) The two components of linear acceleration calculated in parts (*c*) and (*d*) are perpendicular to each other. Thus the total linear acceleration at $t = 8.0\,\text{s}$ (just before the acceleration stops) has magnitude

$$a = \sqrt{a_{\text{tan}}^2 + a_{\text{R}}^2} = \sqrt{(0.33\,\text{m/s}^2)^2 + (1.27\,\text{m/s}^2)^2} = 1.31\,\text{m/s}^2.$$

Its direction (Fig. 10–8b) is

$$\theta = \tan^{-1}\left(\frac{a_{\text{tan}}}{a_{\text{R}}}\right) = \tan^{-1}\left(\frac{0.33\,\text{m/s}^2}{1.27\,\text{m/s}^2}\right) = 0.25\,\text{rad},$$

so $\theta \approx 15°$.

**NOTE** The linear acceleration at this chosen instant is mostly centripetal, and keeps the child moving in a circle with the carousel. The tangential component that speeds up the circular motion is smaller. (After $t = 8.0\,\text{s}$ it is zero.)

We can relate the angular velocity $\omega$ to the frequency of rotation, $f$. The **frequency** is the number of complete revolutions (rev) per second, as we saw in Chapter 5. One revolution (of a wheel, say) corresponds to an angle of $2\pi$ radians, and thus $1\,\text{rev/s} = 2\pi\,\text{rad/s}$. Hence, in general, the frequency $f$ is related to the angular velocity $\omega$ by

$$f = \frac{\omega}{2\pi}$$

or

$$\omega = 2\pi f. \qquad \textbf{(10–7)}$$

The unit for frequency, revolutions per second (rev/s), is given the special name the **hertz** (Hz). That is

$$1\,\text{Hz} = 1\,\text{rev/s}.$$

Note that "revolution" has no dimensions, so we can also write $1\,\text{Hz} = 1\,\text{s}^{-1}$.

The time required for one complete revolution is the **period** $T$, and it is related to the frequency by

$$T = \frac{1}{f}. \qquad \textbf{(10–8)}$$

If a particle rotates at a frequency of three revolutions per second, then the period of each revolution is $\frac{1}{3}\,\text{s}$.

**EXERCISE A** In Example 10–4, we found that the carousel, after 8.0 s, rotates at an angular velocity $\omega = 0.48\,\text{rad/s}$, and continues to do so after $t = 8.0\,\text{s}$ because the acceleration ceased. Determine the frequency and period of the carousel when rotating at this constant angular velocity $\omega = 0.48\,\text{rad/s}$.

**EXAMPLE 10–5** **Given $\omega$ as function of time.** A disk of radius $R = 3.0\,\text{m}$ rotates at an angular velocity $\omega = (1.6 + 1.2\,t)\,\text{rad/s}$, where $t$ is in seconds. At the instant $t = 2.0\,\text{s}$, determine (*a*) the angular acceleration, and (*b*) the speed $v$ and the components of the acceleration $a$ of a point on the edge of the disk.

**APPROACH** We use $\alpha = d\omega/dt$, $v = R\omega$, $a_{\text{tan}} = R\alpha$, and $a_{\text{R}} = \omega^2 R$, which are Eqs. 10–3b, 10–4, 10–5, and 10–6. We can write $\omega$ explicitly showing units of the constants (in case we want to check later): $\omega = [1.6\,\text{s}^{-1} + (1.2\,\text{s}^{-2})t]$ which will give us $\text{s}^{-1}$ (= rad/s) for each term.

**SOLUTION** (*a*) The angular acceleration is

$$\alpha = \frac{d\omega}{dt} = \frac{d}{dt}[1.6\,\text{s}^{-1} + (1.2\,\text{s}^{-2})t] = 1.2\,\text{rad/s}^2.$$

(*b*) The speed $v$ of a point 3.0 m from the center of the rotating disk at $t = 2.0\,\text{s}$ is, using Eq. 10–4,

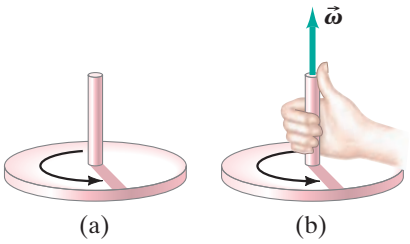
$$v = R\omega = (3.0\,\text{m})(1.6 + 1.2\,t)\,\text{s}^{-1} = (3.0\,\text{m})(4.0\,\text{s}^{-1}) = 12.0\,\text{m/s}.$$

The components of the linear acceleration of this point at $t = 2.0\,\text{s}$ are

$$a_{\text{tan}} = R\alpha = (3.0\,\text{m})(1.2\,\text{rad/s}^2) = 3.6\,\text{m/s}^2$$

$$a_{\text{R}} = \omega^2 R = [(1.6 + 1.2\,t)\,\text{s}^{-1}]^2(3.0\,\text{m}) = (4.0\,\text{s}^{-1})^2(3.0\,\text{m}) = 48\,\text{m/s}^2.$$

# 10–2 Vector Nature of Angular Quantities



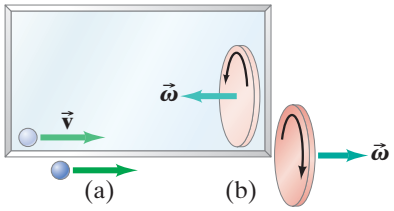


**FIGURE 10–9** (a) Rotating wheel. (b) Right-hand rule for obtaining direction of $\vec{\omega}$.

Both $\vec{\omega}$ and $\vec{\alpha}$ can be treated as vectors, and we define their directions in the following way. Consider the rotating wheel shown in Fig. 10–9a. The linear velocities of different particles of the wheel point in all different directions. The only unique direction in space associated with the rotation is along the axis of rotation, perpendicular to the actual motion. We therefore choose the axis of rotation to be the direction of the angular velocity vector, $\vec{\omega}$. Actually, there is still an ambiguity since $\vec{\omega}$ could point in either direction along the axis of rotation (up or down in Fig. 10–9a). The convention we use, called the **right-hand rule**, is this: when the fingers of the right hand are curled around the rotation axis and point in the direction of the rotation, then the thumb points in the direction of $\vec{\omega}$. This is shown in Fig. 10–9b. Note that $\vec{\omega}$ points in the direction a normal (right-handed) screw would move when turned in the direction of rotation. Thus, if the rotation of the wheel in Fig. 10–9a is counterclockwise, the direction of $\vec{\omega}$ is upward as shown in Fig. 10–9b. If the wheel rotates clockwise, then $\vec{\omega}$ points in the opposite direction, downward. Note that no part of the rotating object moves in the direction of $\vec{\omega}$.

If the axis of rotation is fixed in direction, then $\vec{\omega}$ can change only in magnitude. Then $\vec{\alpha} = d\vec{\omega}/dt$ must also point along the axis of rotation. If the rotation is counterclockwise as in Fig. 10–9a and the magnitude of $\omega$ is increasing, then $\vec{\alpha}$ points upward; but if $\omega$ is decreasing (the wheel is slowing down), $\vec{\alpha}$ points downward. If the rotation is clockwise, $\vec{\alpha}$ points downward if $\omega$ is increasing, and $\vec{\alpha}$ points upward if $\omega$ is decreasing.

## *Pseudovectors (Axial Vectors)

**FIGURE 10–10** (a) Velocity is a true vector. The reflection of $\vec{\mathbf{v}}$ points in the same direction. (b) Angular velocity is a pseudovector since it does not follow this rule. As can be seen, the reflection of the wheel rotates in the opposite direction, so the direction of $\vec{\omega}$ is opposite for the reflection.

Strictly speaking, $\vec{\omega}$ and $\vec{\alpha}$ are not quite vectors. The problem is that they do not behave like vectors under reflection. Suppose, as we are looking directly into a mirror, a particle moving with velocity $\vec{\mathbf{v}}$ to the right passes in front of and parallel to the mirror. In the reflection of the mirror, $\vec{\mathbf{v}}$ still points to the right, Fig. 10–10a. Thus a true vector, like velocity, when pointing parallel to the face of the mirror has the same direction in the reflection as in actuality. Now consider a wheel rotating in front of the mirror, so $\vec{\omega}$ points to the right. (We will be looking at the edge of the wheel.) As viewed in the mirror, Fig. 10–10b, the wheel will be rotating in the opposite direction. So $\vec{\omega}$ will point in the *opposite* direction (to the left) in the mirror. Because $\vec{\omega}$ is different under reflection than a true vector, $\vec{\omega}$ is called a **pseudovector** or **axial vector**. The angular acceleration $\vec{\alpha}$ is also a pseudovector, as are all cross products of true vectors (Section 11–2). The difference between true vectors and pseudovectors is important in elementary particle physics, but will not concern us in this book.

# 10–3 Constant Angular Acceleration

In Chapter 2, we derived the useful kinematic equations (Eqs. 2–12) that relate acceleration, velocity, distance, and time for the special case of uniform linear acceleration. Those equations were derived from the definitions of linear velocity and acceleration, assuming constant acceleration. The definitions of angular velocity and angular acceleration are just like those for their linear counterparts, except that $\theta$ replaces the linear displacement $x$, $\omega$ replaces $v$, and $\alpha$ replaces $a$. Therefore, the angular equations for **constant angular acceleration** will be analogous to Eqs. 2–12 with $x$ replaced by $\theta$, $v$ by $\omega$, and $a$ by $\alpha$, and they can be derived in exactly the same way. We summarize the angular equations here, opposite their linear equivalents, Eqs. 2–12 (for simplicity we chose $x_0 = 0$ and $\theta_0 = 0$ at the initial time $t_0 = 0$):

| Angular | Linear | | | |
|---|---|---|---|---|
| $\omega = \omega_0 + \alpha t$ | $v = v_0 + at$ | [constant $\alpha, a$] | **(10–9a)** | *Kinematic equations* |
| $\theta = \omega_0 t + \frac{1}{2}\alpha t^2$ | $x = v_0 t + \frac{1}{2}at^2$ | [constant $\alpha, a$] | **(10–9b)** | *for constant* |
| $\omega^2 = \omega_0^2 + 2\alpha\theta$ | $v^2 = v_0^2 + 2ax$ | [constant $\alpha, a$] | **(10–9c)** | *angular acceleration* |
| $\overline{\omega} = \frac{\omega + \omega_0}{2}$ | $\overline{v} = \frac{v + v_0}{2}$ | [constant $\alpha, a$] | **(10–9d)** | *$(x_0 = 0,\ \theta_0 = 0)$* |

Note that $\omega_0$ represents the angular velocity at $t_0 = 0$, whereas $\theta$ and $\omega$ represent the angular position and angular velocity, respectively, at time $t$. Since the angular acceleration is constant, $\alpha = \overline{\alpha}$.

**EXAMPLE 10–6** **Centrifuge acceleration.** A centrifuge rotor is accelerated for 30 s from rest to 20,000 rpm (revolutions per minute). (*a*) What is its average angular acceleration (rad/s$^2$)? (*b*) Through how many revolutions has the centrifuge rotor turned during its acceleration period, assuming constant angular acceleration?

**PHYSICS APPLIED** *Centrifuge*

**APPROACH** To determine $\overline{\alpha} = \Delta\omega/\Delta t$, we need the initial and final angular velocities. For (*b*), we use Eqs. 10–9 (recall that one revolution corresponds to $\theta = 2\pi$ rad).

**SOLUTION** (*a*) The initial angular velocity is $\omega = 0$. The final angular velocity is

$$\omega = 2\pi f = (2\pi \text{ rad/rev})\frac{(20{,}000 \text{ rev/min})}{(60 \text{ s/min})} = 2100 \text{ rad/s}.$$

Then, since $\overline{\alpha} = \Delta\omega/\Delta t$ and $\Delta t = 30$ s, we have

$$\overline{\alpha} = \frac{\omega - \omega_0}{\Delta t} = \frac{2100 \text{ rad/s} - 0}{30 \text{ s}} = 70 \text{ rad/s}^2.$$

That is, every second the rotor's angular velocity increases by 70 rad/s, or by (70 rad/s)(1 rev/$2\pi$ rad) = 11 revolutions per second.

(*b*) To find $\theta$ we could use either Eq. 10–9b or 10–9c, or both to check our answer. The former gives

$$\theta = \omega_0 t + \tfrac{1}{2}\alpha t^2 = 0 + \tfrac{1}{2}(70 \text{ rad/s}^2)(30 \text{ s})^2 = 3.15 \times 10^4 \text{ rad},$$

where we have kept an extra digit because this is an intermediate result. To find the total number of revolutions, we divide by $2\pi$ rad/rev and obtain

$$\frac{3.15 \times 10^4 \text{ rad}}{2\pi \text{ rad/rev}} = 5.0 \times 10^3 \text{ rev} = 5{,}000 \text{ revolutions}.$$

**NOTE** Let us calculate $\theta$ using Eq. 10–9c:

$$\theta = \frac{\omega^2 - \omega_0^2}{2\alpha} = \frac{(2100 \text{ rad/s})^2 - 0}{2(70 \text{ rad/s}^2)} = 3.15 \times 10^4 \text{ rad}$$

which checks our answer above using Eq. 10–9b perfectly.

## 10–4 Torque

We have so far discussed rotational kinematics—the description of rotational motion in terms of angular position, angular velocity, and angular acceleration. Now we discuss the dynamics, or causes, of rotational motion. Just as we found analogies between linear and rotational motion for the description of motion, so rotational equivalents for dynamics exist as well.

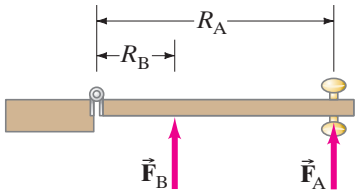

**FIGURE 10–11** Top view of a door. Applying the same force with different lever arms, $R_A$ and $R_B$. If $R_A = 3R_B$, then to create the same effect (angular acceleration), $F_B$ needs to be three times $F_A$.

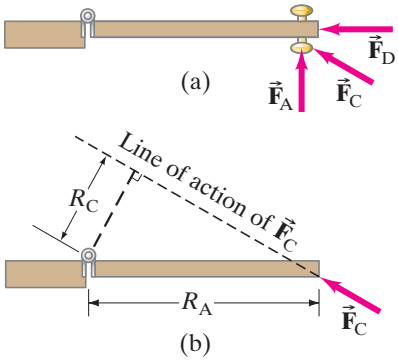
To make an object start rotating about an axis clearly requires a force. But the direction of this force, and where it is applied, are also important. Take, for example, an ordinary situation such as the overhead view of the door in Fig. 10–11. If you apply a force $\vec{\mathbf{F}}_A$ perpendicular to the door as shown, you will find that the greater the magnitude, $F_A$, the more quickly the door opens. But now if you apply the same force at a point closer to the hinge—say, $\vec{\mathbf{F}}_B$ in Fig. 10–11—the door will not open so quickly. The effect of the force is less: *where* the force acts, as well as its magnitude and direction, affects how quickly the door opens. Indeed, if only this one force acts, the angular acceleration of the door is proportional not only to the magnitude of the force, but is also directly proportional to *the perpendicular distance from the axis of rotation to the line along which the force acts*. This distance is called the **lever arm**, or **moment arm**, of the force, and is labeled $R_A$ and $R_B$ for the two forces in Fig. 10–11. Thus, if $R_A$ in Fig. 10–11 is three times larger than $R_B$, then the angular acceleration of the door will be three times as great, assuming that the magnitudes of the forces are the same. To say it another way, if $R_A = 3R_B$, then $F_B$ must be three times as large as $F_A$ to give the same angular acceleration. (Figure 10–12 shows two examples of tools whose long lever arms are very effective.)

**FIGURE 10–12** (a) A plumber can exert greater torque using a wrench with a long lever arm. (b) A tire iron too can have a long lever arm.

(a) (b)



The angular acceleration, then, is proportional to the product of the *force times the lever arm*. This product is called the *moment of the force* about the axis, or, more commonly, it is called the **torque**, and is represented by $\tau$ (Greek lowercase letter tau). Thus, the angular acceleration $\alpha$ of an object is directly proportional to the net applied torque $\tau$:

$$\alpha \propto \tau,$$

and we see that it is torque that gives rise to angular acceleration. This is the rotational analog of Newton's second law for linear motion $(a \propto F)$.

We defined the lever arm as the *perpendicular* distance from the axis of rotation to the line of action of the force—that is, the distance which is perpendicular both to the axis of rotation and to an imaginary line drawn along the direction of the force. We do this to take into account the effect of forces acting at an angle. It is clear that a force applied at an angle, such as $\vec{\mathbf{F}}_C$ in Fig. 10–13, will be less effective than the same magnitude force applied perpendicular to the door, such as $\vec{\mathbf{F}}_A$ (Fig. 10–13a). And if you push on the end of the door so that the force is directed toward the hinge (the axis of rotation), as indicated by $\vec{\mathbf{F}}_D$, the door will not rotate at all.

**FIGURE 10–13** (a) Forces acting at different angles at the doorknob. (b) The lever arm for $\vec{\mathbf{F}}_C$ is defined as the perpendicular distance from the axis of rotation (the hinge) to the line of action of the force ($R_C$ for the force $\vec{\mathbf{F}}_C$).

The lever arm for a force such as $\vec{\mathbf{F}}_C$ is found by drawing a line along the direction of $\vec{\mathbf{F}}_C$ (this is the "line of action" of $\vec{\mathbf{F}}_C$). Then we draw another line, perpendicular to this line of action, that goes to the axis of rotation and is perpendicular also to it. The length of this second line is the lever arm for $\vec{\mathbf{F}}_C$ and is labeled $R_C$ in Fig. 10–13b. The lever arm for $\vec{\mathbf{F}}_A$ is the full distance from the hinge to the doorknob, $R_A$ (just as in Fig. 10–11). Thus $R_C$ is much smaller than $R_A$.

The magnitude of the torque associated with $\vec{\mathbf{F}}_C$ is then $R_C F_C$. This short lever arm $R_C$ and the corresponding smaller torque associated with $\vec{\mathbf{F}}_C$ are consistent with the observation that $\vec{\mathbf{F}}_C$ is less effective in accelerating the door than is $\vec{\mathbf{F}}_A$ with its larger lever arm. When the lever arm is defined in this way, experiment shows that the relation $\alpha \propto \tau$ is valid in general. Notice in Fig. 10–13a that the line of action of the force $\vec{\mathbf{F}}_D$ passes through the hinge, and hence its lever arm is zero. Consequently, zero torque is associated with $\vec{\mathbf{F}}_D$ and it gives rise to no angular acceleration, in accord with everyday experience (you can't get a door to start moving by pushing directly at the hinge).

In general, then, we can write the magnitude of the torque about a given axis as

$$\tau = R_\perp F, \qquad \textbf{(10–10a)}$$

where $R_\perp$ is the lever arm, and the perpendicular symbol ($\perp$) reminds us that we must use the distance from the axis of rotation that is perpendicular to the line of action of the force (Fig. 10–14a).

An equivalent way of determining the torque associated with a force is to resolve the force into components parallel and perpendicular to the line that connects the axis to the point of application of the force, as shown in Fig. 10–14b. The component $F_\parallel$ exerts no torque since it is directed at the rotation axis (its lever arm is zero). Hence the torque will be equal to $F_\perp$ times the distance $R$ from the axis to the point of application of the force:

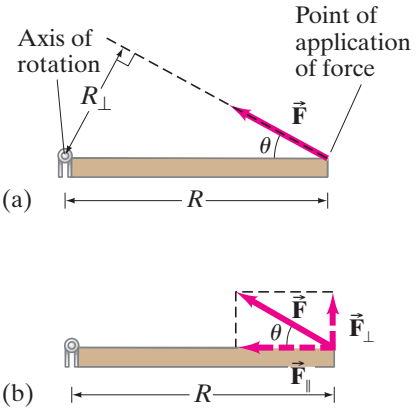
$$\tau = RF_\perp. \qquad \textbf{(10–10b)}$$

This gives the same result as Eq. 10–10a because $F_\perp = F\sin\theta$ and $r_\perp = r\sin\theta$. Thus

$$\tau = RF\sin\theta \qquad \textbf{(10–10c)}$$

in either case. [Note that $\theta$ is the angle between the directions of $\vec{\mathbf{F}}$ and $R$ (radial line from the axis to the point where $\vec{\mathbf{F}}$ acts)]. We can use any of Eqs. 10–10 to calculate the torque, whichever is easiest.

Because torque is a distance times a force, it is measured in units of m · N in SI units,† cm · dyne in the cgs system, and ft · lb in the English system.



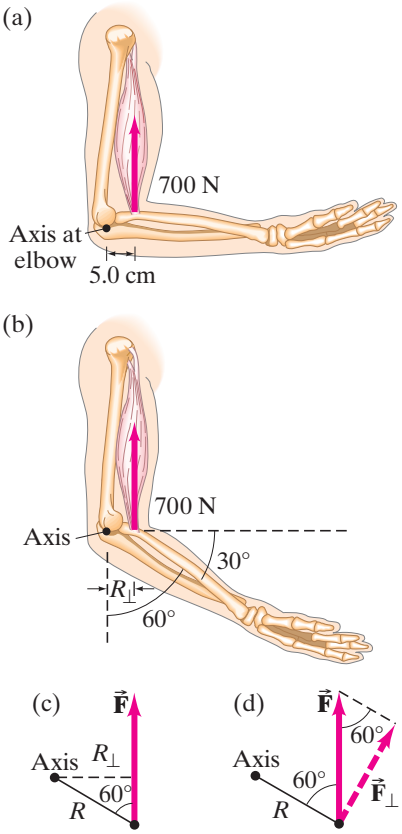


**FIGURE 10–14**
Torque = $R_\perp F = RF_\perp$.

**FIGURE 10–15** Example 10–7.

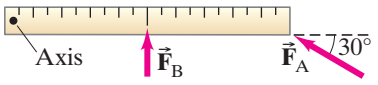
**EXAMPLE 10–7** **Biceps torque.** The biceps muscle exerts a vertical force on the lower arm, bent as shown in Figs. 10–15a and b. For each case, calculate the torque about the axis of rotation through the elbow joint, assuming the muscle is attached 5.0 cm from the elbow as shown.

**APPROACH** The force is given, and the lever arm in (*a*) is given. In (*b*) we have to take into account the angle to get the lever arm.

**SOLUTION** (*a*) $F = 700\,\text{N}$ and $R_\perp = 0.050\,\text{m}$, so

$$\tau = R_\perp F = (0.050\,\text{m})(700\,\text{N}) = 35\,\text{m}\cdot\text{N}.$$

(*b*) Because the arm is at an angle below the horizontal, the lever arm is shorter (Fig. 10–15c) than in part (*a*): $R_\perp = (0.050\,\text{m})(\sin 60°)$, where $\theta = 60°$ is the angle between $\vec{\mathbf{F}}$ and $R$. $F$ is still 700 N, so



$$\tau = (0.050\,\text{m})(\sin 60°)(700\,\text{N}) = 30\,\text{m}\cdot\text{N}.$$

The arm can exert less torque at this angle than when it is at 90°. Weight machines at gyms are often designed to take this variation with angle into account.

**NOTE** In (*b*), we could instead have used $\tau = RF_\perp$. As shown in Fig. 10–15d, $F_\perp = F\sin 60°$. Then $\tau = RF_\perp = RF\sin\theta = (0.050\,\text{m})(700\,\text{N})(\sin 60°)$ gives the same result.

**EXERCISE B** Two forces ($F_\text{B} = 20\,\text{N}$ and $F_\text{A} = 30\,\text{N}$) are applied to a meter stick which can rotate about its left end, Fig. 10–16. Force $\vec{\mathbf{F}}_\text{B}$ is applied perpendicularly at the midpoint. Which force exerts the greater torque: $F_\text{A}$, $F_\text{B}$, or both the same?

**FIGURE 10–16** Exercise B.

When more than one torque acts on an object, the angular acceleration $\alpha$ is found to be proportional to the *net* torque. If all the torques acting on an object tend to rotate it in the same direction about a fixed axis of rotation, the net torque is the sum of the torques. But if, let's say, one torque acts to rotate an object in one direction, and a second torque acts to rotate the object in the opposite direction, the net torque is the difference of the two torques. We normally assign a positive sign to torques that act to rotate the object counterclockwise (just as $\theta$ is usually positive counterclockwise), and a negative sign to torques that act to rotate the object clockwise.

†Note that the units for torque are the same as those for energy. We write the unit for torque here as m · N (in SI) to distinguish it from energy (N · m) because the two quantities are very different. The special name *joule* (1 J = 1 N · m) is used only for energy (and for work), *never* for torque.

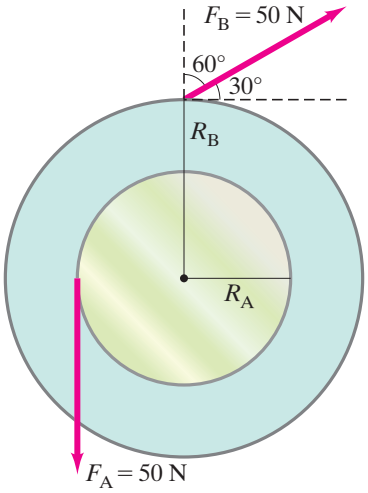


**FIGURE 10–17** Example 10–8. The torque due to $\vec{\mathbf{F}}_A$ tends to accelerate the wheel counterclockwise, whereas the torque due to $\vec{\mathbf{F}}_B$ tends to accelerate the wheel clockwise.

**EXAMPLE 10–8** **Torque on a compound wheel.** Two thin disk-shaped wheels, of radii $R_A = 30$ cm and $R_B = 50$ cm, are attached to each other on an axle that passes through the center of each, as shown in Fig. 10–17. Calculate the net torque on this compound wheel due to the two forces shown, each of magnitude 50 N.

**APPROACH** The force $\vec{\mathbf{F}}_A$ acts to rotate the system counterclockwise, whereas $\vec{\mathbf{F}}_B$ acts to rotate it clockwise. So the two forces act in opposition to each other. We must choose one direction of rotation to be positive—say, counterclockwise. Then $\vec{\mathbf{F}}_A$ exerts a positive torque, $\tau_A = R_A F_A$, since the lever arm is $R_A$. On the other hand, $\vec{\mathbf{F}}_B$ produces a negative (clockwise) torque and does not act perpendicular to $R_B$, so we must use the perpendicular component of $\vec{\mathbf{F}}_B$ to calculate the torque it produces: $\tau_B = -R_B F_{B\perp} = -R_B F_B \sin\theta$, where $\theta = 60°$. (Recall that $\theta$ must be the angle between $\vec{\mathbf{F}}_B$ and a radial line from the axis.)

**SOLUTION** The net torque is

$$\begin{aligned}\tau &= R_A F_A - R_B F_B \sin 60° \\ &= (0.30\text{ m})(50\text{ N}) - (0.50\text{ m})(50\text{ N})(\sin 60°) = -6.7\text{ m}\cdot\text{N}.\end{aligned}$$

This net torque acts to accelerate the rotation of the wheel in the clockwise direction.

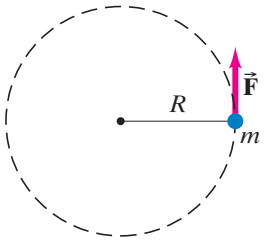
# 10–5 Rotational Dynamics; Torque and Rotational Inertia

We discussed in Section 10–4 that the angular acceleration $\alpha$ of a rotating object is proportional to the net torque $\tau$ applied to it:

$$\alpha \propto \Sigma\tau.$$

We write $\Sigma\tau$ to remind us that it is the *net* torque (sum of all torques acting on the object) that is proportional to $\alpha$. This corresponds to Newton's second law for translational motion, $a \propto \Sigma F$. In the translational case, the acceleration is not only proportional to the net force, but it is also inversely proportional to the inertia of the object, which we call its mass, $m$. Thus we wrote $a = \Sigma F/m$. But what plays the role of mass for the rotational case? That is what we now set out to determine. At the same time, we will see that the relation $\alpha \propto \Sigma\tau$ follows directly from Newton's second law, $\Sigma F = ma$.

We first examine a very simple case: a particle of mass $m$ revolving in a circle of radius $R$ at the end of a string or rod whose mass we can ignore compared to $m$ (Fig. 10–18). Consider a force $F$ that acts on the mass $m$ tangent to the circle as shown. The torque that gives rise to an angular acceleration is $\tau = RF$. If we use Newton's second law for linear quantities, $\Sigma F = ma$, and Eq. 10–5 relating the angular acceleration to the tangential linear acceleration, $a_{\tan} = R\alpha$, then we have



$$\begin{aligned}F &= ma \\ &= mR\alpha,\end{aligned}$$

where $\alpha$ is given in rad/s$^2$. When we multiply both sides of this equation by $R$, we find that the torque $\tau = RF = R(mR\alpha)$, or

$$\tau = mR^2\alpha. \qquad \text{[single particle]} \quad \textbf{(10–11)}$$

Here at last we have a direct relation between the angular acceleration and the applied torque $\tau$. The quantity $mR^2$ represents the *rotational inertia* of the particle and is called its **moment of inertia**.

**FIGURE 10–18** A mass $m$ revolving in a circle of radius $R$ about a fixed point.

Now let us consider a rotating rigid object, such as a wheel rotating about a fixed axis through its center, such as an axle. We can think of the wheel as consisting of many particles located at various distances from the axis of rotation. We can apply Eq. 10–11 to each particle of the object; that is, we write $\tau_i = m_i R_i^2 \alpha$ for the $i^{\text{th}}$ particle of the object. Then we sum over all the particles. The sum of the various torques is just the total torque, $\Sigma\tau$, so we obtain:

$$\Sigma\tau_i = \left(\Sigma m_i R_i^2\right)\alpha \qquad \text{[axis fixed]} \quad \textbf{(10–12)}$$

where we factored out $\alpha$ since it is the same for all the particles of a rigid object.

The sum $\Sigma m_i R_i^2$ in Eq. 10–12 represents the sum of the masses of each particle in the object multiplied by the square of the distance of that particle from the axis of rotation. If we assign each particle a number $(1, 2, 3, \ldots)$, then

$$\Sigma m_i R_i^2 = m_1 R_1^2 + m_2 R_2^2 + m_3 R_3^2 + \cdots.$$

This sum is called the **moment of inertia** (also **rotational inertia**) $I$ of the object:

$$I = \Sigma m_i R_i^2 = m_1 R_1^2 + m_2 R_2^2 + \cdots. \qquad \textbf{(10–13)}$$

Combining Eqs. 10–12 and 10–13, we can write

$$\Sigma\tau = I\alpha. \qquad \left[\begin{array}{c}\text{axis fixed in}\\ \text{inertial reference frame}\end{array}\right] \qquad \textbf{(10–14)}$$

*NEWTON'S SECOND LAW FOR ROTATION*

This is the rotational equivalent of Newton's second law. It is valid for the rotation of a rigid object about a fixed axis.[†] Equation 10–14 is valid even when the object is translating with acceleration, but only if we calculate $I$ and $\alpha$ about the center of mass of the object, and the rotation axis through the CM doesn't change direction. A ball rolling down a ramp is an example. (We show this in Chapter 11.) Thus

$$(\Sigma\tau)_{\text{CM}} = I_{\text{CM}}\alpha_{\text{CM}}, \qquad \left[\begin{array}{c}\text{axis fixed in direction,}\\ \text{but may accelerate}\end{array}\right] \qquad \textbf{(10–15)}$$

where the subscript CM means "calculated about the center of mass." (The axis fixed in direction means a rolling wheel makes no left or right turns).

We see that the moment of inertia, $I$, which is a measure of the rotational inertia of an object, plays the same role for rotational motion that mass does for translational motion. As can be seen from Eq. 10–13, the rotational inertia of an object depends not only on its mass, but also on how that mass is distributed with respect to the axis. For example, a large-diameter cylinder will have greater rotational inertia than one of equal mass but smaller diameter, Fig. 10–19. The former will be harder to start rotating, and harder to stop. When the mass is concentrated farther from the axis of rotation, the rotational inertia is greater. For rotational motion, the mass of an object can *not* be considered as concentrated at its center of mass.

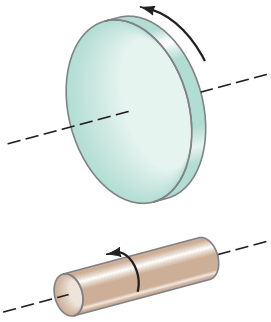


**FIGURE 10–19** A large-diameter cylinder has greater rotational inertia than one of equal mass but smaller diameter.

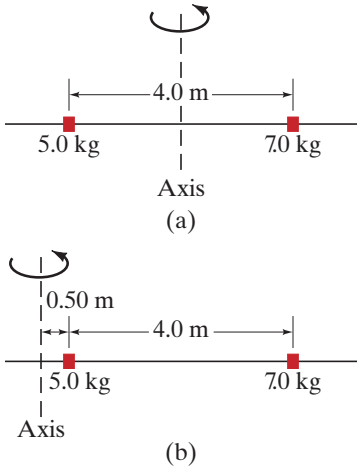
**CAUTION**

*Mass can* not *be considered concentrated at* CM *for rotational motion*

**EXAMPLE 10–9** **Two weights on a bar: different axis, different $I$.** Two small "weights," of mass 5.0 kg and 7.0 kg, are mounted 4.0 m apart on a light rod (whose mass can be ignored), as shown in Fig. 10–20. Calculate the moment of inertia of the system (*a*) when rotated about an axis halfway between the weights, Fig. 10–20a, and (*b*) when rotated about an axis 0.50 m to the left of the 5.0-kg mass (Fig. 10–20b).

**APPROACH** In each case, the moment of inertia of the system is found by summing over the two parts using Eq. 10–13.

**SOLUTION** (*a*) Both weights are the same distance, 2.0 m, from the axis of rotation. Thus



$$\begin{aligned} I = \Sigma mR^2 &= (5.0\,\text{kg})(2.0\,\text{m})^2 + (7.0\,\text{kg})(2.0\,\text{m})^2 \\ &= 20\,\text{kg}\cdot\text{m}^2 + 28\,\text{kg}\cdot\text{m}^2 = 48\,\text{kg}\cdot\text{m}^2. \end{aligned}$$

(*b*) The 5.0-kg mass is now 0.50 m from the axis, and the 7.0-kg mass is 4.50 m from the axis. Then

$$\begin{aligned} I = \Sigma mR^2 &= (5.0\,\text{kg})(0.50\,\text{m})^2 + (7.0\,\text{kg})(4.5\,\text{m})^2 \\ &= 1.3\,\text{kg}\cdot\text{m}^2 + 142\,\text{kg}\cdot\text{m}^2 = 143\,\text{kg}\cdot\text{m}^2. \end{aligned}$$

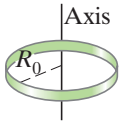
**NOTE** This Example illustrates two important points. First, the moment of inertia of a given system is different for different axes of rotation. Second, we see in part (*b*) that mass close to the axis of rotation contributes little to the total moment of inertia; here, the 5.0-kg object contributed less than 1% to the total.

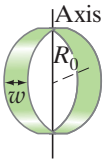
**FIGURE 10–20** Example 10–9. Calculating the moment of inertia.

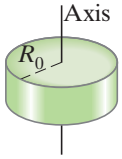
**CAUTION**

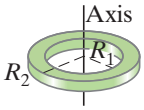
*I depends on axis of rotation and on distribution of mass*

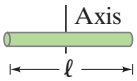
[†]That is, the axis is fixed relative to the object and is fixed in an inertial reference frame. This includes an axis moving at uniform velocity in an inertial frame, since the axis can be considered fixed in a second inertial frame that moves with respect to the first.

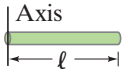


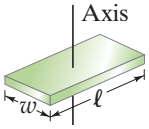












| | Object | Location of axis | | Moment of inertia |
|---|---|---|---|---|
| (a) | **Thin hoop**, radius $R_0$ | Through center |   | $MR_0^2$ |
| (b) | **Thin hoop**, radius $R_0$ width $w$ | Through central diameter |   | $\frac{1}{2}MR_0^2 + \frac{1}{12}Mw^2$ |
| (c) | **Solid cylinder**, radius $R_0$ | Through center |   | $\frac{1}{2}MR_0^2$ |
| (d) | **Hollow cylinder**, inner radius $R_1$ outer radius $R_2$ | Through center |   | $\frac{1}{2}M(R_1^2 + R_2^2)$ |
| (e) | **Uniform sphere**, radius $r_0$ | Through center |   | $\frac{2}{5}Mr_0^2$ |
| (f) | **Long uniform rod**, length $\ell$ | Through center |   | $\frac{1}{12}M\ell^2$ |
| (g) | **Long uniform rod**, length $\ell$ | Through end |   | $\frac{1}{3}M\ell^2$ |
| (h) | **Rectangular thin plate**, length $\ell$, width $w$ | Through center |   | $\frac{1}{12}M(\ell^2 + w^2)$ |

**FIGURE 10–21** Moments of inertia for various objects of uniform composition, each with mass $M$. [We use $R$ for radial distance from an axis, and $r$ for distance from a point (only in e, the sphere), as discussed in Fig. 10–2.]

For most ordinary objects, the mass is distributed continuously, and the calculation of the moment of inertia, $\Sigma mR^2$, can be difficult. Expressions can, however, be worked out (using calculus) for the moments of inertia of regularly shaped objects in terms of the dimensions of the objects, as we will discuss in Section 10–7. Figure 10–21 gives these expressions for a number of solids rotated about the axes specified. The only one for which the result is obvious is that for the thin hoop or ring rotated about an axis passing through its center perpendicular to the plane of the hoop (Fig. 10–21a). For this hoop, all the mass is concentrated at the same distance from the axis, $R_0$. Thus $\Sigma mR^2 = (\Sigma m)R_0^2 = MR_0^2$, where $M$ is the total mass of the hoop.

When calculation is difficult, $I$ can be determined experimentally by measuring the angular acceleration $\alpha$ about a fixed axis due to a known net torque, $\Sigma\tau$, and applying Newton's second law, $I = \Sigma\tau/\alpha$, Eq. 10–14.

## 10–6 Solving Problems in Rotational Dynamics

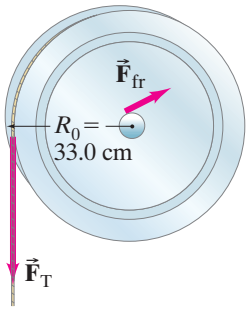
When working with torque and angular acceleration (Eq. 10–14), it is important to use a consistent set of units, which in SI is: $\alpha$ in rad/s$^2$; $\tau$ in m · N; and the moment of inertia, $I$, in kg · m$^2$.

PROBLEM SOLVING

## Rotational Motion

1. As always, draw a clear and complete **diagram**.
2. Choose the object or objects that will be the **system** to be studied.
3. Draw a **free-body diagram** for the object under consideration (or for each object separately, if more than one), showing all (and only) the forces acting on that object and exactly where they act, so you can determine the torque due to each. Gravity acts at the CM of the object (Section 9–8).
4. Identify the axis of rotation and determine the **torques** about it. Choose positive and negative directions of rotation (counterclockwise and clockwise), and assign the correct sign to each torque.
5. Apply **Newton's second law for rotation**, $\Sigma\tau = I\alpha$. If the moment of inertia is not given, and it is not the unknown sought, you need to determine it first. Use consistent units, which in SI are: $\alpha$ in rad/s$^2$; $\tau$ in m · N; and $I$ in kg · m$^2$.
6. Also apply **Newton's second law for translation**, $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$, and **other** laws or principles as needed.
7. **Solve** the resulting equation(s) for the unknown(s).
8. Do a rough **estimate** to determine if your answer is reasonable.

**EXAMPLE 10–10** **A heavy pulley.** A 15.0-N force (represented by $\vec{\mathbf{F}}_T$) is applied to a cord wrapped around a pulley of mass $M = 4.00\,\text{kg}$ and radius $R_0 = 33.0\,\text{cm}$, Fig. 10–22. The pulley accelerates uniformly from rest to an angular speed of 30.0 rad/s in 3.00 s. Assume there is a frictional torque $\tau_{fr} = 1.10\,\text{m} \cdot \text{N}$ at the axle. Determine the moment of inertia of the pulley rotating about its center.



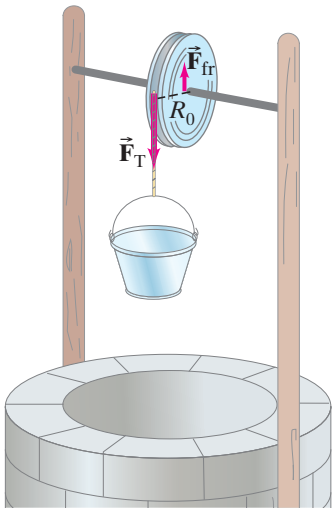


**FIGURE 10–22** Example 10–10.

**APPROACH** We follow the steps of the Problem Solving Strategy above.

**SOLUTION**

1. **Draw a diagram**. The pulley and the attached cord are shown in Fig. 10–22.
2. **Choose the system**: the pulley.
3. **Draw a free-body diagram**. The force that the cord exerts on the pulley is shown as $\vec{\mathbf{F}}_T$ in Fig. 10–22. The friction force acts all around the axle, retarding the motion, as suggested by $\vec{\mathbf{F}}_{fr}$ in Fig. 10–22. We are given only its torque, which is what we need. Two other forces could be included in the diagram: the force of gravity $mg$ down and whatever force keeps the axle in place (they balance each other). They do not contribute to the torque (their lever arms are zero) and so we omit them to keep our diagram simple.
4. **Determine the torques**. The cord exerts a force $\vec{\mathbf{F}}_T$ that acts at the edge of the pulley, so its lever arm is $R_0$. The torque exerted by the cord equals $R_0F_T$ and is counterclockwise, which we choose to be positive. The frictional torque is given as $\tau_{fr} = 1.10\,\text{m} \cdot \text{N}$; it opposes the motion and is negative.
5. **Apply Newton's second law for rotation**. The net torque is
$$\Sigma\tau = R_0F_T - \tau_{fr} = (0.330\,\text{m})(15.0\,\text{N}) - 1.10\,\text{m} \cdot \text{N} = 3.85\,\text{m} \cdot \text{N}.$$
The angular acceleration $\alpha$ is found from the given data that it takes 3.00 s to accelerate the pulley from rest to $\omega = 30.0\,\text{rad/s}$:
$$\alpha = \frac{\Delta\omega}{\Delta t} = \frac{30.0\,\text{rad/s} - 0}{3.00\,\text{s}} = 10.0\,\text{rad/s}^2.$$
Newton's second law, $\Sigma\tau = I\alpha$, can be solved for $I$ which is the unknown: $I = \Sigma\tau/\alpha$.
6. **Other calculations**: None needed.
7. **Solve for unknowns**. From Newton's second law (check units; rad has none):
$$I = \frac{\Sigma\tau}{\alpha} = \frac{3.85\,\text{m} \cdot \text{N}}{10.0\,\text{rad/s}^2} = 0.385\,\text{kg} \cdot \text{m}^2.$$
8. **Do a rough estimate**. We can do a rough estimate of the moment of inertia by assuming the pulley is a uniform cylinder and using Fig. 10–21c:
$$I \approx \tfrac{1}{2}MR_0^2 = \tfrac{1}{2}(4.00\,\text{kg})(0.330\,\text{m})^2 = 0.218\,\text{kg} \cdot \text{m}^2.$$
This is the same order of magnitude as our result, but numerically is less. This makes sense because a pulley is not usually uniform, but instead has more of its mass concentrated toward the outside edge, and would be expected to have a greater moment of inertia. A thin hoop, Fig. 10–21a, ought to have a greater $I$ than our pulley, and indeed it does: $I = MR_0^2 = 0.436\,\text{kg} \cdot \text{m}^2$.

**PROBLEM SOLVING**
*Usefulness and power of rough estimates*

(a)

(b)

**FIGURE 10–23** Example 10–11. (a) Pulley and falling bucket of mass $m$. This is also the free-body diagram for the pulley. (b) Free-body diagram for the bucket.

**EXAMPLE 10–11** **Pulley and bucket.** Consider again the pulley in Example 10–10. But instead of a constant 15.0-N force being exerted on the cord, we now have a bucket of weight $w = 15.0\,\text{N}$ (mass $m = w/g = 1.53\,\text{kg}$) hanging from the cord. See Fig. 10–23a. We assume the cord has negligible mass and does not stretch or slip on the pulley. Calculate the angular acceleration $\alpha$ of the pulley and the linear acceleration $a$ of the bucket. Assume the same frictional torque $\tau_{fr} = 1.10\,\text{m}\cdot\text{N}$ acts on the pulley.

**APPROACH** This situation looks a lot like Example 10–10, Fig. 10–22. But there is a big difference: the tension in the cord is now an unknown, and it is no longer equal to the weight of the bucket if the bucket accelerates. Our system has two parts: the bucket, which can undergo translational motion (Fig. 10–23b is its free-body diagram); and the pulley. The pulley does not translate, but it can rotate. We apply the rotational version of Newton's second law to the pulley, $\Sigma\tau = I\alpha$, and the linear version to the bucket, $\Sigma F = ma$.

**SOLUTION** Let $F_T$ be the tension in the cord. Then a force $F_T$ acts at the edge of the pulley, and we apply Newton's second law, Eq. 10–14, for the rotation of the pulley:

$$I\alpha = \Sigma\tau = R_0F_T - \tau_{fr}. \qquad \text{[pulley]}$$

Next we look at the (linear) motion of the bucket of mass $m$. Figure 10–23b, the free-body diagram for the bucket, shows that two forces act on the bucket: the force of gravity $mg$ acts downward, and the tension of the cord $F_T$ pulls upward. Applying Newton's second law, $\Sigma F = ma$, for the bucket, we have (taking downward as positive):

$$mg - F_T = ma. \qquad \text{[bucket]}$$

Note that the tension $F_T$, which is the force exerted on the edge of the pulley, is *not* equal to the weight of the bucket $(= mg = 15.0\,\text{N})$. There must be a net force on the bucket if it is accelerating, so $F_T < mg$. We can also see this from the last equation above, $F_T = mg - ma$.

To obtain $\alpha$, we note that the tangential acceleration of a point on the edge of the pulley is the same as the acceleration of the bucket if the cord doesn't stretch or slip. Hence we can use Eq. 10–5, $a_{tan} = a = R_0\alpha$. Substituting $F_T = mg - ma = mg - mR_0\alpha$ into the first equation above (Newton's second law for rotation of the pulley), we obtain

$$I\alpha = \Sigma\tau = R_0F_T - \tau_{fr} = R_0(mg - mR_0\alpha) - \tau_{fr} = mgR_0 - mR_0^2\alpha - \tau_{fr}.$$

The unknown $\alpha$ appears on the left and in the second term on the far right, so we bring that term to the left side and solve for $\alpha$:

$$\alpha = \frac{mgR_0 - \tau_{fr}}{I + mR_0^2}.$$

The numerator $(mgR_0 - \tau_{fr})$ is the net torque, and the denominator $(I + mR_0^2)$ is the total rotational inertia of the system. With $mg = 15.0\,\text{N}$ $(m = 1.53\,\text{kg})$ and, from Example 10–10, $I = 0.385\,\text{kg}\cdot\text{m}^2$ and $\tau_{fr} = 1.10\,\text{m}\cdot\text{N}$, then

$$\alpha = \frac{(15.0\,\text{N})(0.330\,\text{m}) - 1.10\,\text{m}\cdot\text{N}}{0.385\,\text{kg}\cdot\text{m}^2 + (1.53\,\text{kg})(0.330\,\text{m})^2} = 6.98\,\text{rad/s}^2.$$

The angular acceleration is somewhat less in this case than the $10.0\,\text{rad/s}^2$ of Example 10–10. Why? Because $F_T\,(= mg - ma = 15.0\,\text{N} - ma)$ is less than the 15.0-N force in Example 10–10. The linear acceleration of the bucket is

$$a = R_0\alpha = (0.330\,\text{m})(6.98\,\text{rad/s}^2) = 2.30\,\text{m/s}^2.$$

**NOTE** The tension in the cord $F_T$ is less than $mg$ because the bucket accelerates.

**EXAMPLE 10–12** **Rotating rod.** A uniform rod of mass $M$ and length $\ell$ can pivot freely (i.e., we ignore friction) about a hinge or pin attached to the case of a large machine, as in Fig. 10–24. The rod is held horizontally and then released. At the moment of release (when you are no longer exerting a force holding it up), determine (*a*) the angular acceleration of the rod and (*b*) the linear acceleration of the tip of the rod. Assume the force of gravity acts at the center of mass of the rod, as shown.

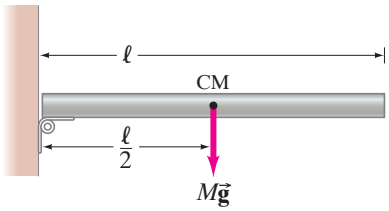

**FIGURE 10–24** Example 10–12.

**APPROACH** (*a*) The only torque on the rod about the hinge is that due to gravity, which acts with a force $F = Mg$ downward with a lever arm $\ell/2$ at the moment of release (the CM is at the center of a uniform rod). There is also a force on the rod at the hinge, but with the hinge as axis of rotation, the lever arm of this force is zero. The moment of inertia of a uniform rod pivoted about its end is (Fig. 10–21g) $I = \frac{1}{3}M\ell^2$. In part (*b*) we use $a_{\tan} = R\alpha$.

**SOLUTION** (*a*) We use Eq. 10–14, solving for $\alpha$ to obtain the initial angular acceleration of the rod:

$$\alpha = \frac{\tau}{I} = \frac{Mg\frac{\ell}{2}}{\frac{1}{3}M\ell^2} = \frac{3}{2}\frac{g}{\ell}.$$

As the rod descends, the force of gravity on it is constant but the torque due to this force is not constant because the lever arm decreases. Hence the rod's angular acceleration is *not* constant.

(*b*) The initial linear acceleration of the tip of the rod is found from the relation $a_{\tan} = R\alpha$ (Eq. 10–5) with $R = \ell$:

$$a_{\tan} = \ell\alpha = \tfrac{3}{2}g.$$

**NOTE** The tip of the rod initially falls with an acceleration greater than $g$! A small object balanced on the tip of the rod would be left behind when the rod is released. In contrast, the CM of the rod, at a distance $\ell/2$ from the pivot, has acceleration $a_{\tan} = (\ell/2)\alpha = \frac{3}{4}g$. (Because the angular acceleration decreases in time, so does the linear acceleration of the rod tip.)

# 10–7 Determining Moments of Inertia

## By Experiment

The moment of inertia of any object about any axis can be determined experimentally, such as by measuring the net torque $\Sigma\tau$ required to give the object an angular acceleration $\alpha$. Then, from Eq. 10–14, $I = \Sigma\tau/\alpha$. See Example 10–10.

## Using Calculus

For simple systems of masses or particles, the moment of inertia can be calculated directly, as in Example 10–9. Many objects can be considered as a continuous distribution of mass. In this case, Eq. 10–13 defining moment of inertia becomes

$$I = \int R^2\, dm, \qquad \textbf{(10–16)}$$

where $dm$ represents the mass of any infinitesimal particle of the object and $R$ is the perpendicular distance of this particle from the axis of rotation. The integral is taken over the whole object. This is easily done only for objects of simple geometric shape.

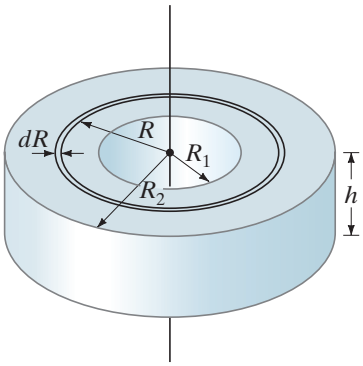

**FIGURE 10–25** Determining the moment of inertia of a hollow cylinder (Example 10–13).

**EXAMPLE 10–13** **Cylinder, solid or hollow.** (*a*) Show that the moment of inertia of a uniform hollow cylinder of inner radius $R_1$, outer radius $R_2$, and mass $M$, is $I = \frac{1}{2}M(R_1^2 + R_2^2)$, as stated in Fig. 10–21d, if the rotation axis is through the center along the axis of symmetry. (*b*) Obtain the moment of inertia for a solid cylinder.

**APPROACH** We know that the moment of inertia of a thin ring of radius $R$ is $mR^2$ (Fig. 10–21a). So we divide the cylinder into thin concentric cylindrical rings or hoops of thickness $dR$, one of which is indicated in Fig. 10–25. The cylinder is uniform, which means its density $\rho$ (mass per unit volume $= M/V$) is constant. So we write the mass $dm$ of one thin ring as

$$dm = \rho\, dV,$$

where $dV$ is the volume of the thin ring of radius $R$, thickness $dR$, and height $h$. Since $dV = (2\pi R)(dR)(h)$, we have

$$dm = 2\pi\rho h R\, dR.$$

**SOLUTION** (*a*) The moment of inertia is obtained by integrating (summing) over all these rings:

$$I = \int R^2\, dm = \int_{R_1}^{R_2} 2\pi\rho h R^3\, dR = 2\pi\rho h\left[\frac{R_2^4 - R_1^4}{4}\right] = \frac{\pi\rho h}{2}(R_2^4 - R_1^4),$$

where we are given that the cylinder has uniform density, $\rho =$ constant. (If this were not so, we would have to know $\rho$ as a function of $R$ before the integration could be carried out.) The volume $V$ of this hollow cylinder is $V = (\pi R_2^2 - \pi R_1^2)h$, so its mass $M$ is

$$M = \rho V = \rho\pi(R_2^2 - R_1^2)h.$$

Since $(R_2^4 - R_1^4) = (R_2^2 - R_1^2)(R_2^2 + R_1^2)$, we have

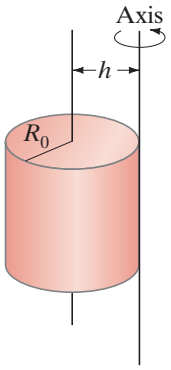
$$I = \frac{\rho\pi h}{2}(R_2^2 - R_1^2)(R_2^2 + R_1^2) = \tfrac{1}{2}M(R_1^2 + R_2^2),$$

as stated in Fig. 10–21d.

(*b*) For a solid cylinder, $R_1 = 0$ and if we set $R_2 = R_0$, then

$$I = \tfrac{1}{2}MR_0^2,$$

which is that given in Fig. 10–21c for a solid cylinder of mass $M$ and radius $R_0$.



## The Parallel-Axis Theorem

There are two simple theorems that are helpful in obtaining moments of inertia. The first is called the **parallel-axis theorem**. It relates the moment of inertia $I$ of an object of total mass $M$ about any axis, and its moment of inertia $I_{CM}$ about an axis passing through the center of mass and parallel to the first axis. If the two axes are a distance $h$ apart, then

$$I = I_{CM} + Mh^2. \qquad \text{[parallel axis]} \quad \textbf{(10–17)}$$

Thus, for example, if the moment of inertia about an axis through the CM is known, the moment of inertia about any axis parallel to this axis is easily obtained.

**FIGURE 10–26** Example 10–14.

**EXAMPLE 10–14** **Parallel axis.** Determine the moment of inertia of a solid cylinder of radius $R_0$ and mass $M$ about an axis tangent to its edge and parallel to its symmetry axis, Fig. 10–26.

**APPROACH** We use the parallel-axis theorem with $I_{CM} = \frac{1}{2}MR_0^2$ (Fig. 10–21c).

**SOLUTION** Since $h = R_0$, Eq. 10–17 gives

$$I = I_{CM} + Mh^2 = \tfrac{3}{2}MR_0^2.$$

**EXERCISE C** In Figs. 10–21f and g, the moments of inertia for a thin rod about two different axes are given. Are they related by the parallel-axis theorem? Please show how.

### *Proof of the Parallel-Axis Theorem

The proof of the parallel-axis theorem is as follows. We choose our coordinate system so the origin is at the CM, and $I_{CM}$ is the moment of inertia about the $z$ axis, perpendicular to the page at the point O. Figure 10–27 shows a cross-section of an object of arbitrary shape in the $xy$ plane. We let $I$ represent the moment of inertia of the object about an axis parallel to the $z$ axis that passes through the point A in Fig. 10–27 where the point A has coordinates $x_A$ and $y_A$. Let $x_i$, $y_i$, and $m_i$ represent the coordinates and mass of an arbitrary particle of the object (shown as a tiny cube). The square of the distance from this particle to A is $[(x_i - x_A)^2 + (y_i - y_A)^2]$. So the moment of inertia, $I$, about the axis through A is

$$\begin{aligned} I &= \Sigma m_i[(x_i - x_A)^2 + (y_i - y_A)^2] \\ &= \Sigma m_i(x_i^2 + y_i^2) - 2x_A\Sigma m_i x_i - 2y_A\Sigma m_i y_i + (\Sigma m_i)(x_A^2 + y_A^2). \end{aligned}$$

The first term on the right is just $I_{CM} = \Sigma m_i(x_i^2 + y_i^2)$ since the CM is at the origin. The second and third terms are zero since, by definition of the CM, $\Sigma m_i x_i = \Sigma m_i y_i = 0$ because $x_{CM} = y_{CM} = 0$. The last term is $Mh^2$ since $\Sigma m_i = M$ and $(x_A^2 + y_A^2) = h^2$ where $h$ is the distance of A from the CM. Thus, $I = I_{CM} + Mh^2$ for this cross-section, and will be for all other cross-sections of the object. Hence we have proved $I = I_{CM} + Mh^2$, which is Eq. 10–17.

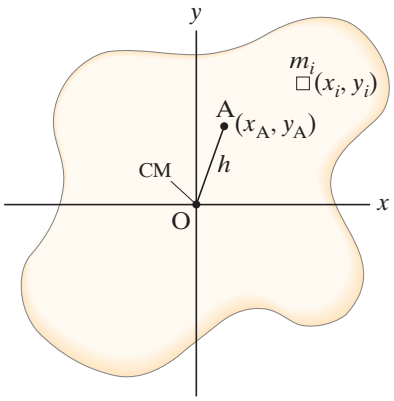


**FIGURE 10–27** Derivation of the parallel-axis theorem.

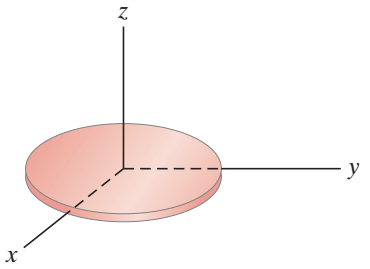

### *The Perpendicular-Axis Theorem

The parallel-axis theorem can be applied to any object. The second theorem, the **perpendicular-axis theorem**, can be applied only to plane (flat) objects—that is, to two-dimensional objects, or objects of uniform thickness whose thickness can be neglected compared to the other dimensions. This theorem states that the sum of the moments of inertia of a thin plane object about any two perpendicular axes in the plane of the object, is equal to the moment of inertia about an axis through their point of intersection perpendicular to the plane of the object. That is, if the object is in the $xy$ plane (Fig. 10–28),

$$I_z = I_x + I_y. \qquad \text{[object in } xy \text{ plane]} \quad \textbf{(10–18)}$$

Here $I_z, I_x, I_y$ are moments of inertia about the $z$, $x$, and $y$ axes. The proof is straightforward: $I_x = \Sigma m_i y_i^2$, because $y_i$ is the perpendicular distance of any particle $i$ of the object from the $x$ axis; similarly, $I_y = \Sigma m_i x_i^2$, and $I_z = \Sigma m_i(x_i^2 + y_i^2)$, and so Eq. 10–18 follows directly.

**FIGURE 10–28** The perpendicular-axis theorem.

## 10–8 Rotational Kinetic Energy

The quantity $\frac{1}{2}mv^2$ is the kinetic energy of an object undergoing translational motion. An object rotating about an axis is said to have **rotational kinetic energy**. By analogy with translational kinetic energy, we might expect this to be given by the expression $\frac{1}{2}I\omega^2$ where $I$ is the moment of inertia of the object and $\omega$ is its angular velocity. We can indeed show this.

Consider any rigid rotating object as made up of many tiny particles, each of mass $m_i$. If we let $R_i$ represent the distance of any one particle from the axis of rotation, then its linear velocity is $v_i = R_i\omega$, where $\omega$ is the same for all particles of the object. The total kinetic energy of the whole object will be the sum of the kinetic energies of all its particles:

$$\begin{aligned} K &= \Sigma(\tfrac{1}{2}m_i v_i^2) = \Sigma(\tfrac{1}{2}m_i R_i^2\omega^2) \\ &= \tfrac{1}{2}\Sigma(m_i R_i^2)\,\omega^2. \end{aligned}$$

We have factored out the $\frac{1}{2}$ and the $\omega^2$ since they are the same for every particle of a rigid object. Since $\Sigma m_i R_i^2 = I$, the moment of inertia, we see that the kinetic energy, $K$, of an object rotating about a fixed axis is, as expected,

$$K = \tfrac{1}{2}I\omega^2. \qquad \text{[rotation about a fixed axis]} \quad \textbf{(10–19)}$$

If the axis is not fixed in space, the rotational kinetic energy can take on a more complicated form.

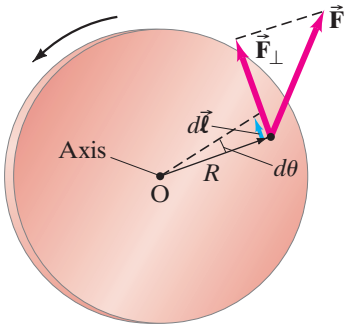

**FIGURE 10–29** Calculating the work done by a torque acting on a rigid object rotating about a fixed axis.

The work done on an object rotating about a fixed axis can be written in terms of angular quantities. Suppose a force $\vec{\mathbf{F}}$ is exerted at a point whose distance from the axis of rotation is $R$, as in Fig. 10–29. The work done by this force is

$$W = \int \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}} = \int F_\perp R \, d\theta,$$

where $d\vec{\boldsymbol{\ell}}$ is an infinitesimal distance perpendicular to $R$ with magnitude $d\ell = R\,d\theta$, and $F_\perp$ is the component of $\vec{\mathbf{F}}$ perpendicular to $R$ and parallel to $d\vec{\boldsymbol{\ell}}$ (Fig. 10–29). But $F_\perp R$ is the torque about the axis, so

$$W = \int_{\theta_1}^{\theta_2} \tau \, d\theta \qquad \textbf{(10–20)}$$

is the work done by a torque $\tau$ to rotate an object through the angle $\theta_2 - \theta_1$. The rate of work done, or power $P$, at any instant is

$$P = \frac{dW}{dt} = \tau \frac{d\theta}{dt} = \tau\omega. \qquad \textbf{(10–21)}$$

The work-energy principle (Section 7–4) holds for rotation of a rigid object about a fixed axis: from Eq. 10–14 we have

$$\tau = I\alpha = I\frac{d\omega}{dt} = I\frac{d\omega}{d\theta}\frac{d\theta}{dt} = I\omega\frac{d\omega}{d\theta},$$

where we used the chain rule and $\omega = d\theta/dt$. Then $\tau\,d\theta = I\omega\,d\omega$ and

$$W = \int_{\theta_1}^{\theta_2} \tau \, d\theta = \int_{\omega_1}^{\omega_2} I\omega \, d\omega = \tfrac{1}{2}I\omega_2^2 - \tfrac{1}{2}I\omega_1^2. \qquad \textbf{(10–22)}$$

This is the work-energy principle for a rigid object rotating about a fixed axis. It states that the work done in rotating an object through an angle $\theta_2 - \theta_1$ is equal to the change in rotational kinetic energy of the object.

**PHYSICS APPLIED**
*Energy from a flywheel*

**EXAMPLE 10–15 ESTIMATE** **Flywheel.** Flywheels, which are simply large rotating disks, have been suggested as a means of storing energy for solar-powered generating systems. Estimate the kinetic energy that can be stored in an 80,000-kg (80-ton) flywheel with a diameter of 10 m (a three-story building). Assume it could hold together (without flying apart due to internal stresses) at 100 rpm.

**APPROACH** We use Eq. 10–19, $K = \frac{1}{2}I\omega^2$, but only after changing 100 rpm to $\omega$ in rad/s.

**SOLUTION** We are given

$$\omega = 100\,\text{rpm} = \left(100\,\frac{\text{rev}}{\text{min}}\right)\left(\frac{1\,\text{min}}{60\,\text{s}}\right)\left(\frac{2\pi\,\text{rad}}{\text{rev}}\right) = 10.5\,\text{rad/s}.$$

The kinetic energy stored in the disk $\left(\text{for which } I = \frac{1}{2}MR_0^2\right)$ is

$$K = \tfrac{1}{2}I\omega^2 = \tfrac{1}{2}\left(\tfrac{1}{2}MR_0^2\right)\omega^2$$

$$= \tfrac{1}{4}\left(8.0\times10^4\,\text{kg}\right)(5\,\text{m})^2(10.5\,\text{rad/s})^2 = 5.5\times10^7\,\text{J}.$$

**NOTE** In terms of kilowatt-hours $\left[1\,\text{kWh} = (1000\,\text{J/s})(3600\,\text{s/h})(1\,\text{h}) = 3.6\times10^6\,\text{J}\right]$, this energy is only about 15 kWh, which is not a lot of energy (one 3-kW oven would use it all in 5 h). Thus flywheels seem unlikely for this application.

**EXAMPLE 10–16** **Rotating rod.** A rod of mass $M$ is pivoted on a frictionless hinge at one end, as shown in Fig. 10–30. The rod is held at rest horizontally and then released. Determine the angular velocity of the rod when it reaches the vertical position, and the speed of the rod's tip at this moment.

**APPROACH** We can use the work-energy principle here. The work done is due to gravity, and is equal to the change in gravitational potential energy of the rod.

**SOLUTION** Since the CM of the rod drops a vertical distance $\ell/2$, the work done by gravity is

$$W = Mg\frac{\ell}{2}.$$

The initial kinetic energy is zero. Hence, from the work-energy principle,

$$\tfrac{1}{2}I\omega^2 = Mg\frac{\ell}{2}.$$

Since $I = \frac{1}{3}M\ell^2$ for a rod pivoted about its end (Fig. 10–21g), we can solve for $\omega$:

$$\omega = \sqrt{\frac{3g}{\ell}}.$$

The tip of the rod will have a linear speed (see Eq. 10–4)

$$v = \ell\omega = \sqrt{3g\ell}.$$

**NOTE** The speed of the rod's tip is greater than the speed of an object that falls vertically a height $\ell$, whose speed is only $v = \sqrt{2g\ell}$.

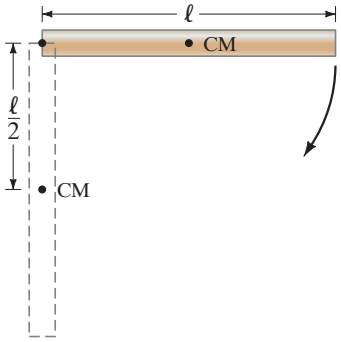

**FIGURE 10–30** Example 10–16.

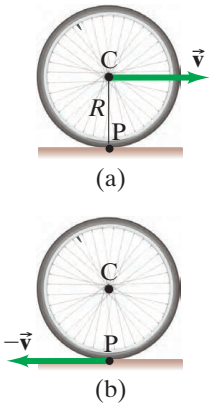
**EXERCISE D** Estimate the energy stored in the rotational motion of a hurricane. Model the hurricane as a uniform cylinder 300 km in diameter and 5 km high, made of air whose mass is 1.3 kg per $m^3$. Estimate the outer edge of the hurricane to move at a speed of 200 km/h.

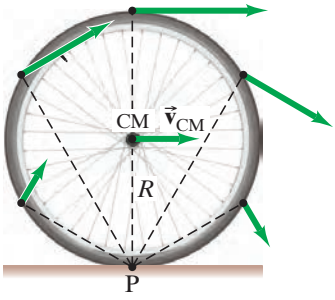
# 10–9 Rotational Plus Translational Motion; Rolling

## Rolling Without Slipping

The rolling motion of a ball or wheel is familiar in everyday life: a ball rolling across the floor, or the wheels and tires of a car or bicycle rolling along the pavement. Rolling *without slipping* depends on static friction between the rolling object and the ground. The friction is static because the rolling object's point of contact with the ground is at rest at each moment.



Rolling without slipping involves both rotation and translation. There is a simple relation between the linear speed $v$ of the axle and the angular velocity $\omega$ of the rotating wheel or sphere: namely, $v = R\omega$, where $R$ is the radius, as we now show. Figure 10–31a shows a wheel rolling to the right without slipping. At the instant shown, point P on the wheel is in contact with the ground and is momentarily at rest. (If P was not at rest, the wheel would be slipping.) The velocity of the axle at the wheel's center C is $\vec{\mathbf{v}}$. In Fig. 10–31b we have put ourselves in the reference frame of the wheel—that is, we are moving to the right with velocity $\vec{\mathbf{v}}$ relative to the ground. In this reference frame the axle C is at rest, whereas the ground and point P are moving to the left with velocity $-\vec{\mathbf{v}}$ as shown. In Fig. 10–31b, we are seeing pure rotation. We can then use Eq. 10–4 to obtain $v = R\omega$ in Fig. 10–31b, where $R$ is the radius of the wheel. This is the same $v$ as in Fig. 10–31a, so we see that the linear speed $v$ of the axle relative to the ground is related to the angular velocity $\omega$ by



$$v = R\omega. \qquad \text{[rolling without slipping]}$$

This is valid only if there is no slipping. If the rotating wheel or sphere is uniform, or at least the CM is at the geometric center C (the axle), then we can write

$$v_{CM} = R\omega. \qquad \text{[rolling without slipping; CM at center]} \quad \textbf{(10–23)}$$

**FIGURE 10–31** (a) A wheel rolling to the right. Its center C moves with velocity $\vec{\mathbf{v}}$. Point P, the point of contact with the ground, is at rest at this instant. (b) The same wheel as seen from a reference frame in which the axle of the wheel C is at rest—that is, we are moving to the right with velocity $\vec{\mathbf{v}}$ relative to the ground. Point P, which was at rest in (a), here in (b) is moving to the left with velocity $-\vec{\mathbf{v}}$ as shown. (See also Section 3–9 on relative velocity.)

(a)

(b)

**FIGURE 10–32** (a) A rolling wheel rotates about the instantaneous axis (perpendicular to the page) passing through the point of contact with the ground, P. The arrows represent the instantaneous velocity of each point. (b) Photograph of a rolling wheel. The spokes are more blurred where the speed is greater.

## Instantaneous Axis

When a wheel rolls without slipping, the point of contact of the wheel with the ground is instantaneously at rest. It is sometimes useful to think of the motion of the wheel as pure rotation about this "instantaneous axis" passing through that point P (Fig. 10–32a). Points close to the ground have a small linear speed, as they are close to this instantaneous axis, whereas points farther away have a greater linear speed. This can be seen in a photograph of a real rolling wheel (Fig. 10–32b): spokes near the top of the wheel appear more blurry because they are moving faster than those near the bottom of the wheel.

## Total Kinetic Energy = $K_{CM} + K_{rot}$

An object that rotates while its center of mass (CM) undergoes translational motion will have both translational and rotational kinetic energy. Equation 10–19, $K = \frac{1}{2}I\omega^2$, gives the rotational kinetic energy if the rotation axis is fixed. If the object is moving, such as a wheel rolling along the ground, Fig. 10–33, there will also be translational kinetic energy. To obtain the total kinetic energy, we note that the rolling wheel undergoes pure rotation about its instantaneous point of contact P, Fig. 10–32. As we saw in the discussion of Fig. 10–31, the speed $v$ of the center relative to the ground equals the speed of a point on the edge of the wheel relative to its center. Both of these speeds are related to the radius $R$ by $v = R\omega$. Thus the angular velocity $\omega$ about point P is the same $\omega$ for the wheel rotating about its center. So the total kinetic energy, which about point P is pure rotation, is

$$K_{tot} = \tfrac{1}{2}I_P\omega^2,$$

where $I_P$ is the rolling object's moment of inertia about the instantaneous axis at P. We can write $K_{tot}$ in terms of the center of mass using the parallel-axis theorem: $I_P = I_{CM} + MR^2$, where we have substituted $h = R$ in Eq. 10–17, the parallel axis theorem. Thus

$$K_{tot} = \tfrac{1}{2}I_{CM}\omega^2 + \tfrac{1}{2}MR^2\omega^2.$$

But $R\omega = v_{CM}$, the speed of the center of mass (Eq. 10–23). So the total kinetic energy of a rolling object is

$$K_{tot} = \tfrac{1}{2}I_{CM}\omega^2 + \tfrac{1}{2}Mv_{CM}^2, \qquad \textbf{(10–24)}$$

where $v_{CM}$ is the linear velocity of the CM, $I_{CM}$ is the moment of inertia about an axis through the CM, $\omega$ is the angular velocity about this axis, and $M$ is the total mass of the object. Equation 10–24 is also valid in general, not just for a rolling wheel or sphere.

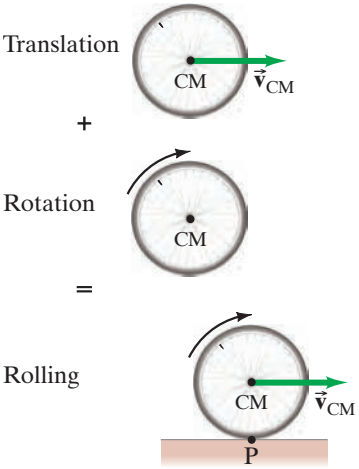


**FIGURE 10–33** A wheel rolling without slipping can be considered as translation of the wheel as a whole with velocity $\vec{\mathbf{v}}_{CM}$ plus rotation about the CM.

**EXAMPLE 10–17** **Sphere rolling down an incline.** What will be the speed of the CM of a uniform solid sphere of mass $M$ and radius $r_0$ when it reaches the bottom of an incline if it starts from rest at a vertical height $H$ and rolls without slipping? See Fig. 10–34. (Assume no slipping occurs because there is plenty of static friction.) Compare your result to that for an object *sliding* down a frictionless incline.

**APPROACH** We use the law of conservation of energy with gravitational potential energy, now including rotational as well as translational kinetic energy.

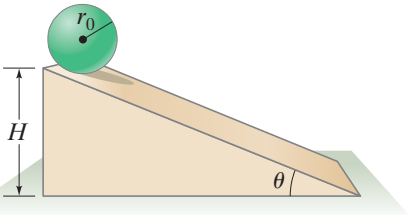

**FIGURE 10–34** A uniform sphere rolling down a hill has both translational and rotational kinetic energy. Example 10–17.

**SOLUTION** The total energy of the sphere when its CM is a vertical distance $y$ above the base of the incline is

$$E = \tfrac{1}{2}Mv_{CM}^2 + \tfrac{1}{2}I_{CM}\omega^2 + Mgy,$$

where $v_{CM}$ is the speed of the center of mass, and $Mgy$ is the gravitational potential energy. Applying conservation of energy, we equate the total energy at the top $(y = H + r_0,\ v_{CM} = 0,\ \omega = 0)$ to the total energy at the bottom $(y = r_0)$:

$$E_{top} = E_{bottom}$$
$$0 + 0 + Mg(H + r_0) = \tfrac{1}{2}Mv_{CM}^2 + \tfrac{1}{2}I_{CM}\omega^2 + Mgr_0. \quad \text{[energy conservation]}$$

The moment of inertia of a solid sphere about an axis through its center of mass is $I_{CM} = \frac{2}{5}Mr_0^2$, Fig. 10–21e. Since the sphere rolls without slipping, we have $\omega = v_{CM}/r_0$ (recall Fig. 10–31). Hence

$$MgH = \tfrac{1}{2}Mv_{CM}^2 + \tfrac{1}{2}\left(\tfrac{2}{5}Mr_0^2\right)\left(\frac{v_{CM}^2}{r_0^2}\right).$$

Canceling the $M$'s and $r_0$'s we obtain

$$\left(\tfrac{1}{2} + \tfrac{1}{5}\right)v_{CM}^2 = gH$$

or

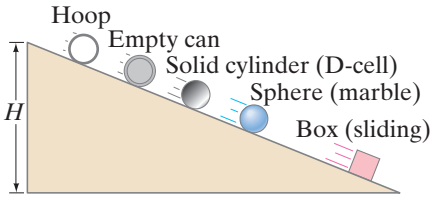
$$v_{CM} = \sqrt{\tfrac{10}{7}gH}. \quad \text{[rolling sphere]}$$

We can compare this result for the speed of the CM of a rolling sphere to the speed of an object sliding down a plane without rotating and without friction, $\frac{1}{2}mv^2 = mgH$. For the sliding object, $v = \sqrt{2gH}$, which is greater than for a rolling sphere $\left(2 > \frac{10}{7}\right)$. An object sliding without friction or rotation transforms its initial potential energy entirely into translational kinetic energy (none into rotational kinetic energy), so the speed of its center of mass is greater.

**CAUTION**
*Rolling objects go slower than sliding objects because of rotational kinetic energy*

**NOTE** Our result for the rolling sphere shows (perhaps surprisingly) that $v_{CM}$ is independent of both the mass $M$ and the radius $r_0$ of the sphere.

**CONCEPTUAL EXAMPLE 10–18 Which is fastest?** Several objects roll without slipping down an incline of vertical height $H$, all starting from rest at the same moment. The objects are a thin hoop (or a plain wedding band), a spherical marble, a solid cylinder (a D-cell battery), and an empty soup can. In addition, a greased box slides down without friction. In what order do they reach the bottom of the incline? All the objects have the same mass $M$ and radius $R$ (if rolling).



**RESPONSE** We use conservation of energy with gravitational potential energy plus rotational and translational kinetic energy. The sliding box would be fastest because the potential energy loss ($MgH$) is transformed completely into translational kinetic energy of the box, whereas for rolling objects the initial potential energy is shared between translational and rotational kinetic energies, and so the speed of the CM is less. For each of the rolling objects we can state that the decrease in potential energy equals the increase in translational plus rotational kinetic energy:

$$MgH = \tfrac{1}{2}Mv_{CM}^2 + \tfrac{1}{2}I_{CM}\omega^2.$$

For all our rolling objects, the moment of inertia $I_{CM}$ is a numerical factor times $MR^2$ (Fig. 10–21). The mass $M$ is in each term of the equation above so it cancels out. Thus the translational speed $v_{CM}$ at the bottom does not depend on $M$. The CM speed also does not depend on the radius $R$ because $\omega = v_{CM}/R$, so $R^2$ cancels out in the term $\frac{1}{2}I_{CM}\omega^2$. Thus the speed $v_{CM}$ at the bottom of the incline depends only on that numerical factor in $I_{CM}$ which expresses how the mass is distributed. The hoop, with all its mass concentrated at radius $R$ $\left(I_{CM} = MR^2\right)$, has the largest moment of inertia. Hence the hoop has the most rotational kinetic energy and the least transational kinetic energy, and lowest speed at the bottom. The hoop arrives behind the D-cell $\left(I_{CM} = \frac{1}{2}MR^2\right)$, which will be behind the marble $\left(I_{CM} = \frac{2}{5}MR^2\right)$. The empty can, which is a hoop plus a thin disk, has most of its mass concentrated at $R$; so it will be a bit faster than the pure hoop but slower than the D-cell. See Fig. 10–35.

**NOTE** The rolling objects do not even have to have the same radius and mass: the speed at the bottom does not depend on the object's mass $M$ or radius $R$, but only on its shape (and the height of the hill $H$).

**FIGURE 10–35** Example 10–18.

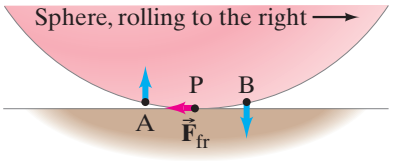


**FIGURE 10–36** A sphere rolling to the right on a plane surface. The point in contact with the ground at any moment, point P, is momentarily at rest. Point A to the left of P is moving nearly vertically upward at the instant shown, and point B to the right is moving nearly vertically downward. An instant later, point B will touch the plane and be at rest momentarily. Thus the force $\vec{\mathbf{F}}_{fr}$ is perpendicular to the motion, so no work is done by the force of static friction.

If there had been little or no static friction between the rolling objects and the plane in these Examples, the round objects would have slid rather than rolled, or a combination of both. Static friction must be present to make a round object roll. We did not need to take friction into account in the energy equation for the rolling objects because it is *static* friction and does no work—the point of contact of a sphere at each instant does not slide, but moves perpendicular to the plane (first down and then up as shown in Fig. 10–36) as it rolls. Thus, no work is done by the static friction force because the force and the motion (displacement) are perpendicular. The reason the rolling objects in Examples 10–17 and 10–18 move down the slope more slowly than if they were sliding is *not* because friction slows them down. Rather, it is because some of the gravitional potential energy is converted to rotational kinetic energy, leaving less for the translational kinetic energy.

**EXERCISE E** Return to the Chapter-Opening Question, page 264, and answer it again now. Try to explain why you may have answered differently the first time.

## Using $\Sigma\tau_{CM} = I_{CM}\alpha_{CM}$

We can examine objects rolling down a plane not only from the point of view of kinetic energy, as we did in Examples 10–17 and 10–18, but also in terms of forces and torques. If we calculate torques about an axis fixed in direction (even if the axis is accelerating) which passes through the center of mass of the rolling sphere, then

$$\Sigma\tau_{CM} = I_{CM}\alpha_{CM}$$

is valid, as we discussed in Section 10–5. See Eq. 10–15, whose validity we will show in Section 11–4. Be careful, however: do not assume $\Sigma\tau = I\alpha$ is always valid. You cannot just calculate $\tau$, $I$, and $\alpha$ about any axis unless the axis is

(1) fixed in an inertial reference frame, or
(2) fixed in direction but passes through the CM of the object.

**CAUTION**
*When is $\Sigma\tau = I\alpha$ valid?*

**EXAMPLE 10–19** **Analysis of a sphere on an incline using forces.** Analyze the rolling sphere of Example 10–17, Fig. 10–34, in terms of forces and torques, and determine the velocity $v_{CM}$ of the sphere's CM at the base of the incline, and the magnitude of the friction force, $F_{fr}$, Fig. 10–37.

**APPROACH** We analyze the motion as translation of the CM plus rotation about the CM. $F_{fr}$ is due to static friction and we cannot assume $F_{fr} = \mu_s F_N$, only $F_{fr} \leq \mu_s F_N$.

**SOLUTION** For translation in the $x$ direction we have from $\Sigma F = ma$,

$$Mg\sin\theta - F_{fr} = Ma_{CM}.$$

In the $y$ direction

$$F_N - Mg\cos\theta = 0$$

since there is no acceleration perpendicular to the plane. This last equation merely tells us the magnitude of the normal force,

$$F_N = Mg\cos\theta.$$

For the rotational motion about the CM, we use Newton's second law for rotation $\Sigma\tau_{CM} = I_{CM}\alpha_{CM}$ (Eq. 10–15), calculating about an axis passing through the CM of the sphere (radius $r_0$) but fixed in direction:

$$F_{fr}r_0 = \left(\tfrac{2}{5}Mr_0^2\right)\alpha_{CM}.$$

The other forces, $\vec{\mathbf{F}}_N$ and $M\vec{\mathbf{g}}$, point through the axis of rotation (CM), so have lever arms equal to zero and do not appear here. As we saw on page 283 and Fig. 10–31, $\omega = v/r_0$ where $v = v_{CM}$ is the speed of the CM. Taking derivatives of $\omega = v_{CM}/r_0$ with respect to time we have $\alpha_{CM} = a_{CM}/r_0$; substituting into the last equation we find

$$F_{fr} = \tfrac{2}{5}Ma_{CM}.$$

When we substitute this into the first equation in this solution, we get

$$Mg\sin\theta - \tfrac{2}{5}Ma_{CM} = Ma_{CM},$$

or

$$a_{CM} = \tfrac{5}{7}g\sin\theta.$$

We thus see that the acceleration of the CM of a rolling sphere is less than that for an object sliding without friction $(a = g\sin\theta)$. The sphere started from

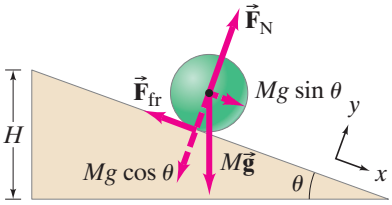

**FIGURE 10–37** Example 10–19.

rest $(v_0 = 0)$ at the top of the incline (height $H$). To find the speed $v_{CM}$ of the CM at the bottom we use Eq. 2–12c for constant linear acceleration $(v^2 = v_0^2 + 2ax)$, where the total distance traveled along the plane is $x = H/\sin\theta$ (see Fig. 10–37). Thus

$$v_{CM} = \sqrt{2a_{CM}x} = \sqrt{2\left(\frac{5}{7}g\sin\theta\right)\left(\frac{H}{\sin\theta}\right)} = \sqrt{\frac{10}{7}gH}.$$

This is the same result obtained in Example 10–17, although less effort was needed there. To get the magnitude of the force of friction, we use the equations obtained above:

$$F_{fr} = \tfrac{2}{5}Ma_{CM} = \tfrac{2}{5}M\left(\tfrac{5}{7}g\sin\theta\right) = \tfrac{2}{7}Mg\sin\theta.$$

**NOTE** If the coefficient of static friction is sufficiently small, or $\theta$ sufficiently large so this equation gives $F_{fr} > \mu_s F_N$, the sphere will not simply roll but will also slip as it moves down the plane. Because $F_{fr} = \frac{2}{7}Mg\sin\theta$ and $\mu_s F_N = \mu_s Mg\cos\theta$, then $F_{fr} > \mu_s F_N$ is equivalent to $\tan\theta > \frac{7}{2}\mu_s$.

## *More Advanced Examples

Here we do three more Examples, all of them fun and interesting. When they use $\Sigma\tau = I\alpha$, we must remember that this equation is valid only if $\tau$, $\alpha$, and $I$ are calculated about an axis that either (1) is fixed in an inertial reference frame, or (2) passes through the CM of the object and remains fixed in direction.

**EXAMPLE 10–20 A falling yo-yo.** String is wrapped around a uniform solid cylinder (something like a yo-yo) of mass $M$ and radius $R$, and the cylinder starts falling from rest, Fig. 10–38a. As the cylinder falls, find $(a)$ the acceleration of its CM and $(b)$ the tension in the string.

**APPROACH** As always we begin with a free-body diagram, Fig. 10–38b, which shows the weight of the cylinder acting at the CM and the tension of the string $\vec{\mathbf{F}}_T$ acting at the edge of the cylinder. We write Newton's second law for the linear motion of the CM, choosing *down* as positive:

$$Ma_{CM} = \Sigma F = Mg - F_T.$$

Since we do not know the tension in the string, we cannot immediately solve for $a_{CM}$. So we try Newton's second law for the rotational motion, calculated about the center of mass (let clockwise be +):

$$\Sigma\tau_{CM} = I_{CM}\alpha_{CM}$$
$$F_T R = \tfrac{1}{2}MR^2\alpha_{CM}.$$

Because the cylinder "rolls without slipping" down the string, we have the additional relation that $a_{CM} = R\alpha_{CM}$. (Because $\frac{d}{dt}(v_{CM} = R\omega)$; Eq. 10–23 and Fig. 10–31.)

**SOLUTION** $(a)$ The torque equation becomes

$$F_T R = \tfrac{1}{2}MR^2\left(\frac{a_{CM}}{R}\right) = \tfrac{1}{2}MRa_{CM}$$

so

$$F_T = \tfrac{1}{2}Ma_{CM}.$$

Substituting this into the force equation above, we obtain

$$Ma_{CM} = Mg - F_T = Mg - \tfrac{1}{2}Ma_{CM}.$$

Solving for $a_{CM}$ we find that $a_{CM} = \frac{2}{3}g$. That is, the linear acceleration of the CM of the cylinder is less than what it would be if the cylinder is simply dropped. This makes sense because gravity is not the only vertical force acting; the tension in the string is acting as well.

$(b)$ Since $a_{CM} = \frac{2}{3}g$, $F_T = \frac{1}{2}Ma_{CM} = \frac{1}{3}Mg$.

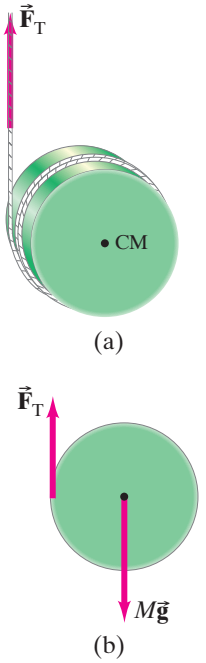

**FIGURE 10–38** Example 10–20.

**EXERCISE F** Find the acceleration $a$ of a yo-yo whose spindle has radius $\frac{1}{2}R$. Assume the moment of inertia is still $\frac{1}{2}MR^2$ (ignore the mass of the spindle).

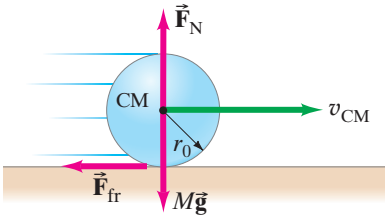

**FIGURE 10–39** Example 10–21. A spherical bowling ball, rolling and slipping.

**EXAMPLE 10–21** **What if a rolling ball slips?** A bowling ball of mass $M$ and radius $r_0$ is thrown along a level surface so that initially $(t = 0)$ it slides with a linear speed $v_0$ but does not rotate $(\omega_0 = 0)$. As it slides, it begins to spin, and eventually rolls without slipping. How long does it take to begin rolling without slipping?

**APPROACH** The free-body diagram is shown in Fig. 10–39, with the ball moving to the right. The friction force does two things: it acts to slow down the translational motion of the CM; and it immediately acts to start the ball rotating clockwise. This may seem like a hard problem, but just watch.

**SOLUTION** Newton's second law for translation of the ball's CM is

$$Ma_{CM} = \Sigma F = -F_{fr} = -\mu_k F_N = -\mu_k Mg,$$

where $\mu_k$ is the coefficient of kinetic friction because the ball is sliding. Thus the ball's acceleration is $a_{CM} = -\mu_k g$, which means the ball slows down. The velocity of the CM is

$$v_{CM} = v_0 + a_{CM}t = v_0 - \mu_k gt. \qquad \textbf{(i)}$$

Next we apply Newton's second law for rotation about the CM, $I_{CM}\alpha_{CM} = \Sigma\tau_{CM}$:

$$\tfrac{2}{5}Mr_0^2\alpha_{CM} = F_{fr}r_0 = \mu_k F_N r_0 = \mu_k Mgr_0.$$

The angular acceleration of the ball while it is slipping is thus $\alpha_{CM} = 5\mu_k g/2r_0$, which is constant. Then the angular velocity of the slipping ball is (Eq. 10–9a)

$$\omega_{CM} = \omega_0 + \alpha_{CM}t = 0 + \frac{5\mu_k gt}{2r_0}. \qquad \textbf{(ii)}$$

The ball starts rolling immediately after it touches the ground, but it rolls and slips at the same time to begin with. It eventually stops slipping, and then rolls without slipping. The condition for *rolling without slipping* is that

$$v_{CM} = \omega_{CM}r_0,$$

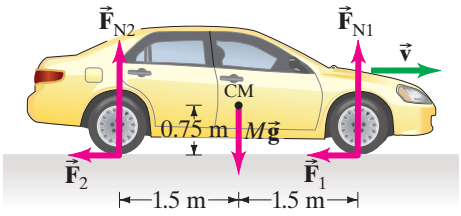
which is Eq. 10–23, and is *not* valid if there is slipping. Thus rolling without slipping begins at a time $t = t_1$ when $v_{CM} = \omega_{CM}r_0$, which we substitute into Eq. (i) $[\omega_{CM}r_0 = v_0 - \mu_k gt_1]$ and then use Eq. (ii) to find

$$\frac{5\mu_k gt_1}{2r_0}r_0 = v_0 - \mu_k gt_1$$

so

$$t_1 = \frac{2v_0}{7\mu_k g}.$$

**NOTE** Kinetic friction slows the ball until $t_1$, when $v_{CM}$ becomes equal to $\omega_{CM}r_0$, after which static friction acts.



**CAUTION**
*Rolling with slipping*

**CAUTION**
*Rolling without slipping*

**PHYSICS APPLIED**
*Braking distribution of a car*

**EXAMPLE 10–22** **ESTIMATE** **Braking a car.** When the brakes of a car are applied, the front of the car dips down a bit; and the force on the front tires is greater than on the rear tires. To see why, estimate the magnitude of the normal forces, $F_{N1}$ and $F_{N2}$, on the front and rear tires of the car shown in Fig. 10–40 when the car brakes and decelerates at a rate $a = 0.50\,g$. The car has mass $M = 1200$ kg, the distance between the front and rear axles is 3.0 m, and its CM (where the force of gravity acts) is midway between the axles 75 cm above the ground.

**FIGURE 10–40** Forces on a braking car (Example 10–22).

**APPROACH** Figure 10–40 is the free-body diagram showing all the forces on the car. $F_1$ and $F_2$ are the frictional forces that decelerate the car. We let $F_1$ be the sum of the forces on both front tires, and $F_2$ likewise for the two rear tires. $F_{N1}$ and $F_{N2}$ are the normal forces the road exerts on the tires and, for our estimate, we assume the static friction force acts the same for all the tires, so that $F_1$ and $F_2$ are proportional respectively to $F_{N1}$ and $F_{N2}$:

$$F_1 = \mu F_{N1} \quad \text{and} \quad F_2 = \mu F_{N2}.$$

The forces $F_1$ and $F_2$ are due to static friction. But $\mu$ is less than the static coefficient of friction $\mu_s$ $(F_{fr} \le \mu_s F_N)$, unless the car is just about to skid.

**SOLUTION** The friction forces $F_1$ and $F_2$ decelerate the car, so Newton's second law gives (we are given $a = 0.50g$)

$$F_1 + F_2 = Ma = 0.50Mg = (1200\,\text{kg})(0.50)(9.8\,\text{m/s}^2) = 5900\,\text{N}. \quad \textbf{(i)}$$

While the car is braking its motion is only translational, so the net torque on the car is zero. If we calculate the torques about the CM as axis, the forces $F_1$, $F_2$, and $F_{N2}$ all act to rotate the car clockwise, and only $F_{N1}$ acts to rotate it counterclockwise; so the torque due to $F_{N1}$ must balance the other three torques. Hence, $F_{N1}$ must be significantly greater than $F_{N2}$. Mathematically, we have for the torques calculated about the CM:

$$(1.5\,\text{m})F_{N1} - (1.5\,\text{m})F_{N2} - (0.75\,\text{m})F_1 - (0.75\,\text{m})F_2 = 0.$$

Since $F_1$ and $F_2$ are proportional to $F_{N1}$ and $F_{N2}$ $(F_1 = \mu F_{N1},\ F_2 = \mu F_{N2})$, we can write this as

$$(1.5\,\text{m})(F_{N1} - F_{N2}) - (0.75\,\text{m})(\mu)(F_{N1} + F_{N2}) = 0. \quad \textbf{(ii)}$$

Also, since the car does not accelerate vertically, we have

$$Mg = F_{N1} + F_{N2} = \frac{F_1 + F_2}{\mu}. \quad \textbf{(iii)}$$

Comparing Eq. (iii) to Eq. (i), we see that $\mu = (F_1 + F_2)/Mg = a/g = 0.50$. Now we solve Eq. (ii) for $F_{N1}$ and use $\mu = 0.50$ to obtain

$$F_{N1} = F_{N2}\left(\frac{2 + \mu}{2 - \mu}\right) = \frac{5}{3}F_{N2}. \quad \textbf{(iv)}$$

Thus $F_{N1}$ is $1\frac{2}{3}$ times greater than $F_{N2}$. (The arrows in Fig. 10–40 representing $\vec{\mathbf{F}}_{N1}$ and $\vec{\mathbf{F}}_{N2}$ should thus be of different lengths.) Actual magnitudes are determined from Eqs. (iii) and (i):

$$F_{N1} + F_{N2} = \frac{F_1 + F_2}{\mu} = \frac{5900\,\text{N}}{0.50} = 11{,}800\,\text{N},$$

and from (iv)

$$F_{N1} + F_{N2} = \tfrac{5}{3}F_{N2} + F_{N2} = (\tfrac{5}{3} + 1)F_{N2} = \tfrac{8}{3}F_{N2}.$$

So $F_{N2} = \frac{3}{8}(F_{N1} + F_{N2}) = \frac{3}{8}(11{,}800\,\text{N}) = 4400\,\text{N}$ and $F_{N1} = 11{,}800\,\text{N} - F_{N2} = 11{,}800\,\text{N} - 4400\,\text{N} = 7400\,\text{N}$.

**NOTE** Because the force on the front tires is generally greater than on the rear tires, cars are often designed with larger brake pads on the front wheels than on the rear. Or, to say it another way, if the brake pads are equal, the front ones wear out a lot faster.

# *10–10 Why Does a Rolling Sphere Slow Down? [Neglected Aspects]

A sphere of mass $M$ and radius $r_0$ rolling on a horizontal flat surface eventually comes to rest. What force causes it to come to rest? You might think it is friction, but when you examine the problem, a paradox seems to arise.

Suppose a sphere is rolling to the right as shown in Fig. 10–41, and is slowing down. By Newton's second law, $\Sigma\vec{\mathbf{F}} = M\vec{\mathbf{a}}$, there must be a force $\vec{\mathbf{F}}$ (presumably frictional) acting to the left as shown, so that the acceleration $\vec{\mathbf{a}}$ will also point to the left and $v$ will decrease. Curiously enough, though, if we now look at the torque equation (calculated about the center of mass), $\Sigma\tau_{CM} = I_{CM}\alpha$, we see that the force $\vec{\mathbf{F}}$ acts to increase the angular acceleration $\alpha$, and thus to *increase* the velocity of the sphere. Thus the paradox. The force $\vec{\mathbf{F}}$ acts to decelerate the sphere if we look at the translational motion, but speeds it up if we look at the rotational motion.

The resolution of this apparent paradox is that other forces are acting on the sphere: gravity, $M\vec{\mathbf{g}}$, and the normal force $\vec{\mathbf{F}}_N$ $(= -M\vec{\mathbf{g}})$. These act vertically and hence do not affect the horizontal translational motion.

**CAUTION**
*Paradox?*

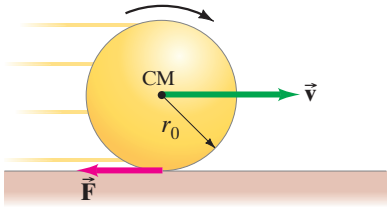


**FIGURE 10–41** Sphere rolling to the right.

**CAUTION**

*Real objects are not perfectly rigid*

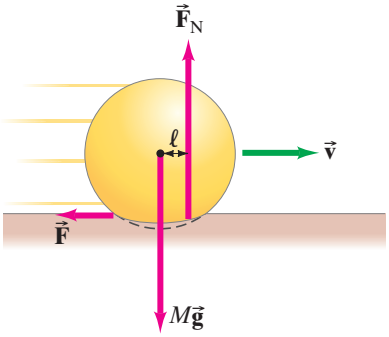

**FIGURE 10–42** The normal force, $\vec{\mathbf{F}}_N$, exerts a torque that slows down the sphere. The deformation of the sphere and the surface it moves on have been exaggerated for detail.

If we assume the sphere and plane are rigid, so the sphere is in contact at only one point, these forces $M\vec{\mathbf{g}}$ and $\vec{\mathbf{F}}_N$ could give rise to no torques about the CM either, since they would act through the CM.

The only recourse we have to resolve the paradox is to give up our *idealization* that the objects are *rigid*. In fact, all objects are deformable to some extent. Our sphere flattens slightly and the level surface also acquires a slight depression where the two are in contact. There is an *area* of contact, not a point. Hence there can be a torque acting in this area of contact in the opposite direction to the torque associated with $\vec{\mathbf{F}}$, and thus acts to slow down the rotation of the sphere. This torque is associated with the normal force $\vec{\mathbf{F}}_N$ that the table exerts on the sphere over the whole area of contact. The net effect is that we can consider $\vec{\mathbf{F}}_N$ acting vertically a distance $\ell$ in front of the CM as shown in Fig. 10–42 (where the deformation is greatly exaggerated).

Is it reasonable that the normal force $\vec{\mathbf{F}}_N$ should effectively act in *front* of the CM as shown in Fig. 10–42? Yes. The sphere is rolling, and the leading edge strikes the surface with a slight impulse. The table therefore pushes upward a bit more strongly on the front part of the sphere than it would if the sphere is at rest. At the back part of the area of contact, the rolling sphere is starting to move away (upward) and so the table is not in as good contact and pushes upward on it less strongly than if the sphere is at rest. The table pushing up more strongly on the front part of the area of contact gives rise to the necessary torque and justifies the effective acting point of $\vec{\mathbf{F}}_N$ being in front of the CM.

When other forces are present, the tiny torque $\tau_N$ due to $\vec{\mathbf{F}}_N$ can usually be ignored. For example, when a sphere or cylinder rolls down an incline, the force of gravity has far more influence than $\tau_N$, so the latter can be ignored. For many purposes (but not all), we can assume a hard sphere is in contact with a hard surface at essentially one point.

# Summary

When a rigid object rotates about a fixed axis, each point of the object moves in a circular path. Lines drawn perpendicularly from the rotation axis to different points in the object all sweep out the same angle $\theta$ in any given time interval.

Angles are conveniently measured in **radians**. One radian is the angle subtended by an arc whose length is equal to the radius $R$, or (since the circumference of a circle is $2\pi R$)

$$2\pi \text{ rad} = 360^\circ \quad \text{so} \quad 1 \text{ rad} \approx 57.3^\circ.$$

All parts of a rigid object rotating about a fixed axis have the same **angular velocity** $\omega$ and the same **angular acceleration** $\alpha$ at any instant, where

$$\omega = \frac{d\theta}{dt} \qquad \textbf{(10–2b)}$$

and

$$\alpha = \frac{d\omega}{dt}. \qquad \textbf{(10–3b)}$$

The units of $\omega$ and $\alpha$ are rad/s and rad/s$^2$.

The linear velocity $v$ and acceleration $a$ of a point located a distance $R$ from a fixed axis of rotation are related to the angular quantities by

$$v = R\omega \qquad \textbf{(10–4)}$$
$$a_{\tan} = R\alpha \qquad \textbf{(10–5)}$$
$$a_R = \omega^2 R = v^2/R \qquad \textbf{(10–6)}$$

where $a_{\tan}$ and $a_R$ are the tangential and radial (centripetal) components of the linear acceleration. The frequency $f$ and period $T$ are related to $\omega$ (rad/s) by

$$\omega = 2\pi f \qquad \textbf{(10–7)}$$
$$T = 1/f. \qquad \textbf{(10–8)}$$

Angular velocity and angular acceleration are vectors. For a rigid object rotating about a fixed axis, both $\vec{\boldsymbol{\omega}}$ and $\vec{\boldsymbol{\alpha}}$ point along the rotation axis. The direction of $\vec{\boldsymbol{\omega}}$ is given by the **right-hand rule**.

If a rigid object undergoes uniformly accelerated rotational motion ($\alpha$ = constant), equations analogous to those for linear motion are valid:

$$\omega = \omega_0 + \alpha t, \qquad \theta = \omega_0 t + \tfrac{1}{2}\alpha t^2,$$
$$\omega^2 = \omega_0^2 + 2\alpha\theta, \qquad \bar{\omega} = \frac{\omega + \omega_0}{2}. \qquad \textbf{(10–9)}$$

The **torque** $\tau$ due to a force $\vec{\mathbf{F}}$ exerted on a rigid object is equal to

$$\tau = R_\perp F = RF_\perp = RF\sin\theta, \qquad \textbf{(10–10)}$$

where $R_\perp$, called the **lever arm**, is the perpendicular distance from the axis of rotation to the line along which the force acts, and $\theta$ is the angle between $\vec{\mathbf{F}}$ and $R$.

The rotational equivalent of Newton's second law is

$$\Sigma\tau = I\alpha, \qquad \textbf{(10–14)}$$

where $I = \Sigma m_i R_i^2$ is the **moment of inertia** of the object about the axis of rotation. This relation is valid for a rigid object rotating about an axis fixed in an inertial reference frame, or when $\tau$, $I$, and $\alpha$ are calculated about the center of mass of an object even if the CM is moving. $I$ depends not only on the mass of the object but also on how the mass is distributed relative to the axis of rotation. For a uniform solid cylinder of radius $R_0$ and mass $M$, $I$ has the form $I = \frac{1}{2}MR_0^2$ (see Fig. 10–21).

The **rotational kinetic energy** of an object rotating about a fixed axis with angular velocity $\omega$ is

$$K = \tfrac{1}{2} I\omega^2. \qquad \textbf{(10–19)}$$

For an object undergoing both translational and rotational motion, the total kinetic energy is the sum of the translational kinetic energy of the object's CM plus the rotational kinetic energy of the object about its CM:

$$K_{\text{tot}} = \tfrac{1}{2} M v_{\text{CM}}^2 + \tfrac{1}{2} I_{\text{CM}}\omega^2 \qquad \textbf{(10–24)}$$

as long as the rotation axis is fixed in direction.

The following Table summarizes angular (or rotational) quantities, comparing them to their translational analogs.

| Translation | Rotation | Connection |
|---|---|---|
| $x$ | $\theta$ | $x = R\theta$ |
| $v$ | $\omega$ | $v = R\omega$ |
| $a$ | $\alpha$ | $a = R\alpha$ |
| $m$ | $I$ | $I = \Sigma mR^2$ |
| $F$ | $\tau$ | $\tau = RF\sin\theta$ |
| $K = \frac{1}{2}mv^2$ | $K = \frac{1}{2}I\omega^2$ | |
| $W = Fd$ | $W = \tau\theta$ | |
| $\Sigma F = ma$ | $\Sigma\tau = I\alpha$ | |

# Questions

1. A bicycle **odometer** (which counts revolutions and is calibrated to report distance traveled) is attached near the wheel hub and is calibrated for 27-inch wheels. What happens if you use it on a bicycle with 24-inch wheels?
2. Suppose a disk rotates at constant angular velocity. (*a*) Does a point on the rim have radial and/or tangential acceleration? (*b*) If the disk's angular velocity increases uniformly, does the point have radial and/or tangential acceleration? (*c*) For which cases would the magnitude of either component of linear acceleration change?
3. Could a nonrigid object be described by a single value of the angular velocity $\omega$? Explain.
4. Why are Eqs. 10–4 and 10–5 valid for radians but not for revolutions or degrees? (Read Section 10–1 and follow the derivations carefully.)
5. The angular velocity of a wheel rotating on a horizontal axle points west. In what direction is the linear velocity of a point on the top of the wheel? If the angular acceleration points east, describe the tangential linear acceleration of this point at the top of the wheel. Is the angular speed increasing or decreasing?
6. In what direction is the Earth's angular velocity vector as it rotates daily about its axis, north or south?
7. Can a small force ever exert a greater torque than a larger force? Explain.
8. Why is it more difficult to do a *sit-up* with your hands behind your head than when your arms are stretched out in front of you? A diagram may help you to answer this.
9. If the net force on a system is zero, is the net torque also zero? If the net torque on a system is zero, is the net force zero? Explain and give examples.
10. Mammals that depend on being able to run fast have slender lower legs with flesh and muscle concentrated high, close to the body (Fig. 10–43). On the basis of rotational dynamics, explain why this distribution of mass is advantageous.

**FIGURE 10–43** Question 10. A gazelle.

11. This book has three symmetry axes through its center, all mutually perpendicular. The book's moment of inertia would be smallest about which of the three? Explain.
12. Can the mass of a rigid object be considered concentrated at its CM for rotational motion? Explain.
13. The moment of inertia of a rotating solid disk about an axis through its CM is $\frac{1}{2}MR_0^2$ (Fig. 10–21c). Suppose instead that a parallel axis of rotation passes through a point on the edge of the disk. Will the moment of inertia be the same, larger, or smaller? Explain why.
14. Why do *tightrope walkers* (Fig. 10–44) carry a long, narrow rod?

**FIGURE 10–44** Question 14.

15. Two inclines have the same height but make different angles with the horizontal. The same steel ball rolls without slipping down each incline. On which incline will the speed of the ball at the bottom be greater? Explain.
16. Two spheres look identical and have the same mass. However, one is hollow and the other is solid. Describe an experiment to determine which is which.
17. A sphere and a cylinder have the same radius and the same mass. They start from rest at the top of an incline. (*a*) Which reaches the bottom first? (*b*) Which has the greater speed at the bottom? (*c*) Which has the greater total kinetic energy at the bottom? (*d*) Which has the greater rotational kinetic energy at the bottom? Explain your answers.
18. Two solid spheres simultaneously start rolling (from rest) down an incline. One sphere has twice the radius and twice the mass of the other. Which reaches the bottom of the incline first? Which has the greater speed there? Which has the greater total kinetic energy at the bottom?

# MisConceptual Questions

**1.** Bonnie sits on the outer rim of a merry-go-round, and Jill sits midway between the center and the rim. The merry-go-round makes one complete revolution every 2 seconds. Jill's linear velocity is:
(*a*) the same as Bonnie's.
(*b*) twice Bonnie's.
(*c*) half of Bonnie's.
(*d*) one-quarter of Bonnie's.
(*e*) four times Bonnie's.

**2.** The rigid disk in Fig. 10–45 rotates about point A. Which statement below is true?
(*a*) Point P has a higher angular velocity than point Q.
(*b*) Point P has a lower angular velocity than point Q.
(*c*) Point P has the same angular velocity as point Q.
(*d*) Point P has the same angular velocity as point Q if the angular velocity is measured in rad/s but not if it is measured in degrees/s.

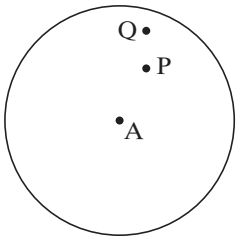

**FIGURE 10–45**
MisConceptual Question 2.

**3.** An object at rest begins to rotate with a constant angular acceleration. If this object rotates through an angle $\theta$ in time $t$, through what angle did it rotate in the time $\frac{1}{2}t$?
(*a*) $\frac{1}{2}\theta$. (*b*) $\frac{1}{4}\theta$. (*c*) $\theta$. (*d*) $2\theta$. (*e*) $4\theta$.

**4.** An accurate car speedometer, which is supposed to read the linear speed of the car, uses a device that actually measures the angular speed of the tires. If larger-diameter tires are mounted on the car instead, how will that affect the speedometer reading? The speedometer
(*a*) will still read the speed accurately.
(*b*) will read low.
(*c*) will read high.

**5.** The solid dot shown in Fig. 10–46 is a pivot point. The board can rotate about the pivot. Which force shown exerts the largest magnitude torque on the board?

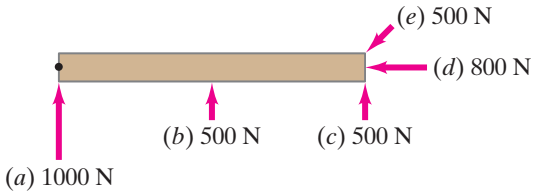

**FIGURE 10–46** MisConceptual Questions 5 and 6.

**6.** Which force (or forces) in Fig. 10–46 exerts the smallest torque on the board?

**7.** Consider a force $F = 80\,\text{N}$ applied to a beam as shown in Fig. 10–47. The length of the beam is $\ell = 5.0\,\text{m}$, and $\theta = 37°$, so that $x = 3.0\,\text{m}$ and $y = 4.0\,\text{m}$. Of the following expressions, which ones give the correct torque produced by the force $\vec{\mathbf{F}}$ around point P?
(*a*) 80 N.
(*b*) (80 N)(5.0 m).
(*c*) (80 N)(5.0 m)(sin 37°).
(*d*) (80 N)(4.0 m).
(*e*) (80 N)(3.0 m).
(*f*) (48 N)(5.0 m).
(*g*) (48 N)(4.0 m)(sin 37°).

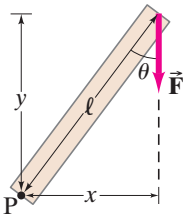

**FIGURE 10–47**
MisConceptual Question 7.

**8.** Two spheres have the same radius and equal mass. One sphere is solid, and the other is hollow and made of a denser material. Which one has the bigger moment of inertia about an axis through its center?
(*a*) The solid one.
(*b*) The hollow one.
(*c*) Both the same.

**9.** Two wheels, having the same radius and mass, rotate at the same angular velocity (Fig. 10–48). One wheel is made with spokes so nearly all the mass is at the rim. The other is a solid disk. How do their rotational kinetic energies compare?
(*a*) They are nearly the same.
(*b*) The wheel with spokes has about twice the kinetic energy.
(*c*) The wheel with spokes has more kinetic energy, but not twice as much.
(*d*) The solid wheel has about twice the kinetic energy.
(*e*) The solid wheel has more kinetic energy, but not twice as much.

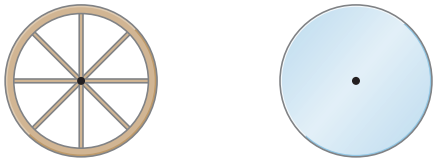

**FIGURE 10–48** MisConceptual Question 9.

**10.** Four identical small masses are connected in a flat perfect square (Fig. 10–49). Rank the relative rotational inertias $(I_A, I_B, I_C)$ about the three axes of rotation shown. Axes A and B are in the plane of the square, and axis C is perpendicular to the plane, through mass $m_1$.
(*a*) $I_A < I_B < I_C$.
(*b*) $I_C < I_B < I_A$.
(*c*) $I_A = I_B = I_C$.
(*d*) $I_B < I_A < I_C$.
(*e*) $I_C < I_A < I_B$.

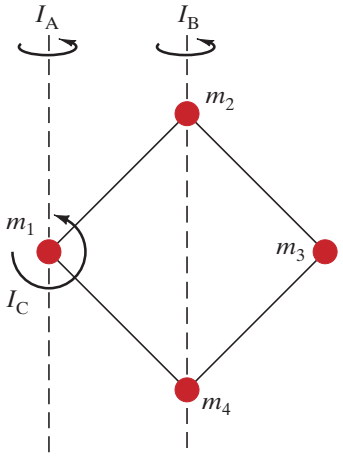

**FIGURE 10–49**
MisConceptual Question 10.

**11.** If you used 1000 J of energy to throw a ball, would it travel faster if you threw the ball (ignoring air resistance)
(*a*) so that it was also rotating?
(*b*) so that it wasn't rotating?
(*c*) It makes no difference.

**12.** A small solid sphere and a small thin hoop are rolling along a horizontal surface with the same translational speed when they encounter a 20° rising slope. If these two objects roll up the slope without slipping, which will rise farther up the slope?
(*a*) The sphere.
(*b*) The hoop.
(*c*) Both the same.
(*d*) More information about the objects' mass and diameter is needed.

**13.** Two uniform spheres simultaneously start rolling (from rest) down an incline. One sphere has twice the radius and twice the mass of the other. (*i*) Which reaches the bottom of the incline first? (*ii*) Which has the greater total kinetic energy at the bottom?
(*a*) The same; the same.
(*b*) The same; the larger one.
(*c*) The larger one; the larger one.
(*d*) The smaller one; the larger one.

**14.** Starting from rest, a solid sphere rolls without slipping down an inclined plane. At the bottom of the incline what does the angular velocity depend upon? Choose all that apply.
(*a*) The height of the incline.
(*b*) The length of the incline.
(*c*) The mass of the sphere.
(*d*) The radius of the sphere.

# Problems

## 10–1 Angular Quantities

**1.** (I) Express the following angles in radians: (*a*) 45.0°, (*b*) 60.0°, (*c*) 90.0°, (*d*) 360.0°, and (*e*) 445°. Give as numerical values and as fractions of $\pi$.

**2.** (I) The Sun subtends an angle of about 0.5° to us on Earth, 150 million km away. Estimate the radius of the Sun.

**3.** (I) A laser beam is directed at the Moon, 380,000 km from Earth. The beam diverges at an angle $\theta$ (Fig. 10–50) of $1.4 \times 10^{-5}$ rad. What diameter spot will it make on the Moon?

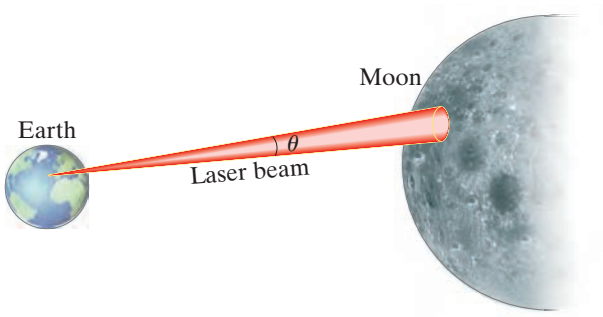

**FIGURE 10–50** Problem 3.

**4.** (I) The blades in a blender rotate at a rate of 8500 rpm (rpm = revolutions per minute = rev/min). When the motor is turned off during operation, the blades slow to rest in 4.0 s. What is the angular acceleration as the blades slow down?

**5.** (II) The platter of the **hard drive** of a computer rotates at 7200 rpm (rpm = revolutions per minute = rev/min). (*a*) What is the angular velocity (rad/s) of the platter? (*b*) If the reading head of the drive is located 3.00 cm from the rotation axis, what is the linear speed of the point on the platter just below it? (*c*) If a single bit requires 0.50 $\mu$m of length along the direction of motion, how many bits per second can the writing head write when it is 3.00 cm from the axis?

**6.** (II) A child rolls a ball on a level floor 3.1 m to another child. If the ball makes 12.0 revolutions, what is its diameter?

**7.** (II) (*a*) A grinding wheel 0.35 m in diameter rotates at 2400 rpm. Calculate its angular velocity in rad/s. (*b*) What are the linear speed and radial acceleration of a point on the edge of the grinding wheel?

**8.** (II) A bicycle with tires 68 cm in diameter travels 8.6 km. How many revolutions do the wheels make?

**9.** (II) Calculate the average angular velocity (*a*) of a clock's second hand, (*b*) its minute hand, and (*c*) its hour hand. State in rad/s. (*d*) What is the average angular acceleration in each case?

**10.** (II) A rotating merry-go-round makes one complete revolution in 4.0 s (Fig. 10–51). (*a*) What is the linear speed of a child seated 1.2 m from the center? (*b*) What is her acceleration?

**FIGURE 10–51** Problem 10.

**11.** (II) **Total solar eclipses** can happen on Earth because of amazing coincidences: for one, the rare near-perfect alignment of Earth, Moon, and Sun. Using the information inside the front cover, calculate the angular diameters (in radians) of the Sun and the Moon, as seen from Earth, and then comment about full vs. partial eclipses.

**12.** (II) What is the linear speed, due to the Earth's rotation, of a point (*a*) on the equator, (*b*) on the Arctic Circle (latitude 66.5° N), and (*c*) at a latitude of 48.0° N?

**13.** (II) Calculate the angular velocity of the Earth (*a*) in its orbit around the Sun, and (*b*) about its axis.

**14.** (II) How fast (in rpm) must a centrifuge rotate if a particle 8.0 cm from the axis of rotation is to experience an acceleration of 100,000 *g*'s?

**15.** (II) A 61-cm-diameter wheel accelerates uniformly about its center from 120 rpm to 280 rpm in 5.0 s. Determine (*a*) its angular acceleration, and (*b*) the radial and tangential components of the linear acceleration of a point on the edge of the wheel 2.0 s after it has started accelerating.

**16.** (II) In traveling to the Moon, astronauts aboard the *Apollo* spacecraft put the spacecraft into a slow rotation to distribute the Sun's energy evenly (so one side would not become too hot). At the start of their trip, they accelerated for 12 minutes from no rotation to 1.0 revolution per minute which they then maintained. Think of the spacecraft as a cylinder with a diameter of 8.5 m rotating about its cylindrical axis. Determine (*a*) the angular acceleration, and (*b*) the radial and tangential components of the linear acceleration of a point on the skin of the ship 6.0 min after it started this acceleration.

**17.** (II) A turntable of radius $R_1$ is turned by a circular rubber roller of radius $R_2$ in contact with it at their outer edges. What is the ratio of their angular velocities, $\omega_1/\omega_2$?

## 10–2 Vector Nature of $\vec{\omega}$ and $\vec{\alpha}$

**18.** (II) The axle of a wheel is mounted on supports that rest on a rotating turntable as shown in Fig. 10–52. The wheel has angular velocity $\omega_1 = 48.0\,\text{rad/s}$ about its axle, and the turntable has angular velocity $\omega_2 = 35.0\,\text{rad/s}$ about a vertical axis. (Note arrows showing these motions in the figure.) (*a*) What are the directions of $\vec{\boldsymbol{\omega}}_1$ and $\vec{\boldsymbol{\omega}}_2$ at the instant shown? (*b*) What is the resultant angular velocity of the wheel, as seen by an outside observer, at the instant shown? Give the magnitude and direction. (*c*) What is the magnitude and direction of the angular acceleration of the wheel at the instant shown? Take the $z$ axis vertically upward and the direction of the axle at the moment shown to be the $x$ axis pointing to the right.

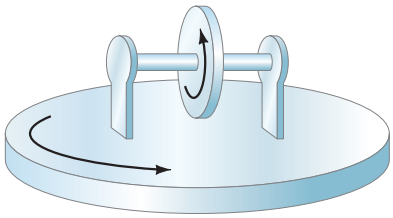

**FIGURE 10–52** Problem 18.

## 10–3 Constant Angular Acceleration

**19.** (I) A centrifuge accelerates uniformly from rest to 15,000 rpm in 220 s. Through how many revolutions did it turn in this time?

**20.** (I) Pilots can be tested for the stresses of flying high-speed jets in a whirling "human centrifuge," which takes 1.0 min to turn through 26 complete revolutions before reaching its final speed. (*a*) What was its angular acceleration (assumed constant), and (*b*) what was its final angular speed in rpm?

**21.** (II) A cooling fan is turned off when it is running at 780 rev/min. It turns 1250 revolutions before it comes to a stop. (*a*) What was the fan's angular acceleration, assumed constant? (*b*) How long did it take the fan to come to a complete stop?

**22.** (II) A wheel 34 cm in diameter accelerates uniformly from 240 rpm to 360 rpm in 6.8 s. How far will a point on the edge of the wheel have traveled in this time?

**23.** (II) The tires of a car make 75 revolutions as the car reduces its speed uniformly from 95 km/h to 55 km/h. The tires have a diameter of 0.80 m. (*a*) What was the angular acceleration of the tires? If the car continues to decelerate at this rate, (*b*) how much more time is required for it to stop, and (*c*) how far does it go before stopping?

**24.** (II) A small rubber wheel is used to drive a large pottery wheel. The two wheels are mounted so that their circular edges touch. The small wheel has a radius of 2.0 cm and accelerates at the rate of $6.8\,\text{rad/s}^2$, and it is in contact with the pottery wheel (radius 27.0 cm) without slipping. Calculate (*a*) the angular acceleration of the pottery wheel, and (*b*) the time it takes the pottery wheel to reach its required speed of 65 rpm.

**25.** (II) The angle through which a rotating wheel has turned in time $t$ is given by $\theta = 9.5\,t - 13.0\,t^2 + 1.6\,t^4$, where $\theta$ is in radians and $t$ in seconds. Determine an expression (*a*) for the instantaneous angular velocity $\omega$ and (*b*) for the instantaneous angular acceleration $\alpha$. (*c*) Evaluate $\omega$ and $\alpha$ at $t = 3.0\,\text{s}$. (*d*) What is the average angular velocity, and (*e*) the average angular acceleration between $t = 2.0\,\text{s}$ and $t = 3.0\,\text{s}$?

**26.** (II) The angular acceleration of a wheel, as a function of time, is $\alpha = 4.2\,t^2 - 9.0\,t$, where $\alpha$ is in $\text{rad/s}^2$ and $t$ in seconds. If the wheel starts from rest ($\theta = 0$, $\omega = 0$, at $t = 0$), determine a formula for (*a*) the angular velocity $\omega$ and (*b*) the angular position $\theta$, both as a function of time. (*c*) Evaluate $\omega$ and $\theta$ at $t = 2.0\,\text{s}$.

## 10–4 Torque

**27.** (I) A 58-kg person riding a bike puts all her weight on each pedal when climbing a hill. The pedals rotate in a circle of radius 17 cm. (*a*) What is the maximum torque she exerts? (*b*) How could she exert more torque?

**28.** (I) Two blocks, each of mass $m$, are attached to the ends of a massless rod which pivots as shown in Fig. 10–53. Initially the rod is held in the horizontal position and then released. Calculate the magnitude and direction of the net torque on this system when it is first released.

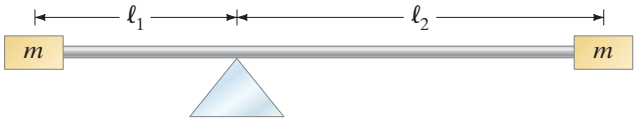

**FIGURE 10–53** Problem 28.

**29.** (II) A person exerts a horizontal force of 37 N on the end of a door 96 cm wide. What is the magnitude of the torque if the force is exerted (*a*) perpendicular to the door and (*b*) at a 60.0° angle to the face of the door?

**30.** (II) Calculate the net torque about the axle of the wheel shown in Fig. 10–54. Assume that a friction torque of $0.60\,\text{m}\cdot\text{N}$ opposes the motion.

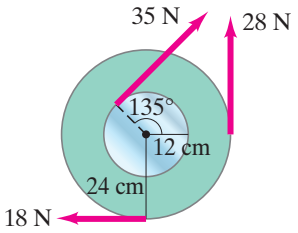

**FIGURE 10–54** Problem 30.

**31.** (II) The bolts on the cylinder head of an engine require tightening to a torque of $95\,\text{m}\cdot\text{N}$. (*a*) If a wrench is 28 cm long, what force perpendicular to the wrench must the mechanic exert at its end? (*b*) If the six-sided bolt head is 15 mm across (Fig. 10–55), estimate the force applied near each of the six points by a wrench.

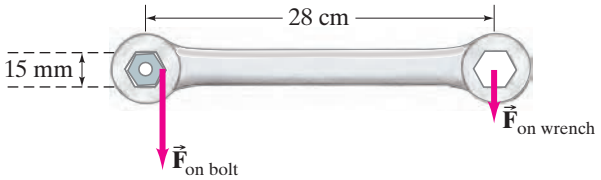

**FIGURE 10–55** Problem 31.

**32.** (II) A wheel of diameter 24.0 cm is constrained to rotate in the $xy$ plane, about the $z$ axis, which passes through its center. A force $\vec{\mathbf{F}} = (-31.0\,\hat{\mathbf{i}} + 43.4\,\hat{\mathbf{j}})$ N acts at a point on the edge of the wheel that lies exactly on the $x$ axis at a particular instant. What is the torque about the rotation axis at this instant?

**33.** (II) Determine the net torque on the 2.0-m-long uniform beam shown in Fig. 10–56. All forces are shown. Calculate about (*a*) point C, the CM, and (*b*) point P at one end.

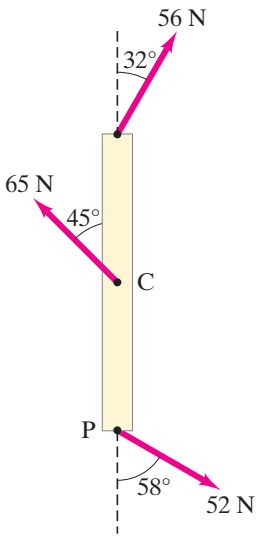

**FIGURE 10–56**
Problem 33.

## 10–5 and 10–6 Rotational Dynamics

**34.** (I) Estimate the moment of inertia of a bicycle wheel 67 cm in diameter. The rim and tire have a combined mass of 1.1 kg. The mass of the hub (at the center) can be ignored (why?).

**35.** (II) A merry-go-round accelerates from rest to 0.72 rad/s in 34 s. Assuming the merry-go-round is a uniform disk of radius 7.0 m and mass 31,000 kg, calculate the net torque required to accelerate it.

**36.** (II) An oxygen molecule consists of two oxygen atoms whose total mass is $5.3 \times 10^{-26}$ kg and whose moment of inertia about an axis perpendicular to the line joining the two atoms, midway between them, is $1.9 \times 10^{-46}\ \text{kg} \cdot \text{m}^2$. From these data, estimate the effective distance between the atoms.

**37.** (II) A grinding wheel is a uniform cylinder with a radius of 8.50 cm and a mass of 0.380 kg. Calculate (*a*) its moment of inertia about its center, and (*b*) the applied torque needed to accelerate it from rest to 1950 rpm in 5.00 s. Take into account a frictional torque that has been measured to slow down the wheel from 1500 rpm to rest in 55.0 s.

**38.** (II) The forearm in Fig. 10–57 accelerates a 3.6-kg ball at $7.0\ \text{m/s}^2$ by means of the triceps muscle, as shown. Calculate (*a*) the torque needed, and (*b*) the force that must be exerted by the triceps muscle. Ignore the mass of the arm.

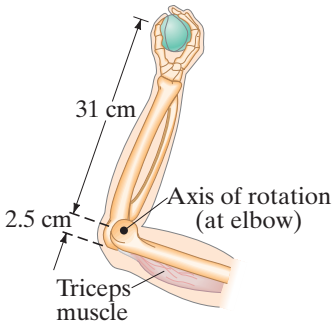

**FIGURE 10–57**
Problems 38 and 39.

**39.** (II) Assume that a 1.00-kg ball is thrown solely by the action of the forearm, which rotates about the elbow joint under the action of the triceps muscle, Fig. 10–57. The ball is accelerated uniformly from rest to 8.5 m/s in 0.38 s, at which point it is released. Calculate (*a*) the angular acceleration of the arm, and (*b*) the force required of the triceps muscle. Assume that the forearm has a mass of 3.7 kg and rotates like a uniform rod about an axis at its end.

**40.** (II) A softball player swings a bat, accelerating it from rest to 2.4 rev/s in a time of 0.20 s. Approximate the bat as a 0.90-kg uniform rod of length 0.95 m, and compute the torque the player applies to one end of it.

**41.** (II) A small 350-gram ball on the end of a thin, light rod is rotated in a horizontal circle of radius 1.4 m. Calculate (*a*) the moment of inertia of the ball about the center of the circle, and (*b*) the torque needed to keep the ball rotating at constant angular velocity if air resistance exerts a force of 0.020 N on the ball. Ignore air resistance on the rod and its moment of inertia.

**42.** (II) Calculate the moment of inertia of the array of point objects shown in Fig. 10–58 about (*a*) the *y* axis, and (*b*) the *x* axis. Assume $m = 2.2$ kg, $M = 3.2$ kg, and the objects are wired together by very light, rigid pieces of wire. The array is rectangular and is split through the middle by the *x* axis. (*c*) About which axis would it be harder to accelerate this array?

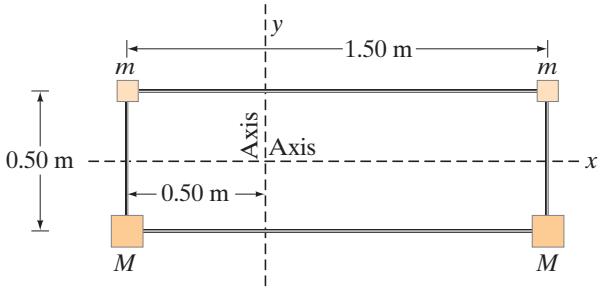

**FIGURE 10–58** Problem 42.

**43.** (II) A potter is shaping a bowl on a potter's wheel rotating at constant angular velocity of 1.6 rev/s (Fig. 10–59). The friction force between her hands and the clay is 1.8 N total. (*a*) How large is her torque on the wheel, if the diameter of the bowl is 9.0 cm? (*b*) How long would it take for the potter's wheel to stop if the only torque acting on it is due to the potter's hands? The moment of inertia of the wheel and the bowl is $0.11\ \text{kg} \cdot \text{m}^2$.

**FIGURE 10–59** Problem 43.

**44.** (II) A dad pushes tangentially on a small hand-driven merry-go-round and is able to accelerate it from rest to a frequency of 15 rpm in 10.0 s. Assume the merry-go-round is a uniform disk of radius 2.5 m and has a mass of 330 kg, and two children (each with a mass of 25 kg) sit opposite each other on the edge. Calculate the torque required to produce the acceleration, neglecting frictional torque. What force is required at the edge?

**45.** (II) Let us treat a helicopter rotor blade as a long thin rod, as shown in Fig. 10–60. (*a*) If each of the three rotor helicopter blades is 3.75 m long and has a mass of 135 kg, calculate the moment of inertia of the three rotor blades about the axis of rotation. (*b*) How much torque must the motor apply to bring the blades from rest up to a speed of 6.5 rev/s in 8.0 s?

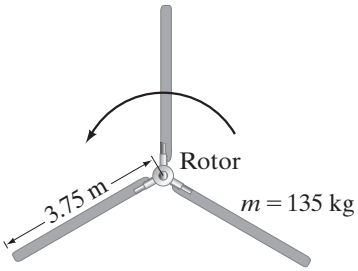

**FIGURE 10–60** Problem 45.

**46.** (II) Suppose the force $F_T$ in the cord hanging from the pulley of Example 10–10, Fig. 10–22, is given by the relation $F_T = 3.00\,t - 0.20\,t^2$ (newtons) where $t$ is in seconds. If the pulley starts from rest, what is the linear speed of a point on its rim 9.0 s later? Ignore friction and use the moment of inertia, calculated in Example 10–10.

**47.** (II) Four equal masses $M$ are spaced at equal intervals, $\ell$, along a horizontal straight rod whose mass can be ignored. The system is to be rotated about a vertical axis passing through the mass at the left end of the rod and perpendicular to it. (*a*) What is the moment of inertia of the system about this axis? (*b*) What minimum force, applied to the farthest mass, will impart an angular acceleration $\alpha$? (*c*) What is the direction of this force?

**48.** (II) To get a flat, uniform cylindrical satellite spinning at the correct rate, engineers fire four tangential rockets as shown in Fig. 10–61. Suppose that the satellite has a mass of 3600 kg and a radius of 4.0 m, and that the rockets each add a mass of 250 kg. What is the steady force required of each rocket if the satellite is to reach 28 rpm in 5.0 min, starting from rest?

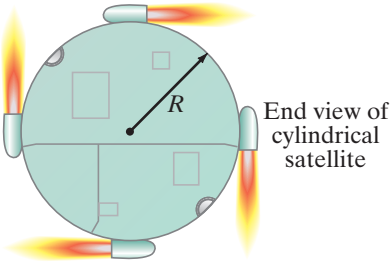

**FIGURE 10–61** Problem 48.

**49.** (II) When discussing moments of inertia, especially for unusual or irregularly shaped objects, it is sometimes convenient to work with the **radius of gyration**, $k$. This radius is defined so that if all the mass of the object were concentrated at this distance from the axis, the moment of inertia would be the same as that of the original object. Thus, the moment of inertia of any object can be written in terms of its mass $M$ and the radius of gyration as $I = Mk^2$. Determine the radius of gyration for each of the objects (hoop, cylinder, sphere, etc.) shown in Fig. 10–21.

**50.** (III) Two blocks are connected by a light string passing over a pulley of radius 0.15 m and moment of inertia $I$. The blocks move (towards the right) with an acceleration of 1.00 m/s$^2$ along their frictionless inclines (see Fig. 10–62). (*a*) Draw free-body diagrams for each of the two blocks and the pulley. (*b*) Determine $F_{TA}$ and $F_{TB}$, the tensions in the two parts of the string. (*c*) Find the net torque acting on the pulley, and determine its moment of inertia, $I$.

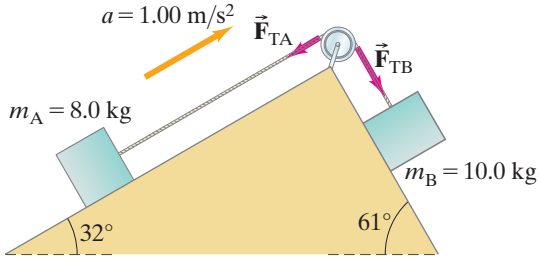

**FIGURE 10–62** Problem 50.

**51.** (III) An *Atwood machine* consists of two masses, $m_A = 65$ kg and $m_B = 75$ kg, connected by a massless inelastic cord that passes over a pulley free to rotate, Fig. 10–63. The pulley is a solid cylinder of radius $R = 0.45$ m and mass 6.0 kg. (*a*) Determine the acceleration of each mass. (*b*) What % error would be made if the moment of inertia of the pulley is ignored? [*Hint*: The tensions $F_{TA}$ and $F_{TB}$ are not equal. We discussed the Atwood machine in Example 4–13, assuming $I = 0$ for the pulley.]

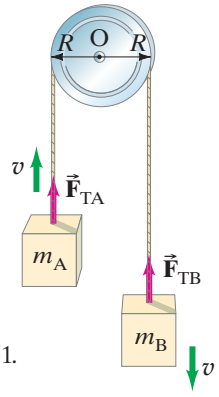

**FIGURE 10–63** Problem 51. Atwood machine.

**52.** (III) A hammer thrower accelerates the hammer of mass 7.30 kg (Fig. 10–64) from rest within four full turns (revolutions) and releases it at a speed of 26.5 m/s. Assuming a uniform rate of increase in angular velocity and a horizontal circular path of radius 1.20 m, calculate (*a*) the angular acceleration, (*b*) the (linear) tangential acceleration, (*c*) the centripetal acceleration just before release, (*d*) the net force being exerted on the hammer by the athlete just before release, and (*e*) the angle of this force with respect to the radius of the circular motion. Ignore gravity.

**FIGURE 10–64** Problem 52.

## 10–7 Determining Moments of Inertia

**53.** (I) Use the parallel-axis theorem to show that the moment of inertia of a thin rod about an axis perpendicular to the rod at one end is $I = \frac{1}{3}M\ell^2$, given that if the axis passes through the center, $I = \frac{1}{12}M\ell^2$ (Fig. 10–21f and g).

**54.** (II) Determine the moment of inertia of a 19-kg door around its hinges along one side. The door is 2.5 m high and 1.0 m wide. Ignore the thickness of the door.

**55.** (II) Two uniform solid spheres of mass $M$ and radius $r_0$ are connected by a thin (massless) rod of length $r_0$ so that the centers are $3r_0$ apart. (*a*) Determine the moment of inertia of this system about an axis perpendicular to the rod at its center (parallel axis theorem). (*b*) What is the percentage error if the masses of each sphere are assumed to be concentrated at their centers and a very simple calculation made?

**56.** (II) A ball of mass $M$ and radius $r_1$ on the end of a thin massless rod is rotated in a horizontal circle of radius $R_0$ about an axis of rotation AB, as shown in Fig. 10–65. (*a*) Assuming the mass of the ball to be concentrated at its center of mass, calculate its moment of inertia about AB. (*b*) Using the parallel-axis theorem and considering the finite radius of the ball, calculate the moment of inertia of the ball about AB. (*c*) Calculate the percentage error introduced by the point mass approximation for $r_1 = 9.25$ cm and $R_0 = 1.0$ m. (*d*) Repeat part *c* assuming $r_1 = 8.0$ cm, and comment.

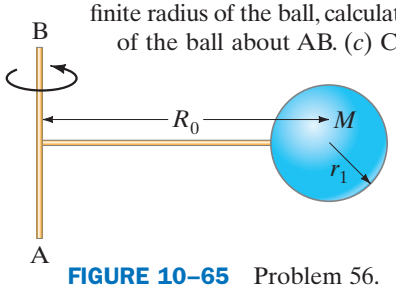

**FIGURE 10–65** Problem 56.

**57.** (II) A thin 7.0-kg wheel of radius 34 cm is a uniform disk and is weighted to one side by a 1.50-kg weight, small in size, placed 24 cm from the center of the wheel. Calculate (*a*) the position of the center of mass of the weighted wheel and (*b*) the moment of inertia about an axis through its CM, perpendicular to its face.

**58.** (III) Integrate to derive the formula for the moment of inertia of a uniform thin rod of length $\ell$ about an axis through its center, perpendicular to the rod (see Fig. 10–21f).

**59.** (III) (*a*) Integrate to obtain the formula given in Fig. 10–21h for the moment of inertia of a uniform, flat, rectangular plate of dimensions $\ell \times w$ about an axis through its center, perpendicular to the plate. (*b*) What is the moment of inertia about each of the axes through the center that are parallel to the edges of the plate?

**60.** (III) Determine the moment of inertia of a uniform solid cone whose base has radius $R_0$, height $L$ and mass $M$. The axis of rotation ($z$) is the symmetry axis perpendicular to the base, Fig. 10–66. [*Hint*: Think of the cone as a stack of infinitesimally thin disks of mass $dm$, radius $R$, and thickness $dz$.]

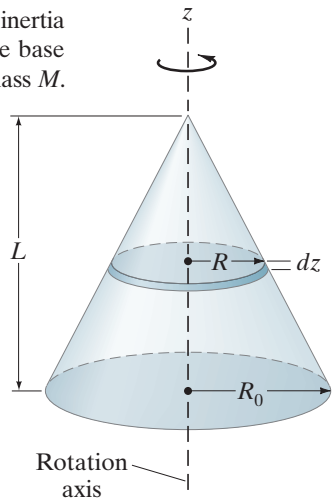

**FIGURE 10–66** Problem 60.

## 10–8 Rotational Kinetic Energy

**61.** (I) An automobile engine develops a torque of 245 m · N at 3150 rpm. What is the horsepower of the engine?

**62.** (I) A centrifuge rotor has a moment of inertia of $3.25 \times 10^{-2}$ kg · m$^2$. How much energy is required to bring it from rest to 8750 rpm?

**63.** (II) Estimate the kinetic energy of the Earth with respect to the Sun as the sum of two terms, (*a*) that due to its daily rotation about its axis, and (*b*) that due to its yearly revolution about the Sun. [Assume the Earth is a uniform sphere with mass $= 6.0 \times 10^{24}$ kg, radius $= 6.4 \times 10^6$ m, and is $1.5 \times 10^8$ km from the Sun.]

**64.** (II) A rotating uniform cylindrical platform of mass 220 kg and radius 5.5 m slows down from 3.8 rev/s to rest in 18 s when the driving motor is disconnected. Estimate the power output of the motor (hp) required to maintain a steady speed of 3.8 rev/s.

**65.** (II) A merry-go-round has a mass of 1240 kg and a radius of 7.50 m. How much net work is required to accelerate it from rest to a rotation rate of 1.00 revolution per 7.00 s? Assume it is a solid cylinder.

**66.** (II) A uniform thin rod of length $\ell$ and mass $M$ is suspended freely from one end. It is pulled to the side an angle $\theta$ and released. If friction can be ignored, what is its angular velocity, and the speed of its free end, at the lowest point?

**67.** (II) Two masses, $m_A = 35.0$ kg and $m_B = 41.0$ kg, are connected by a rope that hangs over a pulley (as in Fig. 10–67). The pulley is a uniform cylinder of radius $R = 0.311$ m and mass 3.1 kg. Initially $m_A$ is on the ground and $m_B$ rests 2.5 m above the ground. If the system is released, use conservation of energy to determine the speed of $m_B$ just before it strikes the ground. Assume the pulley bearing is frictionless.

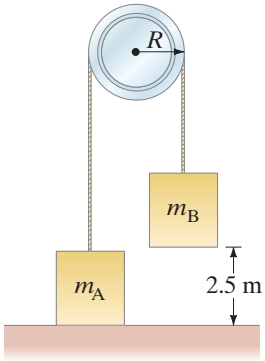

**FIGURE 10–67** Problem 67.

**68.** (III) A 2.30-m-long pole is balanced vertically on its tip. It starts to fall and its lower end does not slip. What will be the speed of the upper end of the pole just before it hits the ground? [*Hint*: Use conservation of energy.]

## 10–9 Rotational Plus Translational Motion

**69.** (I) Calculate the translational speed of a uniform solid cylinder when it reaches the bottom of an incline 6.50 m high. Assume it starts from rest and rolls without slipping.

**70.** (I) A bowling ball of mass 7.3 kg and radius 9.0 cm rolls without slipping down a lane at 3.7 m/s. Calculate its total kinetic energy.

**71.** (II) A uniform solid sphere of radius $r_0 = 24.5$ cm and mass $m = 1.60$ kg starts from rest and rolls without slipping down a 30.0° incline that is 10.0 m long. (*a*) Calculate its translational and rotational speeds when it reaches the bottom. (*b*) What is the ratio of translational to rotational kinetic energy at the bottom? Avoid putting in numbers until the end so you can answer: (*c*) do your answers in (*a*) and (*b*) depend on the radius of the sphere or its mass?

**72.** (II) A narrow but solid spool of thread has radius $R$ and mass $M$. If you pull up on the thread so that the CM of the spool remains suspended in the air at the same place as it unwinds, (*a*) what force must you exert on the thread? (*b*) How much work have you done by the time the spool turns with angular velocity $\omega$?

**73.** (II) A solid rubber ball rests on the floor of a railroad car when the car begins moving with acceleration $a$. Assuming the ball rolls without slipping, what is its acceleration relative to (*a*) the car and (*b*) the ground?

**74.** (II) A thin, hollow 0.545-kg section of pipe of radius 12.0 cm starts rolling (from rest) down a 17.5° incline 5.60 m long. (*a*) If the pipe rolls without slipping, what will be its speed at the base of the incline? (*b*) What will be its total kinetic energy at the base of the incline? (*c*) What minimum value must the coefficient of static friction have if the pipe is not to slip?

***75.** (II) In Example 10–21, (*a*) how far has the ball moved down the lane when it starts rolling without slipping? (*b*) What are its final linear and rotational speeds?

**76.** (II) A ball of radius $r_0$ rolls on the inside of a track of radius $R_0$ (see Fig. 10–68). If the ball starts from rest at the vertical edge of the track, what will be its speed when it reaches the lowest point of the track, rolling without slipping the whole way?

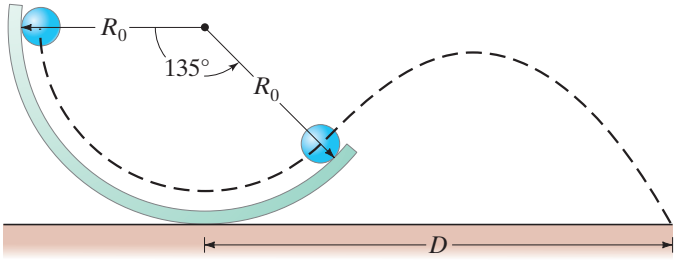

**FIGURE 10–68** Problems 76 and 77.

**77.** (III) A small sphere of radius $r_0 = 1.5$ cm rolls without slipping on the track shown in Fig. 10–68 whose radius is $R_0 = 26.0$ cm. The sphere starts rolling at a height $R_0$ above the bottom of the track. When it leaves the track after passing through an angle of 135° as shown, (*a*) what will be its speed, and (*b*) at what distance $D$ from the base of the track will the sphere hit the ground? (Ignore thickness of track.)

***78.** (III) A wheel with rotational inertia $I = \frac{1}{2}MR^2$ about its horizontal central axle is set spinning with initial angular speed $\omega_0$. It is then lowered, and at the instant its edge touches the ground the speed of the axle (and CM) is zero. Initially the wheel slips when it touches the ground, but then begins to move forward and eventually rolls without slipping. (*a*) In what direction does friction act on the slipping wheel? (*b*) How long does the wheel slip before it begins to roll without slipping? (*c*) What is the wheel's final translational speed, $v_{CM}$? [*Hint*: Use $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$, $\Sigma\tau_{CM} = I_{CM}\alpha_{CM}$, and recall that only when there is rolling without slipping is $v_{CM} = \omega R$.]

**79.** (III) The 1100-kg mass of a car includes four tires, each of mass 35 kg (including wheels) and diameter 0.80 m. Assume each tire and wheel combination acts as a solid cylinder. Determine (*a*) the total kinetic energy of the car when traveling 95 km/h and (*b*) the fraction of the kinetic energy in the tires and wheels. (*c*) If the car is initially at rest and is then pulled by a tow truck with a force of 1500 N, what is the acceleration of the car? Ignore frictional losses. (*d*) What percent error would you make in part (*c*) if you ignored the rotational inertia of the tires and wheels?

### *10–10 Rolling Sphere Slows Down

***80.** (II) A rolling ball slows down because the normal force does not pass exactly through the CM of the ball, but passes in front of the CM. Using Fig. 10–42, show that the torque resulting from the normal force ($\tau_N = \ell F_N$ in Fig. 10–42) is $\frac{2}{5}$ of that due to the frictional force, $\tau_{fr} = r_0 F$ where $r_0$ is the ball's radius; that is, show that $\tau_N = \frac{2}{5}\tau_{fr}$.

## General Problems

**81.** A 1.6-kg grindstone in the shape of a uniform cylinder of radius 0.20 m acquires a rotational rate of 22 rev/s from rest over a 6.0-s interval at constant angular acceleration. Calculate the torque delivered by the motor.

**82.** On a 12.0-cm-diameter *audio compact* disc (CD), digital bits of information are encoded sequentially along an outward spiraling path. The spiral starts at radius $R_1 = 2.5$ cm and winds its way out to radius $R_2 = 5.8$ cm. To read the digital information, a CD player rotates the CD so that the player's readout laser scans along the spiral's sequence of bits at a constant linear speed of 1.25 m/s. Thus the player must accurately adjust the rotational frequency $f$ of the CD as the laser moves outward. Determine the values for $f$ (in units of rpm) when the laser is located at $R_1$ and when it is at $R_2$.

**83.** (*a*) A yo-yo is made of two solid cylindrical disks, each of mass 0.050 kg and diameter 0.075 m, joined by a (concentric) thin solid cylindrical hub of mass 0.0050 kg and diameter 0.013 m. Use conservation of energy to calculate the linear speed of the yo-yo just before it reaches the end of its 1.0-m-long string, if it is released from rest. (*b*) What fraction of its kinetic energy is rotational?

**84.** A cyclist accelerates from rest at a rate of 1.00 m/s$^2$. How fast will a point at the top of the rim of the tire (diameter = 68.0 cm) be moving after 2.75 s? [*Hint*: At any moment, the lowest point on the tire is in contact with the ground and is at rest—see Fig. 10–69.]

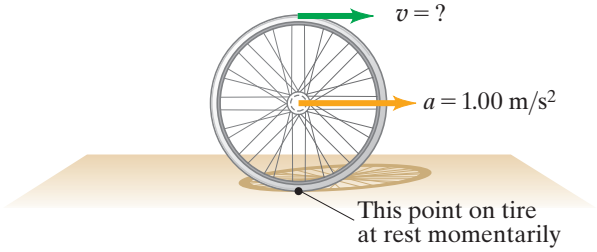

**FIGURE 10–69** Problem 84.

**85.** Suppose David puts a 0.60-kg rock into a sling of length 1.5 m and begins whirling the rock in a nearly horizontal circle, accelerating it from rest to a rate of 75 rpm after 4.5 s. What is the torque required to achieve this feat, and where does the torque come from?

**86.** A large spool of rope rolls on the ground with the end of the rope lying on the top edge of the spool. A person grabs the end of the rope and walks a distance $\ell$, holding onto it, Fig. 10–70. The spool rolls behind the person without slipping. What length of rope unwinds from the spool? How far does the spool's center of mass move?

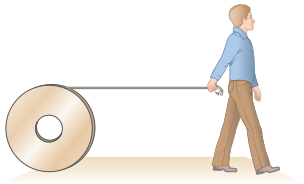

**FIGURE 10–70** Problem 86.

**87.** **Bicycle gears**: (*a*) How is the angular velocity $\omega_R$ of the rear wheel of a bicycle related to the angular velocity $\omega_F$ of the front sprocket and pedals? Let $N_F$ and $N_R$ be the number of teeth on the front and rear sprockets, respectively, Fig. 10–71, and $R_F$ and $R_R$ their respective radii. The teeth are spaced the same on both sprockets and the rear sprocket is firmly attached to the rear wheel. (*b*) Evaluate the ratio $\omega_R/\omega_F$ when the front and rear sprockets have 52 and 13 teeth, respectively, and (*c*) when they have 42 and 28 teeth.

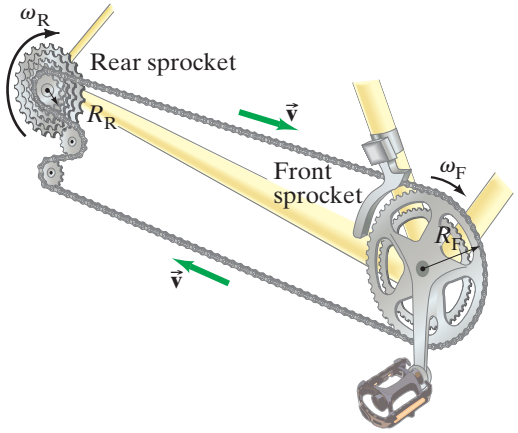

**FIGURE 10–71** Problem 87.

**88.** A string passing over a pulley has a 3.80-kg mass hanging from one end and a 3.05-kg mass hanging from the other end. The pulley is a uniform solid cylinder of radius 4.0 cm and mass 0.60 kg. (*a*) If the bearings of the pulley were frictionless, what would be the acceleration of the two masses? (*b*) In fact, it is found that if the heavier mass is given a downward speed of 0.20 m/s, it comes to rest in 6.2 s. What is the average frictional torque acting on the pulley?

**89.** Figure 10–72 illustrates an $H_2O$ molecule. The O—H bond length is 0.096 nm and the H—O—H bonds make an angle of 104°. Calculate the moment of inertia of the $H_2O$ molecule (assume the atoms are points) about an axis passing through the center of the oxygen atom (*a*) perpendicular to the plane of the molecule, and (*b*) in the plane of the molecule, bisecting the H—O—H bonds.

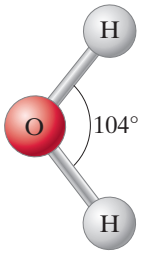

**FIGURE 10–72** Problem 89.

**90.** A hollow cylinder (hoop) is rolling on a horizontal surface at speed $v = 3.0$ m/s when it reaches an 18° incline. (*a*) How far up the incline will it go? (*b*) How long will it be on the incline before it arrives back at the bottom?

**91.** What minimum horizontal force $F$ is needed to pull a wheel of radius $R$ and mass $M$ over a step of height $h$ as shown in Fig. 10–73 ($R > h$)? (*a*) Assume the force is applied at the top edge as shown. (*b*) Assume the force is applied instead at the wheel's center.

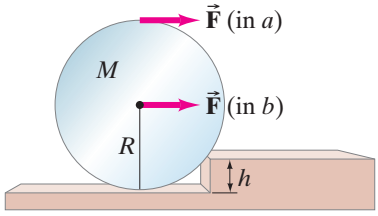

**FIGURE 10–73** Problem 91.

**92.** A 140-g baseball, with a diameter of 7.5 cm, is pitched at 145 km/h. It spins at 1200 rpm. If the baseball is assumed to be a uniform solid sphere, what fraction of its kinetic energy is rotational?

**93.** If the coefficient of static friction between a car's tires and the pavement is 0.65, calculate the minimum torque that must be applied to the 66-cm-diameter tire of a 1250-kg automobile in order to "lay rubber" (make the wheels spin, slipping as the car accelerates). Assume each wheel supports an equal share of the weight.

**94.** A 4.00-kg mass and a 3.00-kg mass are attached to opposite ends of a thin 42.0-cm-long horizontal rod (Fig. 10–74). The system is rotating at angular speed $\omega = 5.20$ rad/s about a vertical axle at the center of the rod. Determine (*a*) the kinetic energy $K$ of the system, and (*b*) the net force on each mass. (*c*) Repeat parts (*a*) and (*b*) assuming that the axle passes through the CM of the system.

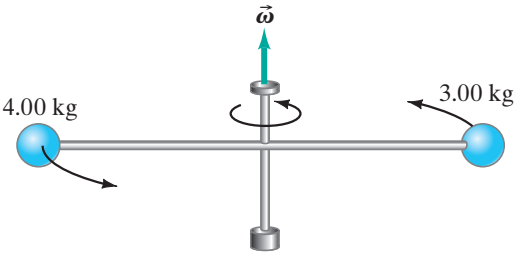

**FIGURE 10–74** Problem 94.

**95.** The radius of the roll of paper shown in Fig. 10–75 is 7.6 cm and its moment of inertia is $I = 3.3 \times 10^{-3}$ kg · m$^2$. A force of 2.5 N is exerted on the end of the roll for 1.1 s; the paper does not tear so it unrolls. A constant friction torque of 0.11 m · N is exerted on the roll which gradually brings it to a stop. Assuming that the paper's thickness is negligible, calculate (*a*) the length of paper that unrolls during the time that the force is applied (1.1 s) and (*b*) the length of paper that unrolls from the time the force ends to the time when the roll has stopped moving.

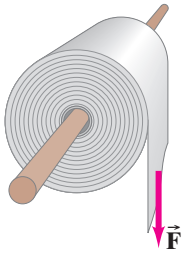

**FIGURE 10–75** Problem 95.

**96.** A solid uniform disk of mass 21.0 kg and radius 85.0 cm is at rest flat on a frictionless surface. Figure 10–76 shows a view from above. A string is wrapped around the rim of the disk and a constant force of 35.0 N is applied to the string. The string does not slip on the rim. (*a*) In what direction does the CM move? When the CM has moved a distance of 5.2 m, determine (*b*) how fast the CM is moving, (*c*) how fast the disk is spinning (in radians per second), and (*d*) how much string has unwrapped from around the rim.

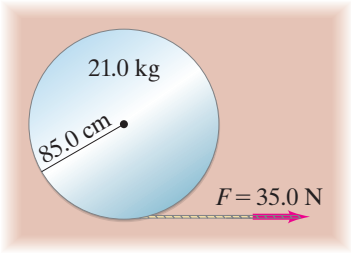

**FIGURE 10–76** Problem 96, looking down on the disk.

**97.** A marble of mass $m$ and radius $r$ rolls along the looped rough track of Fig. 10–77. What is the minimum value of the vertical height $h$ that the marble must drop if it is to reach the highest point of the loop without leaving the track? (*a*) Assume $r \ll R$; (*b*) do not make this assumption. Ignore frictional losses.

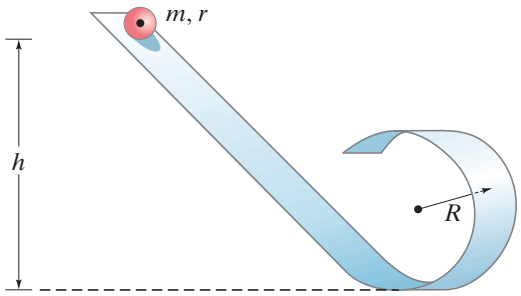

**FIGURE 10–77** Problem 97.

**98.** The density (mass per unit length) of a thin rod of length $\ell$ increases uniformly from $\lambda_0$ at one end to $3\lambda_0$ at the other end. Determine the moment of inertia about an axis perpendicular to the rod through its geometric center.

**99.** If a billiard ball is hit in just the right way by a cue stick, the ball will roll without slipping immediately after losing contact with the stick. Consider a billiard ball (radius $r$, mass $M$) at rest on a horizontal pool table. A cue stick exerts a constant horizontal force $F$ on the ball for a time $t$ at a point that is a height $h$ above the table's surface (see Fig. 10–78). Assume that the coefficient of static friction between the ball and table is $\mu_s$. Determine the value for $h$ so that the ball will roll without slipping immediately after losing contact with the stick.

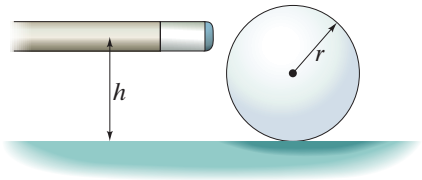

**FIGURE 10–78** Problem 99.

**100.** A 5.0-m-long ladder is leaning against the side of a building making a 35° angle with the building. When a person is about 1/3 of the way up, the ladder slips and falls to the ground in 3.0 s. What is the average angular acceleration of the ladder as it falls?

**101.** When bicycle and motorcycle riders "pop a wheelie," a large acceleration causes the bike's front wheel to leave the ground. Let $M$ be the total mass of the bike-plus-rider system; let $x$ and $y$ be the horizontal and vertical distance of this system's CM from the rear wheel's point of contact with the ground (Fig. 10–79). (*a*) Determine the horizontal acceleration $a$ required to barely lift the bike's front wheel off of the ground. (*b*) To minimize the acceleration necessary to pop a wheelie, should $x$ be made as small or as large as possible? How about $y$? How should a rider position his or her body on the bike in order to achieve these optimal values for $x$ and $y$? (*c*) If $x = 35$ cm and $y = 95$ cm, find $a$.

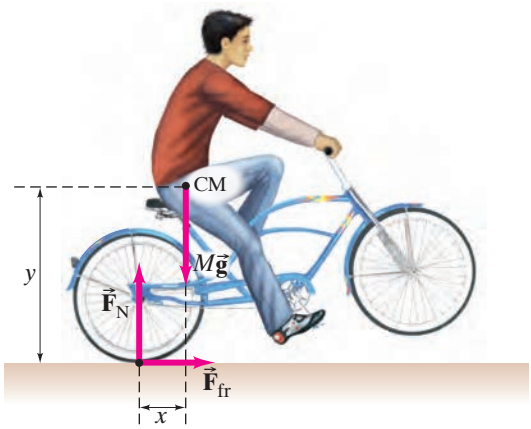

**FIGURE 10–79** Problem 101.

**102.** A crucial part of a piece of machinery starts as a flat uniform cylindrical disk of radius $R_0$ and mass $M$. It then has a circular hole of radius $R_1$ drilled into it (Fig. 10–80). The hole's center is a distance $h$ from the center of the disk. Find the moment of inertia of this disk (with off-center hole) when rotated about its center, C. [*Hint*: Consider a solid disk and "subtract" the hole; use the parallel-axis theorem.]

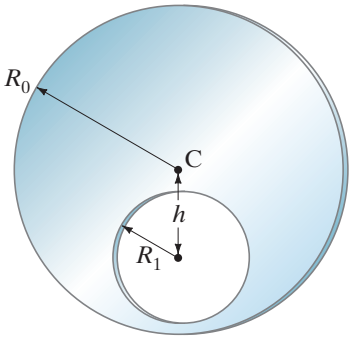

**FIGURE 10–80** Problem 102.

**103.** A thin rod of length $\ell$ stands vertically on a table. The rod begins to fall, but its lower end does not slide. (*a*) Determine the angular velocity of the rod as a function of the angle $\phi$ it makes with the tabletop. (*b*) What is the speed of the tip of the rod just before it strikes the table?

**104.** A cord connected at one end to a block which can slide on an inclined plane has its other end wrapped around a cylinder resting in a depression at the top of the plane as shown in Fig. 10–81. Determine the speed of the block after it has traveled 1.80 m along the plane, starting from rest. Assume (*a*) there is no friction, (*b*) the coefficient of friction between all surfaces is $\mu = 0.035$. [*Hint*: In part (*b*) first determine the normal force on the cylinder, and make any reasonable assumptions needed.]

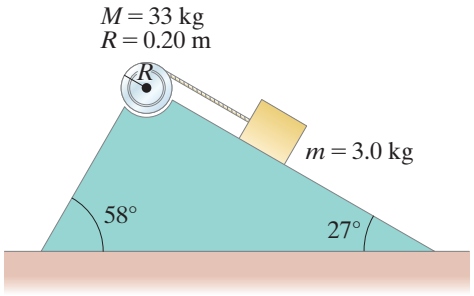

**FIGURE 10–81** Problem 104.

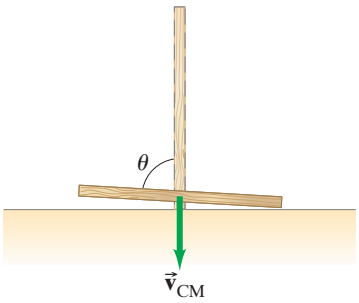
***105.** (*a*) For the yo-yo-like cylinder of Example 10–20, we saw that the downward acceleration of its CM was $a = \frac{2}{3}g$. If it starts from rest, what will be the CM velocity after it has fallen a distance $h$? (*b*) Now use conservation of energy to determine the cylinder's CM velocity after it has fallen a distance $h$, starting from rest.

**106.** A thin uniform stick of mass $M$ and length $\ell$ is positioned vertically, with its tip on a frictionless table. It is released and allowed to fall. Determine the speed of its CM just before it hits the table (Fig. 10–82).



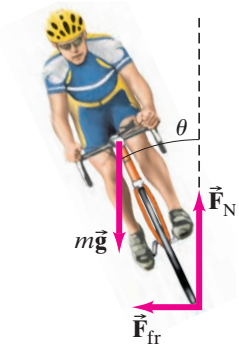


**FIGURE 10–82**
Problem 106.

**107.** One possibility for a low-pollution automobile is for it to use energy stored in a heavy rotating **flywheel**. Suppose such a car has a total mass of 1200 kg, uses a uniform cylindrical flywheel of diameter 1.50 m and mass 270 kg, and should be able to travel 350 km without needing a flywheel "spinup." (*a*) Make reasonable assumptions (average frictional retarding force on car = 450 N, thirty acceleration periods from rest to 95 km/h, equal uphill and downhill, and that energy can be put back into the flywheel as the car goes downhill), and estimate what total energy needs to be stored in the flywheel. (*b*) What is the angular velocity of the flywheel when it has a full "energy charge"? (*c*) About how long would it take a 150-hp motor to give the flywheel a full energy charge before a trip? [N.B. Such a car carries dangers, especially when turning. It can flip over. Easier to see after we discuss angular momentum in the next Chapter.]

**108.** A bicyclist traveling with speed $v = 8.5$ m/s on a flat road is making a turn with a radius $r = 13$ m. There are three forces acting on the cyclist and cycle: the normal force $(\vec{\mathbf{F}}_N)$ and friction force $(\vec{\mathbf{F}}_{fr})$ exerted by the road on the tires; and $m\vec{\mathbf{g}}$, the total weight of the cyclist and cycle. Ignore the small mass of the wheels. (*a*) Explain carefully why the angle $\theta$ the bicycle makes with the vertical (Fig. 10–83) must be given by $\tan\theta = F_{fr}/F_N$ if the cyclist is to maintain balance. (*b*) Calculate $\theta$ for the values given. [*Hint*: Consider the force needed to provide the centripetal acceleration of the bicycle and rider going around the curve.] (*c*) If the coefficient of static friction between tires and road is $\mu_s = 0.65$, what is the minimum turning radius?

(a) (b)

**FIGURE 10–83** Problem 108.

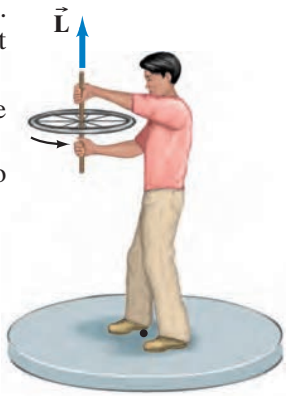
## ANSWERS TO EXERCISES

**A:** $f = 0.076$ Hz; $T = 13$ s.
**B:** $\vec{\mathbf{F}}_A$.
**C:** Yes; $\frac{1}{12}M\ell^2 + M(\frac{1}{2}\ell)^2 = \frac{1}{3}M\ell^2$.
**D:** $4 \times 10^{17}$ J.
**E:** (*c*).
**F:** $a = \frac{1}{3}g$. [*Hint*: $\tau = F_T(R/2)$ and $a = (R/2)\alpha$]

This skater is doing a spin. When her arms are spread outward horizontally, she spins less fast than when her arms are held close to the axis of rotation, as at this moment in the photograph. This is an example of the conservation of angular momentum.

Angular momentum, which we study in this Chapter, is conserved only if no net torque acts on the object or system. Otherwise, the rate of change of angular momentum is proportional to the net applied torque—which, if zero, means the angular momentum is *conserved*. In this Chapter we also examine more complicated aspects of rotational motion.

CHAPTER 11



# Angular Momentum; General Rotation

## CONTENTS

11–1 Angular Momentum—Objects Rotating About a Fixed Axis
11–2 Vector Cross Product; Torque as a Vector
11–3 Angular Momentum of a Particle
11–4 Angular Momentum and Torque for a System of Particles; General Motion
11–5 Angular Momentum and Torque for a Rigid Object
11–6 Conservation of Angular Momentum
*11–7 The Spinning Top and Gyroscope
11–8 Rotating Frames of Reference; Inertial Forces
*11–9 The Coriolis Effect

**CHAPTER-OPENING QUESTION—Guess now!**

You are standing on a platform at rest, but that is free to rotate. You hold a spinning bicycle wheel by its axle as shown here. You then flip the wheel over so its axle points down. What happens then?

**(a)** The platform starts rotating in the direction the bicycle wheel was originally rotating.
**(b)** The platform starts rotating in the direction opposite to the original rotation of the bicycle wheel.
**(c)** The platform stays at rest.
**(d)** The platform turns only while you are flipping the wheel.
**(e)** None of these is correct.

In Chapter 10 we dealt with the kinematics and dynamics of a rigid object rotating about an axis whose direction is fixed in an inertial reference frame. We analyzed the motion in terms of the rotational equivalent of Newton's laws (torque plays the role that force does for translational motion), as well as rotational kinetic energy.

To keep the axis of a rotating object fixed, the object must usually be constrained by external supports (such as bearings at the end of an axle). The motion of objects that are not constrained to rotate about a fixed axis is more difficult to describe and analyze. Indeed, the complete analysis of the general rotational motion of an object (or system of objects) is very complicated, and we will only look at some aspects of general rotational motion in this Chapter.

We start this Chapter by introducing the concept of *angular momentum*, which is the rotational analog of linear momentum. We first treat angular momentum and its conservation for an object rotating about a fixed axis. After that, we examine the vector nature of torque and angular momentum. We will derive some general theorems and apply them to some interesting types of motion, and we will see some examples of axis direction changing.

# 11–1 Angular Momentum—Objects Rotating About a Fixed Axis

In Chapter 10 we saw that if we use the appropriate angular variables, the kinematic and dynamic equations for rotational motion are analogous to those for ordinary linear motion. In like manner, the linear momentum, $p = mv$, has a rotational analog. It is called **angular momentum**, $L$. We consider first the case of an object, with moment of inertia $I$, that is rotating about a fixed axis through the CM. The angular momentum of this object is

$$L = I\omega, \tag{11–1}$$

where $\omega$ is the object's angular velocity. The SI units for $L$ are $\text{kg} \cdot \text{m}^2/\text{s}$ which has no special name.

We saw in Chapter 9 (Section 9–1) that Newton's second law can be written not only as $\Sigma F = ma$, but also more generally in terms of momentum (Eq. 9–2), $\Sigma F = dp/dt$. In a similar way, the rotational equivalent of Newton's second law, which we saw in Eqs. 10–14 and 10–15 can be written as $\Sigma\tau = I\alpha$, can also be written in terms of angular momentum. From Eq. 10–3b, the angular acceleration $\alpha = d\omega/dt$. Then $I\alpha = I(d\omega/dt) = d(I\omega)/dt = dL/dt$, so

$$\Sigma\tau = \frac{dL}{dt}. \tag{11–2}$$

*NEWTON'S SECOND LAW FOR ROTATION*

This derivation assumes that the moment of inertia, $I$, remains constant. However, Eq. 11–2 is valid even if the moment of inertia changes, and it applies also to a *system* of objects rotating about a fixed axis where $\Sigma\tau$ is the net external torque (discussed in Section 11–4). Equation 11–2 is *Newton's second law for rotational motion* about a fixed axis, and is also valid for a moving object if its rotation is about an axis passing through its center of mass (as for Eq. 10–15).

## Conservation of Angular Momentum

Angular momentum is an important concept in physics because, under certain conditions, it is a conserved quantity. What are the conditions for which it is conserved? From Eq. 11–2 we see that if the net external torque $\Sigma\tau$ on an object (or system of objects) is zero, then

$$\frac{dL}{dt} = 0 \quad \text{and} \quad L = I\omega = \text{constant.} \qquad [\Sigma\tau = 0]$$

This is the **law of conservation of angular momentum** for a rotating object:

**The total angular momentum of a rotating object remains constant if the net external torque acting on it is zero.**

*CONSERVATION OF ANGULAR MOMENTUM*

The law of conservation of angular momentum is one of the great conservation laws of physics, along with those for energy and linear momentum.

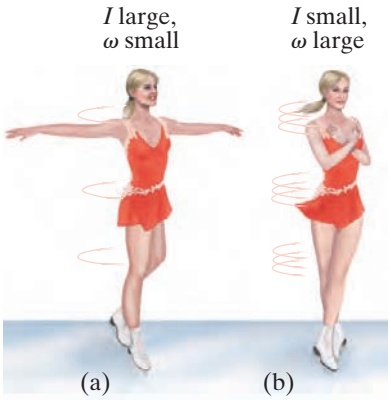


**FIGURE 11–1** A skater spinning on ice, illustrating conservation of angular momentum: (a) $I$ is large and $\omega$ is small; (b) $I$ is smaller so $\omega$ is larger.

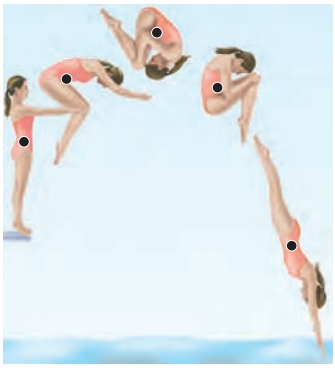
When there is zero net torque acting on an object, and the object is rotating about a fixed axis or about an axis through its center of mass whose direction does not change, we can write



$$I\omega = I_0\omega_0 = \text{constant}.$$

$I_0$ and $\omega_0$ are the moment of inertia and angular velocity, respectively, about that axis at some initial time $(t = 0)$, and $I$ and $\omega$ are their values at some other time. The parts of the object may alter their positions relative to one another, so that $I$ changes. But then $\omega$ changes as well, so that the product $I\omega$ remains constant.

Many interesting phenomena can be understood on the basis of conservation of angular momentum. Consider a skater doing a spin on the tips of her skates, Fig. 11–1. She rotates at a relatively low speed when her arms are outstretched, but when she brings her arms in close to her body, she suddenly spins much faster. From the definition of moment of inertia, $I = \Sigma mR^2$, it is clear that when she pulls her arms in closer to the axis of rotation, $R$ is reduced for the arms so her moment of inertia is reduced. Since the angular momentum $I\omega$ remains constant (we ignore the small torque due to friction), if $I$ decreases, then the angular velocity $\omega$ must increase. If the skater reduces her moment of inertia by a factor of 2, she will then rotate with twice the angular velocity.

**EXERCISE A** When a spinning figure skater pulls in her arms, her moment of inertia decreases; to conserve angular momentum, her angular velocity increases. Does her rotational kinetic energy also increase? If so, where does the energy come from?

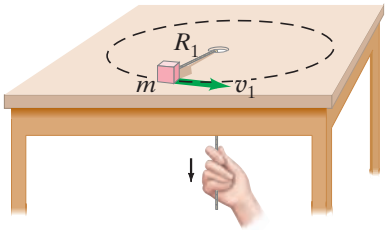


**FIGURE 11–2** A diver rotates faster when arms and legs are tucked in than when they are outstretched. Angular momentum is conserved.

A similar example is the diver shown in Fig. 11–2. The push as she leaves the board gives her an initial angular momentum about her center of mass. When she curls herself into the tuck position, she rotates quickly one or more times. She then stretches out again, increasing her moment of inertia which reduces the angular velocity to a small value, and then she enters the water. The change in moment of inertia from the straight position to the tuck position can be a factor of as much as $3\frac{1}{2}$.

Note that for angular momentum to be conserved, the net torque must be zero, but the net force does not necessarily have to be zero. The net force on the diver in Fig. 11–2, for example, is not zero (gravity is acting), but the net torque about her CM is zero because the force of gravity can be considered to act at her center of mass.

**FIGURE 11–3** Example 11–1.

**EXAMPLE 11–1 Object rotating on a string of changing length.** A small mass $m$ attached to the end of a string revolves in a circle on a frictionless tabletop. The other end of the string passes through a hole in the table (Fig. 11–3). Initially, the mass revolves with a speed $v_1 = 2.4\,\text{m/s}$ in a circle of radius $R_1 = 0.80\,\text{m}$. The string is then pulled slowly through the hole so that the radius is reduced to $R_2 = 0.48\,\text{m}$. What is the speed, $v_2$, of the mass now?

**APPROACH** There is no net torque on the mass $m$ because the force exerted by the string to keep it moving in a circle is exerted toward the axis; hence the lever arm is zero. We can thus apply conservation of angular momentum.

**SOLUTION** Conservation of angular momentum gives

$$I_1\omega_1 = I_2\omega_2.$$

Our small mass is essentially a particle whose moment of inertia about the hole is $I = mR^2$ (Eq. 10–11), so we have

$$mR_1^2\omega_1 = mR_2^2\omega_2,$$

or

$$\omega_2 = \omega_1\left(\frac{R_1^2}{R_2^2}\right).$$

Then, since $v = R\omega$, we can write

$$v_2 = R_2\omega_2 = R_2\omega_1\left(\frac{R_1^2}{R_2^2}\right) = R_2\frac{v_1}{R_1}\left(\frac{R_1^2}{R_2^2}\right) = v_1\frac{R_1}{R_2}$$
$$= (2.4\,\text{m/s})\left(\frac{0.80\,\text{m}}{0.48\,\text{m}}\right) = 4.0\,\text{m/s}.$$

The speed increases as the radius decreases.

**EXAMPLE 11–2** **Clutch.** A simple clutch consists of two cylindrical plates that can be pressed together to connect two sections of an axle, as needed, in a piece of machinery. The two plates have masses $M_A = 6.0\,\text{kg}$ and $M_B = 9.0\,\text{kg}$, with equal radii $R_0 = 0.60\,\text{m}$. They are initially separated (Fig. 11–4). Plate $M_A$ is accelerated from rest to an angular velocity $\omega_1 = 7.2\,\text{rad/s}$ in time $\Delta t = 2.0\,\text{s}$. Calculate (*a*) the angular momentum of $M_A$, and (*b*) the torque required to have accelerated $M_A$ from rest to $\omega_1$. (*c*) Next, plate $M_B$, initially at rest but free to rotate without friction, is placed in firm contact with freely rotating plate $M_A$, and the two plates then both rotate at a constant angular velocity $\omega_2$, which is considerably less than $\omega_1$. Why does this happen, and what is $\omega_2$?

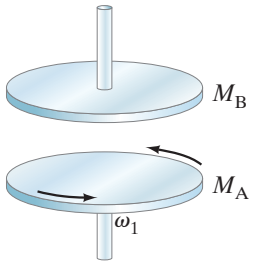

**FIGURE 11–4** Example 11–2, two freely rotating plates. (In a clutch assembly, one plate is made to rotate by a motor. At a certain moment, the machinery is meant to have a second part also rotate; at that moment the two plates are forced together.) In this Example 11–2 we are dealing with two plates that are now not connected to a motor or anything else, and can spin freely.

**APPROACH** We use the definition of angular momentum $L = I\omega$ (Eq. 11–1) plus Newton's second law for rotation, Eq. 11–2.

**SOLUTION** (*a*) The angular momentum of $M_A$, a cylinder, is

$$L_A = I_A\omega_1 = \tfrac{1}{2}M_A R_0^2\omega_1 = \tfrac{1}{2}(6.0\,\text{kg})(0.60\,\text{m})^2(7.2\,\text{rad/s}) = 7.8\,\text{kg}\cdot\text{m}^2/\text{s}.$$

(*b*) The plate started from rest so the torque, assumed constant, was

$$\tau = \frac{\Delta L}{\Delta t} = \frac{7.8\,\text{kg}\cdot\text{m}^2/\text{s} - 0}{2.0\,\text{s}} = 3.9\,\text{m}\cdot\text{N}.$$

(*c*) Initially, before contact, $M_A$ is rotating at constant $\omega_1$ (we ignore friction). When plate B comes in contact, why is their joint rotation speed less? You might think in terms of the torque each exerts on the other upon contact. But quantitatively, it's easier to use conservation of angular momentum, since no external torques are assumed to act. Thus

$$\text{angular momentum before} = \text{angular momentum after}$$
$$I_A\omega_1 = (I_A + I_B)\omega_2.$$

Solving for $\omega_2$ we find (after cancelling factors of $R_0^2$)

$$\omega_2 = \left(\frac{I_A}{I_A + I_B}\right)\omega_1 = \left(\frac{M_A}{M_A + M_B}\right)\omega_1 = \left(\frac{6.0\,\text{kg}}{15.0\,\text{kg}}\right)(7.2\,\text{rad/s}) = 2.9\,\text{rad/s}.$$

**EXAMPLE 11–3** **ESTIMATE** **Neutron star.** Astronomers detect stars that are rotating extremely rapidly, known as neutron stars. A neutron star is believed to form from the inner core of a massive star that collapsed, under its own gravitation, to a star of very small radius and very high density. Before collapse, suppose the core of such a massive star is the size of our Sun $(r \approx 7 \times 10^5\,\text{km})$ with mass 2.0 times as great as the Sun, and is rotating at a frequency of 1.0 revolution every 100 days. If it were to undergo gravitational collapse to a neutron star of radius 10 km, what would its rotation frequency be? Assume the star is a uniform sphere at all times, and loses no mass.

**PHYSICS APPLIED**
*Neutron star*

**APPROACH** We assume the star is isolated (no external forces), so we can use conservation of angular momentum for this process. We use *r* for the radius of a sphere, as compared to *R* used for distance from an axis of rotation or cylindrical symmetry: see Fig. 10–2.

**SOLUTION** From conservation of angular momentum,

$$I_1\omega_1 = I_2\omega_2,$$

where the subscripts 1 and 2 refer to initial (normal star) and final (neutron star), respectively. Then, assuming no mass is lost in the process $(m_1 = m_2)$,

$$\omega_2 = \left(\frac{I_1}{I_2}\right)\omega_1 = \left(\frac{\frac{2}{5}m_1 r_1^2}{\frac{2}{5}m_2 r_2^2}\right)\omega_1 = \frac{r_1^2}{r_2^2}\omega_1.$$

The frequency $f = \omega/2\pi$, so

$$f_2 = \frac{\omega_2}{2\pi} = \frac{r_1^2}{r_2^2}f_1$$
$$= \left(\frac{7 \times 10^5\,\text{km}}{10\,\text{km}}\right)^2\left(\frac{1.0\,\text{rev}}{100\,\text{d}\,(24\,\text{h/d})\,(3600\,\text{s/h})}\right) \approx 6 \times 10^2\,\text{rev/s},$$

which is 600 Hz or $(600\,\text{rev/s})(60\,\text{s/min}) = 36{,}000\,\text{rpm}$.

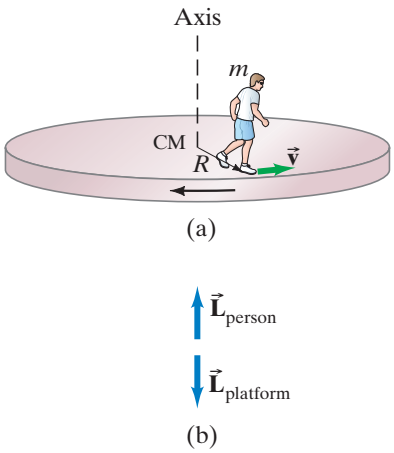

**FIGURE 11–5** (a) A person standing on a circular platform, initially at rest, begins walking along the edge at speed $v$. The platform, mounted on nearly friction-free bearings, begins rotating in the opposite direction, so that (b) the total angular momentum remains zero ($\vec{\mathbf{L}}_{\text{platform}} = -\vec{\mathbf{L}}_{\text{person}}$).

## Directional Nature of Angular Momentum

Angular momentum is a vector, as we shall discuss in detail later in this Chapter. For now we consider the simple case of an object rotating about a fixed axis, and the direction of $\vec{\mathbf{L}}$ is specified by a plus or minus sign, just as we did for one-dimensional linear motion in Chapter 2.

For a symmetrical object rotating about a symmetry axis (such as a cylinder or wheel), the direction of the angular momentum[†] can be taken as the direction of the angular velocity $\vec{\boldsymbol{\omega}}$. That is,

$$\vec{\mathbf{L}} = I\vec{\boldsymbol{\omega}}.$$

As a simple example, consider a person standing at rest on a circular platform capable of rotating friction-free about an axis through its center (that is, a simplified merry-go-round). If the person now starts to walk along the edge of the platform, Fig. 11–5a, the platform starts rotating in the opposite direction. Why? One explanation is that the person's foot exerts a force on the platform. Another explanation (and this is the most useful analysis here) is that this is an example of the conservation of angular momentum. If the person starts walking counterclockwise, the person's angular momentum points upward along the axis of rotation (remember how we defined the direction of $\vec{\boldsymbol{\omega}}$ using the right-hand rule in Section 10–2). The magnitude of the person's angular momentum will be $L = I\omega = (mR^2)(v/R)$, where $v$ is the person's speed (relative to the Earth, not the platform), $R$ is his distance from the rotation axis, $m$ is his mass, and $mR^2$ is his moment of inertia if we consider him a particle (mass concentrated at one point, Eq. 10–11). The platform rotates in the opposite direction, so its angular momentum points downward. If the initial total angular momentum was zero (person and platform at rest), it will remain zero after the person starts walking. That is, the upward angular momentum of the person just balances the oppositely directed downward angular momentum of the platform (Fig. 11–5b), so the total vector angular momentum remains zero. Even though the person exerts a torque on the platform, the platform exerts an equal and opposite torque on the person. So the net torque on the *system* of person plus platform is zero (ignoring friction), and the total angular momentum remains constant.

**EXAMPLE 11–4** **Running on a circular platform.** Suppose a 60-kg person stands at the edge of a 6.0-m-diameter circular platform, which is mounted on frictionless bearings and has a moment of inertia of $1800\ \text{kg}\cdot\text{m}^2$. The platform is at rest initially, but when the person begins running at a speed of 4.2 m/s (with respect to the Earth) around its edge, the platform begins to rotate in the opposite direction as in Fig. 11–5. Calculate the angular velocity of the platform.

**APPROACH** We use conservation of angular momentum. The total angular momentum is zero initially. Since there is no net torque, $\vec{\mathbf{L}}$ is conserved and will remain zero, as in Fig. 11–5. The person's angular momentum is $L_{\text{per}} = (mR^2)(v/R)$, and we take this as positive. The angular momentum of the platform is $L_{\text{plat}} = -I\omega$.

**SOLUTION** Conservation of angular momentum gives

$$L = L_{\text{per}} + L_{\text{plat}}$$

$$0 = mR^2\left(\frac{v}{R}\right) - I\omega.$$

So

$$\omega = \frac{mRv}{I} = \frac{(60\ \text{kg})(3.0\ \text{m})(4.2\ \text{m/s})}{1800\ \text{kg}\cdot\text{m}^2} = 0.42\ \text{rad/s}.$$

**NOTE** The frequency of rotation is $f = \omega/2\pi = 0.067\ \text{rev/s}$ and the period $T = 1/f = 15\ \text{s}$ per revolution.

[†]For more complicated situations of objects rotating about a fixed axis, there will be a component of $\vec{\mathbf{L}}$ along the direction of $\vec{\boldsymbol{\omega}}$ and its magnitude will be equal to $I\vec{\boldsymbol{\omega}}$, but there could be other components as well. If the total angular momentum is conserved, then the component $I\vec{\boldsymbol{\omega}}$ will also be conserved. So our results here can be applied to any rotation about a fixed axis.

**EXERCISE B** Suppose you are standing on the edge of a large freely rotating turntable. If you walk toward the center of the turntable, what will happen? (*a*) The turntable slows down. (*b*) The turntable speeds up. (*c*) Its rotation speed is unchanged. (*d*) The turntable stops. (*e*) You need to know the walking speed to answer.

**CONCEPTUAL EXAMPLE 11–5** **Spinning bicycle wheel.** Your physics teacher is holding a spinning bicycle wheel while he stands on a stationary frictionless turntable (Fig. 11–6). What will happen if the teacher suddenly flips the bicycle wheel over so that it is spinning in the opposite direction?

**RESPONSE** We consider the system of turntable, teacher, and bicycle wheel. The total angular momentum initially is $\vec{\mathbf{L}}$ vertically upward (note black arrow showing direction of rotation). That is also what the system's angular momentum must be afterward, since $\vec{\mathbf{L}}$ is conserved when there is no net torque on the system as a whole. Thus, if the wheel's angular momentum after being flipped over is $-\vec{\mathbf{L}}$ downward, then the angular momentum of teacher plus turntable will have to be $+2\vec{\mathbf{L}}$ upward. We can safely predict that the turntable (and teacher) will begin revolving in the same direction the bike wheel was spinning originally (counterclockwise).

**FIGURE 11–6** Example 11–5.

**EXERCISE C** Return to the Chapter-Opening Question, page 302, and answer it again now. Try to explain why you may have answered differently the first time.

**EXERCISE D** In Example 11–5, Fig. 11–6, what happens to the turntable if the teacher moves the spinning wheel's axis only 90° so it is horizontal? (*a*) It rotates in same direction and speed as in Example 11–5. (*b*) It rotates in that same direction, but slower. (*c*) It rotates in the opposite direction. (*d*) It doesn't start rotating.

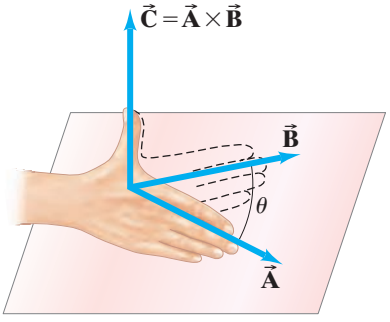
# 11–2 Vector Cross Product; Torque as a Vector

## Vector Cross Product

To deal with the vector nature of angular momentum and torque in general, we will need the concept of the *vector cross product* (often called simply the *vector product* or *cross product*). In general, the **vector** or **cross product** of two vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ is defined as another vector $\vec{\mathbf{C}} = \vec{\mathbf{A}} \times \vec{\mathbf{B}}$ whose *magnitude is*

$$C = |\vec{\mathbf{A}} \times \vec{\mathbf{B}}| = AB \sin\theta, \qquad \textbf{(11–3a)}$$

*where $\theta$ is the angle* ($< 180°$) *between* $\vec{\mathbf{A}}$ *and* $\vec{\mathbf{B}}$, *and whose direction is perpendicular to both* $\vec{\mathbf{A}}$ *and* $\vec{\mathbf{B}}$ *in the sense of the right-hand rule*, Fig. 11–7. The angle $\theta$ is measured between $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ when their tails are together at the same point. According to the right-hand rule, as shown in Fig. 11–7, you orient your right hand so your fingers point along $\vec{\mathbf{A}}$, and when you bend your fingers they point along $\vec{\mathbf{B}}$. When your hand is correctly oriented in this way, your thumb will point along the direction of $\vec{\mathbf{C}} = \vec{\mathbf{A}} \times \vec{\mathbf{B}}$.



The cross product of two vectors, $\vec{\mathbf{A}} = A_x\hat{\mathbf{i}} + A_y\hat{\mathbf{j}} + A_z\hat{\mathbf{k}}$, and $\vec{\mathbf{B}} = B_x\hat{\mathbf{i}} + B_y\hat{\mathbf{j}} + B_z\hat{\mathbf{k}}$, can be written in component form (see Problem 28) as

$$\vec{\mathbf{A}} \times \vec{\mathbf{B}} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ A_x & A_y & A_z \\ B_x & B_y & B_z \end{vmatrix} \qquad \textbf{(11–3b)}$$

$$= (A_yB_z - A_zB_y)\hat{\mathbf{i}} + (A_zB_x - A_xB_z)\hat{\mathbf{j}} + (A_xB_y - A_yB_x)\hat{\mathbf{k}}. \qquad \textbf{(11–3c)}$$

Equation 11–3b is meant to be evaluated using the rules of determinants (and obtain Eq. 11–3c).[†] (Equation 11–3b is not literally a determinant, but a memory aid.)

**FIGURE 11–7** The vector $\vec{\mathbf{C}} = \vec{\mathbf{A}} \times \vec{\mathbf{B}}$ is perpendicular to the plane containing $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$; its direction is given by the right-hand rule.

[†]A vector cross product is not a true vector, but a "pseudovector" or "axial vector" as discussed in Section 10–2. Imagine a mirror behind Fig. 11–7 (as in Fig. 10–10) and you will see that $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ reverse positions and $\vec{\mathbf{C}}$ does not, so $\vec{\mathbf{A}} \times \vec{\mathbf{B}} = -\vec{\mathbf{C}}$ in the mirror.

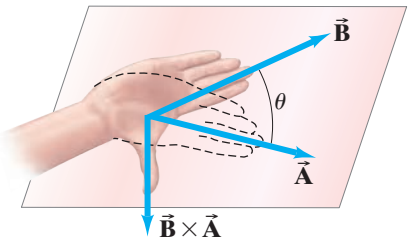


**FIGURE 11–8** The vector $\vec{\mathbf{B}} \times \vec{\mathbf{A}}$ equals $-\vec{\mathbf{A}} \times \vec{\mathbf{B}}$; compare to Fig. 11–7.

**FIGURE 11–9** Exercise E.

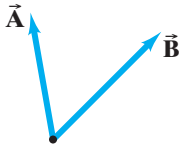

**FIGURE 11–10** The torque due to the force $\vec{\mathbf{F}}$ (in the plane of the wheel) starts the wheel rotating counterclockwise so $\vec{\boldsymbol{\omega}}$ and $\vec{\boldsymbol{\alpha}}$ point out of the page.

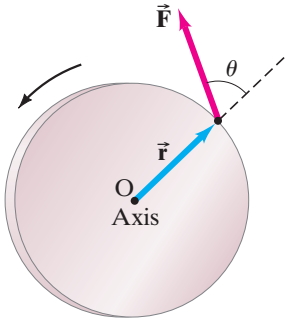

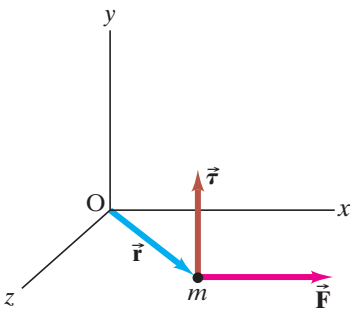

**FIGURE 11–11** $\vec{\boldsymbol{\tau}} = \vec{\mathbf{r}} \times \vec{\mathbf{F}}$, where $\vec{\mathbf{r}}$ is the position vector.

Some properties of the cross product are the following:

$$\vec{\mathbf{A}} \times \vec{\mathbf{A}} = 0 \qquad \textbf{(11–4a)}$$

$$\vec{\mathbf{A}} \times \vec{\mathbf{B}} = -\vec{\mathbf{B}} \times \vec{\mathbf{A}} \qquad \textbf{(11–4b)}$$

$$\vec{\mathbf{A}} \times (\vec{\mathbf{B}} + \vec{\mathbf{C}}) = (\vec{\mathbf{A}} \times \vec{\mathbf{B}}) + (\vec{\mathbf{A}} \times \vec{\mathbf{C}}) \quad \text{[distributive law]} \qquad \textbf{(11–4c)}$$

$$\frac{d}{dt}(\vec{\mathbf{A}} \times \vec{\mathbf{B}}) = \frac{d\vec{\mathbf{A}}}{dt} \times \vec{\mathbf{B}} + \vec{\mathbf{A}} \times \frac{d\vec{\mathbf{B}}}{dt}. \qquad \textbf{(11–4d)}$$

Equation 11–4a follows from Eqs. 11–3 (since $\theta = 0$). So does Eq. 11–4b, since the magnitude of $\vec{\mathbf{B}} \times \vec{\mathbf{A}}$ is the same as that for $\vec{\mathbf{A}} \times \vec{\mathbf{B}}$, but by the right-hand rule the direction is opposite (see Fig. 11–8). Thus the order of the two vectors is crucial. If you change the order, you change the result. That is, the commutative law does *not* hold for the cross product $(\vec{\mathbf{A}} \times \vec{\mathbf{B}} \neq \vec{\mathbf{B}} \times \vec{\mathbf{A}})$, although it does hold for the dot product of two vectors (Section 7–2) and for the product of scalars. Note in Eq. 11–4d that the order of quantities in the two products on the right must not be interchanged (because of Eq. 11–4b). Equation 11–4c follows from Eq. 11–3c (Problem 29).

**EXERCISE E** For the vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ in the plane of the page as shown in Fig. 11–9, in what direction is (i) $\vec{\mathbf{A}} \cdot \vec{\mathbf{B}}$, (ii) $\vec{\mathbf{A}} \times \vec{\mathbf{B}}$, (iii) $\vec{\mathbf{B}} \times \vec{\mathbf{A}}$? (*a*) Into the page; (*b*) out of the page; (*c*) between $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$; (*d*) it is a scalar and has no direction; (*e*) it is zero and has no direction.

## The Torque Vector

Torque is an example of a quantity that can be expressed as a cross product. To see this, let us take a simple example: the thin wheel shown in Fig. 11–10 which is free to rotate about an axle through its center at point O. A force $\vec{\mathbf{F}}$ acts at the edge of the wheel, at a point whose position relative to the center O is given by the position vector $\vec{\mathbf{r}}$ as shown. The force $\vec{\mathbf{F}}$ tends to rotate the wheel (assumed initially at rest) counterclockwise, so the angular velocity $\vec{\boldsymbol{\omega}}$ will point out of the page toward the viewer (remember the right-hand rule from Section 10–2). The torque due to $\vec{\mathbf{F}}$ will tend to increase $\vec{\boldsymbol{\omega}}$, so $\vec{\boldsymbol{\alpha}}$ also points outward along the rotation axis. The relation between angular acceleration and torque that we developed in Chapter 10 for an object rotating about a fixed axis is

$$\Sigma\tau = I\alpha,$$

(Eq. 10–14) where $I$ is the moment of inertia. This scalar equation is the rotational equivalent of $\Sigma F = ma$, and we would like to make it a vector equation just as $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$ is a vector equation. To do so in the case of Fig. 11–10 we must have the direction of $\vec{\boldsymbol{\tau}}$ point outward along the rotation axis, since $\vec{\boldsymbol{\alpha}}$ $(= d\vec{\boldsymbol{\omega}}/dt)$ has that direction; and the magnitude of the torque must be (see Eqs. 10–10 and Fig. 11–10) $\tau = rF_\perp = rF\sin\theta$. We can achieve this by defining the **torque vector** to be the cross product of $\vec{\mathbf{r}}$ and $\vec{\mathbf{F}}$:

$$\vec{\boldsymbol{\tau}} = \vec{\mathbf{r}} \times \vec{\mathbf{F}}. \qquad \textbf{(11–5)}$$

From the definition of the cross product above (Eq. 11–3a) the magnitude of $\vec{\boldsymbol{\tau}}$ will be $rF\sin\theta$ and the direction will be along the axis, as required for this special case.

We will see in Sections 11–3 through 11–5 that if we take Eq. 11–5 as the *general definition of torque*, then the vector relation $\Sigma\vec{\boldsymbol{\tau}} = I\vec{\boldsymbol{\alpha}}$ will hold in general. Thus we state now that Eq. 11–5 is the general definition of torque. It contains both magnitude and direction information. Note that this definition involves the position vector $\vec{\mathbf{r}}$ and thus the torque is being calculated about a point (and not $R$, the distance from the rotation axis, Fig. 10–2). We can choose that point O as we wish.

For a particle of mass $m$ on which a force $\vec{\mathbf{F}}$ is applied, we define the torque about a point O as

$$\vec{\boldsymbol{\tau}} = \vec{\mathbf{r}} \times \vec{\mathbf{F}}$$

where $\vec{\mathbf{r}}$ is the position vector of the particle relative to O (Fig. 11–11). If we have a system of particles (which could be the particles making up a rigid object) the total torque $\vec{\boldsymbol{\tau}}$ on the system will be the sum of the torques on the individual particles:

$$\vec{\boldsymbol{\tau}}_i = \Sigma(\vec{\mathbf{r}}_i \times \vec{\mathbf{F}}_i),$$

where $\vec{\mathbf{r}}_i$ is the position vector of the $i^{\text{th}}$ particle and $\vec{\mathbf{F}}_i$ is the net force on the $i^{\text{th}}$ particle.

**EXAMPLE 11–6** **Torque vector.** Suppose the vector $\vec{\mathbf{r}}$ is in the $xz$ plane, as in Fig. 11–11, and is given by $\vec{\mathbf{r}} = (1.2\,\text{m})\,\hat{\mathbf{i}} + (1.2\,\text{m})\,\hat{\mathbf{k}}$. Calculate the torque vector $\vec{\tau}$ if $\vec{\mathbf{F}} = (150\,\text{N})\,\hat{\mathbf{i}}$.

**APPROACH** We use the determinant form, Eq. 11–3b.

**SOLUTION**
$$\vec{\tau} = \vec{\mathbf{r}} \times \vec{\mathbf{F}} = \begin{vmatrix} \hat{\mathbf{i}} & \hat{\mathbf{j}} & \hat{\mathbf{k}} \\ 1.2\,\text{m} & 0 & 1.2\,\text{m} \\ 150\,\text{N} & 0 & 0 \end{vmatrix} = 0\,\hat{\mathbf{i}} + (180\,\text{m}\cdot\text{N})\,\hat{\mathbf{j}} + 0\,\hat{\mathbf{k}}.$$

So $\tau$ has magnitude $180\,\text{m}\cdot\text{N}$ and points along the positive $y$ axis.

**EXERCISE F** If $\vec{\mathbf{F}} = 5.0\,\text{N}\,\hat{\mathbf{i}}$ and $\vec{\mathbf{r}} = 2.0\,\text{m}\,\hat{\mathbf{j}}$, what is $\vec{\tau}$? (*a*) $10\,\text{m}\cdot\text{N}$, (*b*) $-10\,\text{m}\cdot\text{N}$, (*c*) $10\,\text{m}\cdot\text{N}\,\hat{\mathbf{k}}$, (*d*) $-10\,\text{m}\cdot\text{N}\,\hat{\mathbf{j}}$, (*e*) $-10\,\text{m}\cdot\text{N}\,\hat{\mathbf{k}}$.

# 11–3 Angular Momentum of a Particle

The most general way of writing Newton's second law for the translational motion of a particle (or system of particles) is in terms of the linear momentum $\vec{\mathbf{p}} = m\vec{\mathbf{v}}$ as given by Eq. 9–2 (or 9–5):

$$\Sigma\vec{\mathbf{F}} = \frac{d\vec{\mathbf{p}}}{dt}.$$

The rotational analog of linear momentum is *angular momentum*. Just as the rate of change of $\vec{\mathbf{p}}$ is related to the net force $\Sigma\vec{\mathbf{F}}$, so we might expect the rate of change of angular momentum to be related to the net torque. Indeed, we saw this was true in Section 11–1 for the special case of a rigid object rotating about a fixed axis. Now we will see it is true in general. We first treat a single particle.

Suppose a particle of mass $m$ has momentum $\vec{\mathbf{p}}$ and position vector $\vec{\mathbf{r}}$ with respect to the origin O in some chosen inertial reference frame. Then the general definition of the **angular momentum**, $\vec{\mathbf{L}}$, of the particle about point O is the vector cross product of $\vec{\mathbf{r}}$ and $\vec{\mathbf{p}}$:

$$\vec{\mathbf{L}} = \vec{\mathbf{r}} \times \vec{\mathbf{p}}. \qquad \text{[particle]} \quad \textbf{(11–6)}$$

Angular momentum is a vector whose direction is perpendicular to both $\vec{\mathbf{r}}$ and $\vec{\mathbf{p}}$ as given by the right-hand rule (Fig. 11–12). Its magnitude is given by

$$L = rp\sin\theta$$

or

$$L = rp_\perp = r_\perp p$$

where $\theta$ is the angle between $\vec{\mathbf{r}}$ and $\vec{\mathbf{p}}$ and $p_\perp\,(= p\sin\theta)$ and $r_\perp\,(= r\sin\theta)$ are the components of $\vec{\mathbf{p}}$ and $\vec{\mathbf{r}}$ perpendicular to $\vec{\mathbf{r}}$ and $\vec{\mathbf{p}}$, respectively.

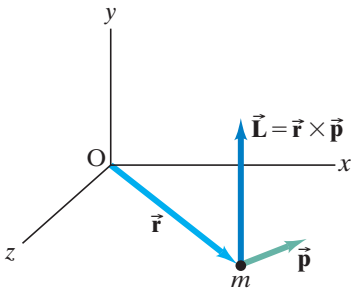

**FIGURE 11–12** The angular momentum of a particle of mass $m$ is given by $\vec{\mathbf{L}} = \vec{\mathbf{r}} \times \vec{\mathbf{p}} = \vec{\mathbf{r}} \times m\vec{\mathbf{v}}$.

Now let us find the relation between angular momentum and torque for a particle. If we take the derivative of $\vec{\mathbf{L}}$ with respect to time we have

$$\frac{d\vec{\mathbf{L}}}{dt} = \frac{d}{dt}(\vec{\mathbf{r}} \times \vec{\mathbf{p}}) = \frac{d\vec{\mathbf{r}}}{dt} \times \vec{\mathbf{p}} + \vec{\mathbf{r}} \times \frac{d\vec{\mathbf{p}}}{dt}.$$

But

$$\frac{d\vec{\mathbf{r}}}{dt} \times \vec{\mathbf{p}} = \vec{\mathbf{v}} \times m\vec{\mathbf{v}} = m(\vec{\mathbf{v}} \times \vec{\mathbf{v}}) = 0,$$

since $\sin\theta = 0$ for this case. Thus

$$\frac{d\vec{\mathbf{L}}}{dt} = \vec{\mathbf{r}} \times \frac{d\vec{\mathbf{p}}}{dt}.$$

If we let $\Sigma\vec{\mathbf{F}}$ represent the resultant force on the particle, then in an inertial reference frame, $\Sigma\vec{\mathbf{F}} = d\vec{\mathbf{p}}/dt$ and

$$\vec{\mathbf{r}} \times \Sigma\vec{\mathbf{F}} = \vec{\mathbf{r}} \times \frac{d\vec{\mathbf{p}}}{dt} = \frac{d\vec{\mathbf{L}}}{dt}.$$

But $\vec{\mathbf{r}} \times \Sigma\vec{\mathbf{F}} = \Sigma\vec{\tau}$ is the net torque on our particle. Hence

$$\Sigma\vec{\tau} = \frac{d\vec{\mathbf{L}}}{dt}. \qquad \text{[particle, inertial frame]} \quad \textbf{(11–7)}$$

The rate of change of angular momentum of a particle equals the net torque applied to it. Equation 11–7 is the rotational equivalent of Newton's second law for a particle.

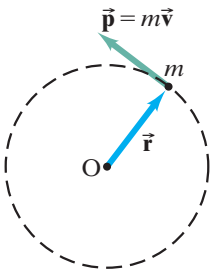

**FIGURE 11–13** The angular momentum of a particle of mass $m$ rotating in a circle of radius $\vec{\mathbf{r}}$ with velocity $\vec{\mathbf{v}}$ is $\vec{\mathbf{L}} = \vec{\mathbf{r}} \times m\vec{\mathbf{v}}$ (Example 11–7).

Equation 11–7 is valid only in an inertial frame since only then is it true that $\Sigma\vec{\mathbf{F}} = d\vec{\mathbf{p}}/dt$, which was used in the proof.

**CONCEPTUAL EXAMPLE 11–7** **A particle's angular momentum.** What is the angular momentum of a particle of mass $m$ moving with speed $v$ in a circle of radius $r$ in a counterclockwise direction?

**RESPONSE** The value of the angular momentum depends on the choice of the point O. Let us calculate $\vec{\mathbf{L}}$ with respect to the center of the circle, Fig. 11–13. Then $\vec{\mathbf{r}}$ is perpendicular to $\vec{\mathbf{p}}$ so $L = |\vec{\mathbf{r}} \times \vec{\mathbf{p}}| = rmv$. By the right-hand rule, the direction of $\vec{\mathbf{L}}$ is perpendicular to the plane of the circle, outward toward the viewer. Since $v = \omega r$ and $I = mr^2$ for a single particle rotating about an axis a distance $r$ away, we can write

$$L = mvr = mr^2\omega = I\omega.$$

# 11–4 Angular Momentum and Torque for a System of Particles; General Motion

## Relation Between Angular Momentum and Torque

Now we consider angular momentum in a more general way where the object is not necessarily symmetric and the rotation axis may not be fixed or through the CM.

Consider a system of $n$ particles which have angular momenta $\vec{\mathbf{L}}_1, \vec{\mathbf{L}}_2, \ldots, \vec{\mathbf{L}}_n$. The system could be anything from a rigid object to a loose assembly of particles whose positions are not fixed relative to each other. The total angular momentum $\vec{\mathbf{L}}$ of the system is defined as the vector sum of the angular momenta of all the particles in the system:

$$\vec{\mathbf{L}} = \sum_{i=1}^{n} \vec{\mathbf{L}}_i. \qquad \textbf{(11–8)}$$

The resultant torque acting on the system is the sum of the net torques acting on all the particles:

$$\vec{\tau}_{\text{net}} = \sum \vec{\tau}_i.$$

This sum includes (1) internal torques due to internal forces that particles of the system exert on other particles of the system, and (2) external torques due to forces exerted by objects outside our system. By Newton's third law, the force each particle exerts on another is equal and opposite (and acts along the same line as) the force that the second particle exerts on the first. Hence the sum of all internal torques adds to zero, and

$$\vec{\tau}_{\text{net}} = \sum_i \vec{\tau}_i = \sum \vec{\tau}_{\text{ext}}.$$

Now we take the time derivative of Eq. 11–8 and use Eq. 11–7 for each particle to obtain

$$\frac{d\vec{\mathbf{L}}}{dt} = \sum_i \frac{d\vec{\mathbf{L}}_i}{dt} = \sum \vec{\tau}_{\text{ext}}$$

or

*NEWTON'S SECOND LAW (rotation; system of particles)*

$$\frac{d\vec{\mathbf{L}}}{dt} = \sum \vec{\tau}_{\text{ext}}. \qquad \text{[inertial reference frame]} \quad \textbf{(11–9a)}$$

This fundamental result states that the time rate of change of the total angular momentum of a system of particles (or a rigid object) equals the resultant external torque on the system. This is **Newton's second law for general rotational motion**. This law is the rotational equivalent of Eq. 9–5, $d\vec{\mathbf{P}}/dt = \Sigma\vec{\mathbf{F}}_{\text{ext}}$ for translational motion. Note that $\vec{\mathbf{L}}$ and $\Sigma\vec{\tau}$ must be calculated about the same origin O.

Equation 11–9a is valid when $\vec{\mathbf{L}}$ and $\vec{\tau}_{\text{ext}}$ are calculated with reference to a point fixed in an inertial reference frame. (In the derivation, we used Eq. 11–7 which is valid only in this case.) It is also valid when $\vec{\tau}_{\text{ext}}$ and $\vec{\mathbf{L}}$ are calculated about a point which is moving uniformly in an inertial reference frame since such

a point can be considered the origin of a second inertial reference frame. It is *not* valid in general when $\vec{\tau}_{\text{ext}}$ and $\vec{\mathbf{L}}$ are calculated about a point that is *accelerating*, except for one special (and very important) case—when that point is the center of mass (CM) of the system:

$$\frac{d\vec{\mathbf{L}}_{\text{CM}}}{dt} = \sum \vec{\tau}_{\text{CM}}. \qquad \text{[even if accelerating]} \quad \textbf{(11–9b)}$$

*NEWTON'S SECOND LAW (for CM even if accelerating)*

Equation 11–9b is valid no matter how the CM moves, and $\Sigma\boldsymbol{\tau}_{\text{CM}}$ is the net external torque calculated about the center of mass. The derivation is in the optional subsection below.

It is because of the validity of Eq. 11–9b that we are justified in describing the general motion of a system of particles, as we did in Chapter 10, as *translational* motion of the center of mass plus *rotation* about the center of mass. Equations 11–9b plus 9–5 $\left(d\vec{\mathbf{P}}_{\text{CM}}/dt = \Sigma\vec{\mathbf{F}}_{\text{ext}}\right)$ provide the more general statement of this principle. (See also Section 9–8.)

## *Derivation of $d\vec{\mathbf{L}}_{\text{CM}}/dt = \Sigma\vec{\tau}_{\text{CM}}$

The proof of Eq. 11–9b is as follows. Let $\vec{\mathbf{r}}_i$ be the position vector of the $i^{\text{th}}$ particle in an inertial reference frame, and $\vec{\mathbf{r}}_{\text{CM}}$ be the position vector of the center of mass of the system in this reference frame. The position of the $i^{\text{th}}$ particle with respect to the CM is $\vec{\mathbf{r}}_i^*$ where (see Fig. 11–14)

$$\vec{\mathbf{r}}_i = \vec{\mathbf{r}}_{\text{CM}} + \vec{\mathbf{r}}_i^*.$$

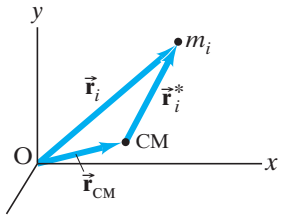

**FIGURE 11–14** The position of $m_i$ in the inertial frame is $\vec{\mathbf{r}}_i$; with regard to the CM (which could be accelerating) it is $\vec{\mathbf{r}}_i^*$, where $\vec{\mathbf{r}}_i = \vec{\mathbf{r}}_i^* + \vec{\mathbf{r}}_{\text{CM}}$ and $\vec{\mathbf{r}}_{\text{CM}}$ is the position of the CM in the inertial frame.

If we take the derivative of this equation and multiply each term by $m_i$, we can write the momentum, $p = mv$, of the $i^{\text{th}}$ particle as

$$\vec{\mathbf{p}}_i = m_i\frac{d\vec{\mathbf{r}}_i}{dt} = m_i\frac{d}{dt}\left(\vec{\mathbf{r}}_i^* + \vec{\mathbf{r}}_{\text{CM}}\right) = m_i\vec{\mathbf{v}}_i^* + m_i\vec{\mathbf{v}}_{\text{CM}} = \vec{\mathbf{p}}_i^* + m_i\vec{\mathbf{v}}_{\text{CM}}.$$

Thus the CM momentum is $\vec{\mathbf{p}}_i^* = \vec{\mathbf{p}}_i - m_i\vec{\mathbf{v}}_{\text{CM}}$, and the angular momentum with respect to the CM is

$$\vec{\mathbf{L}}_{\text{CM}} = \sum_i\left(\vec{\mathbf{r}}_i^* \times \vec{\mathbf{p}}_i^*\right) = \sum_i\vec{\mathbf{r}}_i^* \times \left(\vec{\mathbf{p}}_i - m_i\vec{\mathbf{v}}_{\text{CM}}\right).$$

Then, taking the time derivative, we have

$$\frac{d\vec{\mathbf{L}}_{\text{CM}}}{dt} = \sum_i\left(\frac{d\vec{\mathbf{r}}_i^*}{dt} \times \vec{\mathbf{p}}_i^*\right) + \sum_i\left(\vec{\mathbf{r}}_i^* \times \frac{d}{dt}\left(\vec{\mathbf{p}}_i - m_i\vec{\mathbf{v}}_{\text{CM}}\right)\right).$$

The first term on the right is $\vec{\mathbf{v}}_i^* \times m\vec{\mathbf{v}}_i^*$ and equals zero because $\vec{\mathbf{v}}_i^*$ is parallel to itself $(\sin\theta = 0)$. Thus

$$\begin{aligned}\frac{d\vec{\mathbf{L}}_{\text{CM}}}{dt} &= \sum_i\vec{\mathbf{r}}_i^* \times \frac{d}{dt}\left(\vec{\mathbf{p}}_i - m_i\vec{\mathbf{v}}_{\text{CM}}\right)\\ &= \sum_i\vec{\mathbf{r}}_i^* \times \frac{d\vec{\mathbf{p}}_i}{dt} - \left(\sum_i m_i\vec{\mathbf{r}}_i^*\right) \times \frac{d\vec{\mathbf{v}}_{\text{CM}}}{dt}.\end{aligned}$$

The second term on the right is zero since, by Eq. 9–12, $\Sigma m_i\vec{\mathbf{r}}_i^* = M\vec{\mathbf{r}}_{\text{CM}}^*$, and $\vec{\mathbf{r}}_{\text{CM}}^* = 0$ by definition (the position of the CM is at the origin of the CM reference frame). Furthermore, by Newton's second law we have

$$\frac{d\vec{\mathbf{p}}_i}{dt} = \vec{\mathbf{F}}_i,$$

where $\vec{\mathbf{F}}_i$ is the net force on $m_i$. (Note that $d\vec{\mathbf{p}}_i^*/dt \neq \vec{\mathbf{F}}_i$ because the CM may be accelerating and Newton's second law does not hold in a noninertial reference frame.) Consequently

$$\frac{d\vec{\mathbf{L}}_{\text{CM}}}{dt} = \sum_i\vec{\mathbf{r}}_i^* \times \vec{\mathbf{F}}_i = \sum_i\left(\vec{\tau}_i\right)_{\text{CM}} = \sum\vec{\tau}_{\text{CM}},$$

where $\Sigma\vec{\tau}_{\text{CM}}$ is the resultant external torque on the entire system calculated about the CM. (By Newton's third law, the sum over all the $\vec{\tau}_i$ eliminates the net torque due to internal forces, as we saw on page 310.) This last equation is Eq. 11–9b, and this concludes its proof.

### Limits on Eq. 11–9

To summarize, the relation

$$\sum \vec{\tau}_{\text{ext}} = \frac{d\vec{\mathbf{L}}}{dt}$$

is valid *only* when $\vec{\tau}_{\text{ext}}$ and $\vec{\mathbf{L}}$ are calculated with respect to either (1) the origin of an inertial reference frame or (2) the center of mass of a system of particles (or of a rigid object).

**CAUTION**

*This equation is valid under certain circumstances*

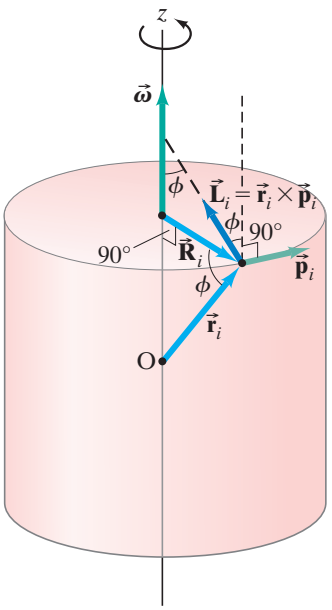

**FIGURE 11–15**
Calculating $L_\omega = L_z = \Sigma L_{iz}$. Note that $\vec{\mathbf{L}}_i$ is perpendicular to $\vec{\mathbf{r}}_i$, and $\vec{\mathbf{R}}_i$ is perpendicular to the $z$ axis, so the three angles marked $\phi$ are equal.

# 11–5 Angular Momentum and Torque for a Rigid Object

Let us now consider the rotation of any rigid object about an axis that has a fixed direction in space (not necessarily through the CM), using the general principles just developed.

Let us calculate the component of angular momentum along the rotation axis ($z$) of the rotating object. We will call this component $L_\omega$ since the angular velocity $\vec{\boldsymbol{\omega}}$ points along the rotation axis. For each particle of the object,

$$\vec{\mathbf{L}}_i = \vec{\mathbf{r}}_i \times \vec{\mathbf{p}}_i.$$

Let $\phi$ be the angle between $\vec{\mathbf{L}}_i$ and the rotation axis. See Fig. 11–15, where we chose the rotation axis as the $z$ axis (but $\phi$ is *not* the angle between $\vec{\mathbf{r}}_i$ and $\vec{\mathbf{p}}_i$, which is 90°). Then the component of $\vec{\mathbf{L}}_i$ along the rotation axis is

$$L_{i\omega} = r_i p_i \cos\phi = m_i v_i r_i \cos\phi,$$

where $m_i$ is the mass and $v_i$ the velocity of the $i^{\text{th}}$ particle. Now $v_i = R_i\omega$ where $\omega$ is the angular velocity of the object and $R_i$ is the perpendicular distance of $m_i$ from the axis of rotation. Furthermore, $R_i = r_i \cos\phi$, as can be seen in Fig. 11–15, so

$$L_{i\omega} = m_i v_i (r_i \cos\phi) = m_i R_i^2 \omega.$$

We sum over all the particles to obtain

$$L_\omega = \sum_i L_{i\omega} = \left(\sum_i m_i R_i^2\right)\omega.$$

But $\Sigma m_i R_i^2$ is the moment of inertia $I$ of the object about the axis of rotation. Therefore the component of the total angular momentum along the rotation axis is given by

$$L_\omega = I\omega. \qquad \textbf{(11–10)}$$

**CAUTION**

*The component of $\vec{\mathbf{L}}$ along rotation axis is $L_\omega = I\omega$.*

Note that we would obtain Eq. 11–10 no matter where we chose the point O (for measuring $\vec{\mathbf{r}}_i$) as long as it is on the axis of rotation. Equation 11–10 is the same as Eq. 11–1, which we have now proved from the general definition of angular momentum.

Although not true in general, $L_\omega$ is the only component of $\vec{\mathbf{L}}$ if the object rotates about a *symmetry* axis through the center of mass, as we now show. For each point on one side of the axis there will be a corresponding point on the opposite side. We can see from Fig. 11–15 that each $\vec{\mathbf{L}}_i$ has a component parallel to the axis $(L_{i\omega})$ and a component perpendicular to the axis. The components parallel to the axis add together for each pair of opposite points, but the components perpendicular to the axis for opposite points will have the same magnitude but opposite direction and so will cancel. Hence, for an object rotating about a symmetry axis, the angular momentum vector is parallel to the axis and we can write

$$\vec{\mathbf{L}} = I\vec{\boldsymbol{\omega}}, \qquad \text{[rotation axis = symmetry axis, through CM]} \quad \textbf{(11–11)}$$

where $\vec{\mathbf{L}}$ is measured relative to the center of mass.

The general relation between angular momentum and torque is Eq. 11–9:

$$\Sigma\vec{\tau} = \frac{d\vec{\mathbf{L}}}{dt}$$

where $\Sigma\vec{\tau}$ and $\vec{\mathbf{L}}$ are calculated either about (1) the origin of an inertial reference frame, or (2) the center of mass of the system. This is a vector relation, and must therefore be valid for each component. Hence, for a rigid object, the component along the rotation axis is

$$\Sigma\tau_{\text{axis}} = \frac{dL_\omega}{dt} = \frac{d}{dt}(I\omega) = I\frac{d\omega}{dt} = I\alpha,$$

which is valid for a rigid object rotating about an axis fixed relative to the object; also this axis must be either (1) fixed in an inertial system or (2) passing through the CM of the object. This is equivalent to Eqs. 10–14 and 10–15, which we now see are special cases of Eq. 11–9, $\Sigma\vec{\tau} = d\vec{\mathbf{L}}/dt$.

**EXAMPLE 11–8** **Atwood's machine.** An *Atwood machine* consists of two masses, $m_A$ and $m_B$, which are connected by an inelastic cord of negligible mass that passes over a pulley, Fig. 11–16. If the pulley has radius $R_0$ and moment of inertia $I$ about its axle, determine the acceleration of the masses $m_A$ and $m_B$, and compare to the situation where the moment of inertia of the pulley is ignored. Ignore friction at the axle O.

**APPROACH** We first determine the angular momentum of the system, and then apply Newton's second law, $\tau = dL/dt$.

**SOLUTION** We can calculate the angular momentum about an axis along the axle through the center O of the pulley. The pulley has angular momentum $I\omega$, where $\omega = v/R_0$ and $v$ is the velocity of $m_A$ and $m_B$ at any instant. The angular momentum of $m_A$ is $R_0 m_A v$ and that of $m_B$ is $R_0 m_B v$. The total angular momentum is

$$L = (m_A + m_B)\,vR_0 + I\frac{v}{R_0}.$$

The external torque on the system, calculated about the axis O (taking clockwise as positive), is

$$\tau = m_B g R_0 - m_A g R_0.$$

(The normal force on the pulley exerted by the axle gives rise to no torque because the lever arm is zero.) We apply Eq. 11–9a:

$$\tau = \frac{dL}{dt}$$

$$(m_B - m_A)\,gR_0 = (m_A + m_B)\,R_0\frac{dv}{dt} + \frac{I}{R_0}\frac{dv}{dt}.$$

Solving for $a = dv/dt$, we get

$$a = \frac{dv}{dt} = \frac{(m_B - m_A)\,g}{(m_A + m_B) + I/R_0^2}.$$

If we were to ignore $I$, $a = (m_B - m_A)\,g/(m_B + m_A)$ and we see that the effect of the moment of inertia of the pulley is to slow down the system. This is just what we would expect.

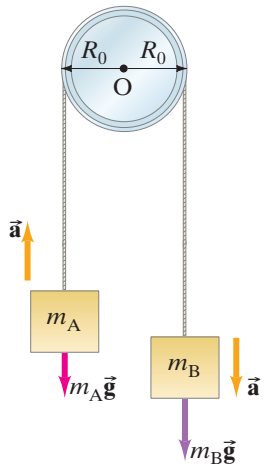

**FIGURE 11–16** Atwood's machine, Example 11–8. We also discussed this in Example 4–13. We assume in this diagram that $m_B > m_A$.

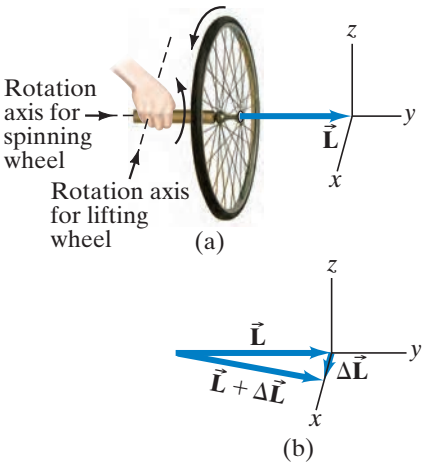

**FIGURE 11–17** When you try to tilt a rotating bicycle wheel vertically upward, it swerves to the side instead.

**CONCEPTUAL EXAMPLE 11–9** **Bicycle wheel.** Suppose you are holding a bicycle wheel by a handle connected to its axle as in Fig. 11–17a. The wheel is spinning so that its angular momentum $\vec{\mathbf{L}}$ points horizontally (along the $y$ axis) as shown. Now you suddenly try to tilt the axle upward (along the $z$ axis, so the CM moves vertically). You expect the wheel to go up, and it would if it weren't rotating. But it unexpectedly swerves to the right! Explain. Take the system as wheel, axle, and handle; your hand is external.

**RESPONSE** To explain this seemingly odd behavior—you may need to do it to believe it—we only need to use the relation $\vec{\boldsymbol{\tau}}_{\text{ext}} = d\vec{\mathbf{L}}/dt$. In the short time $\Delta t$, you exert an external torque (about an axis through your wrist) that points along the $x$ axis perpendicular to $\vec{\mathbf{L}}$. Thus the change in $\vec{\mathbf{L}}$ is (using $\tau_{\text{ext}} \approx \Delta L/\Delta t$)

$$\Delta\vec{\mathbf{L}} \approx \vec{\boldsymbol{\tau}}_{\text{ext}}\,\Delta t;$$

so $\Delta\vec{\mathbf{L}}$ must point (approximately) along the $x$ axis, because $\vec{\boldsymbol{\tau}}_{\text{ext}}$ does. Thus, if you are looking along the $+y$ axis, the new angular momentum, $\vec{\mathbf{L}} + \Delta\vec{\mathbf{L}}$, points to the right as shown in Fig. 11–17b. Since the angular momentum is directed along the axle of the wheel, we see that the axle, which now is along $\vec{\mathbf{L}} + \Delta\vec{\mathbf{L}}$, must move sideways to the right, which is what we observe.

**CAUTION**
*$\vec{\mathbf{L}} = I\vec{\boldsymbol{\omega}}$ is not always valid*

Although Eq. 11–11, $\vec{\mathbf{L}} = I\vec{\boldsymbol{\omega}}$, is not valid in general, it is valid in some useful cases, such as when the rotation axis is along a *symmetry* axis through the center of mass. Also, it can be shown that every rigid object, no matter what its shape, has three "principal axes" about which Eq. 11–11 is valid (we will not go into the details here). As an example of a case where Eq. 11–11 is not valid, consider the nonsymmetrical object shown in Fig. 11–18. It consists of two equal masses, $m_{\text{A}}$ and $m_{\text{B}}$, attached to the ends of a rigid (massless) rod which makes an angle $\phi$ with the axis of rotation. We calculate the angular momentum about the CM at point O. At the instant shown, $m_{\text{A}}$ is coming toward the viewer, and $m_{\text{B}}$ is moving away, so $\vec{\mathbf{L}}_{\text{A}} = \vec{\mathbf{r}}_{\text{A}} \times \vec{\mathbf{p}}_{\text{A}}$ and $\vec{\mathbf{L}}_{\text{B}} = \vec{\mathbf{r}}_{\text{B}} \times \vec{\mathbf{p}}_{\text{B}}$ are as shown. The total angular momentum is $\vec{\mathbf{L}} = \vec{\mathbf{L}}_{\text{A}} + \vec{\mathbf{L}}_{\text{B}}$, which is clearly *not* along $\vec{\boldsymbol{\omega}}$ if $\phi \neq 90°$.

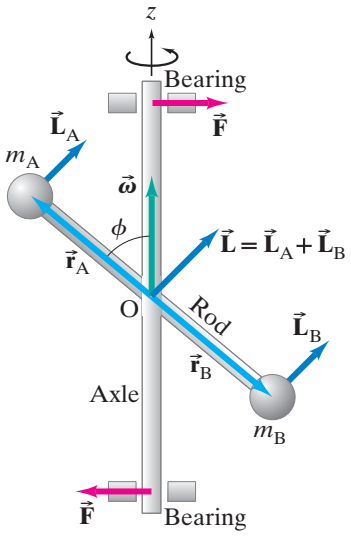

**FIGURE 11–18** In this system $\vec{\mathbf{L}}$ and $\vec{\boldsymbol{\omega}}$ are not parallel. This is an example of rotational imbalance. The forces $\vec{\mathbf{F}}$ act on the axle, exerted by the bearing.

## *Rotational Imbalance

Let us go one step further with the system shown in Fig. 11–18, since it is a fine illustration of $\Sigma\vec{\boldsymbol{\tau}}_{\text{ext}} = d\vec{\mathbf{L}}/dt$. If the system (axle, rod, and two masses) rotates with constant angular velocity, $\omega$, the magnitude of $\vec{\mathbf{L}}$ will not change, but its direction will. As the rod and two masses rotate about the $z$ axis, $\vec{\mathbf{L}}$ also rotates about the axis. At the moment shown in Fig. 11–18, $\vec{\mathbf{L}}$ is in the plane of the paper. A time $dt$ later, when the rod has rotated through an angle $d\theta = \omega\,dt$, $\vec{\mathbf{L}}$ will also have rotated through an angle $d\theta$ ($\vec{\mathbf{L}}$ remains perpendicular to the rod). $\vec{\mathbf{L}}$ will then have a component pointing into the page. Thus $d\vec{\mathbf{L}}$ points into the page and so must $d\vec{\mathbf{L}}/dt$. From

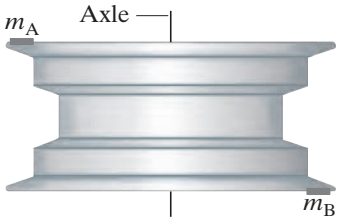
$$\Sigma\vec{\boldsymbol{\tau}}_{\text{ext}} = \frac{d\vec{\mathbf{L}}}{dt},$$

we see that an external net torque, directed into the page at the moment shown, must be applied to the axle on which the rod is mounted. The torque is supplied by bearings (or other constraint) at the ends of the axle. The forces $\vec{\mathbf{F}}$ exerted by the bearings on the axle are shown in Fig. 11–18. The direction of each force $\vec{\mathbf{F}}$ rotates as the system does, always being in the plane of $\vec{\mathbf{L}}$ and $\vec{\boldsymbol{\omega}}$ for this system. If the torque due to these forces were not present, the system would not rotate about the fixed axis as desired.

**PHYSICS APPLIED**
*Automobile wheel balancing*

The axle tends to move in the direction of $\vec{\mathbf{F}}$ and thus tends to wobble as it rotates. This has many practical applications, such as wear on bearings and the vibrations felt in a car whose wheels are not balanced. Consider an automobile wheel that is symmetrical except for an extra mass $m_{\text{A}}$ on one rim and an equal mass $m_{\text{B}}$ opposite it on the other rim, as shown in Fig. 11–19. Because of the nonsymmetry of $m_{\text{A}}$ and $m_{\text{B}}$, the wheel bearings would have to exert a force perpendicular to the axle at all times simply to keep the wheel rotating, just as in Fig. 11–18.

The bearings would wear excessively and the wobble of the wheel would be felt by occupants of the car. When the wheels are balanced, they rotate smoothly without wobble. This is why "dynamic balancing" of automobile wheels and tires is important. The wheel of Fig. 11–19 would balance *statically* just fine. If equal masses $m_C$ and $m_D$ are added symmetrically, below $m_A$ and above $m_B$, the wheel will be balanced dynamically as well ($\vec{\mathbf{L}}$ will be parallel to $\vec{\boldsymbol{\omega}}$, and $\vec{\boldsymbol{\tau}}_{ext} = 0$).



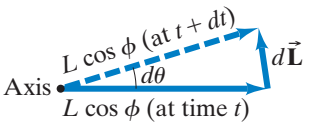


**FIGURE 11–19** Unbalanced automobile wheel.

**EXAMPLE 11–10** **Torque on unbalanced system.** Determine the magnitude of the external torque $\tau_{ext}$ needed to keep the system of axle, rod, and two masses turning in Fig. 11–18.

**APPROACH** Figure 11–20 is a view of the angular momentum vector, looking down along the rotation axis ($z$ axis) of the system depicted in Fig. 11–18, as it rotates. (Think of your head being at the top of Fig. 11–18 and you are looking down along the $z$ axis toward the bottom of the diagram.) $L\cos\phi$ is the component of $\vec{\mathbf{L}}$ perpendicular to the axle (points to the right in Fig. 11–18). We find $dL$ from Fig. 11–20 and use $\tau_{ext} = dL/dt$.

**FIGURE 11–20** Angular momentum vector looking down along the rotation axis ($z$) of the system of Fig. 11–18 as it rotates during a time $dt$.

**SOLUTION** In a time $dt$, $\vec{\mathbf{L}}$ changes by an amount (Fig. 11–20 and Eq. 10–2b, $\omega = d\theta/dt$)

$$dL = (L\cos\phi)\,d\theta = L\cos\phi\,\omega\,dt.$$

Hence

$$\tau_{ext} = \frac{dL}{dt} = \omega L\cos\phi.$$

But

$$L = L_A + L_B = r_A m_A v_A + r_B m_B v_B$$
$$= r_A m_A(\omega r_A \sin\phi) + r_B m_B(\omega r_B \sin\phi) = (m_A r_A^2 + m_B r_B^2)\,\omega\sin\phi.$$

The moment of inertia about the axis of rotation is $I = (m_A r_A^2 + m_B r_B^2)\sin^2\phi$, since the distance of each mass from the rotation axis is $R = r\sin\phi$. Thus $L = I\omega/\sin\phi$ and

$$\tau_{ext} = \omega L\cos\phi = (m_A r_A^2 + m_B r_B^2)\omega^2\sin\phi\cos\phi = I\omega^2/\tan\phi.$$

The situation of Fig. 11–18 illustrates the usefulness of the vector nature of torque and angular momentum. If we had considered only the components of angular momentum and torque along the rotation axis, we could not have calculated the external torque due to the bearings (since the forces $\vec{\mathbf{F}}$ act at the axle and hence produce no torque along that axis). By using the concept of vector angular momentum we have a far more powerful technique for understanding nature, and for attacking problems.

## 11–6 Conservation of Angular Momentum

In Chapter 9 we saw that the most general form of Newton's second law for the translational motion of a particle or system of particles is

$$\Sigma\vec{\mathbf{F}}_{ext} = \frac{d\vec{\mathbf{P}}}{dt},$$

where $\vec{\mathbf{P}}$ is the (linear) momentum, defined as $m\vec{\mathbf{v}}$ for a particle, or $M\vec{\mathbf{v}}_{CM}$ for a system of particles of total mass $M$ whose CM moves with velocity $\vec{\mathbf{v}}_{CM}$, and $\Sigma\vec{\mathbf{F}}_{ext}$ is the net external force acting on the particle or system. This relation is valid only in an inertial reference frame.

In this Chapter, we have found a similar relation to describe the general rotation of a system of particles (including rigid objects):

$$\Sigma\vec{\boldsymbol{\tau}}_{ext} = \frac{d\vec{\mathbf{L}}}{dt},$$

where $\Sigma\vec{\boldsymbol{\tau}}_{ext}$ is the net external torque acting on the system, and $\vec{\mathbf{L}}$ is the total angular momentum. This relation is valid when $\Sigma\vec{\boldsymbol{\tau}}_{ext}$ and $\vec{\mathbf{L}}$ are calculated about a point fixed in an inertial reference frame, or about the CM of the system. It is a more general form of Eq. 11–2.

For translational motion, if the net force on the system is zero, $d\vec{\mathbf{P}}/dt = 0$, so the total linear momentum of the system remains constant. This is the law of conservation of linear momentum. For rotational motion, if the net external torque on the system is zero, then

$$\frac{d\vec{\mathbf{L}}}{dt} = 0 \quad \text{and} \quad \vec{\mathbf{L}} = \text{constant.} \qquad [\Sigma\vec{\tau}_{\text{ext}} = 0] \quad \textbf{(11–12)}$$

*CONSERVATION OF ANGULAR MOMENTUM*

In words:

**The total angular momentum of a system remains constant if the net external torque acting on the system is zero.**

This is the **law of conservation of angular momentum** in full vector form. It ranks with the laws of conservation of energy and linear momentum (and others to be discussed later) as one of the great laws of physics. In Section 11–1 we saw some Examples of this important law applied to the special case of a rigid object rotating about a fixed axis. Here we have it in general form. We use it now in interesting Examples.

**EXAMPLE 11–11 Kepler's second law derived.** Kepler's second law states that each planet moves so that a line from the Sun to the planet sweeps out equal areas in equal times (Section 6–5). Use conservation of angular momentum to show this.

**APPROACH** We determine the angular momentum of a planet in terms of the area swept out with the help of Fig. 11–21.

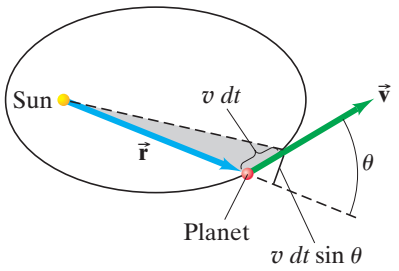

**FIGURE 11–21** Kepler's second law of planetary motion.

**SOLUTION** The planet moves in an ellipse as shown in Fig. 11–21. In an infinitesimal time $dt$, the planet moves a distance $v\,dt$ and sweeps out an area $dA$ equal to the area of a triangle of base $r$ and height $v\,dt\sin\theta$ (shown exaggerated in Fig. 11–21). Hence

$$dA = \tfrac{1}{2}(r)(v\,dt\sin\theta)$$

and

$$\frac{dA}{dt} = \tfrac{1}{2}rv\sin\theta.$$

The magnitude of the angular momentum $\vec{\mathbf{L}}$ about the Sun is

$$L = |\vec{\mathbf{r}} \times m\vec{\mathbf{v}}| = mrv\sin\theta,$$

so

$$\frac{dA}{dt} = \frac{1}{2m}L.$$

But $L =$ constant, since the gravitational force $\vec{\mathbf{F}}$ is directed toward the Sun so the torque it produces is zero (we ignore the pull of the other planets). Hence $dA/dt =$ constant, which is what we set out to prove.

**EXAMPLE 11–12** **Bullet strikes cylinder edge.** A bullet of mass $m$ moving with velocity $v$ strikes and becomes embedded at the edge of a cylinder of mass $M$ and radius $R_0$, as shown in Fig. 11–22. The cylinder, initially at rest, begins to rotate about its symmetry axis, which remains fixed in position. Assuming no frictional torque, what is the angular velocity of the cylinder after this collision? Is kinetic energy conserved?

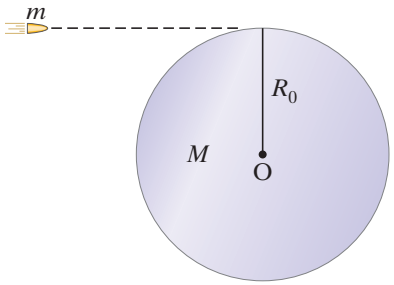

**FIGURE 11–22** Bullet strikes and becomes embedded in cylinder at its edge (Example 11–12).

**APPROACH** We take as our system the bullet and cylinder, on which there is no net external torque. Thus we can use conservation of angular momentum, and we calculate all angular momenta about the center O of the cylinder.

**SOLUTION** Initially, because the cylinder is at rest, the total angular momentum about O is solely that of the bullet, of magnitude

$$L = |\vec{\mathbf{r}} \times \vec{\mathbf{p}}| = R_0 mv,$$

since $R_0$ is the perpendicular distance of $\vec{\mathbf{p}}$ from O. After the collision, the cylinder $\left(I_{\text{cyl}} = \frac{1}{2}MR_0^2\right)$ rotates with the bullet $\left(I_{\text{b}} = mR_0^2\right)$ embedded in it at angular velocity $\omega$:

$$L = I\omega = \left(I_{\text{cyl}} + mR_0^2\right)\omega = \left(\tfrac{1}{2}M + m\right)R_0^2\omega.$$

Hence, because angular momentum is conserved, we find that $\omega$ is

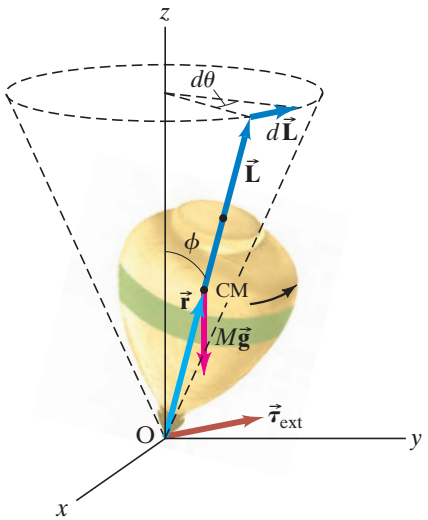
$$\omega = \frac{L}{\left(\frac{1}{2}M + m\right)R_0^2} = \frac{mvR_0}{\left(\frac{1}{2}M + m\right)R_0^2} = \frac{mv}{\left(\frac{1}{2}M + m\right)R_0}.$$

Angular momentum is conserved in this collision. But kinetic energy, which initially is only that of the bullet, $K_{\text{i}} = \frac{1}{2}mv^2$ is not conserved:

$$\begin{aligned} K_{\text{f}} - K_{\text{i}} &= \tfrac{1}{2}I_{\text{cyl}}\omega^2 + \tfrac{1}{2}\left(mR_0^2\right)\omega^2 - \tfrac{1}{2}mv^2 \\ &= \tfrac{1}{2}\left(\tfrac{1}{2}MR_0^2\right)\omega^2 + \tfrac{1}{2}\left(mR_0^2\right)\omega^2 - \tfrac{1}{2}mv^2 \\ &= \tfrac{1}{2}\left(\tfrac{1}{2}M + m\right)\left(\frac{mv}{\frac{1}{2}M + m}\right)^2 - \tfrac{1}{2}mv^2 \\ &= -\frac{mM}{2M + 4m}v^2, \end{aligned}$$

which is less than zero. Hence $K_{\text{f}} < K_{\text{i}}$. This energy is transformed to thermal energy as a result of the inelastic collision.

# *11–7 The Spinning Top and Gyroscope



The motion of a spinning top, or a gyroscope, is another interesting example of rotational motion and of the use of the vector equation

$$\sum \vec{\boldsymbol{\tau}}_{\text{ext}} = \frac{d\vec{\mathbf{L}}}{dt}.$$

Consider a symmetrical top of mass $M$ spinning rapidly about its symmetry axis, as in Fig. 11–23. The top is balanced on its tip at point O in an inertial reference frame. If the axis of the top makes an angle $\phi$ to the vertical ($z$ axis), when the top is carefully released its axis will move, sweeping out a cone about the vertical as shown by the dashed lines in Fig. 11–23. This type of motion, in which a torque produces a change in the direction of the rotation axis, is called **precession**. The rate at which the rotation axis moves about the vertical ($z$) axis is called the angular velocity of precession, $\Omega$ (capital Greek omega). Let us now try to understand the reasons for this motion, and calculate $\Omega$.

If the top was not spinning, it would immediately fall to the ground when released due to the pull of gravity. The apparent mystery of a top is that when it is spinning, it does not immediately fall to the ground but instead precesses—its rotation axis moves slowly around the vertical ($z$) axis. But this is not really so mysterious if we examine it from the point of view of angular momentum and torque, which we calculate about the point O.

**FIGURE 11–23** Spinning top. It is difficult to release a spinning top so that it spins around a perfectly vertical axis. It usually makes some angle $\phi$ to the vertical.

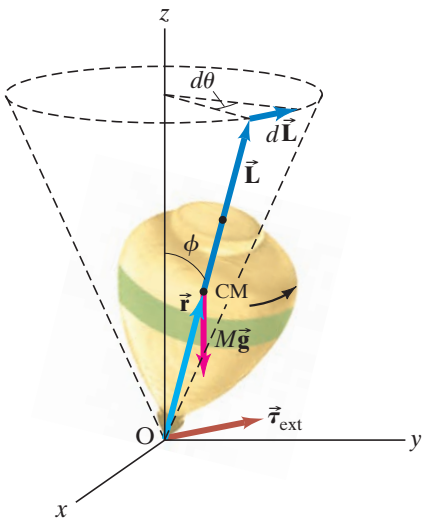


**FIGURE 11–23** (Repeated.) A spinning top precesses.

When the top is spinning with angular velocity $\omega$ about its symmetry axis, it has an angular momentum $\vec{\mathbf{L}}$ directed along its axis, as shown in Fig. 11–23. (There is also angular momentum due to the precessional motion, so that the total $\vec{\mathbf{L}}$ is not exactly along the axis of the top; but if $\Omega \ll \omega$, which is usually the case, we can ignore this.) To change the angular momentum, a torque is required. If no torque were applied to the spinning top, $\vec{\mathbf{L}}$ would have to remain constant in magnitude and direction; the top would neither fall nor precess. But the slightest tip to the side (angle $\phi$) means the spinning top experiences a net external torque about O, equal to $\vec{\boldsymbol{\tau}}_{\text{ext}} = \vec{\mathbf{r}} \times M\vec{\mathbf{g}}$, where $\vec{\mathbf{r}}$ is the position vector of the top's center of mass with respect to O, and $M$ is the mass of the top. The direction of $\vec{\boldsymbol{\tau}}_{\text{ext}}$ is perpendicular to both $\vec{\mathbf{r}}$ and $M\vec{\mathbf{g}}$—and by the right-hand rule is in the horizontal $(xy)$ plane, as shown in Fig. 11–23. The change in $\vec{\mathbf{L}}$ in a time $dt$ is

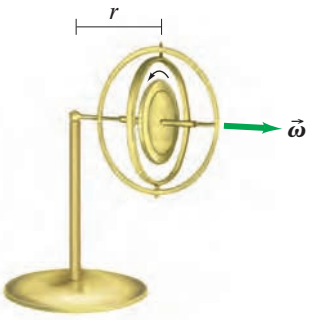
$$d\vec{\mathbf{L}} = \vec{\boldsymbol{\tau}}_{\text{ext}}\, dt,$$

which is perpendicular to $\vec{\mathbf{L}}$ and horizontal (parallel to $\vec{\boldsymbol{\tau}}_{\text{ext}}$), as shown in Fig. 11–23. Since $d\vec{\mathbf{L}}$ is perpendicular to $\vec{\mathbf{L}}$, the magnitude of $\vec{\mathbf{L}}$ does not change. Only the direction of $\vec{\mathbf{L}}$ changes. Since $\vec{\mathbf{L}}$ points along the axis of the top, we see that this axis moves to the right in Fig. 11–23. That is, the upper end of the top's axis moves in a horizontal direction perpendicular to $\vec{\mathbf{L}}$. This explains why the top precesses rather than falls. The vector $\vec{\mathbf{L}}$ and the top's axis move together in a horizontal circle. As they do so, $\vec{\boldsymbol{\tau}}_{\text{ext}}$ and $d\vec{\mathbf{L}}$ rotate as well so as to be horizontal and perpendicular to $\vec{\mathbf{L}}$.

To determine $\Omega$, we see from Fig. 11–23 that the angle $d\theta$ (which is in a horizontal plane) is related to $dL$ by

$$dL = L \sin\phi\, d\theta,$$

since $\vec{\mathbf{L}}$ makes an angle $\phi$ to the $z$ axis. The angular velocity of precession (using $\Omega$, which is capital $\omega$) is $\Omega = d\theta/dt$, which becomes (since $d\theta = dL/L\sin\phi$)



$$\Omega = \frac{1}{L\sin\phi}\frac{dL}{dt} = \frac{\tau}{L\sin\phi}. \qquad \text{[spinning top]} \quad \textbf{(11–13a)}$$

But $\tau_{\text{ext}} = |\vec{\mathbf{r}} \times M\vec{\mathbf{g}}| = rMg\sin\phi$ [because $\sin(\pi - \phi) = \sin\phi$] so we can also write

$$\Omega = \frac{Mgr}{L}. \qquad \text{[spinning top]} \quad \textbf{(11–13b)}$$

Thus the rate of precession does not depend on the angle $\phi$; but it is inversely proportional to the top's angular momentum. The faster the top spins, the greater $L$ is and the slower the top precesses.

**FIGURE 11–24** A toy gyroscope.

From Eq. 11–1 (or Eq. 11–11) we can write $L = I\omega$, where $I$ and $\omega$ are the moment of inertia and angular velocity of the spinning top about its spin axis. Then Eq. 11–13b for the top's precession angular velocity becomes

$$\Omega = \frac{Mgr}{I\omega}. \qquad \textbf{(11–13c)}$$

Equations 11–13 apply also to a toy gyroscope, which consists of a rapidly spinning wheel mounted on an axle (Fig. 11–24). One end of the axle rests on a support. The other end of the axle is free and will precess like a top if its "spin" angular velocity $\omega$ is large compared to the precession rate $(\omega \gg \Omega)$. As $\omega$ decreases due to friction and air resistance, the gyroscope will begin to fall, just as does a top.

# 11–8 Rotating Frames of Reference; Inertial Forces

## Inertial and Noninertial Reference Frames

Up to now, we have examined the motion of objects, including circular and rotational motion, from the outside, as observers fixed on the Earth. Sometimes it is convenient to place ourselves (in theory, if not physically) into a reference frame that is rotating. Let us examine the motion of objects from the point of view, or frame of reference, of persons seated on a rotating platform such as a merry-go-round.

It looks to them as if the rest of the world is going around *them*. But let us focus attention on what they observe when they place a tennis ball on the floor of the rotating platform, which we assume is frictionless. If they put the ball down gently, without giving it any push, they will observe that it accelerates from rest and moves outward as shown in Fig. 11–25a. According to Newton's first law, an object initially at rest should stay at rest if no net force acts on it. But, according to the observers on the rotating platform, the ball starts moving even though there is no net force acting on it. To observers on the ground this is all very clear: the ball has an initial velocity when it is released (because the platform is moving), and it simply continues moving in a straight-line path as shown in Fig. 11–25b, in accordance with Newton's first law.

But what shall we do about the frame of reference of the observers on the rotating platform? Since the ball starts moving with no net force on it, Newton's first law, the law of inertia, does not hold in this rotating frame of reference. For this reason, such a frame is called a **noninertial reference frame**. An **inertial reference frame** (as discussed in Chapter 4) is one in which the law of inertia—Newton's first law—does hold, and so do Newton's second and third laws. In a noninertial reference frame, such as our rotating platform, Newton's second law also does not hold. For instance in the situation described above, there is no net force on the ball; yet, with respect to the rotating platform, the ball accelerates.

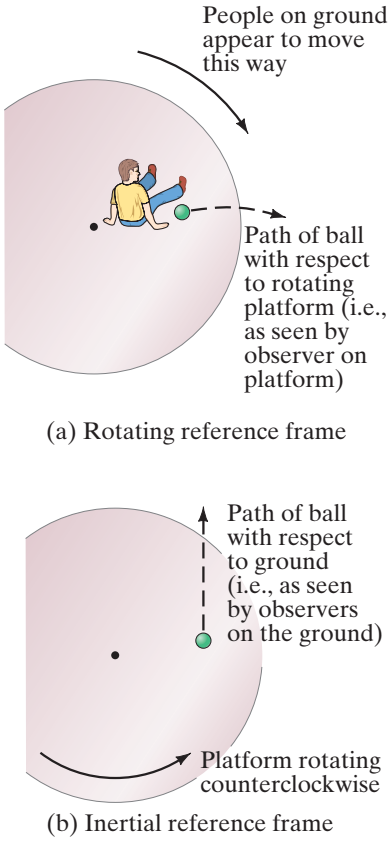


**FIGURE 11–25** Path of a ball released on a rotating merry-go-round (a) in the reference frame of the merry-go-round, and (b) in a reference frame fixed on the ground.

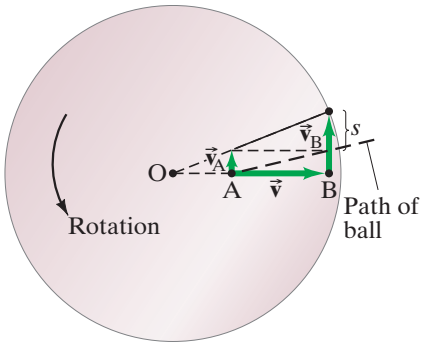
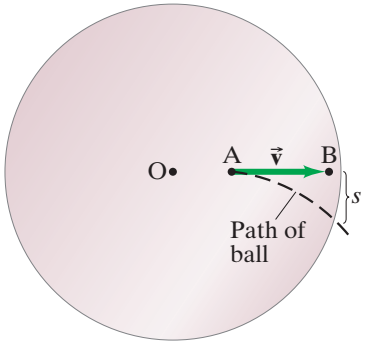
## Fictitious (Inertial) Forces



Because Newton's laws do not hold when observations are made with respect to a noninertial frame of reference, calculation of motion can be complicated. But there is a way around it for this rotating reference frame. The ball on the rotating platform of Fig. 11–25a flies outward when released (even though no force is actually acting on it). What we can do is write down the equation $\Sigma F = ma$ as if a force equal to $mv^2/r$ (or $m\omega^2 r$) is acting radially outward on the object in addition to any other forces that may be acting. This extra force, which might be designated as "centrifugal force" since it *seems* to act outward, is called a **fictitious force** or **pseudoforce**. It is a pseudoforce ("pseudo" means "false") because there is no object that exerts this force. Furthermore, when viewed from an inertial reference frame, the effect doesn't exist at all (Fig. 11–25b). We have made up this pseudoforce so that we can make calculations in a noninertial frame using Newton's second law, $\Sigma F = ma$. Thus the observer in the noninertial frame of Fig. 11–25a uses Newton's second law for the ball's outward motion by assuming that a force equal to $mv^2/r$ acts on it. Such pseudoforces are also called **inertial forces** because they "appear" only in a noninertial reference frame due to that frame's acceleration.

In Section 5–4 we discussed the forces on a person in a car going around a curve (Fig. 5–21) from the point of view of an inertial frame. The car, on the other hand, is not an inertial frame. Passengers in such a car could interpret this being pressed outward as the effect of a "centrifugal" force. But they need to recognize that it is a pseudoforce because it is an effect of being in a noninertial frame of reference, and there is no identifiable object exerting it.



The Earth itself is rotating on its axis. Thus, strictly speaking, Newton's laws are not valid on the Earth. However, the effect of the Earth's rotation is usually so small that it can be ignored, although it does influence the movement of large air masses and ocean currents. Because of the Earth's rotation, the material of the Earth is concentrated slightly more at the equator. The Earth is thus not a perfect sphere but is slightly fatter at the equator than at the poles.

# *11–9 The Coriolis Effect

In a reference frame that rotates at a constant angular speed $\omega$ (relative to an inertial frame), there exists another pseudoforce known as the *Coriolis force*. It appears to act on an object in a rotating reference frame only if the object is moving relative to that rotating reference frame, and it acts to deflect the object sideways. It, too, is an effect of the rotating reference frame being noninertial and hence is referred to as an *inertial force*. It also affects the weather.

(a) Inertial reference frame

(b) Rotating reference frame

**FIGURE 11–26** The origin of the Coriolis effect. Looking down on a platform rotating counterclockwise, (a) as seen from a nonrotating inertial reference frame, and (b) as seen from the rotating platform as frame of reference.

To see how the Coriolis force arises, consider two people, A and B, at rest on a platform rotating with angular speed $\omega$, as shown in Fig. 11–26a. They are situated at distances $r_A$ and $r_B$ from the axis of rotation (at O). The woman at A throws a ball with a horizontal velocity $\vec{\mathbf{v}}$ (in her reference frame) radially outward toward the man at B near the outer edge of the platform. In Fig. 11–26a, we view the situation from an inertial reference frame. The ball initially has not only the velocity $\vec{\mathbf{v}}$ radially outward, but also a tangential velocity $\vec{\mathbf{v}}_A$ due to the rotation of the platform. Now Eq. 10–4 tells us that $v_A = r_A\omega$, where $r_A$ is the woman's radial distance from the axis of rotation at O. If the man at B had this same velocity $v_A$, the ball would reach him perfectly. But his speed is $v_B = r_B\omega$, which is greater than $v_A$ because $r_B > r_A$. Thus, when the ball reaches the outer edge of the platform, it passes a point that the man at B has already gone by because his speed in that direction is greater than the ball's. So the ball passes behind him.

Figure 11–26b shows the situation as seen from the rotating platform as frame of reference. Both A and B are at rest, and the ball is thrown with velocity $\vec{\mathbf{v}}$ toward B, but the ball deflects to the right as shown and passes behind B as previously described. This is not a centrifugal-force effect, because that would act radially outward. Instead, this effect acts sideways, perpendicular to $\vec{\mathbf{v}}$, and is called a **Coriolis acceleration**; it is said to be due to the Coriolis force, which is a fictitious inertial force. Its explanation as seen from an inertial system was given above: it is an effect of being in a rotating system, for which a point farther from the rotation axis has a higher linear speed. On the other hand, when viewed from the rotating system, we can describe the motion using Newton's second law, $\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$, if we add a "pseudoforce" term corresponding to this Coriolis effect.

Let us determine the magnitude of the Coriolis acceleration for the simple case described above. (We assume $v$ is large and distances short, so we can ignore gravity.) We do the calculation from the inertial reference frame (Fig. 11–26a). The ball moves radially outward a distance $r_B - r_A$ at speed $v$ in a short time $t$ given by

$$r_B - r_A = vt.$$

During this time, the ball moves to the side a distance $s_A$ given by

$$s_A = v_A t.$$

The man at B, in this time $t$, moves a distance

$$s_B = v_B t.$$

The ball therefore passes behind him a distance $s$ (Fig. 11–26a) given by

$$s = s_B - s_A = (v_B - v_A)t.$$

We saw earlier that $v_A = r_A\omega$ and $v_B = r_B\omega$, so

$$s = (r_B - r_A)\omega t.$$

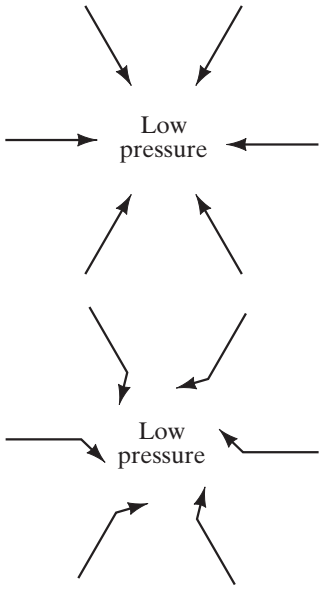
We substitute $r_B - r_A = vt$ (see above) and get

$$s = \omega v t^2. \qquad \textbf{(11–14)}$$

This same $s$ equals the sideways displacement as seen from the noninertial rotating system (Fig. 11–26b).

Equation 11–14 corresponds to motion at constant acceleration, because as we saw in Chapter 2 (Eq. 2–12b), $y = \frac{1}{2}at^2$ for a constant acceleration (with zero initial velocity in the $y$ direction). Thus, if we write Eq. 11–14 in the form $s = \frac{1}{2}a_{Cor}t^2$, we see that the Coriolis acceleration $a_{Cor}$ is

$$a_{Cor} = 2\omega v. \qquad \textbf{(11–15)}$$



This relation is valid for any velocity in the plane of rotation perpendicular to the axis of rotation[†] (in Fig. 11–26, the axis through point O perpendicular to the page).

[†]The Coriolis acceleration can be written in general in terms of the vector cross product as $\vec{\mathbf{a}}_{Cor} = -2\vec{\boldsymbol{\omega}} \times \vec{\mathbf{v}}$ where $\vec{\boldsymbol{\omega}}$ has direction along the rotation axis; its magnitude is $a_{Cor} = 2\omega v_\perp$ where $v_\perp$ is the component of velocity perpendicular to the rotation axis.

Because the Earth rotates, the Coriolis effect has some interesting manifestations on the Earth. It affects the movement of air masses and thus has an influence on weather. In the absence of the Coriolis effect, air would rush directly into a region of low pressure, as shown in Fig. 11–27a. But because of the Coriolis effect, the winds are deflected to the right (Fig. 11–27b). This is true in the Northern Hemisphere, for which Fig. 11–26 applies as if looking down on Earth from above the North Pole and seeing the Earth rotate counterclockwise (the Earth rotates from west to east). So there tends to be a counterclockwise wind pattern around a low-pressure area. The reverse is true in the Southern Hemisphere (imagine looking down on Earth from above the South Pole and seeing the Earth rotate clockwise, the reverse of Fig. 11–26). Thus large storms, such as cyclones, hurricanes, and typhoons,[†] rotate counterclockwise in the Northern Hemisphere and clockwise in the Southern Hemisphere. The same effect explains the easterly trade winds near the equator: any winds heading south toward the equator will be deflected toward the west (that is, as if coming from the east).

In the vicinity of a *high*-pressure region, the air moves outward. So the winds, acted on by the Coriolis "force" to the right in the Northern Hemisphere, move in a clockwise direction. This is called an *anticyclone*, or anticyclonic behavior. In the Southern Hemisphere, winds circulate counterclockwise around a high-pressure, anticyclonic, region.

The Coriolis effect also acts on a falling object. An object released from the top of a high tower will not hit the ground directly below the release point, but will be deflected slightly to the east. Viewed from an inertial frame, this happens because the top of the tower revolves with the Earth at a slightly higher speed than the bottom of the tower.

(a)

(b)

(c)

**FIGURE 11–27** (a) Winds (moving air masses) would flow directly toward a low-pressure area if the Earth did not rotate. (b) and (c): Because of the Earth's rotation, the winds are deflected to the right in the Northern Hemisphere (as in Fig. 11–26) as if a fictitious (Coriolis) force were acting.

[†]These three names are used in different places for the same phenomenon: a large cyclonic storm near Florida is a hurricane, if near Japan it is called a typhoon.

# Summary

The **angular momentum** $\vec{\mathbf{L}}$ of a rigid object rotating about a fixed rotation axis is given by

$$L = I\omega. \qquad \textbf{(11–1)}$$

Newton's second law, in terms of angular momentum, is

$$\Sigma\tau = \frac{dL}{dt}. \qquad \textbf{(11–2)}$$

If the net torque on an object is zero, $dL/dt = 0$, so $L$ = constant. This is the **law of conservation of angular momentum** for a rotating object.

The **vector product** or **cross product** of two vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ is another vector $\vec{\mathbf{C}} = \vec{\mathbf{A}} \times \vec{\mathbf{B}}$ whose magnitude is $AB\sin\theta$ and whose direction is perpendicular to both $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ in the sense of the right-hand rule.

The **torque** $\vec{\boldsymbol{\tau}}$ due to a force $\vec{\mathbf{F}}$ is a vector quantity and is always calculated about some point O (the origin of a coordinate system) as follows:

$$\vec{\boldsymbol{\tau}} = \vec{\mathbf{r}} \times \vec{\mathbf{F}}, \qquad \textbf{(11–5)}$$

where $\vec{\mathbf{r}}$ is the position vector of the point at which the force $\vec{\mathbf{F}}$ acts.

Angular momentum is also a vector. For a particle having momentum $\vec{\mathbf{p}} = m\vec{\mathbf{v}}$, the angular momentum $\vec{\mathbf{L}}$ about some point O is

$$\vec{\mathbf{L}} = \vec{\mathbf{r}} \times \vec{\mathbf{p}}, \qquad \textbf{(11–6)}$$

where $\vec{\mathbf{r}}$ is the position vector of the particle relative to the point O at any instant. The net torque $\Sigma\vec{\boldsymbol{\tau}}$ on a particle is related to its angular momentum by

$$\Sigma\vec{\boldsymbol{\tau}} = \frac{d\vec{\mathbf{L}}}{dt}. \qquad \textbf{(11–7)}$$

For a system of particles, the total angular momentum $\vec{\mathbf{L}} = \Sigma\vec{\mathbf{L}}_i$. The total angular momentum of the system is related to the total net torque $\Sigma\vec{\boldsymbol{\tau}}$ on the system by

$$\Sigma\vec{\boldsymbol{\tau}}_{\text{ext}} = \frac{d\vec{\mathbf{L}}}{dt}. \qquad \textbf{(11–9a)}$$

This last relation is the vector rotational equivalent of Newton's second law. It is valid when $\vec{\mathbf{L}}$ and $\Sigma\vec{\boldsymbol{\tau}}_{\text{ext}}$ are calculated about an origin (1) fixed in an inertial reference system or (2) situated at the CM of the system. For a rigid object rotating about a fixed axis, the component of angular momentum about the rotation axis is given by $L_\omega = I\omega$. If an object rotates about an axis of symmetry, then the vector relation $\vec{\mathbf{L}} = I\vec{\boldsymbol{\omega}}$ holds, but this is not true in general.

If the total external torque on a system is zero, then the total vector angular momentum $\vec{\mathbf{L}}$ remains constant. This is the important **law of conservation of angular momentum**. It applies to the vector $\vec{\mathbf{L}}$ and therefore also to each of its components.

# Questions

1. Can the diver of Fig. 11–2 do a somersault without having any initial rotation when she leaves the board? Explain.
2. When a motorcyclist leaves the ground on a jump and leaves the throttle on (so the rear wheel spins), why does the front of the cycle rise up?
3. Suppose you are standing on the edge of a large freely rotating turntable. What happens if you walk toward the center?
4. We claim that momentum and angular momentum are conserved. Yet most moving or rotating objects eventually slow down and stop. Explain.
5. A shortstop may leap into the air to catch a ball and throw it quickly. As he throws the ball, the upper part of his body rotates. If you look quickly you will notice that his hips and legs rotate in the opposite direction (Fig. 11–28). Explain.

**FIGURE 11–28**
Question 5. A shortstop in the air, throwing the ball.

6. If all the components of the vectors $\vec{\mathbf{V}}_1$ and $\vec{\mathbf{V}}_2$ were reversed in direction, how would this alter $\vec{\mathbf{V}}_1 \times \vec{\mathbf{V}}_2$?
7. A force $\vec{\mathbf{F}} = F\hat{\mathbf{j}}$ is applied to an object at a position $\vec{\mathbf{r}} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$ where the origin is at the CM. Does the torque about the CM depend on $x$? On $y$? On $z$?
8. A particle moves with constant speed along a straight line. How does its angular momentum, calculated about any point not on its path, change in time?
9. If the net force on a system is zero, is the net torque also zero? If the net torque on a system is zero, is the net force zero? Give examples.
10. Explain how a child "pumps" on a swing to make it go higher.
11. Describe the torque needed if the person in Fig. 11–17 is to tilt the axle of the rotating wheel directly upward without it swerving to the side.
12. An astronaut floats freely in a weightless environment. Describe how the astronaut can move her limbs so as to (*a*) turn her body upside down and (*b*) turn her body about-face.
13. On the basis of the law of conservation of angular momentum, discuss why a helicopter must have more than one rotor (or propeller). Discuss one or more ways the second propeller can operate in order to keep the helicopter stable.
14. A wheel is rotating freely about a vertical axis with constant angular velocity. Small parts of the wheel come loose and fly off. How does this affect the rotational speed of the wheel? Is angular momentum conserved? Is kinetic energy conserved? Explain.
15. Consider the following vector quantities: displacement, velocity, acceleration, momentum, angular momentum, torque. (*a*) Which of these are independent of the choice of origin of coordinates? (Consider different points as origin which are at rest with respect to each other.) (*b*) Which are independent of the (constant) velocity of the coordinate system?
16. How does a car make a right turn? Where does the torque come from that is needed to change the angular momentum?
17. In a rotating frame of reference, Newton's first and second laws remain useful if we assume that a pseudoforce equal to $m\omega^2 r$ is acting. What effect does this assumption have on the validity of Newton's third law?

*18. Why is it that at most locations on the Earth, a plumb bob does not hang precisely in the direction of the Earth's center?

*19. In the *battle* of the Falkland Islands in 1914, the shots of British gunners initially fell wide of their marks because their calculations were based on naval battles fought in the Northern Hemisphere. The Falklands are in the Southern Hemisphere. Explain the origin of their problem.

# MisConceptual Questions

1. A small mass $m$ on a string is rotating without friction in a circle. The string is shortened by pulling it through the axis of rotation without any external torque, Fig. 11–29. What happens to the angular velocity of the object?
(*a*) It increases.
(*b*) It decreases.
(*c*) It remains the same.

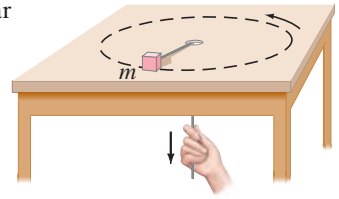


**FIGURE 11–29**
MisConceptual Questions 1 and 2.

2. A small mass $m$ on a string is rotating without friction in a circle. The string is shortened by pulling it through the axis of rotation without any external torque, Fig. 11–29. What happens to the tangential velocity of the object?
(*a*) It increases.
(*b*) It decreases.
(*c*) It remains the same.

3. Suppose you are sitting on a rotating stool holding a 2-kg mass in each outstretched hand. If you suddenly drop the masses, your angular velocity will
(*a*) increase.
(*b*) decrease.
(*c*) stay the same.

4. Two spinning disks have the same angular momentum, but disk A has more kinetic energy than disk B. Which has the greater moment of inertia?
(*a*) Disk A.
(*b*) Disk B.
(*c*) Not enough information to tell.

5. The cross product of two vectors, $\vec{\mathbf{V}}_1 \times \vec{\mathbf{V}}_2$, would have to be zero if
(*a*) $V_1 = 0$.
(*b*) $V_2 = 0$.
(*c*) $\vec{\mathbf{V}}_1$ is parallel to $\vec{\mathbf{V}}_2$.
(*d*) $\vec{\mathbf{V}}_1$ is perpendicular to $\vec{\mathbf{V}}_2$.
(*e*) $\vec{\mathbf{V}}_1$ and $\vec{\mathbf{V}}_2$ are in the same plane.
(*f*) $\vec{\mathbf{V}}_1$ and $\vec{\mathbf{V}}_2$ make a 45° angle with each other.

6. If there were a great migration of people toward the Earth's equator, the length of the day would
(*a*) increase because of conservation of angular momentum.
(*b*) decrease because of conservation of angular momentum.
(*c*) decrease because of conservation of energy.
(*d*) increase because of conservation of energy.
(*e*) remain unaffected.

7. A particle moves with constant speed along a straight line. How does its angular momentum, calculated about any point O not on its path, change in time?
(*a*) Decreases as it approaches O, then increases.
(*b*) Increases as it approaches O, then decreases.
(*c*) Would remain the same.

8. The angular momentum vector can be written $\vec{\mathbf{L}} = I\vec{\boldsymbol{\omega}}$
(*a*) always.
(*b*) always for an object rotating about any axis.
(*c*) always for an object rotating about an axis fixed in space.
(*d*) for any rotation axis passing through the CM of the object.
(*e*) always for the component of $\vec{\mathbf{L}}$ that is along the (fixed) axis of rotation.

9. A person sits on a freely spinning chair (no friction), Fig. 11–30. When this person extends her arms,
(*a*) her moment of inertia increases and her angular velocity decreases.
(*b*) her moment of inertia decreases and her angular velocity decreases.
(*c*) her moment of inertia increases and her angular velocity increases.
(*d*) her moment of inertia increases and her angular velocity remains the same.
(*e*) her moment of inertia decreases and her angular velocity increases.

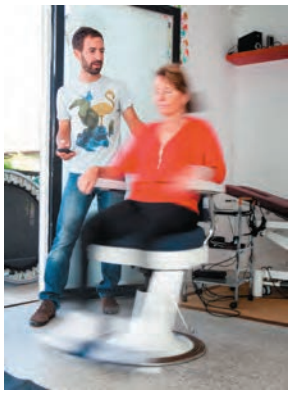

**FIGURE 11–30** MisConceptual Question 9.

10. You are holding on to the ends of the horizontal axle of a spinning bicycle wheel with your hands. The top part of the wheel is rotating *toward* you. If you start to turn your whole body toward the left, you feel the right side of the axle
(*a*) pull on your right hand away from you.
(*b*) push on your right hand toward the left.
(*c*) push on your right hand vertically down.
(*d*) push on your right hand toward you.
(*e*) push on your right hand vertically up.

11. You are looking horizontally at a wheel which is rotating in a clockwise direction. Take the origin of coordinates at the center of the wheel. The $x$ axis points toward you, the $y$ axis points to the right, and the $z$ axis is up. The direction of the angular momentum vector is
(*a*) clockwise.
(*b*) counterclockwise.
(*c*) $\hat{\mathbf{i}}$.
(*d*) $-\hat{\mathbf{i}}$.
(*e*) $\hat{\mathbf{j}}$.
(*f*) $-\hat{\mathbf{j}}$.
(*g*) $\hat{\mathbf{k}}$.
(*h*) $-\hat{\mathbf{k}}$.

# Problems

## 11–1 Angular Momentum

1. (I) What is the angular momentum of a 0.210-kg ball revolving on the end of a thin string in a circle of radius 1.25 m at an angular speed of 10.4 rad/s?

2. (I) (*a*) What is the angular momentum of a 2.8-kg uniform cylindrical grinding wheel of radius 18 cm when rotating at 1500 rpm? (*b*) How much torque is required to stop it in 6.0 s?

3. (I) A nonrotating cylindrical disk of moment of inertia $I$ is dropped onto an identical disk rotating at angular speed $\omega$. Assuming no external torques, what is the final common angular speed of the two disks?

4. (II) A diver (such as the one shown in Fig. 11–2) can reduce her moment of inertia by a factor of about 3.5 when changing from the straight position to the tuck position. If she makes 2.0 rotations in 1.5 s when in the tuck position, what is her angular speed (rev/s) when in the straight position?

5. (II) A figure skater can increase her spin rotation rate from an initial rate of 1.0 rev every 1.5 s to a final rate of 2.5 rev/s. If her initial moment of inertia was $4.9\,\text{kg}\cdot\text{m}^2$, what is her final moment of inertia? How does she physically accomplish this change?

**6.** (II) A person stands, hands at his side, on a platform that is rotating at a rate of 0.80 rev/s. If he raises his arms to a horizontal position, Fig. 11–31, the speed of rotation decreases to 0.60 rev/s. (*a*) Why? (*b*) By what factor has his moment of inertia changed?

**FIGURE 11–31**
Problem 6.

**7.** (II) Determine the angular momentum of the Earth (*a*) about its rotation axis (assume the Earth is a uniform sphere), and (*b*) in its orbit around the Sun (treat the Earth as a particle orbiting the Sun).

**8.** (II) (*a*) What is the angular momentum of a figure skater spinning at 2.8 rev/s with arms in close to her body, assuming her to be a uniform cylinder with a height of 1.5 m, a radius of 15 cm, and a mass of 48 kg? (*b*) How much torque is required to slow her to a stop in 4.0 s, assuming she does *not* move her arms?

**9.** (II) A uniform disk turns at 4.1 rev/s around a frictionless central axis. A nonrotating rod, of the same mass as the disk and length equal to the disk's diameter, is dropped onto the freely spinning disk, Fig. 11–32. They then turn together around the spindle with their centers superposed. What is the angular frequency in rev/s of the combination?

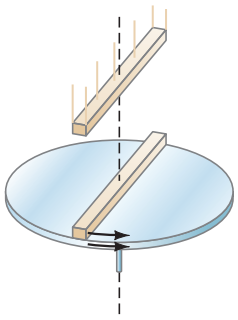

**FIGURE 11–32**
Problem 9.

**10.** (II) A person of mass 75 kg stands at the center of a rotating merry-go-round platform of radius 3.0 m and moment of inertia $920\ \text{kg}\cdot\text{m}^2$. The platform rotates without friction with angular velocity 0.95 rad/s. The person walks radially to the edge of the platform. (*a*) Calculate the angular velocity when the person reaches the edge. (*b*) Calculate the rotational kinetic energy of the system of platform plus person before and after the person's walk.

**11.** (II) A person stands on a platform, initially at rest, that can rotate freely without friction. The moment of inertia of the person plus the platform is $I_P$. The person holds a spinning bicycle wheel with its axis horizontal. The wheel has moment of inertia $I_W$ and angular velocity $\omega_W$. What will be the angular velocity $\omega_P$ of the platform if the person moves the axis of the spinning wheel so that it points (*a*) vertically upward, (*b*) at a 60° angle to the vertical, (*c*) vertically downward? (*d*) What will $\omega_P$ be if the person reaches up and stops the spinning wheel in part (*a*)?

**12.** (II) A potter's wheel is rotating around a vertical axis through its center at a frequency of 1.5 rev/s. The wheel can be considered a uniform disk of mass 5.0 kg and diameter 0.40 m. The potter then throws a 2.8-kg chunk of clay, approximately shaped as a flat disk of radius 8.0 cm, onto the center of the rotating wheel. What is the frequency of the wheel after the clay sticks to it?

**13.** (II) A 4.2-m-diameter merry-go-round is rotating freely with an angular velocity of 0.80 rad/s. Its total moment of inertia is $1630\ \text{kg}\cdot\text{m}^2$. Four people standing on the ground, each of mass 65 kg, suddenly step onto the edge of the merry-go-round. (*a*) What is the angular velocity of the merry-go-round now? (*b*) What if the people were on it initially and then jumped off in a radial direction (relative to the merry-go-round)?

**14.** (II) A woman of mass $m$ stands at the edge of a solid cylindrical platform of mass $M$ and radius $R$. At $t = 0$, the platform is rotating with negligible friction at angular velocity $\omega_0$ about a vertical axis through its center, and the woman begins walking with speed $v$ (relative to the platform) toward the center of the platform. (*a*) Determine the angular velocity of the system as a function of time. (*b*) What will be the angular velocity when the woman reaches the center?

**15.** (II) Model a figure skater's body (mass $M$) as a solid cylinder ($\approx 0.75M$ including head and thighs) and her arms as thin rods ($0.13M$ for both), making reasonable estimates for the dimensions. Then calculate the ratio of the angular speeds for a spinning skater with outstretched arms, and with arms held tightly against her body. (Ignore contributions from lower legs and feet.)

**16.** (II) A 3.0-kg cylindrical grindstone of radius 8.0 cm is attached to a motor. The angular momentum of the grindstone after the motor is turned on is given by

$$L = (1.2\ \text{kg}\cdot\text{m}^2/\text{s})\left(1 - e^{-0.050t}\right),$$

where $t$ is in seconds. (*a*) What is the final rotation rate in rpm of the grindstone? (*b*) What is the net torque applied to the grindstone, as a function of time?

**17.** (II) A uniform horizontal rod of mass $M$ and length $\ell$ rotates with angular velocity $\omega$ about a vertical axis through its center. Attached to each end of the rod is a small mass $m$. Determine the angular momentum of the system about the axis.

**18.** (II) Suppose our Sun eventually collapses into a *white dwarf*, losing about half its mass in the process, and ending up with a radius 1.0% of its existing radius. Assuming the lost mass carries away no angular momentum, (*a*) what would the Sun's new rotation rate be? Take the *Sun's* current *period* to be about 30 days. (*b*) What would be its final kinetic energy in terms of its initial kinetic energy of today?

**19.** (II) Hurricanes can involve winds in excess of 120 km/h at the outer edge. Make a rough estimate of (*a*) the energy, and (*b*) the angular momentum, of such a hurricane, approximating it as a rigidly rotating uniform cylinder of air (density $1.3\ \text{kg/m}^3$) of radius 85 km and height 4.5 km.

**20.** (III) An asteroid of mass $2.0 \times 10^5$ kg, traveling at a speed of 35 km/s relative to the Earth, hits the Earth at the equator tangentially, in the direction of Earth's rotation, and is embedded there. Use angular momentum to estimate the percent change in the angular speed of the Earth as a result of the collision.

**21.** (III) Suppose a 65-kg person stands at the edge of a 9.8-m-diameter merry-go-round turntable that is mounted on frictionless bearings and has a moment of inertia of $1850\ \text{kg}\cdot\text{m}^2$. The turntable is at rest initially, but when the person begins running at a speed of 3.8 m/s (with respect to the turntable) around its edge, the turntable begins to rotate in the opposite direction. Calculate the angular velocity of the turntable.

## 11–2 Vector Cross Product and Torque

**22.** (I) If vector $\vec{\mathbf{A}}$ points along the negative $x$ axis and vector $\vec{\mathbf{B}}$ along the positive $z$ axis, what is the direction of (*a*) $\vec{\mathbf{A}} \times \vec{\mathbf{B}}$ and (*b*) $\vec{\mathbf{B}} \times \vec{\mathbf{A}}$? (*c*) What is the magnitude of $\vec{\mathbf{A}} \times \vec{\mathbf{B}}$ and $\vec{\mathbf{B}} \times \vec{\mathbf{A}}$?

**23.** (I) Show that (*a*) $\hat{\mathbf{i}} \times \hat{\mathbf{i}} = \hat{\mathbf{j}} \times \hat{\mathbf{j}} = \hat{\mathbf{k}} \times \hat{\mathbf{k}} = 0$, (*b*) $\hat{\mathbf{i}} \times \hat{\mathbf{j}} = \hat{\mathbf{k}}$, $\hat{\mathbf{i}} \times \hat{\mathbf{k}} = -\hat{\mathbf{j}}$, and $\hat{\mathbf{j}} \times \hat{\mathbf{k}} = \hat{\mathbf{i}}$.

**24.** (I) The directions of vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ are given below for several cases. For each case, state the direction of $\vec{\mathbf{A}} \times \vec{\mathbf{B}}$. (*a*) $\vec{\mathbf{A}}$ points east, $\vec{\mathbf{B}}$ points south. (*b*) $\vec{\mathbf{A}}$ points east, $\vec{\mathbf{B}}$ points straight down. (*c*) $\vec{\mathbf{A}}$ points straight up, $\vec{\mathbf{B}}$ points north. (*d*) $\vec{\mathbf{A}}$ points straight up, $\vec{\mathbf{B}}$ points straight down.

**25.** (II) What is the angle $\theta$ between two vectors $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$, if $|\vec{\mathbf{A}} \times \vec{\mathbf{B}}| = \vec{\mathbf{A}} \cdot \vec{\mathbf{B}}$?

**26.** (II) A particle is located at $\vec{\mathbf{r}} = (5.0\hat{\mathbf{i}} + 3.5\hat{\mathbf{j}} + 6.0\hat{\mathbf{k}})$ m. A force $\vec{\mathbf{F}} = (8.0\hat{\mathbf{j}} - 4.0\hat{\mathbf{k}})$ N acts on it. What is the torque, calculated about the origin?

**27.** (II) Consider a particle of a rigid object rotating about a fixed axis. Show that the tangential and radial vector components of the linear acceleration are:

$$\vec{\mathbf{a}}_{\tan} = \vec{\boldsymbol{\alpha}} \times \vec{\mathbf{r}} \quad \text{and} \quad \vec{\mathbf{a}}_{\mathrm{R}} = \vec{\boldsymbol{\omega}} \times \vec{\mathbf{v}}.$$

**28.** (II) Let us show that Eq. 11–3c is equivalent to the *definition* of *cross product*, Eq. 11–3a and the sentence below it including the right-hand rule and Fig. 11–7. We do this in three parts. (i) First show that the magnitude $\vec{\mathbf{C}}$ as given by Eq. 11–3c equals $AB\sin\theta$, Eq. 11–3a. Start with Eq. 11–3c and write $C^2 = |\vec{\mathbf{A}} \times \vec{\mathbf{B}}|^2$ in terms of the components in Eq. 11–3c. Use algebra to arrange the terms in the form $[A_x^2(B_y^2 + B_z^2) + \text{two similar terms}]$ plus a term $[-2(A_xB_xA_yB_y + 2 \text{ more terms})]$. To this long equation for $C^2$, add and subtract three terms of the form $[0 = A_x^2B_x^2 - A_x^2B_x^2, \ldots]$ and then gather terms together of the form $[(A_x^2 + \ldots)(B_x^2 + \ldots) - 2(A_xB_xA_yB_y + 2 \text{ more terms}) - (A_x^2B_x^2 + 2 \text{ more terms})]$. Simplify this long equation to the form $[A^2B^2 - (\vec{\mathbf{A}} \cdot \vec{\mathbf{B}})^2]$, from which show that $C^2 = A^2B^2\sin^2\theta$, which gives us Eq. 11–3a. (ii) Secondly, starting with Eq. 11–3c, show that $\vec{\mathbf{C}}$ is perpendicular to both $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ (as stated in the definition, the italic sentence below Eq. 11–3a) by taking the products $\vec{\mathbf{A}} \cdot \vec{\mathbf{C}}$ and $\vec{\mathbf{B}} \cdot \vec{\mathbf{C}}$ and showing they are zero (i.e. $\cos\theta = 0$ so $\theta = 90°$). (iii) Finally, choose a coordinate system so that $\vec{\mathbf{A}} = A_x\hat{\mathbf{i}}$ and $\vec{\mathbf{B}} = B_x\hat{\mathbf{i}} + B_y\hat{\mathbf{j}}$ and show that $\vec{\mathbf{C}} = \vec{\mathbf{A}} \times \vec{\mathbf{B}}$ follows the right-hand rule.

**29.** (II) Using Eq. 11–3c, show that the *distributive law* (Eq. 11–4c) is valid.

**30.** (II) An engineer estimates that under the most adverse expected weather conditions, the total force on the highway sign in Fig. 11–33 will be $\vec{\mathbf{F}} = (\pm 2.4\hat{\mathbf{i}} - 4.1\hat{\mathbf{j}})$ kN, acting at the CM. What torque does this force exert about the base O?

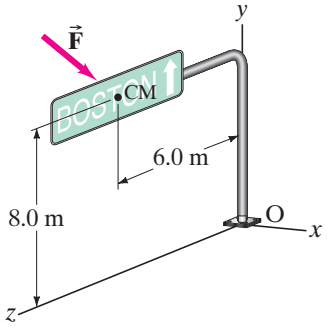

**FIGURE 11–33** Problem 30.

**31.** (II) Determine (*a*) the vector product $\vec{\mathbf{A}} \times \vec{\mathbf{B}}$ and (*b*) the angle between $\vec{\mathbf{A}}$ and $\vec{\mathbf{B}}$ if $\vec{\mathbf{A}} = 7.4\hat{\mathbf{i}} - 3.5\hat{\mathbf{j}}$ and $\vec{\mathbf{B}} = -8.5\hat{\mathbf{i}} + 4.6\hat{\mathbf{j}} + 2.0\hat{\mathbf{k}}$. [*Hint*: To resolve an ambiguity, the dot product may prove useful.]

**32.** (II) The origin of a coordinate system is at the center of a wheel which rotates in the $xy$ plane about its axle which is the $z$ axis. A force $F = 215$ N acts in the $xy$ plane, at a $+28.0°$ angle to the $x$ axis, at the point $x = 28.0$ cm, $y = 33.5$ cm. Determine the magnitude and direction of the torque produced by this force about the axis.

**33.** (III) Show that the velocity $\vec{\mathbf{v}}$ of any point in an object rotating with *angular velocity* $\vec{\boldsymbol{\omega}}$ about a fixed axis can be written

$$\vec{\mathbf{v}} = \vec{\boldsymbol{\omega}} \times \vec{\mathbf{r}}$$

where $\vec{\mathbf{r}}$ is the position vector of the point relative to an origin O located on the axis of rotation. Can O be anywhere on the rotation axis? Will $\vec{\mathbf{v}} = \vec{\boldsymbol{\omega}} \times \vec{\mathbf{r}}$ if O is located at a point not on the axis of rotation?

## 11–3 Angular Momentum of a Particle

**34.** (I) What are the $x$, $y$, and $z$ components of the angular momentum about the origin for a particle located at $\vec{\mathbf{r}} = x\hat{\mathbf{i}} + y\hat{\mathbf{j}} + z\hat{\mathbf{k}}$ which has momentum $\vec{\mathbf{p}} = p_x\hat{\mathbf{i}} + p_y\hat{\mathbf{j}} + p_z\hat{\mathbf{k}}$?

**35.** (I) Show that the kinetic energy $K$ of a particle of mass $m$, moving in a circular path, is $K = L^2/2I$, where $L$ is its angular momentum and $I$ is its moment of inertia about the center of the circle.

**36.** (I) Calculate the angular momentum of a particle of mass $m$ moving with constant velocity $v$ for two cases (see Fig. 11–34): (*a*) about origin O, and (*b*) about O′.

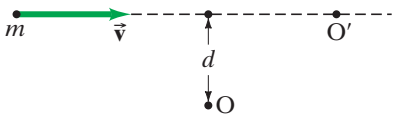

**FIGURE 11–34** Problem 36.

**37.** (II) Two identical particles have equal but opposite momenta, $\vec{\mathbf{p}}$ and $-\vec{\mathbf{p}}$, but they are not traveling along the same line. Show that the total angular momentum of this system does not depend on the choice of origin.

**38.** (II) Determine the angular momentum of an 85-g particle about the origin of coordinates when the particle is at $x = 4.4$ m, $y = -6.0$ m, and it has velocity $v = (3.2\hat{\mathbf{i}} - 8.0\hat{\mathbf{k}})$ m/s.

**39.** (II) A particle is at the position $(x, y, z) = (1.0, 2.0, 3.0)$ m. It is traveling with a vector velocity $(-5.0, +2.8, -3.1)$ m/s. Its mass is 4.3 kg. What is its vector angular momentum about the origin?

## 11–4 and 11–5 Angular Momentum and Torque: General Motion; Rigid Objects

**40.** (II) An Atwood machine (Fig. 11–16) consists of two masses, $m_A = 7.0$ kg and $m_B = 8.2$ kg, connected by a cord that passes over a pulley free to rotate about a fixed axis. The pulley is a solid cylinder of radius $R_0 = 0.45$ m and mass 0.80 kg. (*a*) Determine the acceleration $a$ of each mass. (*b*) What percentage of error in $a$ would be made if the moment of inertia of the pulley were ignored? Ignore friction in the pulley bearings. Use angular momentum.

**41.** (II) Four identical particles of mass $m$ are mounted at equal intervals on a thin rod of length $\ell$ and mass $M$, with one mass at each end of the rod. If the system is rotated with angular velocity $\omega$ about an axis perpendicular to the rod through one of the end masses, determine (*a*) the kinetic energy and (*b*) the angular momentum of the system.

**42.** (II) Two lightweight rods 24 cm in length are mounted perpendicular to an axle and at 180° to each other (Fig. 11–35). At the end of each rod is a 480-g mass. The rods are spaced 42 cm apart along the axle. The axle rotates at 4.5 rad/s. (*a*) What is the component of the total angular momentum along the axle? (*b*) What angle does the vector angular momentum make with the axle? [*Hint*: Remember that the vector angular momentum must be calculated about the *same point* for *both* masses, which could be the CM.]

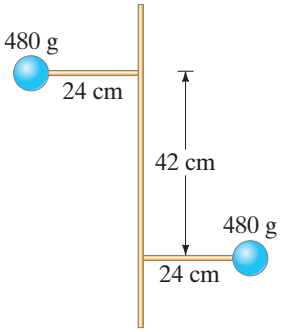

**FIGURE 11–35** Problem 42.

**43.** (II) Figure 11–36 shows two masses connected by a cord passing over a pulley of radius $R_0$ and moment of inertia $I$. Mass $M_A$ slides on a frictionless surface, and $M_B$ hangs freely. Determine a formula for (*a*) the angular momentum of the system about the pulley axis, as a function of the speed $v$ of mass $M_A$ or $M_B$, and (*b*) the acceleration of the masses.

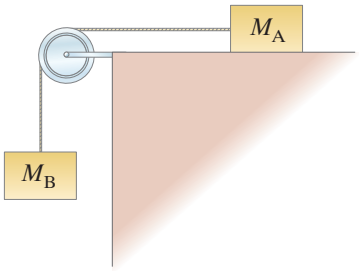

**FIGURE 11–36** Problem 43.

***44.** (III) Show that the total angular momentum $\vec{\mathbf{L}} = \Sigma \vec{\mathbf{r}}_i \times \vec{\mathbf{p}}_i$ of a system of particles about the origin of an inertial reference frame can be written as the sum of the angular momentum about the CM, $\vec{\mathbf{L}}^*$ (spin angular momentum), plus the angular momentum of the CM about the origin (orbital angular momentum): $\vec{\mathbf{L}} = \vec{\mathbf{L}}^* + \vec{\mathbf{r}}_{CM} \times M\vec{\mathbf{v}}_{CM}$. [*Hint*: See the derivation of Eq. 11–9b.]

***45.** (III) (*a*) Determine the magnitude of the force $\vec{\mathbf{F}}$ exerted by each bearing in Fig. 11–18 (Example 11–10). The bearings are a distance $d$ from point O. Ignore the effects of gravity. (*b*) Suppose in Fig. 11–18 that $m_A = m_B = 0.60$ kg, $r_A = r_B = 0.30$ m, and the distance between the bearings is 0.23 m. Evaluate the force that each bearing must exert on the axle if $\phi = 28.0°$, $\omega = 11.0$ rad/s.

***46.** (III) Suppose in Fig. 11–18 that $m_B = 0$; that is, only one mass, $m_A$, is actually present. If the bearings are each a distance $d$ from O, determine the forces $F_A$ and $F_B$ at the upper and lower bearings respectively. [*Hint*: Choose an origin—different than O in Fig. 11–18—such that $\vec{\mathbf{L}}$ is parallel to $\vec{\boldsymbol{\omega}}$. Ignore effects of gravity.]

## 11–6 Angular Momentum Conservation

**47.** (II) A thin rod of mass $M$ and length $\ell$ is suspended vertically from a frictionless pivot at its upper end. A mass $m$ of putty traveling horizontally with a speed $v$ strikes the rod at its CM and sticks there. How high does the bottom of the rod swing?

**48.** (II) A uniform stick 1.0 m long with a total mass of 270 g is pivoted at its center. A 3.5-g bullet is shot through the stick midway between the pivot and one end (Fig. 11–37). The bullet approaches at 250 m/s and leaves at 140 m/s. With what angular speed is the stick spinning after the collision?

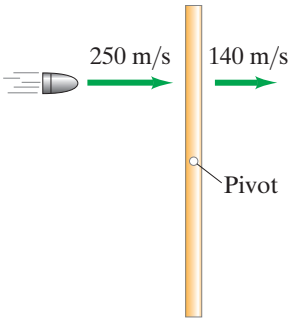

**FIGURE 11–37** Problem 48.

**49.** (II) Two ice skaters, both of mass 68 kg, approach on parallel paths 1.6 m apart. Both are moving at 3.5 m/s with their arms outstretched. They join hands as they pass, still maintaining their 1.6-m separation, and begin rotating about one another. Treat the skaters as particles with regard to their rotational inertia. (*a*) What is their common angular speed after joining hands? (*b*) Calculate the change in kinetic energy for this process. (*c*) If they now pull on each other's hands, reducing their radius to half its original value, what is their common angular speed after reducing their radius? (*d*) Calculate the change in kinetic energy for this process. Why is it different than in part (*b*)?

**50.** (II) Suppose a $5.2 \times 10^{10}$ kg meteorite struck the Earth at the equator with a speed $v = 2.2 \times 10^4$ m/s, as shown in Fig. 11–38 and remained stuck. By what factor would this affect the rotational frequency of the Earth (1 rev/day)?

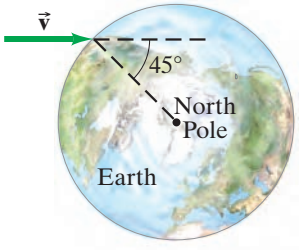

**FIGURE 11–38** Problem 50.

**51.** (III) A 260-kg beam 2.7 m in length slides broadside down the ice with a speed of 18 m/s (Fig. 11–39). A 65-kg man at rest grabs one end as it goes past and hangs on as both he and the beam go spinning down the ice. Assume frictionless motion. (*a*) How fast does the center of mass of the system move after the collision? (*b*) With what angular velocity does the system rotate about its CM?

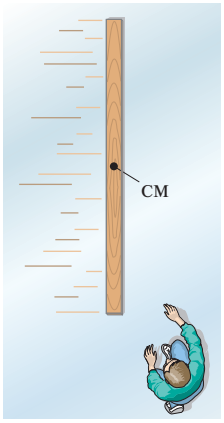

**FIGURE 11–39**
Problem 51.

**52.** (III) A thin uniform rod of mass $M$ and length $\ell$ rests on a frictionless table and is struck at a point $\ell/4$ from its CM by a clay ball of mass $m$ moving at speed $v$ (Fig. 11–40). The ball sticks to the rod. Determine the translational and rotational motion of the rod after the collision.

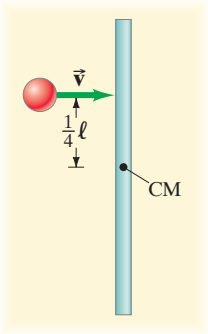

**FIGURE 11–40**
Problem 52.

**53.** (III) On a level billiards table a cue ball, initially at rest at point O on the table, is struck so that it leaves the cue stick with a center-of-mass speed $v_0$ and a "reverse" spin of angular speed $\omega_0$ (see Fig. 11–41). A kinetic friction force acts on the ball as it initially skids across the table. (*a*) Explain why the ball's angular momentum is conserved about point O. (*b*) Using conservation of angular momentum, find the critical angular speed $\omega_C$ such that, if $\omega_0 = \omega_C$, kinetic friction will bring the ball to a complete (as opposed to momentary) stop. (*c*) If $\omega_0$ is 10% smaller than $\omega_C$, i.e., $\omega_0 = 0.90\,\omega_C$, determine the ball's CM velocity $v_{CM}$ when it starts to roll without slipping. (*d*) If $\omega_0$ is 10% larger than $\omega_C$, i.e., $\omega_0 = 1.10\,\omega_C$, determine the ball's CM velocity $v_{CM}$ when it starts to roll without slipping. [*Hint*: The ball possesses two types of angular momentum, the first due to the linear speed $v_{CM}$ of its CM relative to point O, the second due to the spin at angular velocity $\omega$ about its own CM. The ball's total $L$ about O is the sum of these two angular momenta.]

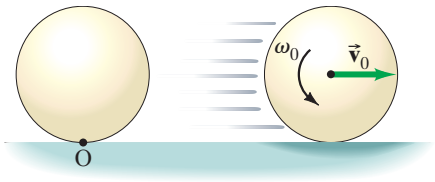

**FIGURE 11–41** Problem 53.

## *11–7 Spinning Top

***54.** (II) A 220-g top spinning at 15 rev/s makes an angle of 25° to the vertical and precesses at a rate of 1.00 rev per 5.5 s. If its CM is 3.5 cm from its tip along its symmetry axis, what is the moment of inertia of the top?

***55.** (II) A toy gyroscope consists of a 170-g disk with a radius of 5.5 cm mounted at the center of a thin axle 21 cm long (Fig. 11–42). The gyroscope spins at 45 rev/s. One end of its axle rests on a stand and the other end precesses horizontally about the stand. (*a*) How long does it take the gyroscope to precess once around? (*b*) If all the dimensions of the gyroscope were doubled (radius = 11 cm, axle = 42 cm), how long would it take to precess once?

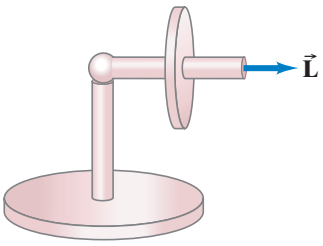

**FIGURE 11–42**
A wheel, rotating about a horizontal axle supported at one end, precesses. Problems 55, 56, and 57.

***56.** (II) Suppose the solid wheel of Fig. 11–42 has a mass of 260 g and rotates at 85 rad/s; it has radius 6.0 cm and is mounted at the center of a horizontal thin axle 25 cm long. At what rate does the axle precess?

***57.** (II) If a mass equal to half the mass of the wheel in Problem 56 is placed at the free end of the axle, what will be the precession rate now? Treat the extra mass as insignificant in size.

***58.** (II) A bicycle wheel of diameter 65 cm and mass $m$ rotates on its axle; two 20-cm-long wooden handles, one on each side of the wheel, act as the axle. You tie a rope to a small hook on the end of one of the handles, and then spin the bicycle wheel with a flick of the hand. You release the spinning wheel, holding it by a short section of rope from your hand. The wheel then precesses about the vertical axis defined by the rope, instead of falling toward the ground (as it would if it were not spinning). Estimate the rate and direction of precession if the wheel rotates counterclockwise at 2.5 rev/s and its axle remains horizontal.

***59.** (III) The axis of the *Earth precesses* with a period of about 26,000 years (sometimes called the *precession of the equinoxes*). This is much like the precession of a top. Explain how the *Earth's equatorial bulge* gives rise to a torque exerted by the Sun and Moon on the Earth; see Fig. 11–43, which is drawn for the winter solstice (December 21), and has greatly exaggerated the Earth's equatorial bulge. About what axis would you expect the Earth's rotation axis to precess as a result of the torque due to the Sun? Does the torque exist three months later? Explain.

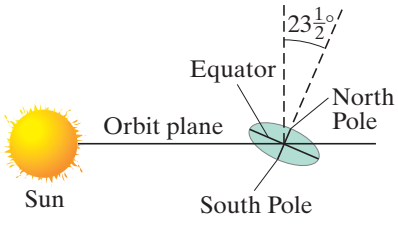

**FIGURE 11–43** Problem 59. (Not to scale.)

## 11–8 Rotating Reference Frames; Inertial Forces

**60.** (II) If a plant is allowed to grow from seed on a rotating platform, it will grow at an angle, pointing inward. Calculate what this angle will be (put yourself in the rotating frame) in terms of $g$, $r$, and $\omega$. Why does it grow inward rather than outward?

**61.** (III) Let $\vec{\mathbf{g}}'$ be the effective acceleration of gravity at a point on the rotating Earth, equal to the vector sum of the "true" value $\vec{\mathbf{g}}$ plus the effect of the rotating reference frame ($m\omega^2 r$ term). See Fig. 11–44. Determine the magnitude and direction of $\vec{\mathbf{g}}'$ relative to a radial line from the center of the Earth (*a*) at the North Pole, (*b*) at a latitude of 45.0° north, and (*c*) at the equator. Assume that $g$ (if $\omega$ were zero) is a constant $9.80\,\text{m/s}^2$.

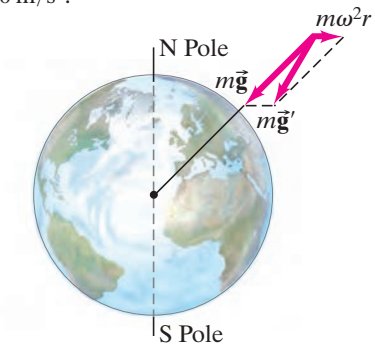

**FIGURE 11–44** Problem 61.

## *11–9 Coriolis Effect

***62.** (II) Suppose the man at B in Fig. 11–26 throws the ball toward the woman at A. (*a*) In what direction is the ball deflected as seen in the noninertial reference frame? (*b*) Determine a formula for the amount of deflection and for the (Coriolis) acceleration in this case.

***63.** (II) For what directions of velocity would the Coriolis effect on an object moving at the Earth's equator be zero?

***64.** (III) We can alter Eqs. 11–14 and 11–15 for use on Earth by considering only the component of $\vec{\mathbf{v}}$ perpendicular to the axis of rotation. From Fig. 11–45 we see that this is $v\cos\lambda$ for a vertically falling object, where $\lambda$ is the latitude of the place on the Earth. If a lead ball is dropped vertically from a 110-m-high tower in Florence, Italy (latitude = 44°), how far from the base of the tower is it deflected by the Coriolis force?

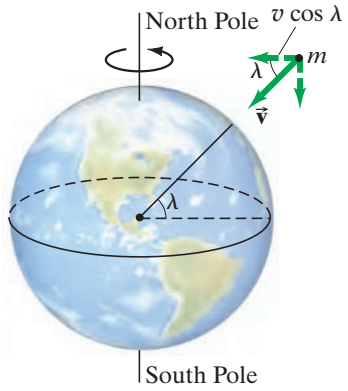

**FIGURE 11–45** Problem 64. Object of mass $m$ falling vertically to Earth at a latitude $\lambda$.

***65.** (III) An ant crawls with constant speed outward along a radial spoke of a wheel rotating at constant angular velocity $\omega$ about a vertical axis. Write a vector equation for all the forces (including inertial forces) acting on the ant. Take the $x$ axis along the spoke, $y$ perpendicular to the spoke pointing to the ant's left, and the $z$ axis vertically upward. The wheel rotates counterclockwise as seen from above.

# General Problems

**66.** A thin string is wrapped around a cylindrical hoop of radius $R$ and mass $M$ (Fig. 11–46). One end of the string is fixed, and the hoop is allowed to fall vertically, starting from rest, as the string unwinds. (*a*) Determine the angular momentum of the hoop about its CM as a function of time. (*b*) What is the tension in the string as a function of time?

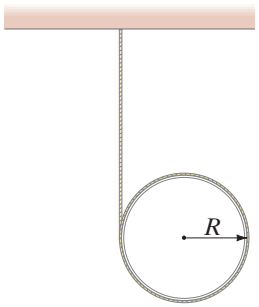

**FIGURE 11–46** Problem 66.

**67.** A particle of mass 1.50 kg is moving with velocity $\vec{\mathbf{v}} = (7.0\,\hat{\mathbf{i}} + 6.0\,\hat{\mathbf{j}})\,\text{m/s}$. (*a*) Find the angular momentum $\vec{\mathbf{L}}$ relative to the origin when the particle is at $\vec{\mathbf{r}} = (2.0\,\hat{\mathbf{j}} + 4.0\,\hat{\mathbf{k}})\,\text{m}$. (*b*) At position $\vec{\mathbf{r}}$ a force of $\vec{\mathbf{F}} = 4.0\,\text{N}\,\hat{\mathbf{i}}$ is applied to the particle. Find the torque relative to the origin.

**68.** A merry-go-round with a moment of inertia equal to $860\,\text{kg}\cdot\text{m}^2$ and a radius of 3.0 m rotates with negligible friction at 1.70 rad/s. A child initially standing still next to the merry-go-round jumps onto the edge of the platform straight toward the axis of rotation causing the platform to slow to 1.25 rad/s. What is her mass?

**69.** Why might tall narrow SUVs and buses be prone to *rollover*? Consider a vehicle rounding a curve of radius $R$ on a flat road. When just on the verge of rollover, its tires on the inside of the curve are about to leave the ground, so the friction and normal force on these two tires are zero. The total normal force on the outside tires is $F_\text{N}$ and the total friction force is $F_\text{fr}$. Assume that the vehicle is not skidding. (*a*) Analysts define a *vehicle static stability factor* SSF = $w/2h$, where a vehicle's "track width" $w$ is the distance between tires on the same axle, and $h$ is the height of the CM above the ground. Show that the critical rollover speed is

$$v_\text{C} = \sqrt{Rg\left(\frac{w}{2h}\right)}.$$

[*Hint*: Take torques about an axis through the center of mass of the SUV, parallel to its direction of motion.] (*b*) Determine the ratio of highway curve radii (minimum possible) for a typical passenger car with SSF = 1.40 and an SUV with SSF = 1.05 at a speed of 90 km/h.

**70.** A projectile with mass $m$ is launched from the ground and follows a trajectory given by

$$\vec{\mathbf{r}} = (v_{x0}t)\,\hat{\mathbf{i}} + \left(v_{y0}t - \frac{1}{2}gt^2\right)\hat{\mathbf{j}}$$

where $v_{x0}$ and $v_{y0}$ are the initial velocities in the $x$ and $y$ direction, respectively, and $g$ is the acceleration due to gravity. The launch position is defined to be the origin. Determine the torque acting on the projectile about the origin using (*a*) $\vec{\boldsymbol{\tau}} = \vec{\mathbf{r}} \times \vec{\mathbf{F}}$, (*b*) $\vec{\boldsymbol{\tau}} = d\vec{\mathbf{L}}/dt$.

**71.** A small 250-g ball is moving in a 0.50-m-radius horizontal circle (the $xy$ plane). The ball is moving clockwise when viewed from above and has kinetic energy 0.40 J. What is the ball's angular momentum?

**72.** A spherical asteroid with radius $r = 123\,\text{m}$ and mass $M = 2.65 \times 10^{10}\,\text{kg}$ rotates about an axis at 4.0 revolutions per day. A "tug" spaceship attaches itself to the asteroid's south pole (as defined by the axis of rotation) and fires its engine, applying a force $F$ tangentially to the asteroid's surface as shown in Fig. 11–47. If $F = 265\,\text{N}$, how long will it take the tug to rotate the asteroid's axis of rotation through an angle of 6.0° by this method?

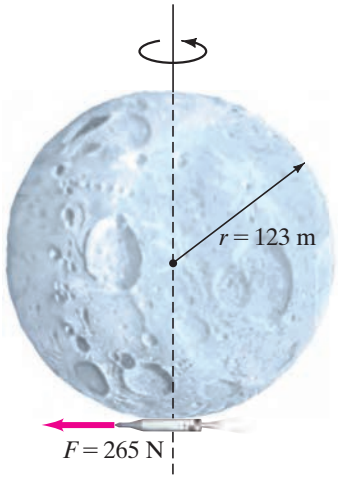

**FIGURE 11–47** Problem 72.

**73.** The time-dependent position of a point object which moves counterclockwise along the circumference of a circle (radius $R$) in the $xy$ plane with constant speed $v$ is given by

$$\vec{\mathbf{r}} = \hat{\mathbf{i}} R\cos\omega t + \hat{\mathbf{j}} R\sin\omega t$$

where the constant $\omega = v/R$. Determine the velocity $\vec{\mathbf{v}}$ and angular velocity $\vec{\boldsymbol{\omega}}$ of this object and then show that these three vectors obey the relation $\vec{\mathbf{v}} = \vec{\boldsymbol{\omega}} \times \vec{\mathbf{r}}$.

**74.** The position of a particle with mass $m$ traveling on a *helical path* (see Fig. 11–48) is given by

$$\vec{\mathbf{r}} = R\cos\left(\frac{2\pi z}{d}\right)\hat{\mathbf{i}} + R\sin\left(\frac{2\pi z}{d}\right)\hat{\mathbf{j}} + z\,\hat{\mathbf{k}}$$

where $R$ and $d$ are the radius and pitch of the helix, respectively, and $z$ has time dependence $z = v_z t$ where $v_z$ is the (constant) component of velocity in the $z$ direction. Determine the time-dependent angular momentum $\vec{\mathbf{L}}$ of the particle about the origin.

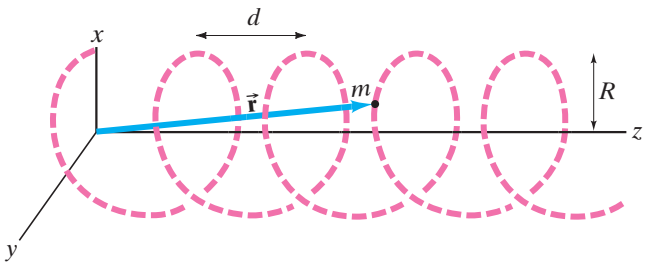

**FIGURE 11–48** Problem 74.

**75.** A boy rolls a tire along a straight level street. The tire has mass 8.0 kg, radius 0.32 m and moment of inertia about its central axis of symmetry of $0.83\,\text{kg}\cdot\text{m}^2$. The boy pushes the tire forward away from him at a speed of 2.1 m/s and sees that the tire leans 12° to the right (Fig. 11–49). (*a*) How will the resultant torque due to gravity and the normal force $\vec{\mathbf{F}}_\text{N}$ affect the subsequent motion of the tire? (*b*) Compare the change in angular momentum caused by this torque in 0.20 s to the original magnitude of angular momentum.

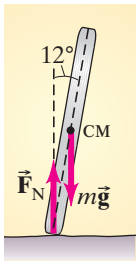

**FIGURE 11–49** Problem 75.

**76.** A 70.0-kg person stands on a tiny rotating platform with arms outstretched. (*a*) Estimate the moment of inertia of the person using the following approximations: the body (including head and legs) is a 62.0-kg cylinder, 16 cm in radius and 1.70 m high; and each arm is a 4.0-kg thin rod, 60.0 cm long, attached to the cylinder. (*b*) Using the same approximations, estimate the moment of inertia when the arms are at the person's sides. (*c*) If one rotation takes 1.2 s when the person's arms are outstretched, what is the time for each rotation with arms at the sides? Ignore the moment of inertia of the lightweight platform. (*d*) Determine the change in kinetic energy when the arms are lifted from the sides to the horizontal position. (*e*) From your answer to part (*d*), would you expect it to be harder or easier to lift your arms when rotating or when at rest?

**77.** Water drives a waterwheel (or turbine) of radius $R = 3.0\,\text{m}$ as shown in Fig. 11–50. The water enters at a speed $v_1 = 7.0\,\text{m/s}$ and exits from the waterwheel at a speed $v_2 = 3.8\,\text{m/s}$. (*a*) If 85 kg of water passes through per second, what is the rate at which the water delivers angular momentum to the waterwheel? (*b*) What is the torque the water applies to the waterwheel? (*c*) If the water causes the waterwheel to make one revolution every 6.0 s, how much power is delivered to the wheel?

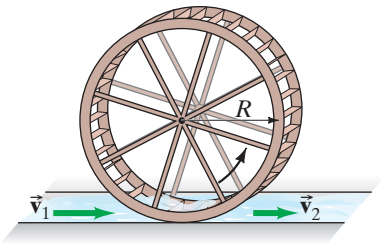

**FIGURE 11–50** Problem 77.

**78.** In Example 11–1, the hand slowly pulls the string, causing the rotating mass $(m = 0.75\,\text{kg})$ to gain speed. (*a*) Calculate the work done by the hand. (*b*) Check that the work–energy theorem is satisfied.

**79.** A particle of mass $m$ uniformly accelerates as it moves counterclockwise along the circumference of a circle of radius $R$:

$$\vec{\mathbf{r}} = \hat{\mathbf{i}} R\cos\theta + \hat{\mathbf{j}} R\sin\theta$$

with $\theta = \omega_0 t + \frac{1}{2}\alpha t^2$, where the constants $\omega_0$ and $\alpha$ are the initial angular velocity and angular acceleration, respectively. Determine the object's tangential acceleration $\vec{\mathbf{a}}_\text{tan}$ and determine the torque acting on the object using (*a*) $\vec{\boldsymbol{\tau}} = \vec{\mathbf{r}} \times \vec{\mathbf{F}}$, (*b*) $\vec{\boldsymbol{\tau}} = I\vec{\boldsymbol{\alpha}}$.

**80.** The Moon orbits the Earth such that the same side always faces the Earth. Determine the ratio of the Moon's spin angular momentum (about its own axis) to its orbital angular momentum. (In the latter case, treat the Moon as a particle orbiting the Earth.)

**81.** Most of our Solar System's mass is contained in the Sun, and the planets possess almost all of the Solar System's angular momentum. This observation plays a key role in theories attempting to explain the formation of our Solar System. Estimate the fraction of the Solar System's total angular momentum from the planets using a simplified model which includes only the large outer planets with the most angular momentum. The central Sun (mass $1.99 \times 10^{30}$ kg, radius $6.96 \times 10^{8}$ m) spins about its axis once every 25 days and the planets Jupiter, Saturn, Uranus, and Neptune move in nearly circular orbits around the Sun with orbital data given in the Table below. Ignore each planet's spin about its own axis.

| Planet | Mean Distance from Sun ($\times 10^6$ km) | Orbital Period (Earth Years) | Mass ($\times 10^{25}$ kg) |
|---|---|---|---|
| Jupiter | 778 | 11.9 | 190 |
| Saturn | 1427 | 29.5 | 56.8 |
| Uranus | 2870 | 84.0 | 8.68 |
| Neptune | 4500 | 165 | 10.2 |

**82.** Competitive ice skaters commonly perform single, double, and triple axel jumps in which they rotate $1\frac{1}{2}$, $2\frac{1}{2}$, and $3\frac{1}{2}$ revolutions, respectively, about a vertical axis while airborne. For each of these jumps, a typical skater remains airborne for about 0.70 s. Suppose a skater leaves the ground in an "open" position (e.g., arms outstretched) with moment of inertia $I_0$ and rotational frequency $f_0 = 1.2$ rev/s, maintaining this position for 0.10 s. The skater then assumes a "closed" position (arms brought closer) with moment of inertia $I$, acquiring a rotational frequency $f$, which is maintained for 0.50 s. Finally, the skater immediately returns to the "open" position for 0.10 s until landing (see Fig. 11–51). (*a*) Why is angular momentum conserved during the skater's jump? Neglect air resistance. (*b*) Determine the minimum rotational frequency $f$ during the flight's middle section for the skater to successfully complete a single and a triple axel. (*c*) Show that, according to this model, a skater must be able to reduce his or her moment of inertia in midflight by a factor of about 2 and 5 in order to complete a single and triple axel, respectively.

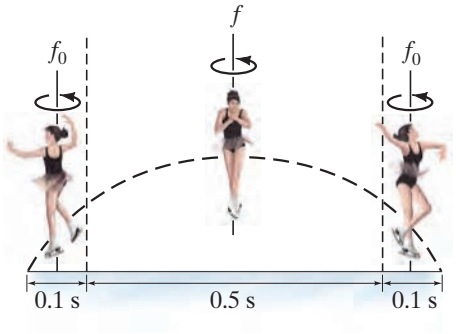

**FIGURE 11–51** Problem 82.

**83.** Suppose a star the size of our Sun, but with mass 8.0 times as great, were rotating at a speed of 1.0 revolution every 9.0 days. If it were to undergo gravitational collapse to a *neutron star* of radius 12 km, losing 0.70 of its mass in the process, what would its rotation speed be? Assume the star is a uniform sphere at all times. Assume also that the thrown-off mass carries off either (*a*) no angular momentum, or (*b*) its proportional share (0.70) of the initial angular momentum.

**84.** A radio transmission tower has a mass of 76 kg and is 12 m high. The tower is anchored to the ground by a flexible joint at its base, but it is secured by three cables 120° apart (Fig. 11–52). In an analysis of a potential failure, a mechanical engineer needs to determine the behavior of the tower if one of the cables breaks. The tower would fall away from the broken cable, rotating about its base. Determine the speed of the top of the tower as a function of the rotation angle $\theta$. Start your analysis with the rotational dynamics equation of motion $d\vec{\mathbf{L}}/dt = \vec{\tau}_{\text{ext}}$. Approximate the tower as a tall thin rod.

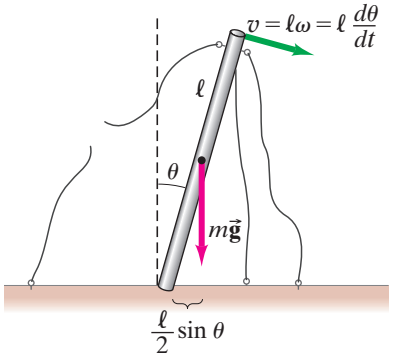

**FIGURE 11–52** Problem 84.

**85.** A baseball bat has a *sweet spot* where a ball can be hit with almost effortless transmission of energy. A careful analysis of baseball dynamics shows that this special spot is located at the point where an applied force would result in pure rotation of the bat about the handle grip. Determine the location of the sweet spot, $x_s$, of the bat shown in Fig. 11–53. The linear mass density of the bat is given roughly by $(0.61 + 3.3x^2)$ kg/m, where $x$ is in meters measured from the end of the handle. The entire bat is 0.84 m long. The desired rotation point should be 5.0 cm from the thin end where the bat is held. [*Hint*: Where is the CM of the bat?]

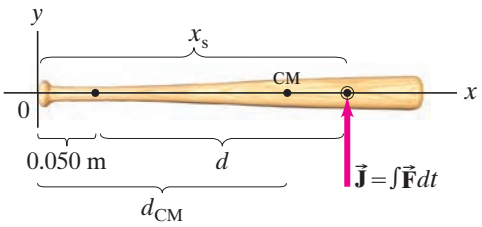

**FIGURE 11–53** Problem 85.

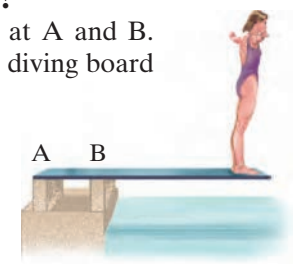
**86.** Let $\vec{\mathbf{A}}, \vec{\mathbf{B}}$, and $\vec{\mathbf{C}}$ be three vectors, which for generality we assume do not all lie in the same plane. Show that $\vec{\mathbf{A}} \cdot (\vec{\mathbf{B}} \times \vec{\mathbf{C}}) = \vec{\mathbf{B}} \cdot (\vec{\mathbf{C}} \times \vec{\mathbf{A}}) = \vec{\mathbf{C}} \cdot (\vec{\mathbf{A}} \times \vec{\mathbf{B}})$.

## ANSWERS TO EXERCISES

**A:** Yes. She does work to pull in her arms.
**B:** (*b*), it speeds up.
**C:** (*a*).
**D:** (*b*) The turntable revolves the same, counterclockwise but slower than in Example 11–5.
**E:** (i) (*d*); (ii) (*a*); (iii) (*b*).
**F:** (*e*).

Our whole built environment, from medieval cathedrals and modern bridges to skyscrapers, has required architects and engineers to determine the forces and stresses within these structures. The object is to keep these structures standing, or "static"—that is, not in motion, especially not falling down.

The study of statics applies equally well to the human body, including balance, the forces in muscles, joints, and bones, and ultimately the possibility of fracture.



Six centuries ago the great Cathedral at the center of this photo in Florence, Italy, required great intuition and cleverness to construct the largest dome ever built (previous to prestressed concrete in the 20th century), as we will see in Section 12–8.

CHAPTER 12

# Static Equilibrium; Elasticity and Fracture

**CHAPTER-OPENING QUESTION—Guess now!**
The diving board shown here is held by two supports at A and B. Which statement is true about the forces exerted *on* the diving board at A and B?

**(a)** $\vec{\mathbf{F}}_A$ is down, $\vec{\mathbf{F}}_B$ is up, and $F_B$ is larger than $F_A$.
**(b)** Both forces are up and $F_B$ is larger than $F_A$.
**(c)** $\vec{\mathbf{F}}_A$ is down, $\vec{\mathbf{F}}_B$ is up, and $F_A$ is larger than $F_B$.
**(d)** Both forces are down and approximately equal.
**(e)** $\vec{\mathbf{F}}_B$ is down, $\vec{\mathbf{F}}_A$ is up, and they are equal.
**(f)** Both forces are up and are equal.

In this Chapter, we will study a special case in mechanics—when the net force and the net torque on an object, or system of objects, are both zero. In this case both the linear acceleration and the angular acceleration of the object or system are zero. The object is either at rest, or its center of mass is moving at constant velocity. We will be concerned mainly with the first situation, in which the object or objects are all at rest, or *static* (= not moving).

The net force and the net torque can be zero, but this does not imply that no forces at all act on the objects. In fact it is virtually impossible to find an object on which no forces act. Just how and where these forces act can be very important, both for buildings and other structures, and in the human body.

**FIGURE 12–1** Elevated walkway collapse in a Kansas City hotel in 1981. How a simple physics calculation could have prevented the tragic loss of over 100 lives is considered in Example 12–11.

Sometimes, as we shall see in this Chapter, the forces may be so great that the object is seriously *deformed*, or it may even *fracture* (break)—and avoiding such problems gives this field of *statics* even greater importance.

**Statics** is concerned with the calculation of the forces acting on and within structures that are in *equilibrium*. Determination of these forces, which occupies us in the first part of this Chapter, then allows a determination of whether the structures can sustain the forces without significant deformation or fracture, subjects we discuss later in this Chapter. These techniques can be applied in a wide range of fields. Architects and engineers must be able to calculate the forces on the structural components of buildings, bridges, machines, vehicles, and other structures, since any material will buckle or break if too much force is applied (Fig. 12–1). In the human body a knowledge of the forces in muscles, bones, and joints is of great value for doctors, physical therapists, and athletes.

# 12–1 The Conditions for Equilibrium

Objects in daily life have at least one force acting on them (gravity). If they are at rest, then there must be other forces acting on them as well so that the net force is zero. A book at rest on a table, for example, has two forces acting on it, the downward force of gravity and the normal force the table exerts upward on it (Fig. 12–2). Because the book is at rest, Newton's second law tells us that the net force on it is zero. Thus the upward force exerted by the table on the book must be equal in magnitude to the force of gravity acting downward on the book. Such an object is said to be in **equilibrium** (Latin for "equal forces" or "balance") under the action of these two forces.

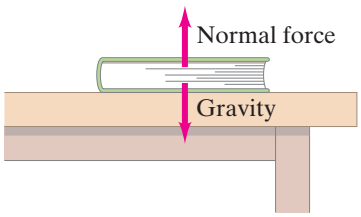

**FIGURE 12–2** The book is in equilibrium; the net force on it is zero.

Do not confuse the two forces in Fig. 12–2 with the equal and opposite forces of Newton's third law, which act on different objects. In Fig. 12–2, both forces act on the same object; and they happen to add up to zero.

## The First Condition for Equilibrium

For an object to be at rest, Newton's second law tells us that the sum of the forces acting on it must add up to zero. Since force is a vector, the components of the net force must each be zero. Hence, a condition for equilibrium is that

$$\Sigma F_x = 0, \qquad \Sigma F_y = 0, \qquad \Sigma F_z = 0. \tag{12–1}$$

We will mainly be dealing with forces that act in a plane, so we usually need only the $x$ and $y$ components. We must remember that if a particular force component points along the negative $x$ or $y$ axis, it must have a negative sign. Equations 12–1 represent the **first condition for equilibrium**.

We saw in Chapter 4 that to solve Problems involving forces, we need to draw a *free-body diagram*, indicating *all* the forces on a given object (see Section 4–7).

**EXAMPLE 12–1** **Chandelier cord tension.** Calculate the tensions $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_B$ in the two cords that are connected to the vertical cord supporting the 200-kg chandelier in Fig. 12–3. Ignore the mass of the cords.

**APPROACH** We need a free-body diagram, but for which object? If we choose the chandelier, the cord supporting it must exert a force equal to the chandelier's weight $mg = (200\,\text{kg})(9.80\,\text{m/s}^2) = 1960\,\text{N}$. But the forces $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_B$ don't get involved. Instead, let us choose as our object the point where the three cords join (it could be a knot). The free-body diagram is then as shown in Fig. 12–3a. The three forces—$\vec{\mathbf{F}}_A$, $\vec{\mathbf{F}}_B$, and the tension in the vertical cord equal to the weight of the 200-kg chandelier—act at this point where the three cords join. For this junction point we write $\Sigma F_x = 0$ and $\Sigma F_y = 0$, since the problem is laid out in two dimensions. The directions of $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_B$ are known, since tension in a cord can only be along the cord—any other direction would cause the cord to bend, as already pointed out in Chapter 4. Thus, our unknowns are the magnitudes $F_A$ and $F_B$.

**SOLUTION** We first resolve $\vec{\mathbf{F}}_A$ into its horizontal ($x$) and vertical ($y$) components. Although we don't know the value of $F_A$, we can write (see Fig. 12–3b) $F_{Ax} = -F_A \cos 60°$ and $F_{Ay} = F_A \sin 60°$. $\vec{\mathbf{F}}_B$ has only an $x$ component. In the vertical direction, we have the downward force exerted by the vertical cord equal to the weight of the chandelier $mg = (200\,\text{kg})(g)$, and the vertical component of $\vec{\mathbf{F}}_A$ upward:

$$\Sigma F_y = 0$$
$$F_A \sin 60° - (200\,\text{kg})(g) = 0$$

so

$$F_A = \frac{(200\,\text{kg})g}{\sin 60°} = (231\,\text{kg})g = (231\,\text{kg})(9.80\,\text{m/s}^2) = 2260\,\text{N}.$$

In the horizontal direction, with $\Sigma F_x = 0$,

$$\Sigma F_x = F_B - F_A \cos 60° = 0.$$

Thus

$$F_B = F_A \cos 60° = (231\,\text{kg})(g)(0.500) = (115\,\text{kg})g = 1130\,\text{N}.$$

The magnitudes of $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_B$ determine the strength of cord or wire that must be used. In this case, the cord must be able to support a mass of more than 230 kg.

**NOTE** We didn't insert the value of $g$, the acceleration due to gravity, until the end. In this way we found the magnitude of the force in terms of $g$ times the number of kilograms (which may be a more familiar quantity than newtons).

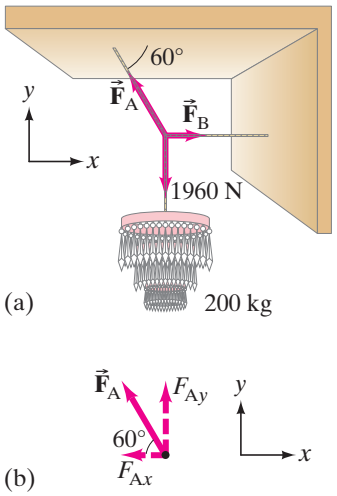

**FIGURE 12–3** Example 12–1.

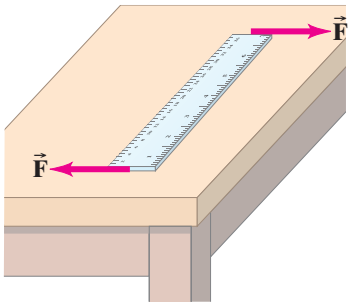
**EXERCISE A** In Example 12–1, $F_A$ has to be greater than the chandelier's weight, $mg$. Why?

## The Second Condition for Equilibrium



Although Eqs. 12–1 are a necessary condition for an object to be in equilibrium, they are not always a sufficient condition. Figure 12–4 shows an object on which the net force is zero. Although the two forces labeled $\vec{\mathbf{F}}$ add up to give zero net force on the object, they do give rise to a net torque that will rotate the object. Referring to Eq. 10–14, $\Sigma\tau = I\alpha$, we see that if an object is to remain at rest, the net torque applied to it (calculated about *any* axis) must be zero. Thus we have the **second condition for equilibrium**: that the sum of the torques acting on an object, as calculated about any axis, must be zero:

$$\Sigma\tau = 0. \qquad \textbf{(12–2)}$$

This condition will ensure that the angular acceleration, $\alpha$, about any axis will be zero. If the object is not rotating initially ($\omega = 0$), it will not start rotating. Equations 12–1 and 12–2 are the only requirements for an object to be in equilibrium.

We will mainly consider cases in which the forces all act in a plane (we call it the $xy$ plane). In such cases the torque is calculated about an axis that is perpendicular to the $xy$ plane. *The choice of this axis is arbitrary*. If the object is at rest, then $\Sigma\tau = 0$ is valid about any axis. Therefore we can choose any axis that makes our calculation easier. Once the axis is chosen, all torques must be calculated about that axis.

**FIGURE 12–4** Although the net force on the ruler is zero, it will move (rotate). A pair of equal forces acting in opposite directions but at different points on an object (as shown here) is referred to as a *couple*.

**CAUTION**

*Axis choice for $\Sigma\tau = 0$ is arbitrary. All torques must be calculated about the same axis*

PHYSICS APPLIED
*The lever*

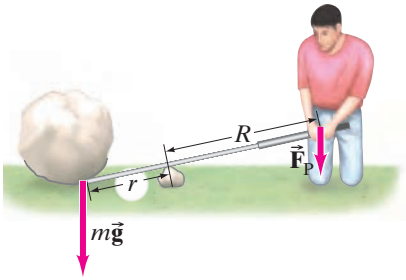


**FIGURE 12–5** Example 12–2. A lever can "multiply" your force.

**CONCEPTUAL EXAMPLE 12–2** **A lever.** The bar in Fig. 12–5 is being used as a lever to pry up a large rock. The small rock acts as a fulcrum (pivot point). The force $F_P$ exerted at the long end of the bar can be quite a bit smaller than the rock's weight $mg$, since it is the *torques* that balance in the rotation about the fulcrum. If, however, the leverage isn't sufficient, and the large rock isn't budged, what are two ways to increase the lever arm (Section 10–4)?

**RESPONSE** One way is to increase the lever arm of the force $F_P$ by slipping a pipe over the end of the bar and thereby pushing with a longer lever arm. A second way is to move the fulcrum closer to the large rock. This may change the long lever arm $R$ only a little, but it changes the short lever arm $r$ by a substantial fraction and therefore changes the ratio of $R/r$ dramatically. In order to pry the rock, the torque due to $F_P$ must at least balance the torque due to $mg$; that is, $mgr = F_P R$ and

$$\frac{r}{R} = \frac{F_P}{mg}.$$

With $r$ smaller, the weight $mg$ can be balanced with less force $F_P$. The ratio $R/r$ is the **mechanical advantage** of the system. A lever is a "simple machine." We discussed another simple machine, the pulley, in Chapter 4, Example 4–14.

# 12–2 Solving Statics Problems

The subject of statics is important because it allows us to calculate certain forces on (or within) a structure when some of the forces on it are already known. We will mainly consider situations in which all the forces act in a plane, so we can have two force equations ($x$ and $y$ components) and one torque equation, for a total of three equations. Of course, you do not have to use all three equations if they are not needed. When using a torque equation, a torque that tends to rotate the object counterclockwise is usually considered positive, whereas a torque that tends to rotate it clockwise is considered negative. (But the opposite convention would be OK too.)

PROBLEM SOLVING
$\tau > 0$ *counterclockwise*
$\tau < 0$ *clockwise*

One of the forces that acts on objects is the force of gravity. As we discussed in Section 9–8, we can consider the force of gravity on an object as acting at its center of gravity (CG) or center of mass (CM), which for practical purposes are the same point. For uniform symmetrically shaped objects, the CG is at the geometric center. For more complicated objects, the CG can be determined as discussed in Section 9–8.

There is no single technique for attacking statics problems, but the following procedure may be helpful.

PROBLEM SOLVING

## Statics

1. Choose one object at a time for consideration. Make a careful **free-body diagram** by showing all the forces acting on that object, including gravity, and the points at which these forces act. If you aren't sure of the direction of a force, choose a direction; if the actual direction of the force (or component of a force) is opposite, your eventual calculation will give a result with a minus sign.
2. Choose a convenient **coordinate system**, and resolve the forces into their components.
3. Using letters to represent unknowns, write down the **equilibrium equations** for the **forces**:
$$\Sigma F_x = 0$$
and
$$\Sigma F_y = 0,$$
assuming all the forces act in a plane.
4. For the **torque equation**,
$$\Sigma\tau = 0,$$
choose any axis perpendicular to the $xy$ plane that might make the calculation easier. (For example, you can reduce the number of unknowns in the resulting equation by choosing the axis so that one of the unknown forces acts through that axis; then this force will have zero lever arm and produce zero torque, and so won't appear in the torque equation.) Pay careful attention to determining the lever arm for each force correctly. Give each torque a + or − sign to indicate torque direction. For example, if torques tending to rotate the object counterclockwise are positive, then those tending to rotate it clockwise are negative.
5. **Solve** these equations for the unknowns. Three equations allow a maximum of three unknowns to be solved for. They can be forces, distances, or even angles.

**EXAMPLE 12–3** **Balancing a seesaw.** A board of mass $M = 4.0\,\text{kg}$ serves as a seesaw for two children, as shown in Fig. 12–6a. Child A has a mass of 30 kg and sits 2.5 m from the pivot point, P (his center of mass is 2.5 m from the pivot). At what distance $x$ from the pivot must child B, of mass 25 kg, place herself to balance the seesaw? Assume the board is uniform and centered over the pivot.

PHYSICS APPLIED
*Balancing a seesaw*

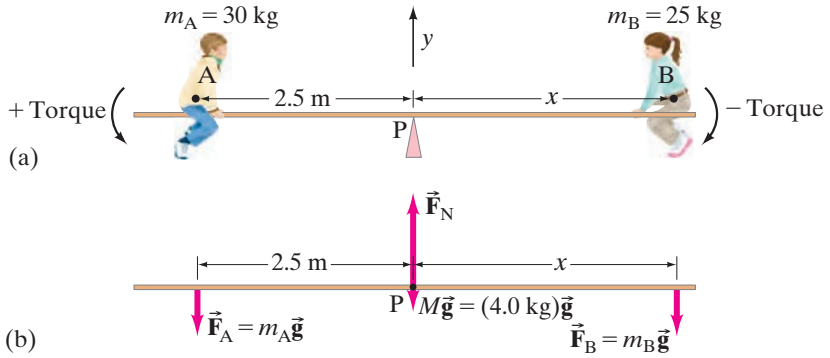

**FIGURE 12–6** (a) Two children on a seesaw, Example 12–3. (b) Free-body diagram of the board.

**APPROACH** We follow the steps of the Problem Solving Strategy above.

**SOLUTION**

1. **Free-body diagram**. We choose the board as our object, and assume it is horizontal. Its free-body diagram is shown in Fig. 12–6b. The forces acting on the board are the forces exerted downward on it by each child, $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_B$, the upward force exerted by the pivot $\vec{\mathbf{F}}_N$, and the force of gravity on the board $(= M\vec{\mathbf{g}})$ which acts at the center of the uniform board.
2. **Coordinate system**. We choose $y$ to be vertical, with positive upward, and $x$ horizontal to the right, with origin at the pivot.
3. **Force equation**. All the forces are in the $y$ (vertical) direction, so
$$\Sigma F_y = 0$$
$$F_N - m_A g - m_B g - Mg = 0,$$
where $F_A = m_A g$ and $F_B = m_B g$.
4. **Torque equation**. Let us calculate the torque about an axis through the board at the pivot point, P. Then the lever arms for $F_N$ and for the weight of the board are zero, and they will contribute zero torque about point P. Thus the torque equation will involve only the forces $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_B$, which are equal to the weights of the children. The torque exerted by each child will be $mg$ times the appropriate lever arm, which here is the distance of each child from the pivot point. $\vec{\mathbf{F}}_A$ tends to rotate the board counterclockwise $(+)$ and $\vec{\mathbf{F}}_B$ clockwise $(-)$, so the torque equation is
$$\Sigma\tau = 0$$
$$m_A g(2.5\,\text{m}) - m_B g x + Mg(0\,\text{m}) + F_N(0\,\text{m}) = 0$$
or
$$m_A g(2.5\,\text{m}) - m_B g x = 0,$$
where two terms were dropped because their lever arms were zero.
5. **Solve**. We solve the torque equation for $x$ and find
$$x = \frac{m_A}{m_B}(2.5\,\text{m}) = \frac{30\,\text{kg}}{25\,\text{kg}}(2.5\,\text{m}) = 3.0\,\text{m}.$$
To balance the seesaw, child B must sit so that her CG is 3.0 m from the pivot point. This makes sense: since she is lighter, she must sit farther from the pivot than the heavier child in order to provide torques of equal magnitude.

**EXERCISE B** We did not need to use the force equation to solve Example 12–3 because of our choice of the axis. Use the force equation to find the force exerted by the pivot.

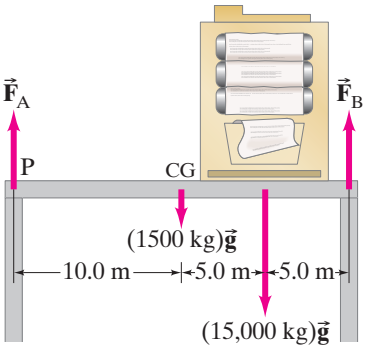

**FIGURE 12–7** A 1500-kg beam supports a 15,000-kg machine. Example 12–4.

**EXAMPLE 12–4** **Forces on a beam and supports.** A uniform 1500-kg beam, 20.0 m long, supports a 15,000-kg printing press 5.0 m from the right support column (Fig. 12–7). Calculate the force on each of the vertical support columns.

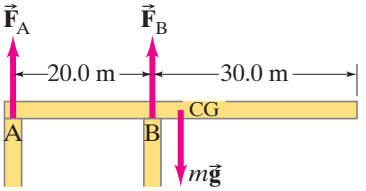
**APPROACH** We analyze the forces on the beam (the force the beam exerts on each column is equal and opposite to the force exerted by the column on the beam). We label the forces on the beam due to the supporting columns as $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_B$ in Fig. 12–7. The force of gravity (= weight of the beam) acts at its center of gravity, 10.0 m from either end. We choose a convenient axis for writing the torque equation: the point of application of $\vec{\mathbf{F}}_A$ (labeled P), so $\vec{\mathbf{F}}_A$ will not enter the equation (its lever arm will be zero) and we will have an equation in only one unknown, $F_B$.

**SOLUTION** The torque equation, $\Sigma\tau = 0$, with the counterclockwise direction as positive, gives

$$\Sigma\tau = -(10.0\,\text{m})(1500\,\text{kg})g - (15.0\,\text{m})(15{,}000\,\text{kg})g + (20.0\,\text{m})F_B = 0.$$

Solving for $F_B$, we find $F_B = (12{,}000\,\text{kg})g = 118{,}000\,\text{N}$. To find $F_A$, we use $\Sigma F_y = 0$, with $+y$ upward:

$$\Sigma F_y = F_A - (1500\,\text{kg})g - (15{,}000\,\text{kg})g + F_B = 0.$$



Putting in $F_B = (12{,}000\,\text{kg})g$, we find that $F_A = (4500\,\text{kg})g = 44{,}100\,\text{N}$.

**PHYSICS APPLIED**
*Cantilever*

**PROBLEM SOLVING**
*If a force comes out negative*

Figure 12–8 shows a uniform beam that extends beyond its support like a diving board. Such a beam is called a **cantilever**. The forces acting on the beam in Fig. 12–8 are those due to the supports, $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_B$, and the force of gravity which acts at the CG, 5.0 m to the right of the right-hand support. If you follow the procedure of the last Example and calculate $F_A$ and $F_B$, assuming they point upward as shown in Fig. 12–8, you will find that $F_A$ comes out negative. If the beam has a mass of 1200 kg and a weight $mg = 12{,}000\,\text{N}$, then $F_B = 15{,}000\,\text{N}$ and $F_A = -3000\,\text{N}$ (try it yourself: write $\Sigma F_y$ and $\Sigma\tau$ equations). Whenever an unknown force comes out negative, it merely means that the force actually points in the opposite direction from what you assumed. Thus in Fig. 12–8, $\vec{\mathbf{F}}_A$ actually must pull downward (by means of bolts, screws, fasteners, and/or glue). To see why $\vec{\mathbf{F}}_A$ has to act downward, note that the board's weight acting at the CG would otherwise rotate the board clockwise about support B.

**FIGURE 12–8** A cantilever.

**EXERCISE C** Return to the Chapter-Opening Question, page 331, and answer it again now. Try to explain why you may have answered differently the first time.

Our next Example involves a beam that is attached to a wall by a hinge and is supported by a cable or cord (Fig. 12–9). It is important to remember that a flexible cable can support a force only along its length. (If there were a component of force perpendicular to the cable, it would bend because it is flexible.) But for a rigid device, such as the hinge in Fig. 12–9, the force can be in any direction and we can know the direction only after solving the equations. (The hinge is assumed small and smooth, so it can exert no internal torque on the beam.)

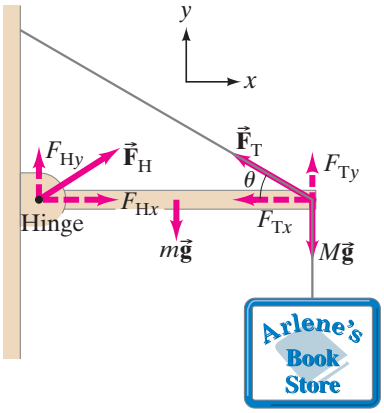


**FIGURE 12–9** Hinged beam and cable, Example 12–5.

**EXAMPLE 12–5** **Hinged beam and cable.** A uniform beam, 2.20 m long with mass $m = 25.0\,\text{kg}$, is mounted by a small hinge on a wall as shown in Fig. 12–9. The beam is held in a horizontal position by a cable that makes an angle $\theta = 30.0°$. The beam supports a sign of mass $M = 28.0\,\text{kg}$ suspended from its end. Determine the components of the force $\vec{\mathbf{F}}_\text{H}$ that the (smooth) hinge exerts on the beam, and the tension $F_\text{T}$ in the supporting cable.

**APPROACH** Figure 12–9 is the free-body diagram for the beam, showing all the forces acting on the beam. It also shows the components of $\vec{\mathbf{F}}_\text{T}$ and a guess for the direction of $\vec{\mathbf{F}}_\text{H}$. We have three unknowns, $F_{\text{H}x}$, $F_{\text{H}y}$, and $F_\text{T}$ (we are given $\theta$), so we will need all three equations, $\Sigma F_x = 0$, $\Sigma F_y = 0$, $\Sigma\tau = 0$.

**SOLUTION** The sum of the forces in the vertical ($y$) direction is

$$\begin{aligned} \Sigma F_y &= 0 \\ F_{\text{H}y} + F_{\text{T}y} - mg - Mg &= 0. \end{aligned} \qquad \textbf{(i)}$$

In the horizontal ($x$) direction, the sum of the forces is

$$\begin{aligned} \Sigma F_x &= 0 \\ F_{\text{H}x} - F_{\text{T}x} &= 0. \end{aligned} \qquad \textbf{(ii)}$$

For the torque equation, we choose the axis at the point where $\vec{\mathbf{F}}_\text{T}$ and $M\vec{\mathbf{g}}$ act. Then our torque equation will contain only one unknown, $F_{\text{H}y}$, because the lever arms for $\vec{\mathbf{F}}_\text{T}$, $M\vec{\mathbf{g}}$, and $F_{\text{H}x}$ are zero. We choose torques that tend to rotate the beam counterclockwise as positive. The weight $mg$ of the (uniform) beam acts at its center, so we have

$$\begin{aligned} \Sigma\tau &= 0 \\ -(F_{\text{H}y})(2.20\,\text{m}) + mg(1.10\,\text{m}) &= 0. \end{aligned}$$

We solve for $F_{\text{H}y}$:

$$F_{\text{H}y} = \left(\frac{1.10\,\text{m}}{2.20\,\text{m}}\right)mg = (0.500)(25.0\,\text{kg})\left(9.80\,\text{m/s}^2\right) = 123\,\text{N}. \qquad \textbf{(iii)}$$

Next, since the tension $\vec{\mathbf{F}}_\text{T}$ in the cable acts along the cable ($\theta = 30.0°$), we see from Fig. 12–9 that $\tan\theta = F_{\text{T}y}/F_{\text{T}x}$, or

$$F_{\text{T}y} = F_{\text{T}x}\tan\theta = F_{\text{T}x}(\tan 30.0°). \qquad \textbf{(iv)}$$

Equation (i) above gives

$$F_{\text{T}y} = (m + M)g - F_{\text{H}y} = (53.0\,\text{kg})\left(9.80\,\text{m/s}^2\right) - 123\,\text{N} = 396\,\text{N}.$$

Equations (iv) and (ii) give

$$\begin{aligned} F_{\text{T}x} &= F_{\text{T}y}/\tan 30.0° = 396\,\text{N}/\tan 30.0° = 686\,\text{N}; \\ F_{\text{H}x} &= F_{\text{T}x} = 686\,\text{N}. \end{aligned}$$

The components of $\vec{\mathbf{F}}_\text{H}$ are $F_{\text{H}y} = 123\,\text{N}$ and $F_{\text{H}x} = 686\,\text{N}$. The tension in the wire is $F_\text{T} = \sqrt{F_{\text{T}x}^2 + F_{\text{T}y}^2} = \sqrt{(686\,\text{N})^2 + (396\,\text{N})^2} = 792\,\text{N}$.[†]

***Alternate Solution*** Let us see the effect of choosing a different axis for calculating torques, such as an axis through the hinge. Then the lever arm for $F_\text{H}$ is zero, and the torque equation ($\Sigma\tau = 0$) becomes

$$-mg(1.10\,\text{m}) - Mg(2.20\,\text{m}) + F_{\text{T}y}(2.20\,\text{m}) = 0.$$

We solve this for $F_{\text{T}y}$ and find

$$F_{\text{T}y} = \frac{m}{2}g + Mg = (12.5\,\text{kg} + 28.0\,\text{kg})\left(9.80\,\text{m/s}^2\right) = 397\,\text{N}.$$

We get the same result, within the precision of our significant figures.

**NOTE** It doesn't matter which axis we choose for $\Sigma\tau = 0$. Using a second axis can serve as a check.

[†]Our calculation used numbers rounded off to 3 significant figures. If you keep an extra digit, or leave the numbers in your calculator, you get $F_{\text{T}y} = 396.5\,\text{N}$, $F_{\text{T}x} = F_{\text{H}x} = 686.8\,\text{N}$, $F_\text{T} = 793\,\text{N}$, and $F_{\text{H}y} = 122.5\,\text{N}$, all within the expected precision of 3 significant figures (Section 1–3).

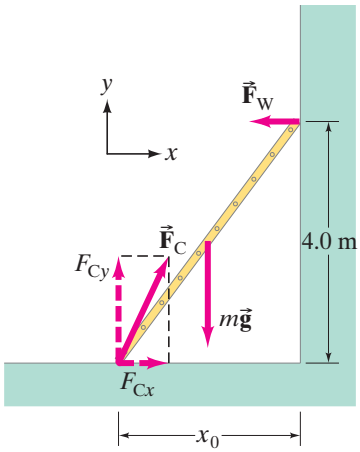

**FIGURE 12–10** A ladder leaning against a wall. Example 12–6. The force $\vec{\mathbf{F}}_C$ that the cement floor exerts on the ladder need not be along the ladder which (unlike a cord) is rigid.

**EXAMPLE 12–6 Ladder.** A 5.0-m-long ladder leans against a smooth wall at a point 4.0 m above a cement floor as shown in Fig. 12–10. The ladder is uniform and has mass $m = 12.0\,\text{kg}$. Assuming the wall is frictionless, but the floor is not, determine the forces exerted on the ladder by the floor and by the wall.

**APPROACH** Figure 12–10 is the free-body diagram for the ladder, showing all the forces acting on the ladder. The wall, since it is frictionless, can exert a force only perpendicular to the wall, and we label that force $\vec{\mathbf{F}}_W$. The cement floor exerts a force $\vec{\mathbf{F}}_C$ which has both horizontal and vertical force components: $F_{Cx}$ is frictional and $F_{Cy}$ is the normal force. Finally, gravity exerts a force $mg = (12.0\,\text{kg})\,(9.80\,\text{m/s}^2) = 118\,\text{N}$ on the ladder at its midpoint, since the ladder is uniform.

**SOLUTION** Again we use the equilibrium conditions, $\Sigma F_x = 0$, $\Sigma F_y = 0$, $\Sigma\tau = 0$. We will need all three since there are three unknowns: $F_W$, $F_{Cx}$, and $F_{Cy}$. The $y$ component of the force equation is

$$\Sigma F_y = F_{Cy} - mg = 0,$$

so immediately we have

$$F_{Cy} = mg = 118\,\text{N}.$$

The $x$ component of the force equation is

$$\Sigma F_x = F_{Cx} - F_W = 0.$$

To determine both $F_{Cx}$ and $F_W$, we need a torque equation. If we choose to calculate torques about an axis through the point where the ladder touches the cement floor, then $\vec{\mathbf{F}}_C$, which acts at this point, will have a lever arm of zero and so won't enter the equation. The ladder touches the floor a distance $x_0 = \sqrt{(5.0\,\text{m})^2 - (4.0\,\text{m})^2} = 3.0\,\text{m}$ from the wall (right triangle, $c^2 = a^2 + b^2$). The lever arm for $mg$ is half this, or 1.5 m, and the lever arm for $F_W$ is 4.0 m, Fig. 12–10. The torque equation about the ladder's contact point on the cement is

$$\Sigma\tau = (4.0\,\text{m})F_W - (1.5\,\text{m})mg = 0.$$

Thus

$$F_W = \frac{(1.5\,\text{m})\,(12.0\,\text{kg})\,(9.8\,\text{m/s}^2)}{4.0\,\text{m}} = 44\,\text{N}.$$

Then, from the $x$ component of the force equation,

$$F_{Cx} = F_W = 44\,\text{N}.$$

Since the components of $\vec{\mathbf{F}}_C$ are $F_{Cx} = 44\,\text{N}$ and $F_{Cy} = 118\,\text{N}$, then

$$F_C = \sqrt{(44\,\text{N})^2 + (118\,\text{N})^2} = 126\,\text{N} \approx 130\,\text{N}$$

(rounded off to two significant figures), and it acts at an angle to the floor of

$$\theta = \tan^{-1}(118\,\text{N}/44\,\text{N}) = 70°.$$

**NOTE** The force $\vec{\mathbf{F}}_C$ does *not* have to act along the ladder's direction because the ladder is rigid and not flexible like a cord or cable (see page 99).

**EXERCISE D** Why is it reasonable to ignore friction along the wall, but not reasonable to ignore it along the floor?

# *12–3 Applications to Muscles and Joints

The techniques we have been discussing for calculating forces on objects in equilibrium can be applied to the human body to study forces on muscles, bones, and joints. Generally a muscle is attached, via tendons, to two different bones, as in Fig. 12–11. The points of attachment are called *insertions*. Two bones are flexibly connected at a *joint*, such as at the elbow, knee, shoulder, and hip. A muscle exerts a pull when its fibers contract under stimulation by a nerve, but a muscle can *not* exert a push. Muscles that tend to bring two limbs closer together, such as the biceps muscle in the upper arm (Fig. 12–11), are called *flexors*; those that act to extend a limb outward, such as the triceps muscle in Fig. 12–11, are *extensors*. You use the flexor muscle in the upper arm when lifting an object in your hand; you use the extensor muscle when throwing a ball.

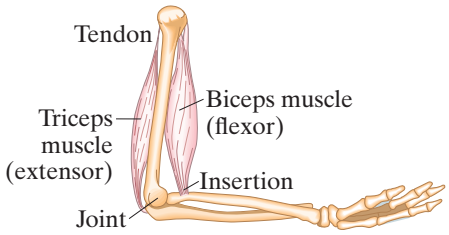

**FIGURE 12–11** The biceps (flexor) and triceps (extensor) muscles in the human arm.

**PHYSICS APPLIED**
*Forces in muscles and joints*

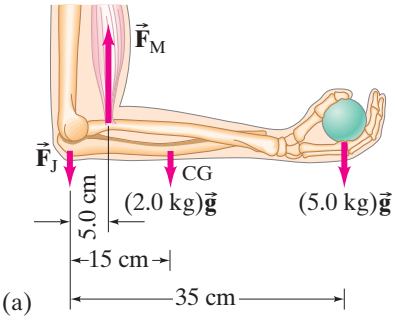
**EXAMPLE 12–7** **Force exerted by biceps muscle.** How much force must the biceps muscle exert when a 5.0-kg ball is held in the hand (*a*) with the arm horizontal as in Fig. 12–12a, and (*b*) when the arm is at a 45° angle as in Fig. 12–12b? The biceps muscle is connected to the forearm by a tendon attached 5.0 cm from the elbow joint. Assume that the mass of forearm and hand together is 2.0 kg and their CG is as shown.

**APPROACH** The free-body diagram for the forearm is shown in Fig. 12–12; the forces are the weights of the forearm and ball, the upward force $\vec{\mathbf{F}}_M$ exerted by the muscle, and a force $\vec{\mathbf{F}}_J$ exerted at the joint by the bone in the upper arm (all assumed to act vertically). We wish to find the magnitude of $\vec{\mathbf{F}}_M$, which can be done using the torque equation and by choosing our axis through the joint so that $\vec{\mathbf{F}}_J$ contributes zero torque.

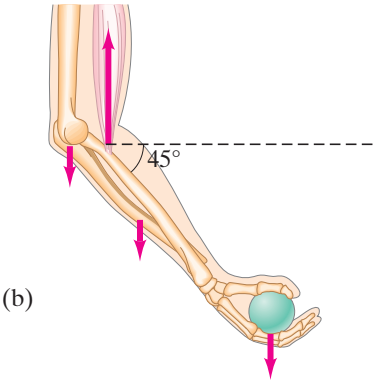
**SOLUTION** (*a*) We calculate torques about the point where $\vec{\mathbf{F}}_J$ acts in Fig. 12–12a. The $\Sigma\tau = 0$ equation gives

$$(0.050\,\text{m})F_M - (0.15\,\text{m})(2.0\,\text{kg})g - (0.35\,\text{m})(5.0\,\text{kg})g = 0.$$

We solve for $F_M$:



$$F_M = \frac{(0.15\,\text{m})(2.0\,\text{kg})g + (0.35\,\text{m})(5.0\,\text{kg})g}{0.050\,\text{m}} = (41\,\text{kg})g = 400\,\text{N}.$$



(*b*) The lever arm, as calculated about the joint, is reduced by the factor cos 45° for all three forces. Our torque equation will look like the one just above, except that each term will have its lever arm reduced by the same factor, which will cancel out. The same result is obtained, $F_M = 400\,\text{N}$.

**NOTE** The force required of the muscle (400 N) is quite large compared to the weight of the object lifted ($= mg = 49\,\text{N}$). Indeed, the muscles and joints of the body are generally subjected to quite large forces.

**NOTE** Forces exerted on joints can be large and even painful or injurious. Using $\Sigma F_y = 0$ we calculate for this case $F_J = F_M - (2.0\,\text{kg})g - (5.0\,\text{kg})g = 330\,\text{N}$.

**FIGURE 12–12** Example 12–7, forces on forearm.

**EXERCISE E** How much mass could the person in Example 12–7 hold in the hand with a biceps force of 450 N if the tendon was attached 6.0 cm from the elbow instead of 5.0 cm?

Note that an increase in the distance of the joint to the point of insertion of the biceps muscle can be a considerable advantage for lifting and throwing. Champion athletes are often found to have muscle insertions farther from the joint than the average person, and if this applies to one muscle, it usually applies to all.

**PHYSICS APPLIED**
*What can make an athlete*

**PHYSICS APPLIED**
*Forces on the spine, and back pain*

As another example of the large forces acting within the human body, we consider the muscles used to support the body when you bend forward (Fig. 12–13a). The lowest vertebra on the spinal column (fifth lumbar vertebra) acts as a fulcrum for this bending position. Figure 12–13b is a simplified schematic drawing showing the forces on the upper body. The force exerted by the back muscles is $\vec{\mathbf{F}}_M$, the force on the base of the spine at the lowest vertebra is $\vec{\mathbf{F}}_V$, and $\vec{\mathbf{w}}_H$, $\vec{\mathbf{w}}_A$, and $\vec{\mathbf{w}}_T$ represent the weights of the **h**ead, freely hanging **a**rms, and **t**orso, respectively. Values are approximations. The distances (in cm) refer to a person 180 cm tall, but are approximately in the same ratio of 3 : 1 : 2 for an average person of any height; the result in the following Example is then independent of the height of the person.

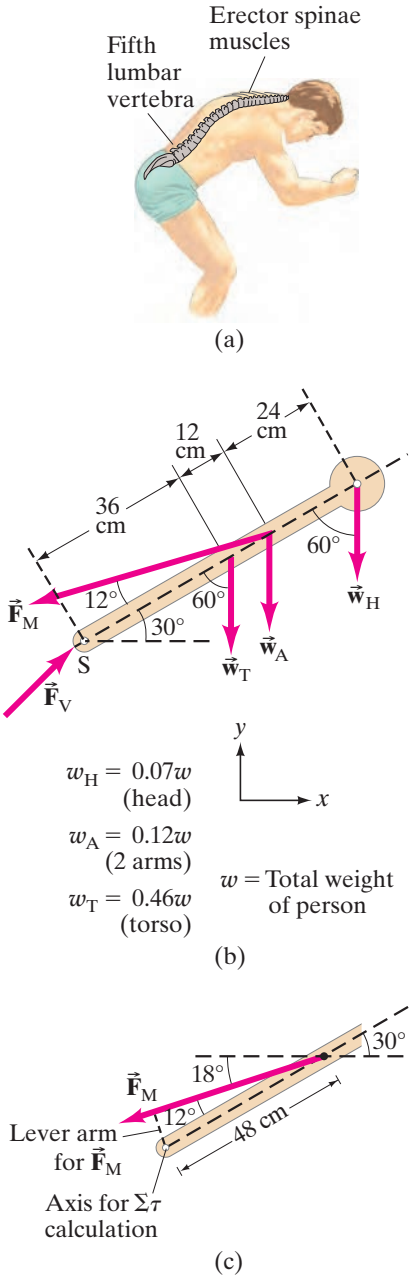


**FIGURE 12–13** (a) A person bending over. (b) Forces on the back exerted by the back muscles ($\vec{\mathbf{F}}_M$) and by the vertebrae ($\vec{\mathbf{F}}_V$) when a person bends over. (c) Finding the lever arm for $\vec{\mathbf{F}}_M$.

**EXAMPLE 12–8** **Forces on your back.** (*a*) Estimate the magnitude of the force $\vec{\mathbf{F}}_M$ the muscles exert on the back to support the upper body of a person bending forward, Fig. 12–13b. (*b*) Estimate the magnitude and direction of the force $\vec{\mathbf{F}}_V$ acting on the fifth lumbar vertebra (exerted by the spine below).

**APPROACH** We can calculate $F_M$ using the torque equation if we take the axis at the base of the spine (point S); with this choice, the other unknown, $F_V$, doesn't appear in the equation because its lever arm is zero. To determine the lever arms, we need to use trigonometric functions.

**SOLUTION** (*a*) For $\vec{\mathbf{F}}_M$, the lever arm (perpendicular distance from axis to line of action of the force) will be the real distance to where the force acts (48 cm) multiplied by sin 12°, as shown in Fig. 12–13c. The lever arms for $\vec{\mathbf{w}}_H$, $\vec{\mathbf{w}}_A$, and $\vec{\mathbf{w}}_T$ can be seen from Fig. 12–13b to be their respective distances from S times sin 60°. $F_M$ tends to rotate the torso counterclockwise, which we take to be positive. Then $\vec{\mathbf{w}}_H$, $\vec{\mathbf{w}}_A$, $\vec{\mathbf{w}}_T$ will contribute negative torques. Thus $\Sigma\tau = 0$ gives

$$(0.48\,\text{m})(\sin 12^\circ)(F_M) - (0.72\,\text{m})(\sin 60^\circ)(w_H) - (0.48\,\text{m})(\sin 60^\circ)(w_A) - (0.36\,\text{m})(\sin 60^\circ)(w_T) = 0.$$

Solving for $F_M$ and putting in the values for $w_H$, $w_A$, $w_T$ given in Fig. 12–13b, we find

$$F_M = \frac{(0.72\,\text{m})(0.07w) + (0.48\,\text{m})(0.12w) + (0.36\,\text{m})(0.46w)}{(0.48\,\text{m})(\sin 12^\circ)}(\sin 60^\circ)$$
$$= 2.37w \approx 2.4w,$$

where $w$ is the total weight of the person.

(*b*) To get the components of $\vec{\mathbf{F}}_V$ we use the $x$ and $y$ components of the force equation (noting that $30^\circ - 12^\circ = 18^\circ$):

$$\Sigma F_y = F_{Vy} - F_M \sin 18^\circ - w_H - w_A - w_T = 0$$

so

$$F_{Vy} = (2.37 \sin 18^\circ + 0.07 + 0.12 + 0.46)w = 1.38w \approx 1.4w;$$

the $x$-component $\Sigma F_x = 0$ gives

$$\Sigma F_x = F_{Vx} - F_M \cos 18^\circ = 0$$

so

$$F_{Vx} = 2.37 \cos 18^\circ w = 2.25w \approx 2.3w,$$

where we keep 3 significant figures for calculating, but round off to 2 for giving the answer. Then

$$F_V = \sqrt{F_{Vx}^2 + F_{Vy}^2} = 2.6w.$$

The angle $\theta$ that $F_V$ makes with the horizontal is given by $\tan\theta = F_{Vy}/F_{Vx} = 1.38/2.25 = 0.613$, so $\theta = 32^\circ$.

**NOTE** The force on the lowest vertebra is over $2\frac{1}{2}$ times the total body weight! The disks at the base of the spine are clearly being compressed under very large forces. [If the body was less bent over (say, the 30° angle in Fig. 12–13b becomes 40° or 50°), then the stress on the lower back will be less (see Problem 32).]

If the person in Fig. 12–13 has a mass of 90 kg and is holding 20 kg in his hands (this increases $w_A$ to $0.34w$), then $F_V$ is increased to almost four times the person's weight ($3.7w$). For this 200-lb person, the force on the disk would be over 700 lb! It is little wonder so many people suffer from low back pain at one time or another.

## 12–4 Stability and Balance

An object in static equilibrium, if left undisturbed, will undergo no translational or rotational acceleration since the sum of all the forces and the sum of all the torques acting on it are zero. However, if the object is displaced slightly, three outcomes are possible: (1) the object returns to its original position, in which case it is said to be in **stable equilibrium**; (2) the object moves even farther from its original position, and it is said to be in **unstable equilibrium**; or (3) the object remains in its new position, and it is said to be in **neutral equilibrium**.

Consider the following examples. A ball suspended freely from a string is in stable equilibrium, for if it is displaced to one side, it will return to its original position (Fig. 12–14a) due to the net force and torque exerted on it. On the other hand, a pencil standing on its point is in unstable equilibrium. If its center of gravity is directly over its tip (Fig. 12–14b), the net force and net torque on it will be zero. But if it is displaced ever so slightly as shown—say, by a slight vibration or tiny air current—there will be a torque on it, and this torque acts to make the pencil continue to fall in the direction of the original displacement. Finally, an example of an object in neutral equilibrium is a sphere resting on a horizontal tabletop. If it is moved slightly to one side, it will remain in its new position—no net torque acts on it.

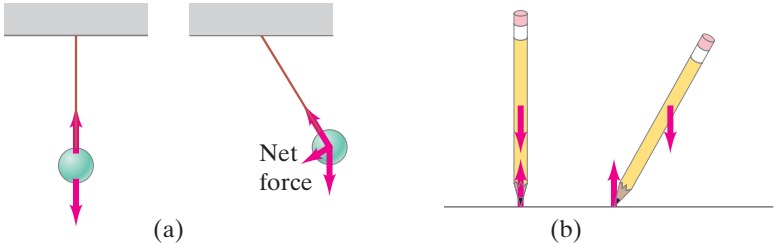

**FIGURE 12–14** (a) Stable equilibrium, and (b) unstable equilibrium.

In most situations, such as in the design of structures and in working with the human body, we are interested in maintaining stable equilibrium, or *balance*, as we sometimes say. In general, an object whose center of gravity (CG) is below its point of support, such as a ball on a string, will be in stable equilibrium. If the CG is above the base of support, we have a more complicated situation. Consider a standing refrigerator (Fig. 12–15a). If it is tipped slightly, it will return to its original position due to the torque on it as shown in Fig. 12–15b. But if it is tipped too far, Fig. 12–15c, it will fall over. The critical point is reached when the CG shifts from one side of the pivot point to the other. When the CG is on one side, the torque pulls the object back onto its original base of support, Fig. 12–15b. If the object is tipped further, the CG goes past the pivot point and the torque causes the object to topple, Fig. 12–15c. In general, *an object whose center of gravity is above its base of support will be stable if a vertical line projected downward from the CG falls within the base of support*. This is because the normal force upward on the object (which balances out gravity) can be exerted only within the area of contact, so if the force of gravity acts beyond this area, a net torque will act to topple the object.

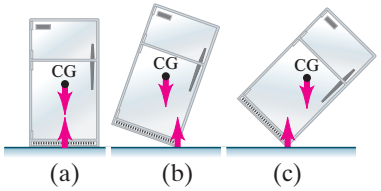

**FIGURE 12–15** Equilibrium of a refrigerator resting on a flat floor.

Stability, then, can be relative. A brick lying on its widest face is more stable than a brick standing on its end, for it will take more of an effort to tip it over. In the extreme case of the pencil in Fig. 12–14b, the base is practically a point and the slightest disturbance will topple it. In general, the larger the base and the lower the CG, the more stable the object.

**PHYSICS APPLIED**
*Humans and balance*

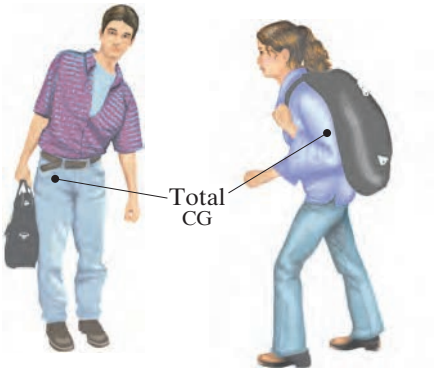

**FIGURE 12–16** Humans adjust their posture to achieve stability when carrying loads.

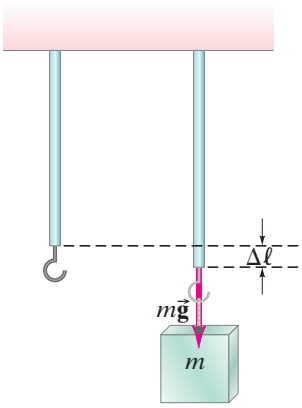
**FIGURE 12–17** Hooke's law: $\Delta\ell \propto$ applied force.



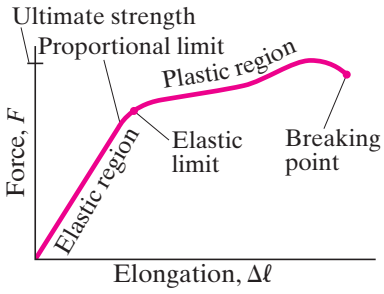


**FIGURE 12–18** Applied force vs. elongation for a typical metal under tension.

In this sense, humans are less stable than four-legged mammals, which have a larger base of support because of their four legs, and most also have a lower center of gravity. When walking and performing other kinds of movement, a person continually shifts the body so that its CG is over the feet, although in the normal adult this requires no conscious thought. Even as simple a movement as bending over requires moving the hips backward so that the CG remains over the feet, and you do this repositioning without thinking about it. To see this, position yourself with your heels and back to a wall and try to touch your toes. You won't be able to do it without falling. Persons carrying heavy loads automatically adjust their posture so that the CG of the total mass is over their feet, Fig. 12–16.

# 12–5 Elasticity; Stress and Strain

In the first part of this Chapter we studied how to calculate the forces on objects in equilibrium. In this Section we study the effects of these forces: any object changes shape under the action of applied forces. If the forces are great enough, the object will break, or *fracture*, as we will discuss in the next Section.

## Elasticity and Hooke's Law

If a force is exerted on an object, such as the vertically suspended metal rod shown in Fig. 12–17, the length of the object changes. If the amount of elongation, $\Delta\ell$, is small compared to the length of the object, experiment shows that $\Delta\ell$ is proportional to the force exerted on the object. This proportionality can be written as an equation:

$$F = k\,\Delta\ell. \qquad \textbf{(12–3)}$$

Here $F$ represents the force pulling on the object, $\Delta\ell$ is the change in length, and $k$ is a proportionality constant. Equation 12–3, which is sometimes called **Hooke's law**† after Robert Hooke (1635–1703), who first noted it, is found to be valid for almost any solid material from iron to bone—but it is valid only up to a point. If the force is too great, the object stretches excessively and eventually breaks.

Figure 12–18 shows a typical graph of applied force versus elongation. Up to a point called the **proportional limit**, Eq. 12–3 is a good approximation for many common materials, and the curve is a straight line. Beyond this point, the graph deviates from a straight line, and no simple relationship exists between $F$ and $\Delta\ell$. Nonetheless, up to a point farther along the curve called the **elastic limit**, the object will return to its original length if the applied force is removed. The region from the origin to the elastic limit is called the *elastic region*. If the object is stretched beyond the elastic limit, it enters the *plastic region*: it does not return to the original length upon removal of the external force, but remains permanently deformed (such as a bent paper clip). The maximum elongation is reached at the *breaking point*. The maximum force that can be applied without breaking is called the **ultimate strength** of the material (actually, force per unit area, as we discuss in the next Section).

## Young's Modulus

The amount of elongation of an object, such as the rod shown in Fig. 12–17, depends not only on the force applied to it, but also on the material of which it is made and on its dimensions. That is, the constant $k$ in Eq. 12–3 can be written in terms of these factors.

If we compare rods made of the same material but of different lengths and cross-sectional areas, it is found that for the same applied force, the amount of stretch (again assumed small compared to the total length) is proportional to the original length and inversely proportional to the cross-sectional area.

†The term "law" applied to this relation is historical, but today it is not really appropriate. First of all, it is only an approximation, and second, it refers only to a limited set of phenomena. Most physicists today prefer to reserve the word "law" for those relations that are deeper and more encompassing and precise, such as Newton's laws of motion or the law of conservation of energy.

That is, the longer the object, the more it elongates for a given force; and the thicker it is, the less it elongates. These findings can be combined with Eq. 12–3 to yield

$$\Delta\ell = \frac{1}{E}\frac{F}{A}\ell_0, \qquad \textbf{(12–4)}$$

where $\ell_0$ is the original length of the object, $A$ is the cross-sectional area, and $\Delta\ell$ is the change in length due to the applied force $F$. $E$ is a constant of proportionality[‡] known as the **elastic modulus**, or **Young's modulus**; its value depends only on the material. The value of Young's modulus for various materials is given in Table 12–1 (the shear modulus and bulk modulus in this Table are discussed later in this Section). Because $E$ is a property only of the material and is independent of the object's size or shape, Eq. 12–4 is far more useful for practical calculation than Eq. 12–3.

**TABLE 12–1 Elastic Moduli**

| Material | Young's Modulus, $E$ ($N/m^2$) | Shear Modulus, $G$ ($N/m^2$) | Bulk Modulus, $B$ ($N/m^2$) |
|---|---|---|---|
| *Solids* | | | |
| Iron, cast | $100 \times 10^9$ | $40 \times 10^9$ | $90 \times 10^9$ |
| Steel | $200 \times 10^9$ | $80 \times 10^9$ | $140 \times 10^9$ |
| Brass | $100 \times 10^9$ | $35 \times 10^9$ | $80 \times 10^9$ |
| Aluminum | $70 \times 10^9$ | $25 \times 10^9$ | $70 \times 10^9$ |
| Concrete | $20 \times 10^9$ | | |
| Brick | $14 \times 10^9$ | | |
| Marble | $50 \times 10^9$ | | $70 \times 10^9$ |
| Granite | $45 \times 10^9$ | | $45 \times 10^9$ |
| Wood (pine) (parallel to grain) | $10 \times 10^9$ | | |
| (perpendicular to grain) | $1 \times 10^9$ | | |
| Nylon | $\approx 3 \times 10^9$ | | |
| Bone (limb) | $15 \times 10^9$ | $80 \times 10^9$ | |
| *Liquids* | | | |
| Water | | | $2.0 \times 10^9$ |
| Alcohol (ethyl) | | | $1.0 \times 10^9$ |
| Mercury | | | $25 \times 10^9$ |
| *Gases*[†] | | | |
| Air, $H_2$, He, $CO_2$ | | | $1.01 \times 10^5$ |

[†]At normal atmospheric pressure; no variation in temperature during process.

**EXAMPLE 12–9 Tension in piano wire.** A 1.60-m-long steel piano wire has a diameter of 0.20 cm. How great is the tension in the wire if it stretches 0.25 cm when tightened?

**APPROACH** We assume Hooke's law holds, and use it in the form of Eq. 12–4, finding $E$ for steel in Table 12–1.

**SOLUTION** We solve for $F$ in Eq. 12–4 and note that the area of the wire is $A = \pi r^2 = (3.14)(0.0010\,\text{m})^2 = 3.14 \times 10^{-6}\,\text{m}^2$, so $F$ is

$$F = E\frac{\Delta\ell}{\ell_0}A = (2.0 \times 10^{11}\,\text{N/m}^2)\left(\frac{0.0025\,\text{m}}{1.60\,\text{m}}\right)(3.14 \times 10^{-6}\,\text{m}^2) = 980\,\text{N}.$$

**NOTE** The large tension in all the wires in a piano must be supported by a strong frame.

**EXERCISE F** Two steel wires have the same length and are under the same tension. But wire A has twice the diameter of wire B. Which of the following is true? (*a*) Wire B stretches twice as much as wire A. (*b*) Wire B stretches four times as much as wire A. (*c*) Wire A stretches twice as much as wire B. (*d*) Wire A stretches four times as much as wire B. (*e*) Both wires stretch the same amount.

[‡]The fact that $E$ is in the denominator, so $1/E$ is the actual proportionality constant, is merely a convention. When we rewrite Eq. 12–4 to get Eq. 12–5, $E$ is found in the numerator.

## Stress and Strain

From Eq. 12–4, we see that the change in length of an object is directly proportional to the product of the object's length $\ell_0$ and the force per unit area $F/A$ applied to it. It is general practice to define the force per unit area as the **stress**:

$$\text{stress} = \frac{\text{force}}{\text{area}} = \frac{F}{A},$$

which has SI units of $N/m^2$. The **strain** is defined to be the ratio of the change in length to the original length:

$$\text{strain} = \frac{\text{change in length}}{\text{original length}} = \frac{\Delta\ell}{\ell_0},$$

and is dimensionless (no units). Strain is thus the fractional change in length of the object, and is a measure of how much the object has been deformed. Stress is applied to the material by external agents, whereas strain is the material's response to the stress. Equation 12–4 can be rewritten as

$$\frac{F}{A} = E\frac{\Delta\ell}{\ell_0} \qquad \textbf{(12–5)}$$

or

$$E = \frac{F/A}{\Delta\ell/\ell_0} = \frac{\text{stress}}{\text{strain}}.$$

Thus we see that the strain is directly proportional to the stress, in the linear (elastic) region of Fig. 12–18.

## Tension, Compression, and Shear Stress

The rod shown in Fig. 12–19a is said to be under *tension* or **tensile stress**. Not only is there a force pulling down on the rod at its lower end, but since the rod is in equilibrium we know that the support at the top is exerting an equal[†] upward force on the rod at its upper end, Fig. 12–19a. In fact, this tensile stress exists throughout the material. Consider, for example, the lower half of a suspended rod as shown in Fig. 12–19b. This lower half is in equilibrium, so there must be an upward force on it to balance the downward force at its lower end. What exerts this upward force? It must be the upper part of the rod. Thus we see that external forces applied to an object give rise to internal forces, or stress, within the material itself.

Strain or deformation due to tensile stress is only one type of stress to which materials can be subjected. There are two other common types of stress: compressive and shear. **Compressive stress** is the exact opposite of tensile stress. Instead of being stretched, the material is compressed: the forces act inwardly on the object. Columns that support a weight, such as the columns of a Greek temple (Fig. 12–20), are subjected to compressive stress. Equations 12–4 and 12–5 apply equally well to compression and tension, and the values for the modulus $E$ are usually the same.

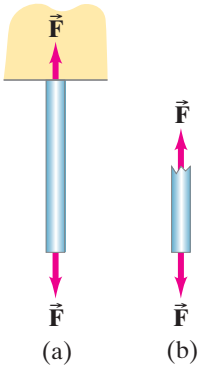

**FIGURE 12–19** Stress exists *within* the material.

[†]Or a greater force if the weight of the rod cannot be ignored compared to $F$.

**FIGURE 12–20** This Greek temple, in Agrigento, Sicily, built 2500 years ago, shows the post-and-beam construction. The columns are under compression.

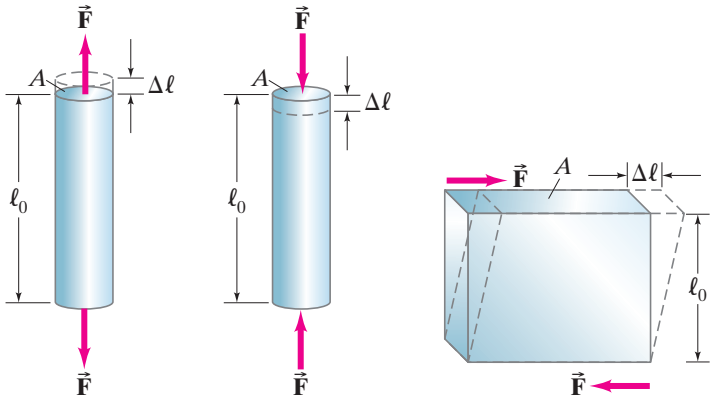

**FIGURE 12–21** The three types of stress for rigid objects.

Figure 12–21 compares tensile and compressive stresses as well as the third type, shear stress. An object under **shear stress** has equal and opposite forces applied *across* its opposite faces. A simple example is a book or brick firmly attached to a tabletop, on which a force is exerted parallel to the top surface. The table exerts an equal and opposite force along the bottom surface. Although the dimensions of the object do not change significantly, the shape of the object does change, Fig. 12–21c. An equation similar to Eq. 12–4 can be applied to calculate shear strain:

$$\Delta\ell = \frac{1}{G}\frac{F}{A}\ell_0 \qquad \textbf{(12–6)}$$

but $\Delta\ell$, $\ell_0$, and $A$ must be reinterpreted as indicated in Fig. 12–21c. Note that $A$ is the area of the surface *parallel* to the applied force (and not perpendicular as for tension and compression), and $\Delta\ell$ is *perpendicular* to $\ell_0$. The constant of proportionality $G$ is called the **shear modulus** and is generally one-half to one-third the value of Young's modulus $E$ (see Table 12–1). Figure 12–22 suggests why $\Delta\ell \propto \ell_0$: the fatter book shifts more for the same shearing force.

**FIGURE 12–22** The fatter book (a) shifts more than the thinner book (b) with the same applied shear force.

(a)

(b)

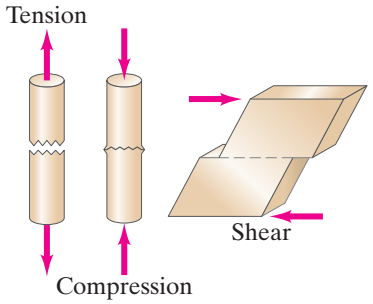
## Volume Change—Bulk Modulus

If an object is subjected to inward forces from all sides, its volume will decrease. A common situation is an object submerged in a fluid. In this case, the fluid exerts a pressure on the object in all directions, as we shall discuss in Chapter 13. *Pressure* is defined as force per unit area, and thus is the equivalent of stress. For this situation the change in volume, $\Delta V$, is proportional to the original volume, $V_0$, and to the change in the pressure, $\Delta P$. We thus obtain a relation of the same form as Eq. 12–4 but with a proportionality constant called the **bulk modulus** $B$:

$$\frac{\Delta V}{V_0} = -\frac{1}{B}\Delta P \qquad \textbf{(12–7)}$$

or

$$B = -\frac{\Delta P}{\Delta V/V_0}.$$



The minus sign means the volume *decreases* with an increase in pressure.

Values for the bulk modulus are given in Table 12–1. Since liquids and gases do not have fixed shapes, only the bulk modulus (not the Young's or shear moduli) applies to them.

# 12–6 Fracture

If the stress on a solid object is too great, the object fractures, or breaks (Fig. 12–23). Table 12–2 lists the **ultimate strengths** for tension, compression, and shear for a variety of materials. These values give the maximum force per unit area, or stress, that an object can withstand under each of these three types of stress for various types of material. They are, however, representative values only, and the actual value for a given specimen can differ considerably. It is therefore necessary to maintain a **safety factor** of from 3 to perhaps 10 or more: so the actual stresses should not exceed one-tenth to one-third of the values given in the Table.

**FIGURE 12–23** Fracture as a result of the three types of stress.

You may encounter tables of "allowable stresses" in which appropriate safety factors have already been included.

**TABLE 12–2 Ultimate Strengths of Materials** (force/area)

| Material | Tensile Strength ($N/m^2$) | Compressive Strength ($N/m^2$) | Shear Strength ($N/m^2$) |
|---|---|---|---|
| Iron, cast | $170 \times 10^6$ | $550 \times 10^6$ | $170 \times 10^6$ |
| Steel, typical | $500 \times 10^6$ | $500 \times 10^6$ | $250 \times 10^6$ |
| Steel, high-carbon | $\approx 2500 \times 10^6$ | $\approx 2000 \times 10^6$ | |
| Brass | $250 \times 10^6$ | $250 \times 10^6$ | $200 \times 10^6$ |
| Aluminum | $200 \times 10^6$ | $200 \times 10^6$ | $200 \times 10^6$ |
| Concrete | $2 \times 10^6$ | $20 \times 10^6$ | $2 \times 10^6$ |
| Brick | | $35 \times 10^6$ | |
| Marble | | $80 \times 10^6$ | |
| Granite | | $170 \times 10^6$ | |
| Wood (pine) (parallel to grain) | $40 \times 10^6$ | $35 \times 10^6$ | $5 \times 10^6$ |
| (perpendicular to grain) | | $10 \times 10^6$ | |
| Nylon | $500 \times 10^6$ | | |
| Bone (limb) | $130 \times 10^6$ | $170 \times 10^6$ | |

**EXAMPLE 12–10 ESTIMATE Breaking the piano wire.** The steel piano wire we discussed in Example 12–9 was 1.60 m long with a diameter of 0.20 cm. Approximately what tension force would break it?

**APPROACH** We set the tensile stress $F/A$ equal to the ultimate tensile strength of typical steel given in Table 12–2.

**SOLUTION** The wire's area is $A = \pi r^2$, where $r = 0.10\,\text{cm} = 1.0 \times 10^{-3}\,\text{m}$. Table 12–2 tells us

$$\frac{F}{A} = 500 \times 10^6\,\text{N/m}^2,$$

so the wire would likely break if the force exceeded

$$F = (500 \times 10^6\,\text{N/m}^2)(\pi)(1.0 \times 10^{-3}\,\text{m})^2 = 1600\,\text{N}.$$

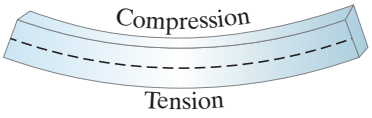


**FIGURE 12–24** A beam sags, at least a little (but is exaggerated here), even under its own weight. The beam thus changes shape: the upper edge is compressed, and the lower edge is under tension (elongated). Shearing stress also occurs within the beam.

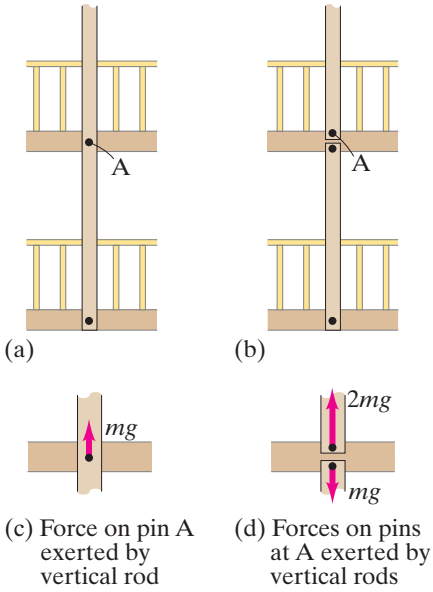
As can be seen in Table 12–2, concrete (like stone and brick) is reasonably strong under compression but extremely weak under tension. Thus concrete can be used as vertical columns placed under compression, but is of little value as a beam because it cannot withstand the tensile forces that result from the inevitable sagging of the lower edge of a beam (see Fig. 12–24). *Reinforced concrete*, in which iron rods are embedded in the concrete (Fig. 12–25), is much stronger than plain concrete. But the concrete on the lower edge of a loaded beam still tends to crack because it is weak under tension. This problem is solved with *prestressed concrete*, which also contains iron rods or a wire mesh, but during the pouring of the concrete, the rods or wire are held under tension. After the concrete dries, the tension on the iron is released, putting the concrete under compression. The amount of compressive stress is carefully predetermined so that when loads are applied to the beam, the compression on the lower edge is never allowed to be reduced so far as to put the concrete into tension.

**FIGURE 12–25** Steel rods around which concrete is poured for strength.

**CONCEPTUAL EXAMPLE 12–11 A tragic substitution.** Two walkways, one above the other, are suspended from vertical rods attached to the ceiling of a high hotel lobby, Fig. 12–26a. The original design called for single rods 14 m long, but when such long rods proved to be unwieldy to install, it was decided to replace each long rod with two shorter ones as shown schematically in Fig. 12–26b. Determine the net force exerted by the rods on the supporting pin A (assumed to be the same size) for each design. Assume each vertical rod supports a mass $m$ of each bridge.

**RESPONSE** The single long vertical rod in Fig. 12–26a exerts an upward force equal to $mg$ on pin A to support the mass $m$ of the upper bridge (Fig. 12–26c). Why? Because the pin is in equilibrium, and the other force that balances this is the downward force $mg$ exerted on pin A by the upper bridge. There is thus a shear stress on the pin because the rod pulls up on one side of the pin, and the bridge pulls down on the other side. The situation when two shorter rods support the bridges (Fig. 12–26b) is shown in Fig. 12–26d, in which only the connections at the upper bridge are shown. The lower rod exerts a force $mg$ downward on the lower of the two pins because it supports the lower bridge. The upper rod exerts a force $2mg$ on the upper pin (labelled A) because the upper rod supports both bridges. Thus we see that when the builders substituted two shorter rods for each single long one, the stress in the supporting pin A was *doubled*. What perhaps seemed like a simple substitution did, in fact, lead to a tragic collapse in 1981 with a loss of life of over 100 people (see Fig. 12–1). Having a feel for physics, and being able to make calculations based on physics, can have a great effect, literally, on people's lives.



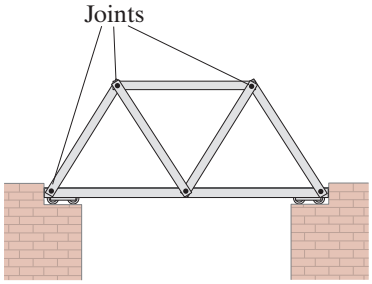


**FIGURE 12–26** Example 12–11.

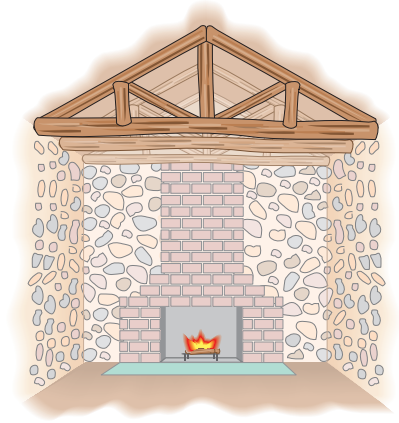
## *12–7 Trusses and Bridges



A beam used to span a wide space, as for a bridge, is subject to strong stresses of all three types as we saw in Fig. 12–24: compression, tension, and shear. A basic engineering device to support large spans is the *truss*, an example of which is shown in Fig. 12–27. Wooden truss bridges were first designed by the great architect Andrea Palladio (1518–1580), famous for his design of public buildings and villas. With the introduction of steel in the nineteenth century, much stronger steel trusses came into use, although wood trusses are still used to support the roofs of houses and mountain lodges (Fig. 12–28).

**FIGURE 12–27** A truss bridge.

Basically, a **truss** is a framework of rods or struts joined together at their ends by **pins** (bolts) or rivets, always arranged as triangles. (Triangles are relatively stable, as compared to a rectangle, which easily becomes a parallelogram under sideways forces and then collapses.) The place where the struts are joined by a pin is called a **joint**.

**FIGURE 12–28** (Below.) A roof truss.

It is commonly assumed that the struts of a truss are under pure compression or pure tension—that is, the forces act along the length of each strut, Fig. 12–29a. This is an ideal, valid only if a strut has no mass and supports no weight along its length, in which case a strut has only two forces on it, at the ends, as shown in Fig. 12–29a. If the strut is in equilibrium, these two forces must be equal and opposite in direction $(\Sigma\vec{\mathbf{F}} = 0)$. But couldn't they be at an angle, as in Fig. 12–29b? No, because then $\Sigma\vec{\boldsymbol{\tau}}$ would not be zero. The two forces *must* act along the strut if the strut is in equilibrium. But in a real case of a strut with mass, there are three forces on the strut, as shown in Fig. 12–29c, and $\vec{\mathbf{F}}_1$ and $\vec{\mathbf{F}}_2$ do not act along the strut; the vector diagram in Fig. 12–29d shows $\Sigma\vec{\mathbf{F}} = \vec{\mathbf{F}}_1 + \vec{\mathbf{F}}_2 + m\vec{\mathbf{g}} = 0$. Can you see why $\vec{\mathbf{F}}_1$ and $\vec{\mathbf{F}}_2$ both point *above* the strut? (Do $\Sigma\tau$ about each end.)

In Example 12–5, Fig. 12–9, the force $\vec{\mathbf{F}}_H$ at the hinge is *not* along the beam, but acts at an upward angle. If that beam were massless, we see from Eq. (iii) in Example 12–5 with $m = 0$, that $F_{Hy} = 0$, and $\vec{\mathbf{F}}_H$ would be along the beam.

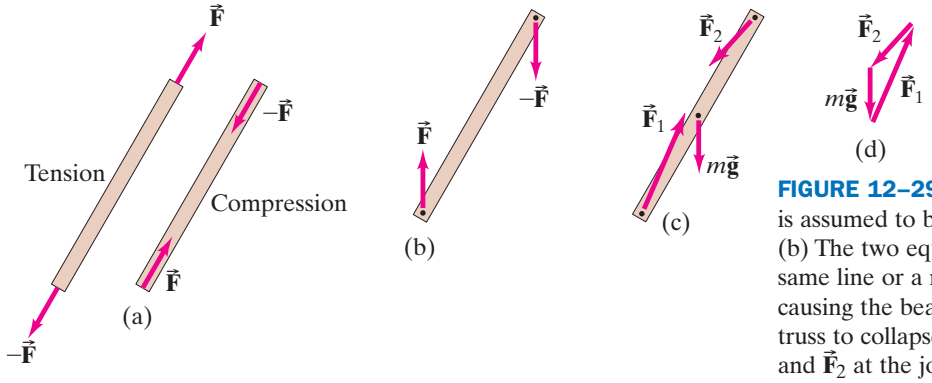


**FIGURE 12–29** (a) If you ignore its mass, a strut (or rod) is assumed to be under pure tension or compression. (b) The two equal and opposite forces must be along the same line or a net torque would exist, as shown here, causing the beam to rotate (no longer be static) and the truss to collapse. (c) Real struts have mass, so the forces $\vec{\mathbf{F}}_1$ and $\vec{\mathbf{F}}_2$ at the joints or pins do not act precisely along the strut. (d) Vector diagram of part (c).

The assumption that the forces in each strut of a truss are purely along the strut is still very useful whenever the loads act only at the joints and are much greater than the weight of the struts themselves.

**EXAMPLE 12–12** **A truss bridge.** Determine the tension or compression in each of the struts of the truss bridge shown in Fig. 12–30a. The bridge is 64 m long and supports a uniform level concrete roadway whose total mass is $1.40 \times 10^6$ kg. Use the **method of joints**, which involves (1) drawing a free-body diagram of the truss as a whole, and (2) drawing a free-body diagram for each of the pins (joints), one by one, and setting $\Sigma\vec{\mathbf{F}} = 0$ for each pin. Ignore the mass of the struts. Assume all triangles are equilateral.

**APPROACH** Any truss bridge has two trusses, one on each side of the roadway. Consider only one truss, Fig. 12–30a, and it will support half the weight of the roadway. That is, our truss supports a total mass $M = 7.0 \times 10^5$ kg. First we draw a free-body diagram for the entire truss as a single unit, which we assume rests on supports at either end that exert upward forces $\vec{\mathbf{F}}_1$ and $\vec{\mathbf{F}}_2$, Fig. 12–30b. We assume the mass of the roadway acts entirely at the center, on pin C, as shown. From *symmetry* we can see that each of the end supports carries half the weight [or do a torque equation about, say, point A: $(F_2)(\ell) - Mg(\ell/2) = 0$], so

$$F_1 = F_2 = \tfrac{1}{2}Mg.$$

**SOLUTION** We look at pin A and apply $\Sigma\vec{\mathbf{F}} = 0$ to it. We label the forces on pin A due to each strut with two subscripts: $\vec{\mathbf{F}}_{AB}$ means the force exerted by the strut AB on pin A, and $\vec{\mathbf{F}}_{AC}$ is the force exerted by strut AC on A. $\vec{\mathbf{F}}_{AB}$ and $\vec{\mathbf{F}}_{AC}$ act along their respective struts; but not knowing whether each is compressive or tensile, we can draw four different free-body diagrams that satisfy this requirement, as shown in Fig. 12–30c. Only the one on the left could provide $\Sigma\vec{\mathbf{F}} = 0$, so we immediately know the directions of $\vec{\mathbf{F}}_{AB}$ and $\vec{\mathbf{F}}_{AC}$.† These forces act on pin A. The force that pin A exerts on strut AB is opposite in direction to $\vec{\mathbf{F}}_{AB}$ (Newton's third law), so strut AB is under compression, and strut AC, in turn, is under tension. Now let's calculate the magnitudes of $\vec{\mathbf{F}}_{AB}$ and $\vec{\mathbf{F}}_{AC}$. At pin A:

$$\Sigma F_x = F_{AC} - F_{AB}\cos 60^\circ = 0$$
$$\Sigma F_y = F_1 - F_{AB}\sin 60^\circ = 0.$$

Thus (recall $\cos 60^\circ = \sin 30^\circ = \frac{1}{2}$, and $\sin 60^\circ = \sqrt{1-\cos^2 60^\circ} = \sqrt{1-(\frac{1}{2})^2} = \sqrt{3}/2$):

$$F_{AB} = \frac{F_1}{\sin 60^\circ} = \frac{\frac{1}{2}Mg}{\frac{1}{2}\sqrt{3}} = \frac{1}{\sqrt{3}}Mg,$$

which equals $(7.0 \times 10^5\ \text{kg})(9.8\ \text{m/s}^2)/\sqrt{3} = 4.0 \times 10^6\ \text{N}$.
Then

$$F_{AC} = F_{AB}\cos 60^\circ = \frac{1}{2\sqrt{3}}Mg.$$

Next we look at pin B, and Fig. 12–30d is the free-body diagram. [Convince yourself that if $\vec{\mathbf{F}}_{BD}$ or $\vec{\mathbf{F}}_{BC}$ were in the opposite direction, $\Sigma\vec{\mathbf{F}}$ could not be zero; note that $\vec{\mathbf{F}}_{BA} = -\vec{\mathbf{F}}_{AB}$ (and $F_{BA} = F_{AB}$) because now we are at the opposite end of strut AB.] We see that BC is under tension and BD compression. (Recall that the forces on the struts are opposite to the forces shown which are on the pin.) We set $\Sigma\vec{\mathbf{F}} = 0$ on pin B (Fig. 12–30d):

$$\Sigma F_x = F_{BA}\cos 60^\circ + F_{BC}\cos 60^\circ - F_{BD} = 0$$
$$\Sigma F_y = F_{BA}\sin 60^\circ - F_{BC}\sin 60^\circ = 0.$$

Then, because $F_{BA} = F_{AB}$, we have from the $\Sigma F_y$ equation

$$F_{BC} = F_{AB} = \frac{1}{\sqrt{3}}Mg.$$

From the $\Sigma F_x$ equation, Fig. 12–30d,

$$F_{BD} = F_{BA}\cos 60^\circ + F_{BC}\cos 60^\circ = \frac{1}{\sqrt{3}}Mg(\tfrac{1}{2}) + \frac{1}{\sqrt{3}}Mg(\tfrac{1}{2}) = \frac{1}{\sqrt{3}}Mg.$$

The solution is complete. By symmetry, $F_{DE} = F_{AB}$, $F_{CE} = F_{AC}$, and $F_{CD} = F_{BC}$.

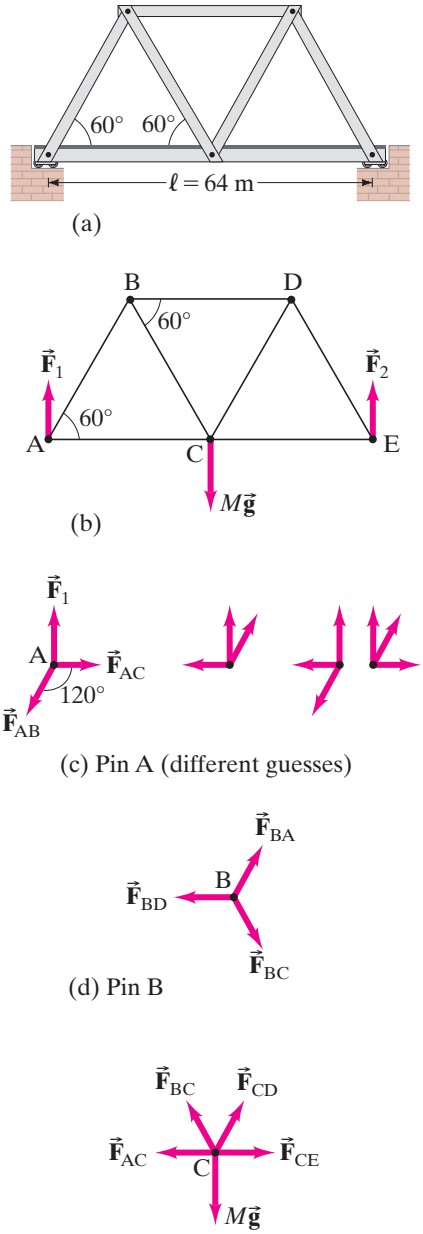

**FIGURE 12–30** Example 12–12. (a) A truss bridge. Then free-body diagrams: (b) for the entire truss, (c) for pin A (different guesses), (d) for pin B and (e) for pin C.

†If we were to choose the direction of a force on a diagram opposite to what it really is, we would get a minus sign.

**NOTE** As a check, calculate $\Sigma F_x$ and $\Sigma F_y$ for pin C and see if they equal zero. Figure 12–30e shows the free-body diagram.

Example 12–12 put the roadway load at the center, C. Now consider a heavy load, such as a heavy truck, supported by strut AC at its middle, as shown in Fig. 12–31a. The strut AC sags under this load, telling us there is shear stress in strut AC. Figure 12–31b shows the forces exerted on strut AC: the weight of the truck $m\vec{\mathbf{g}}$, and the forces $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_C$ that pins A and C exert on the strut. [Note that $\vec{\mathbf{F}}_1$ does not appear because it is a force (exerted by external supports) that acts on pin A, not on strut AC.] The forces that pins A and C exert on strut AC will act not only along the strut, but will have vertical components too, perpendicular to the strut to balance the weight of the truck, $m\vec{\mathbf{g}}$, creating shear stress. The other struts, not bearing weight, remain under pure tension or compression. Problem 57 deals with this situation, and an early step in its solution is to calculate the forces $\vec{\mathbf{F}}_A$ and $\vec{\mathbf{F}}_C$ by using torque equations for the strut.

For very large bridges, truss structures are too heavy. One solution is to build suspension bridges, with the load being carried by relatively light suspension cables under tension, supporting the roadway by means of closely spaced vertical wires, as shown in Fig. 12–32a.

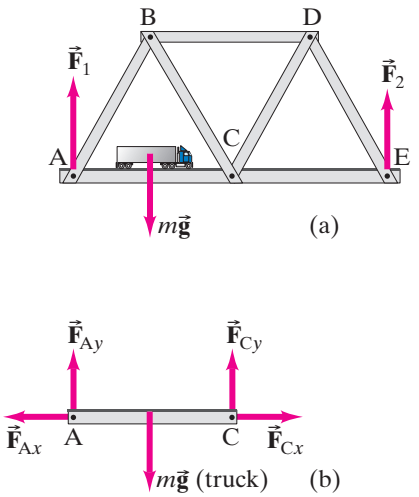

**FIGURE 12–31** (a) Truss with truck of mass $m$ at center of strut AC. (b) Forces on strut AC.

**EXAMPLE 12–13** **Suspension bridge.** Determine the shape of the cable between the two towers of a suspension bridge (as in Fig. 12–32a), assuming the weight of the roadway is supported uniformly along its length. Ignore the weight of the cable.

**APPROACH** We take $x = 0$, $y = 0$ at the center of the span, as shown in Fig. 12–32b. Let $\vec{\mathbf{F}}_{T0}$ be the tension in the cable at $x = 0$; it acts horizontally as shown. Let $F_T$ be the tension in the cable at some other place where the horizontal coordinate is $x$, as shown. This section of cable supports a portion of the roadway whose weight $w$ is proportional to the distance $x$, since the roadway is assumed uniform; that is,

$$w = \lambda x$$

where $\lambda$ is the weight per unit length.

**SOLUTION** We set $\Sigma\vec{\mathbf{F}} = 0$:

$$\Sigma F_x = F_T \cos\theta - F_{T0} = 0$$
$$\Sigma F_y = F_T \sin\theta - w = 0$$

We divide these two equations and we use $w = \lambda x$,

$$\tan\theta = \frac{w}{F_{T0}} = \frac{\lambda x}{F_{T0}}.$$

The slope of our curve (the cable) at any point is

$$\frac{dy}{dx} = \tan\theta$$

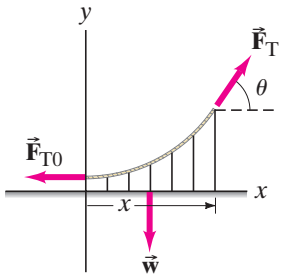
or, since we just saw $\tan\theta = \lambda x/F_{T0}$,

$$\frac{dy}{dx} = \frac{\lambda}{F_{T0}} x.$$

We integrate this:

$$\int dy = \frac{\lambda}{F_{T0}} \int x\, dx$$
$$y = Ax^2 + B$$

where we set $A = \lambda/F_{T0}$ and $B$ is a constant of integration. This is just the equation of a parabola.



**NOTE** Real bridges have cables that do have mass, so the cables hang only approximately as a parabola, although often it is quite close.

# *12–8 Arches and Domes

There are various ways that engineers and architects can span an interior or exterior space. In this Section we discuss arches and domes.

(a)

(b)

**FIGURE 12–33** (a) Round arches in the Roman Forum, over 2000 years old. The one in the background is the Arch of Titus. (b) A modern arch is used here to good effect for a bridge over a chasm on the California coast.

**PHYSICS APPLIED**
*Architecture: Beams, arches and domes*

The semicircular **arch** (Fig. 12–33a) was introduced by the ancient Romans 2000 years ago. Aside from its aesthetic appeal, it was a tremendous technological innovation. The advantage of the "true" or semicircular arch is that, if well designed, its wedge-shaped stones experience stress which is mainly compressive even when supporting a large load such as the wall and roof of a cathedral. Because the wedge-shaped stones are forced to squeeze against one another, they are mainly under compression (see Fig. 12–34). A round arch consisting of many well-shaped stones could span a very wide space. When supporting a vertical "load" above it, the arch would tend to split apart if there were not horizontal forces exerted on it by some sort of buttressing, as we discuss shortly.

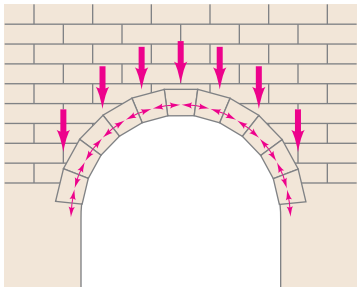

**FIGURE 12–34** Stones in a round arch (see Fig. 12–33a) are mainly under compression.

**FIGURE 12–35** Flying buttresses (on the cathedral of Notre Dame, in Paris).

The pointed arch came into use about A.D. 1100 and became the hallmark of the great Gothic cathedrals. It too was an important technical innovation, and was first used to support heavy loads such as the tower and central arch of a cathedral. Apparently the builders realized that, because of the steepness of the pointed arch, the forces due to the weight above would act more nearly vertically, so less horizontal buttressing would be needed. The pointed arch reduced the load on the walls, so there could be more window openings and light. The smaller buttressing needed was provided on the outside by graceful flying buttresses (Fig. 12–35).

The technical innovation of the pointed arch was achieved not through calculation but through experience and intuition; it was not until much later that detailed calculations, such as those presented earlier in this Chapter, came into use.

To make an accurate analysis of a stone arch is quite difficult in practice. But if we make some simplifying assumptions, we can show why the horizontal component of the external force needed at the base is less for a pointed arch than for a round one. Figure 12–36 shows a round arch and a pointed arch, each with an 8.0-m span. The height of the round arch is thus 4.0 m, whereas that of the pointed arch is larger and has been chosen to be 8.0 m. Each arch

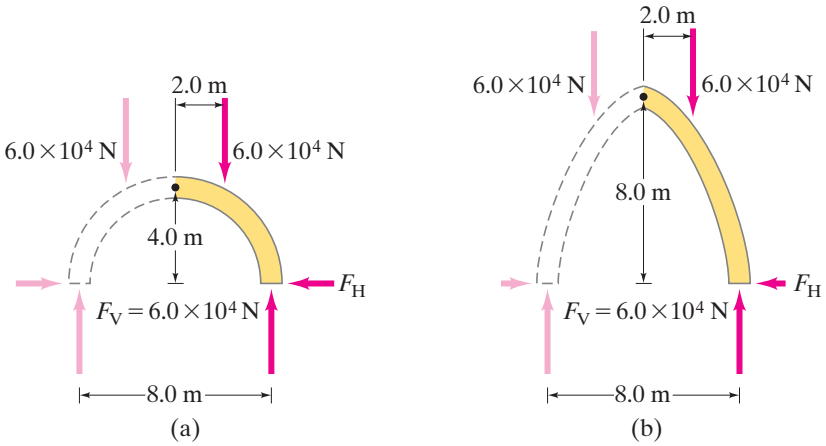

**FIGURE 12–36** (a) Forces in a round arch, compared (b) with those in a pointed arch.

supports a weight of $12.0 \times 10^4\,\text{N}$ $(= 12{,}000\,\text{kg} \times g)$ which, for simplicity, we have divided into two parts (each $6.0 \times 10^4\,\text{N}$) acting on the two halves of each arch as shown. To be in equilibrium, each of the supports below the arch must exert an upward force of $6.0 \times 10^4\,\text{N}$. For rotational equilibrium, each support also exerts a horizontal force, $F_\text{H}$, at the base of the arch, and it is this we want to calculate. Due to the *symmetry*, we can focus only on the right half of each arch. We set equal to zero the total torque calculated about the apex of the arch due to the three forces exerted on that half arch. The torque equation $(\Sigma\tau = 0)$ contains three terms: the weight above the arch, the support $F_\text{V}$ below, and the horizontal force $F_\text{H}$, which for the round arch (see Fig. 12–36a) is

$$-(2.0\,\text{m})(6.0 \times 10^4\,\text{N}) + (4.0\,\text{m})(6.0 \times 10^4\,\text{N}) - (4.0\,\text{m})(F_\text{H}) = 0.$$

Thus $F_\text{H} = 3.0 \times 10^4\,\text{N}$ for the round arch. For the pointed arch, the torque equation is (see Fig. 12–36b)

$$-(2.0\,\text{m})(6.0 \times 10^4\,\text{N}) + (4.0\,\text{m})(6.0 \times 10^4\,\text{N}) - (8.0\,\text{m})(F_\text{H}) = 0.$$

Solving, we find that $F_\text{H} = 1.5 \times 10^4\,\text{N}$—only half as much as for the round arch! From this calculation we can see that the horizontal buttressing force required for a pointed arch is less because the arch is higher, and there is therefore a longer lever arm for this force. Indeed, the steeper the arch, the less the horizontal component of the force needs to be, and hence the more nearly vertical is the force exerted at the base of the arch.

Whereas an arch spans a two-dimensional space, a **dome**—which is basically an arch rotated about a vertical axis—spans a three-dimensional space. The Romans built the first large domes. Their shape was hemispherical and some still stand, such as that of the Pantheon in Rome (Fig. 12–37), built 2000 years ago.

(a) (b)

**FIGURE 12–37** Interior of the Pantheon in Rome, Italy, built almost 2000 years ago. (a) This view, showing the great dome and its central opening for light, was painted about 1740 by Panini. Photographs (b) do not capture it as well as this painting does.

**FIGURE 12–38** Brunelleschi's dome on the cathedral of Florence, Italy.

Fourteen centuries later, a new cathedral being built in Florence was to have a dome 43 m in diameter to rival that of the Pantheon. This new dome was to rest on a "drum" with no external abutments. Filippo Brunelleschi (1377–1446) designed a pointed dome (Fig. 12–38), since a pointed dome, like a pointed arch, exerts a smaller side thrust against its base. A dome, like an arch, is not stable until all the stones are in place. To support smaller domes during construction, wooden frameworks were used. But no trees big enough or strong enough could be found to span the 43-m space required. Brunelleschi decided to try to build the dome in horizontal layers, each bonded to the previous one, holding it in place until the last stone of the circle was placed. Each closed ring was then strong enough to support the next layer. It was an amazing feat, an engineering marvel, and so its picture is also on the cover. Only in the twentieth century were larger domes built. One of the largest is the Superdome in New Orleans, completed in 1975, whose 200-m-diameter dome is made of steel trusses and concrete.

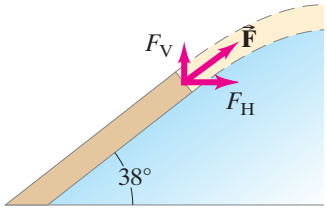
**EXAMPLE 12–14 A modern dome.** The $1.2 \times 10^6$ kg dome of the Small Sports Palace in Rome (Fig. 12–39a) is supported by 36 buttresses positioned at a 38° angle so that they connect smoothly with the dome. Calculate the components of the force, $F_H$ and $F_V$, that each buttress exerts on the dome so that the force acts purely in compression—that is, at a 38° angle (Fig. 12–39b).

**APPROACH** We can find the vertical component $F_V$ exerted upward by each buttress because each supports $\frac{1}{36}$ of the dome's weight. We find $F_H$ knowing that the buttress needs to be under compression so $\vec{\mathbf{F}} = \vec{\mathbf{F}}_V + \vec{\mathbf{F}}_H$ acts at a 38° angle.

**SOLUTION** The vertical load on *each* buttress is $\frac{1}{36}$ of the total weight. Thus

$$F_V = \frac{mg}{36} = \frac{(1.2 \times 10^6\,\text{kg})(9.8\,\text{m/s}^2)}{36} = 330{,}000\,\text{N}.$$

The force must act at a 38° angle at the base of the dome in order to be purely compressive. Thus



$$\tan 38° = \frac{F_V}{F_H};$$

$$F_H = \frac{F_V}{\tan 38°} = \frac{330{,}000\,\text{N}}{\tan 38°} = 420{,}000\,\text{N}.$$

**NOTE** For each buttress to exert this 420,000-N horizontal force, a prestressed-concrete tension ring surrounds the base of the buttresses beneath the ground (see Problem 58 and Fig. 12–83).

(a)

(b)

**FIGURE 12–39** Example 12–14. (a) The dome of the Small Sports Palace in Rome, built by Pier Luigi Nervi for the 1960 Olympics. (b) The force components that each buttress exerts on the dome.

# Summary

An object at rest is said to be in **equilibrium**. The subject concerned with the determination of the forces within a structure at rest is called **statics**.

The two necessary conditions for an object to be in equilibrium are (1) the vector sum of all the forces on it must be zero, and (2) the sum of all the torques (calculated about any arbitrary axis) must also be zero. For a two-dimensional problem we can write

$$\Sigma F_x = 0, \quad \Sigma F_y = 0, \quad \Sigma\tau = 0. \qquad \textbf{(12–1, 12–2)}$$

Apply these equilibrium equations to one object at a time.

An object in static equilibrium is said to be in (*a*) **stable**, (*b*) **unstable**, or (*c*) **neutral equilibrium**, depending on whether a slight displacement leads to (*a*) a return to the original position, (*b*) further movement away from the original position, or (*c*) rest in the new position. An object in stable equilibrium is also said to be in *balance*.

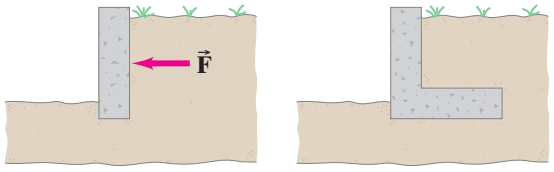
**Hooke's law** applies to many elastic solids, and states that the change in length of an object is proportional to the applied force:

$$F = k\,\Delta\ell. \qquad \textbf{(12–3)}$$

If the force is too great, the object will exceed its **elastic limit**, which means it will no longer return to its original shape when the distorting force is removed. If the force is even greater, the **ultimate strength** of the material can be exceeded, and the object will **fracture**. The force per unit area acting on an object is the **stress**, and the resulting fractional change in length is the **strain**.

The stress on an object is present within the object and can be of three types: **compression**, **tension**, or **shear**. The ratio of stress to strain is called the **elastic modulus** of the material. **Young's modulus** applies for compression and tension, and the **shear modulus** for shear. **Bulk modulus** applies to an object (or a fluid) whose volume changes as a result of pressure on all sides. All three moduli are constants for a given material when distorted within the elastic region.

[*Arches and domes are special ways to span a space that allow the stresses to be managed well. **Truss** structures, as on a bridge, require detailed statics calculations.]



# Questions

1. Describe several situations in which an object is not in equilibrium, even though the net force on it is zero.
2. A bungee jumper momentarily comes to rest at the bottom of the dive before he springs back upward. At that moment, is the bungee jumper in equilibrium? Explain.
3. You can find the center of gravity of a meter stick by resting it horizontally on your two index fingers, and then slowly drawing your fingers together. First the meter stick will slip on one finger, and then on the other, but eventually the fingers meet at the CG. Why does this work?
4. Your doctor's scale has arms on which weights slide to counter your weight, Fig. 12–40. These weights are much lighter than you are. How does this work?

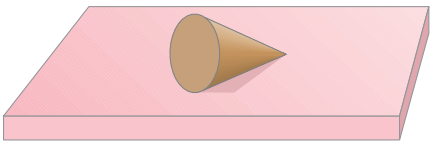
**FIGURE 12–40** Question 4.

5. A ground retaining wall is shown in Fig. 12–41a. The ground, particularly when wet, can exert a significant force $F$ on the wall. (*a*) What force produces the torque to keep the wall upright? (*b*) Explain why the retaining wall in Fig. 12–41b would be much less likely to overturn than that in Fig. 12–41a.

(a) (b)

**FIGURE 12–41** Question 5.

6. Can the sum of the torques on an object be zero while the net force on the object is nonzero? Explain.
7. A ladder, leaning against a wall, makes a 60° angle with the ground. When is it more likely to slip: when a person stands on the ladder near the top or near the bottom? Explain.
8. Figure 12–42 shows a cone. Explain how to lay it on a flat table so that it is in (*a*) stable equilibrium, (*b*) unstable equilibrium, (*c*) neutral equilibrium.



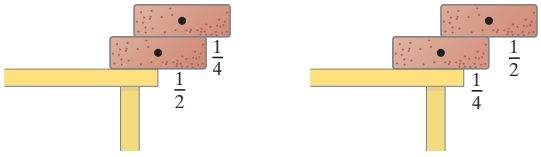


**FIGURE 12–42** Question 8.

9. Stand facing a wall with your toes tight against the wall, and go up on your tiptoes. Try it again after turning around and push your back against the wall with your heels tight against the wall. Explain why you can or cannot perform these motions.
10. Place yourself facing the edge of an open door. Position your feet astride the door with your nose and abdomen touching the door's edge. Try to rise on your tiptoes. Why can't this be done?
11. Why is it not possible to sit upright in a chair and rise to your feet without first leaning forward?
12. Why is it more difficult to do sit-ups when your knees are bent than when your legs are stretched out?
13. Explain why touching your toes while you are seated on the floor with outstretched legs produces less stress on the lower spinal column than when touching your toes from a standing position. Use a diagram.
14. Which configurations of brick, Fig. 12–43a or Fig. 12–43b, is more likely to be stable? Why?

(a) (b)

**FIGURE 12–43** Question 14. The dots indicate the CG of each brick (assumed uniform). The fractions $\frac{1}{4}$ and $\frac{1}{2}$ indicate what portion of each brick is hanging beyond its support.

15. Is the Young's modulus for an elastic bungee cord smaller or larger than that for an ordinary rope?
16. Examine how a pair of scissors or shears cuts through a piece of cardboard. Is the name "shears" justified? Explain.
17. Materials such as ordinary concrete and stone are very weak under tension or shear. Would it be wise to use such a material for either of the supports of the cantilever shown in Fig. 12–8? If so, which one(s)? Explain.

# MisConceptual Questions

**1.** A uniform meter stick supported at the 25-cm mark is in equilibrium when a 1-kg rock is suspended at the 0-cm end (as shown in Fig. 12–44). The mass of the meter stick is
(*a*) greater than the mass of the rock.
(*b*) equal to the mass of the rock.
(*c*) less than the mass of the rock.
(*d*) none of these.

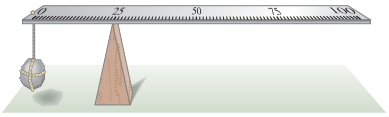

**FIGURE 12–44** MisConceptual Question 1.

**2.** When you apply the torque equation $\Sigma\tau = 0$ to an object in equilibrium, the axis about which torques are calculated
(*a*) must be located at a pivot.
(*b*) must be located at the object's center of gravity.
(*c*) should be located at the edge of the object.
(*d*) can be located anywhere.

**3.** A uniform beam is hinged at one end and held in a horizontal position by a cable, as shown in Fig. 12–45. The tension in the cable
(*a*) must be at least half the weight of the beam, no matter what the angle of the cable.
(*b*) could be less than half the beam's weight for some angles.
(*c*) will be half the beam's weight for all angles.
(*d*) will equal the beam's weight for all angles.

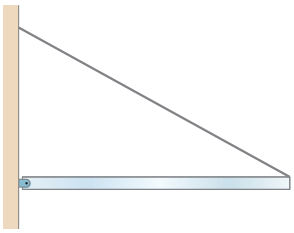

**FIGURE 12–45**
MisConceptual Question 3: beam and cable.

**4.** A heavy ball suspended by a cable is pulled to the side by a horizontal force $\vec{\mathbf{F}}$ as shown in Fig. 12–46. If angle $\theta$ is small, the magnitude of the force $F$ can be less than the weight of the ball because:
(*a*) the force holds up only part of the ball's weight.
(*b*) even though the ball is stationary, it is not really in equilibrium.
(*c*) $\vec{\mathbf{F}}$ is equal to only the $x$ component of the tension in the cable.
(*d*) the original statement is not true. To move the ball, $\vec{\mathbf{F}}$ must be at least equal to the ball's weight.

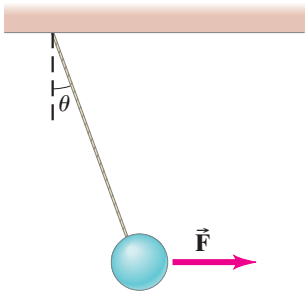

**FIGURE 12–46**
MisConceptual Question 4.

**5.** Two children are balanced on opposite sides of a seesaw. If one child leans inward toward the pivot point, her side will
(*a*) rise.
(*b*) fall.
(*c*) neither rise nor fall.

**6.** A 10.0-N weight is suspended by two cords as shown in Fig. 12–47. What can you say about the tension in the two cords?
(*a*) The tension in both cords is 5.0 N.
(*b*) The tension in both cords is equal but not 5.0 N.
(*c*) The tension in cord A is greater than that in cord B.
(*d*) The tension in cord B is greater than that in cord A.

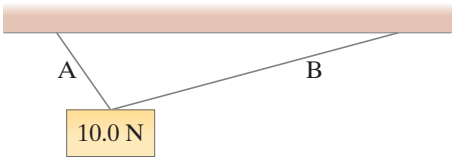

**FIGURE 12–47** MisConceptual Question 6.

**7.** As you increase the force that you apply while pulling on a rope, which of the following is NOT affected?
(*a*) The stress on the rope.
(*b*) The strain on the rope.
(*c*) The Young's modulus of the rope.
(*d*) All of the above.
(*e*) None of the above.

**8.** A woman is balancing on a high wire which is tightly strung, dipping only slightly from horizontal, as shown in Fig. 12–48. The tension in the wire is
(*a*) about half the woman's weight.
(*b*) about twice the woman's weight.
(*c*) about equal to the woman's weight.
(*d*) much less than the woman's weight.
(*e*) much more than the woman's weight.

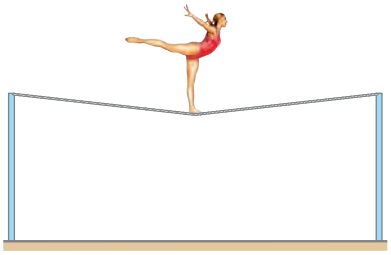

**FIGURE 12–48** MisConceptual Question 8.

**9.** A parking garage is designed for two levels of cars. To make more money, the owner decides to double the height of the garage. For the support columns to hold up four floors of cars instead of two, how should he change the columns' diameter?
(*a*) Double the area of the columns by increasing their diameter by a factor of 2.
(*b*) Double the area of the columns by increasing their diameter by a factor of $\sqrt{2}$.
(*c*) Quadruple the area of the columns by increasing their diameter by a factor of 2.
(*d*) Increase the area of the columns by a factor of 8 by increasing their diameter by a factor of $2\sqrt{2}$.
(*e*) He doesn't need to increase the diameter of the columns.

**10.** A perfectly elastic rubber band is stretched by 1.0 cm when a force of 0.35 N is applied to each end. If instead a force of 0.70 N is applied to each end, estimate how far the rubber band will stretch from its unstretched length:
(*a*) 0.25 cm.
(*b*) 0.5 cm.
(*c*) 1.0 cm.
(*d*) 2.0 cm.
(*e*) 4.0 cm.

**11.** A larger boy and a smaller girl are balanced on a massless seesaw board. If they both move forward so that they are one-half their original distances from the pivot point, what will happen to the seesaw?
(*a*) It is impossible to say without knowing the masses.
(*b*) Nothing, the seesaw will still be balanced.
(c) The side the girl is sitting on will tilt downward.
(*d*) The side the boy is sitting on will tilt downward.
(*e*) It is impossible to say without knowing the distances.

# Problems

## 12–1 and 12–2 Equilibrium

**1.** (I) Three forces are applied to a tree sapling, as shown in Fig. 12–49, to stabilize it. If $\vec{\mathbf{F}}_A = 385\text{ N}$ and $\vec{\mathbf{F}}_B = 515\text{ N}$, find $\vec{\mathbf{F}}_C$ in magnitude and direction.

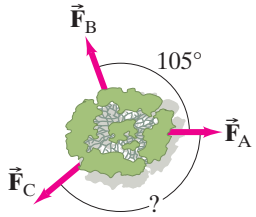

**FIGURE 12–49** Problem 1.

**2.** (I) Calculate the mass $m$ needed in order to suspend the leg shown in Fig. 12–50. Assume the leg (with cast) has a mass of 15.0 kg, and its CG is 35.0 cm from the hip joint; the cord holding the sling is 78.0 cm from the hip joint.

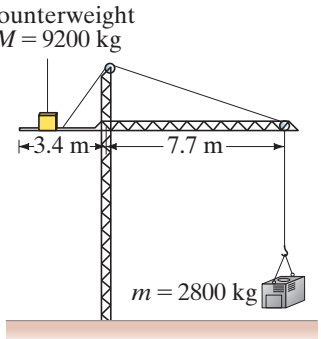

**FIGURE 12–50** Problem 2.

**3.** (I) A tower crane (Fig. 12–51a) must always be carefully balanced so that there is no net torque tending to tip it. A particular crane at a building site is about to lift a 2800-kg air-conditioning unit. The crane's dimensions are shown in Fig. 12–51b. (*a*) Where must the crane's 9200-kg counterweight be placed when the load is lifted from the ground? (The counterweight is usually moved automatically via sensors and motors to precisely compensate for the load.) (*b*) Determine the maximum load that can be lifted with this counterweight when it is placed at its full extent. Ignore the mass of the beam.

(a)

(b)

**FIGURE 12–51** Problem 3.

**4.** (I) What is the mass of the diver in Fig. 12–52 if she exerts a torque of 1800 m · N on the board, relative to the left (A) support post?

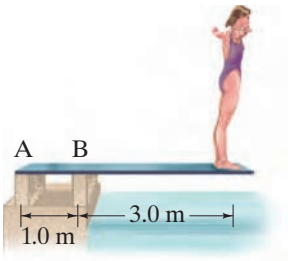

**FIGURE 12–52** Problems 4 and 5.

**5.** (II) Calculate the forces $F_A$ and $F_B$ that the supports exert on the diving board of Fig. 12–52 when a 58-kg person stands at its tip. (*a*) Ignore the weight of the board. (*b*) Take into account the board's mass of 28 kg. Assume the board's CG is at its center.

**6.** (II) Figure 12–53 shows a pair of forceps used to hold a thin plastic rod firmly. If the thumb and finger each squeeze with a force $F_T = F_F = 11.0\text{ N}$, what force do the forceps jaws exert on the plastic rod?

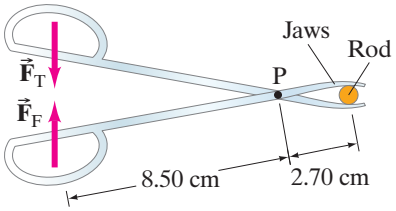

**FIGURE 12–53** Problem 6.

**7.** (II) A 110-kg horizontal beam is supported at each end. A 320-kg piano rests a quarter of the way from one end. What is the vertical force on each of the supports?

**8.** (II) The two trees in Fig. 12–54 are 6.2 m apart. A backpacker is trying to lift his pack out of the reach of bears. Calculate the magnitude of the force $\vec{\mathbf{F}}$ that he must exert downward to hold a 19-kg backpack so that the rope sags at its midpoint by (*a*) 1.5 m, (*b*) 0.15 m.

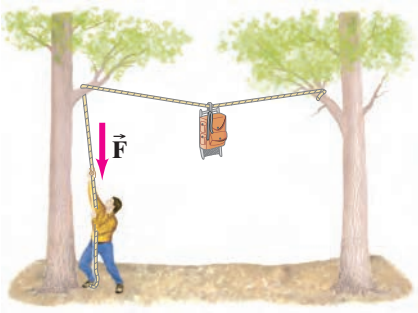

**FIGURE 12–54** Problem 8.

**9.** (II) A 75-kg adult sits at one end of a 9.0-m-long board. His 25-kg child sits on the other end. (*a*) Where should the pivot be placed so that the board is balanced, ignoring the board's mass? (*b*) Find the pivot point if the board is uniform and has a mass of 18 kg.

**10.** (II) Find the tension in the two cords shown in Fig. 12–55. Neglect the mass of the cords, and assume that the angle $\theta$ is 33° and the mass $m$ is 170 kg.

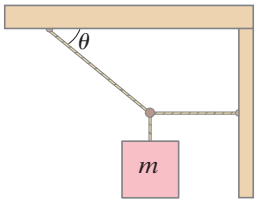

**FIGURE 12–55** Problem 10.

**11.** (II) Find the tension in the two wires supporting the traffic light shown in Fig. 12–56.

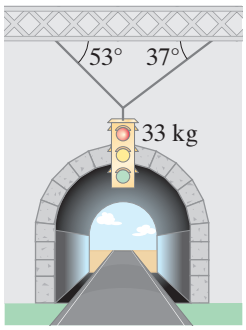

**FIGURE 12–56**
Problem 11.

**12.** (II) How close to the edge of the 27.0-kg table shown in Fig. 12–57 can a 66.0-kg person sit without tipping it over?

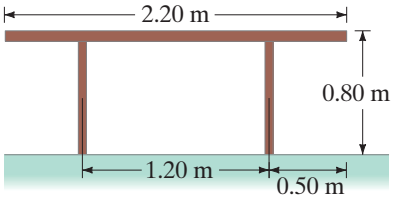

**FIGURE 12–57** Problem 12.

**13.** (II) The force required to pull the cork out of the top of a wine bottle is in the range of 200 to 400 N. What range of forces $F$ is required to open a wine bottle with the bottle opener shown in Fig. 12–58?

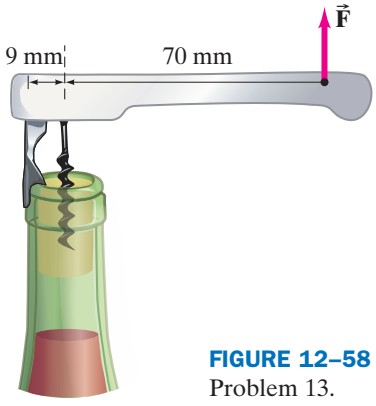

**FIGURE 12–58**
Problem 13.

**14.** (II) A shop sign weighing 215 N hangs from the end of a uniform 135-N beam as shown in Fig. 12–59. Find the tension in the supporting wire (at 35.0°), and the horizontal and vertical forces exerted by the hinge on the beam at the wall.

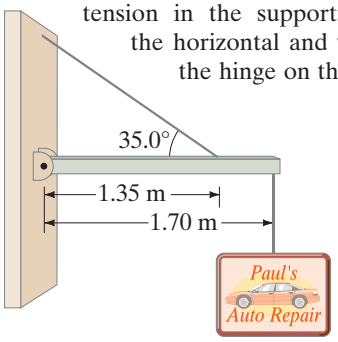

**FIGURE 12–59**
Problem 14.

**15.** (II) Three children are trying to balance on a seesaw, which includes a fulcrum rock acting as a pivot at the center, and a very light board 3.2 m long (Fig. 12–60). Two playmates are already on either end. Boy A has a mass of 45 kg, and boy B a mass of 35 kg. Where should girl C, whose mass is 25 kg, place herself so as to balance the seesaw?

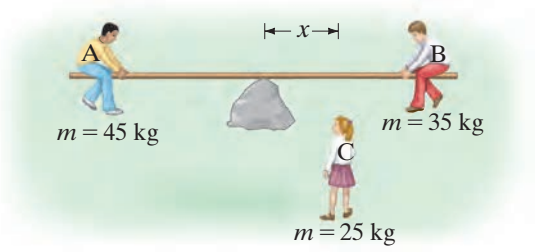

**FIGURE 12–60** Problem 15.

**16.** (II) A uniform steel beam has a mass of 980 kg. On it is resting half of an identical beam, as shown in Fig. 12–61. What is the vertical support force at each end?

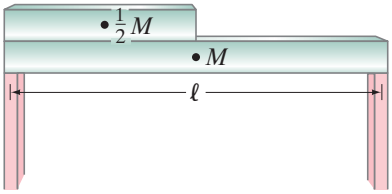

**FIGURE 12–61** Problem 16.

**17.** (II) A traffic light hangs from a pole as shown in Fig. 12–62. The uniform aluminum pole AB is 7.20 m long and has a mass of 12.0 kg. The mass of the traffic light is 21.5 kg. Determine (*a*) the tension in the horizontal massless cable CD, and (*b*) the vertical and horizontal components of the force exerted by the pivot A on the aluminum pole.

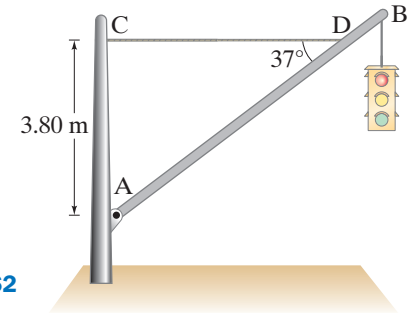

**FIGURE 12–62**
Problem 17.

**18.** (II) Figure 12–63 shows how a scale with a capacity of only 250 N can be used to weigh an object that is heavier than that. The board is 3.0 m long, has a mass of 3.4 kg, and is of uniform density. What is the weight of an object that is 1.2 m from the pivot end, if the scale reads 210 N? Assume that the beam remains nearly horizontal.

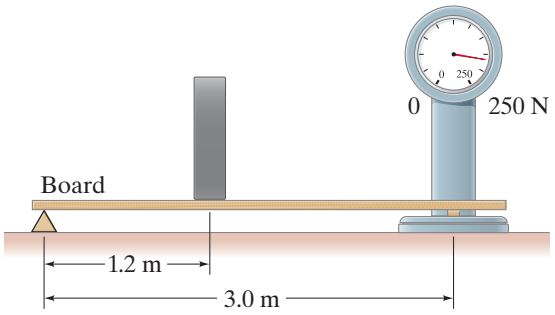

**FIGURE 12–63** Problem 18.

**19.** (II) A 2300-kg trailer is attached to a stationary truck at point B, Fig. 12–64. Determine the normal force exerted by the road on the rear tires at A, and the vertical force exerted on the trailer by the support B.

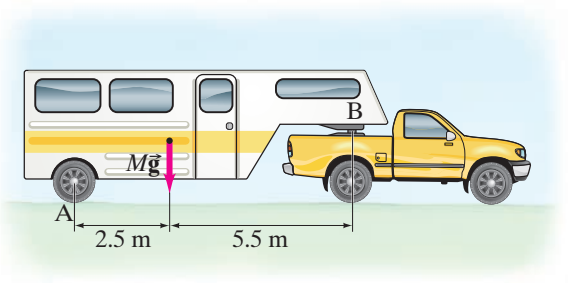

**FIGURE 12–64** Problem 19.

**20.** (II) A 172-cm-tall person lies on a light (massless) board which is supported by two scales, one under the top of her head and one beneath the bottom of her feet (Fig. 12–65). The two scales read, respectively, 35.1 and 31.6 kg. What distance is the center of gravity of this person from the top of her head?

**FIGURE 12–65** Problem 20.

**21.** (II) A man doing push-ups pauses in the position shown in Fig. 12–66. His mass $m = 68$ kg. Determine the normal force exerted by the floor (*a*) on each hand; (*b*) on each foot.

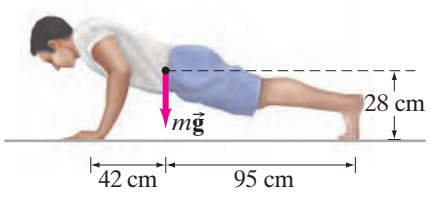

**FIGURE 12–66** Problem 21.

**22.** (II) You are on a pirate ship and being forced to walk the plank (Fig. 12–67). You are standing at the point marked C. The plank is nailed onto the deck at point A, and rests on the support 0.75 m away from A. The center of mass of the uniform plank is located at point B. Your mass is 65 kg and the mass of the plank is 45 kg. What is the minimum downward force the nails must exert on the plank to hold it in place?

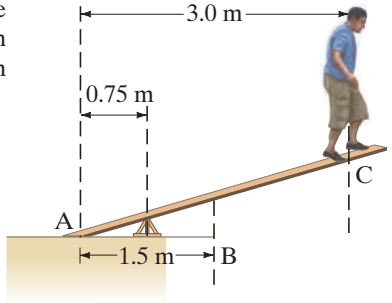

**FIGURE 12–67** Problem 22.

**23.** (II) (*a*) A large 66.0-kg board is propped at a 45.0° angle against the edge of a barn door that is 2.6 m wide. How great a horizontal force must a person behind the door exert (at the edge) in order to open it? Assume that there is negligible friction between the door and the board but that the board is firmly set against the ground. (*b*) Repeat, assuming the coefficient of static friction between the board and the door is 0.35.

**24.** (II) A door 2.30 m high and 1.30 m wide has a mass of 13.0 kg. A hinge 0.40 m from the top and another hinge 0.40 m from the bottom each support half the door's weight (Fig. 12–68). Assume that the center of gravity is at the geometrical center of the door, and determine the horizontal and vertical force components exerted by each hinge on the door.

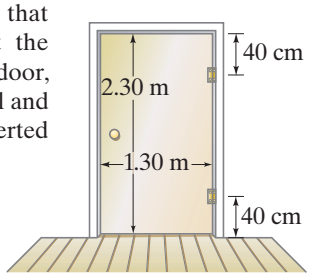

**FIGURE 12–68** Problem 24.

**25.** (II) A uniform rod AB of length 4.5 m and mass $M = 3.8$ kg is hinged at A and held in equilibrium by a light cord, as shown in Fig. 12–69. A load $W = 22$ N hangs from the rod at a distance $d$ so that the tension in the cord is 85 N. (*a*) Draw a free-body diagram for the rod. (*b*) Determine the vertical and horizontal forces on the rod exerted by the hinge. (*c*) Determine $d$ from the appropriate torque equation.

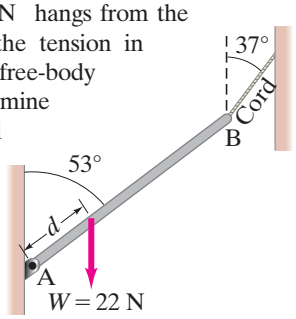

**FIGURE 12–69** Problem 25.

**26.** (III) Two wires run from the top of a pole 2.6 m tall that supports a volleyball net. The two wires are anchored to the ground 2.0 m apart, and each is 2.0 m from the pole (Fig. 12–70). The tension in each wire is 125 N. What is the tension in the net, assumed horizontal and attached at the top of the pole?

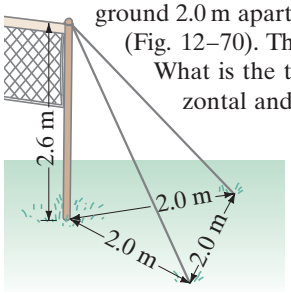

**FIGURE 12–70** Problem 26.

**27.** (III) Consider a ladder with a painter climbing up it (Fig. 12–71). The mass of the uniform ladder is 12.0 kg, and the mass of the painter is 55.0 kg. If the ladder begins to slip at its base when the painter's feet are 70% of the way up the length of the ladder, what is the coefficient of static friction between the ladder and the floor? Assume the wall is frictionless.

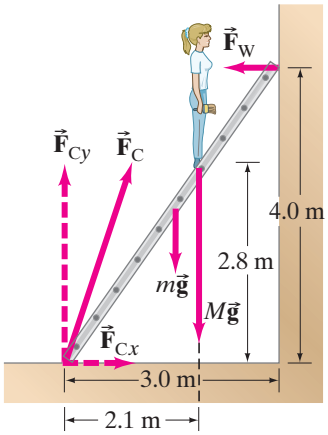

**FIGURE 12–71**
Problem 27.

**28.** (III) A uniform ladder of mass $m$ and length $\ell$ leans at an angle $\theta$ against a frictionless wall, Fig. 12–72. If the coefficient of static friction between the ladder and the ground is $\mu_s$, determine a formula for the minimum angle at which the ladder will not slip.

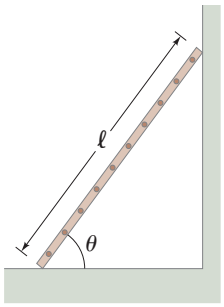

**FIGURE 12–72**
Problem 28.

**29.** (III) A refrigerator is approximately a uniform rectangular solid 1.9 m tall, 1.0 m wide, and 0.75 m deep. If it sits upright on a truck with its 1.0-m dimension in the direction of travel, and if the refrigerator cannot slide on the truck, how rapidly can the truck accelerate without tipping the refrigerator over? [*Hint*: The normal force would act at one corner.]

**30.** (III) A 56.0-kg person stands 2.0 m from the bottom of the stepladder shown in Fig. 12–73. Determine (*a*) the tension in the horizontal tie rod, which is halfway up the ladder, (*b*) the normal force the ground exerts on each side of the ladder, and (*c*) the force (magnitude and direction) that the left side of the ladder exerts on the right side at the hinge on the top. Ignore the mass of the ladder and assume the ground is frictionless. [*Hint*: Consider free-body diagrams for both sections of the ladder.]

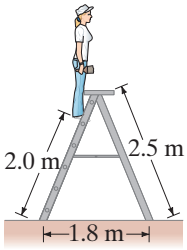

**FIGURE 12–73**
Problem 30.

## *12–3 Muscles and Joints

***31.** (I) Approximately what magnitude force, $F_M$, must the extensor muscle in the upper arm exert on the lower arm to hold a 7.3-kg shot put (Fig. 12–74)? Assume the lower arm has a mass of 2.3 kg and its CG is 12.0 cm from the elbow-joint pivot.

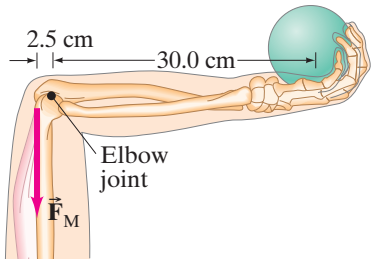

**FIGURE 12–74**
Problem 31.

***32.** (II) Redo Example 12–8 assuming now that the person is less bent over so that the 30° in Fig. 12–13b is instead 45°. What will be the magnitude of $F_V$ on the vertebra?

***33.** (II) (*a*) Calculate the magnitude of the force, $F_M$, required of the "deltoid" muscle to hold up the outstretched arm shown in Fig. 12–75. The total mass of the arm is 3.6 kg. (*b*) Calculate the magnitude of the force $F_J$ exerted by the shoulder joint on the upper arm and the angle (to the horizontal) at which it acts.

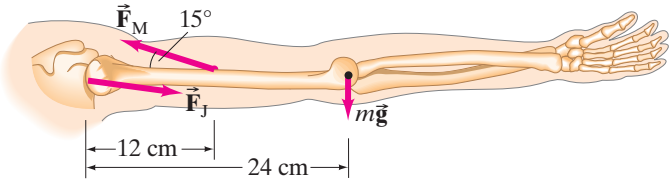

**FIGURE 12–75** Problems 33 and 34.

***34.** (II) Suppose the hand in Problem 33 holds an 8.5-kg mass. What force, $F_M$, is required of the deltoid muscle, assuming the mass is 52 cm from the shoulder joint?

***35.** (II) The Achilles tendon is attached to the rear of the foot as shown in Fig. 12–76. When a person stands on one foot and lifts the heel to stand on the "ball of one foot," estimate the tension $F_T$ in the Achilles tendon (pulling upward), and the (downward) force $F_B$ exerted by the lower leg bone on the foot. Assume the person has a mass of 72 kg and $D$ is twice as long as $d$.

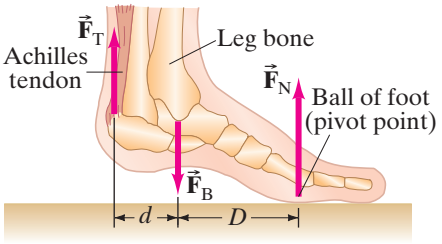

**FIGURE 12–76** Problem 35.

## 12–4 Stability and Balance

**36.** (II) The Leaning Tower of Pisa is 55 m tall and about 7.7 m in radius. The top is 4.5 m off center. Is the tower in stable equilibrium? If so, how much farther can it lean before it becomes unstable? Assume the tower is of uniform composition.

**37.** (II) The center of gravity of a loaded truck depends on how the truck is packed. If it is 4.0 m high and 2.4 m wide, and its CG is 2.2 m above the ground, on how steep a slope can the truck be parked without tipping over (Fig. 12–77)?

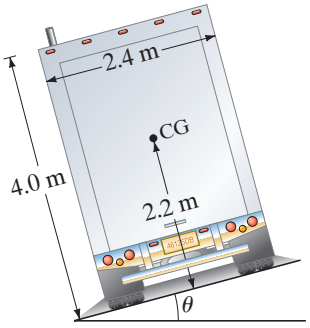

**FIGURE 12–77** Problem 37.

**38.** (III) Four bricks are to be stacked at the edge of a table, each brick overhanging the one below it, so that the top brick extends as far as possible beyond the edge of the table. (*a*) To achieve this, show that successive bricks must extend no more than (starting at the top) $\frac{1}{2}$, $\frac{1}{4}$, $\frac{1}{6}$, and $\frac{1}{8}$ of their length beyond the one below (Fig. 12–78a). (*b*) Is the top brick completely beyond the base? (*c*) Determine a general formula for the maximum total distance spanned by *n* bricks if they are to remain stable. (*d*) A builder wants to construct a *corbeled arch* (Fig. 12–78b) based on the principle of stability discussed in (*a*) and (*c*) above. What minimum number of bricks, each 0.30 m long and uniform, is needed if the arch is to span 1.0 m?

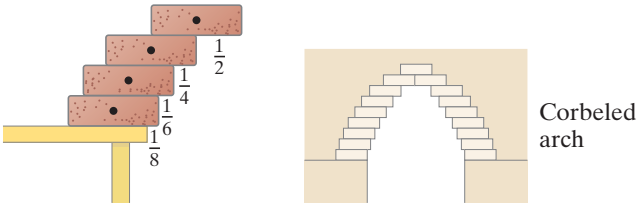

**FIGURE 12–78** Problem 38.

## 12–5 Elasticity; Stress and Strain

**39.** (I) A nylon string on a tennis racket is under a tension of 315 N. If its diameter is 1.00 mm, by how much is it lengthened from its untensioned length of 30.0 cm?

**40.** (I) A marble column of cross-sectional area 1.4 $m^2$ supports a mass of 22,000 kg. (*a*) What is the stress within the column? (*b*) What is the strain? (*c*) By how much is the column shortened if it is 8.6 m high?

**41.** (I) A sign (mass 1700 kg) hangs from the bottom end of a vertical steel girder with a cross-sectional area of 0.012 $m^2$. (*a*) What is the stress within the girder? (*b*) What is the strain on the girder? (*c*) If the girder is 9.50 m long, how much is it lengthened? (Ignore the mass of the girder itself.)

**42.** (II) A 15-cm-long tendon was found to stretch 3.7 mm by a force of 13.4 N. The tendon was approximately round with an average diameter of 8.5 mm. Calculate Young's modulus of this tendon.

**43.** (II) How much pressure is needed to compress the volume of an iron block by 0.10%? Express your answer in $N/m^2$, and compare it to atmospheric pressure $(1.0 \times 10^5\ N/m^2)$.

**44.** (II) At depths of 2000 m in the sea, the pressure is about 200 times atmospheric pressure $(1\ atm = 1.0 \times 10^5\ N/m^2)$. By what percentage does the interior space of an iron bathysphere's volume change at this depth?

**45.** (II) A steel wire 2.6 mm in diameter stretches by 0.030% when a mass is suspended from it. How large is the mass?

## 12–6 Fracture

**46.** (I) The femur bone in the human leg has a minimum effective cross section of about 3.0 $cm^2$ $(= 3.0 \times 10^{-4}\ m^2)$. How much compressive force can it withstand before breaking?

**47.** (I) What diameter aluminum wire would have the same tensile breaking force as a 2.0-mm-diameter steel wire?

**48.** (II) (*a*) What is the maximum tension possible in a 1.00-mm-diameter nylon tennis racket string? (*b*) If you want tighter strings, what do you do to prevent breakage: use thinner or thicker strings? Why? What causes strings to break when they are hit by the ball?

**49.** (II) If a compressive force of $3.3 \times 10^4$ N is exerted on the end of a 22-cm-long bone of cross-sectional area 3.6 $cm^2$, (*a*) will the bone break, and (*b*) if not, by how much does it shorten?

**50.** (II) (*a*) What is the minimum cross-sectional area required of a vertical steel cable from which is suspended a 240-kg chandelier? Assume a safety factor of 7.0. (*b*) If the cable is 7.5 m long, how much does it elongate?

**51.** (II) Assume the supports of the uniform cantilever shown in Fig. 12–79 $(m = 2900\ kg)$ are made of wood. Calculate the minimum cross-sectional area required of each, assuming a safety factor of 9.0.

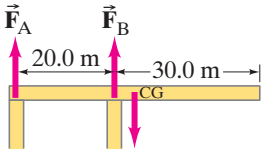

**FIGURE 12–79**
Problem 51.

**52.** (II) An iron bolt is used to connect two iron plates together. The bolt must withstand shear forces up to about 3600 N. Calculate the minimum diameter for the bolt, based on a safety factor of 7.0.

**53.** (III) A steel cable is to support an elevator whose total (loaded) mass is not to exceed 3100 kg. If the maximum acceleration of the elevator is 1.8 $m/s^2$, calculate the diameter of cable required. Assume a safety factor of 8.0.

## *12–7 Trusses and Bridges

***54.** (II) Figure 12–80 shows a simple truss that carries a load at the center (C) of $1.65 \times 10^4$ N. (*a*) Calculate the force on each strut at the pins, A, B, C, and D. (*b*) Determine which struts (ignore their masses) are under tension and which are under compression.

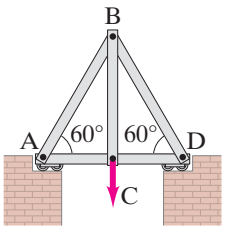

**FIGURE 12–80**
Problem 54.

*55. (II) A heavy load $Mg = 62.0\,\text{kN}$ hangs at point E of the single cantilever truss shown in Fig. 12–81. (*a*) Use a torque equation for the truss as a whole to determine the tension $F_T$ in the support cable, and then determine the force $\vec{\mathbf{F}}_A$ on the truss at pin A. (*b*) Determine the force in each member of the truss. Neglect the weight of the trusses, which is small compared to the load.

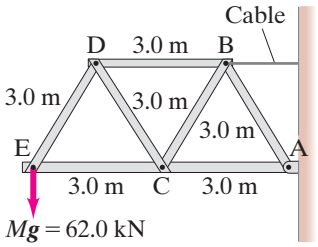

**FIGURE 12–81** Problem 55.

*56. (III) (*a*) Consider again Example 12–12 but this time assume the roadway is supported also at the center C of Fig. 12–30b, as well as at the ends. That is, $\frac{1}{2}$ the mass $M$ $(= 7.0 \times 10^5\,\text{kg})$ acts at the center and $\frac{1}{4}M$ at each end support (think of the bridge as two spans, AC and CE, so the center pin supports two span ends). Calculate the magnitude of the force in each truss member, and whether compression or tension. Compare to Example 12–12. (*b*) This time determine the force in each truss assuming $\frac{1}{2}M$ acts downward at the center of span AC, and $\frac{1}{2}M$ at the center of span CE. (*c*) Which of these approaches is the most valid? [*Hint*: The forces on the main span ACE may not be purely horizontal; see paragraph after Example 12–12].

*57. (III) The truss shown in Fig. 12–82 supports a railway bridge. Determine the compressive or tension force in each strut if a 53-ton $(1\,\text{ton} = 10^3\,\text{kg})$ train locomotive is stopped at the midpoint between the center and one end. Ignore the masses of the rails and truss, and use only $\frac{1}{2}$ the mass of train because there are two trusses (one on each side of the train). Assume all triangles are equilateral. [*Hint*: See Fig. 12–31.]

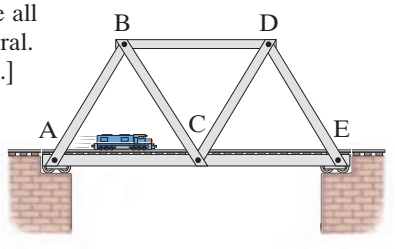

**FIGURE 12–82** Problem 57.

## *12–8 Arches and Domes

*58. (II) The subterranean tension ring that surrounds the dome in Fig. 12–39 exerts the balancing horizontal force on the abutments for the dome and is 36-sided, so each segment makes a 10° angle with the adjacent one (Fig. 12–83). Calculate the tension $F$ that must exist in each segment so that the required force of $4.2 \times 10^5\,\text{N}$ can be exerted at each corner (Example 12–14).

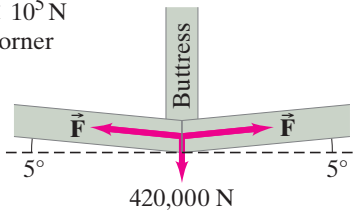

**FIGURE 12–83** Problem 58.

*59. (II) How high must a pointed arch be if it is to span a space 8.0 m wide and exert one-third the horizontal force at its base that a round arch would?

# General Problems

60. A woman holds a 1.8-m-long uniform 10.0-kg pole as shown in Fig. 12–84. (*a*) Determine the forces she must exert with each hand (magnitude and direction). To what position should she move her left hand so that neither hand has to exert a force greater than (*b*) 150 N? (*c*) 85 N?

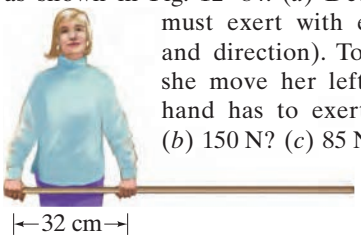

**FIGURE 12–84** Problem 60.

61. A uniform cube of side $\ell$ rests on a rough floor. It is subjected to a steady horizontal pull $F$, exerted a distance $h$ above the floor as shown in Fig. 12–85. As $F$ is increased, the block will either begin to slide, or begin to tip over. Determine the coefficient of static friction $\mu_S$ so that: (*a*) the block begins to slide rather than tip; (*b*) the block begins to tip. [*Hint*: Where will the normal force on the block act if it tips?]

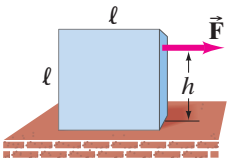

**FIGURE 12–85** Problem 61.

62. A 50-story building is being planned. It is to be 180.0 m high with a base 46.0 m by 76.0 m. Its total mass will be about $1.8 \times 10^7\,\text{kg}$, and its weight therefore about $1.8 \times 10^8\,\text{N}$. Suppose a 200-km/h wind exerts a force of $950\,\text{N/m}^2$ over the 76.0-m-wide face (Fig. 12–86). Calculate the torque about the potential pivot point, the rear edge of the building (where $\vec{\mathbf{F}}_E$ acts in Fig. 12–86), and determine whether the building will topple. Assume the total force of the wind acts at the midpoint of the building's face, and that the building is not anchored in bedrock. [*Hint*: $\vec{\mathbf{F}}_E$ in Fig. 12–86 represents the force that the Earth would exert on the building in the case where the building would just begin to tip.]

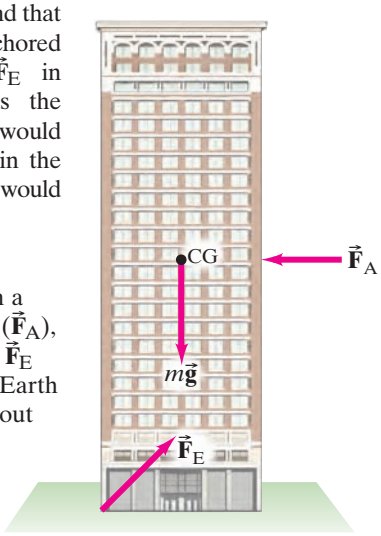

**FIGURE 12–86** Forces on a building subjected to wind ($\vec{\mathbf{F}}_A$), gravity ($m\vec{\mathbf{g}}$), and the force $\vec{\mathbf{F}}_E$ on the building due to the Earth if the building were just about to tip. Problem 62.

**63.** When a wood shelf of mass 6.6 kg is fastened inside a slot in a vertical support as shown in Fig. 12–87, the support exerts a torque on the shelf. (*a*) Draw a free-body diagram for the shelf, assuming three vertical forces (two exerted by the support slot—explain why). Then calculate (*b*) the magnitudes of the three forces and (*c*) the torque exerted by the support (about the left end of the shelf).

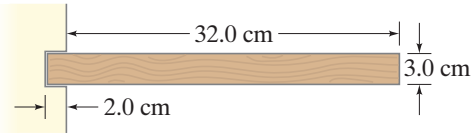

**FIGURE 12–87** Problem 63.

**64.** A pole projects horizontally from the front wall of a shop. A 6.1-kg sign hangs from the pole at a point 2.2 m from the wall (Fig. 12–88). (*a*) What is the torque due to this sign calculated about the point where the pole meets the wall? (*b*) If the pole is not to fall off, there must be another torque exerted to balance it. What exerts this torque? Use a diagram to show how this torque must act. (*c*) Discuss whether compression, tension, and/or shear play a role in part (*b*).

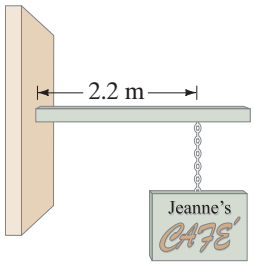

**FIGURE 12–88**
Problem 64.

**65.** A uniform meter stick with a mass of 180 g is supported horizontally by two vertical strings, one at the 0-cm mark and the other at the 90-cm mark (Fig. 12–89). What is the tension in the string (*a*) at 0 cm? (*b*) at 90 cm?

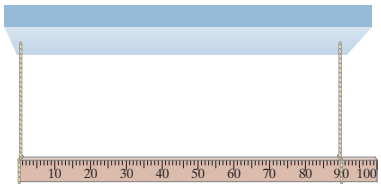

**FIGURE 12–89** Problem 65.

**66.** There is a maximum height of a uniform vertical column made of any material that can support itself without buckling, and it is independent of the cross-sectional area (why?). Calculate this height for (*a*) ordinary steel (density $7.8 \times 10^3$ kg/m$^3$), and (*b*) granite (density $2.7 \times 10^3$ kg/m$^3$).

**67.** When a mass of 25 kg is hung from the middle of a fixed straight aluminum wire, the wire sags to make an angle of 12° with the horizontal as shown in Fig. 12–90. Determine the radius of the wire.

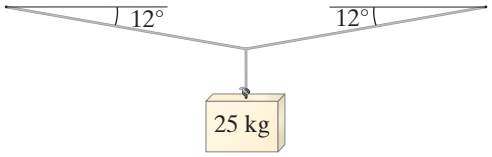

**FIGURE 12–90** Problem 67.

**68.** The *mobile* in Fig. 12–91 is in equilibrium. Object B has mass of 0.748 kg. Determine the masses of objects A, C, and D. (Neglect the weights of the crossbars.)

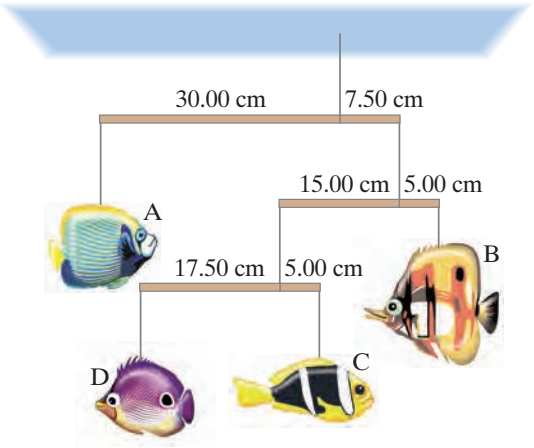

**FIGURE 12–91** Problem 68.

**69.** A 65.0-kg painter is on a uniform 25-kg scaffold supported from above by ropes (Fig. 12–92). There is a 4.0-kg pail of paint to one side, as shown. Can the painter walk safely to both ends of the scaffold? If not, which end(s) is dangerous, and how close to the end can he approach safely?

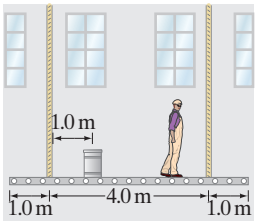

**FIGURE 12–92**
Problem 69.

**70.** The roof over a 9.0-m × 10.0-m room in a school has a total mass of 12,400 kg. The roof is to be supported by vertical wooden "2 × 4s" (2 × 4 in inches, but actually about 4.0 cm × 9.0 cm) equally spaced along the 10.0-m sides. How many supports are required on each side, and how far apart must they be? Consider only compression, and assume a safety factor of 12.

**71.** A 25-kg object is being lifted by two people pulling on the ends of a 1.15-mm-diameter nylon cord that goes over two 3.00-m-high poles that are 4.5 m apart, as shown in Fig. 12–93. How high above the floor will the object be when the cord breaks?

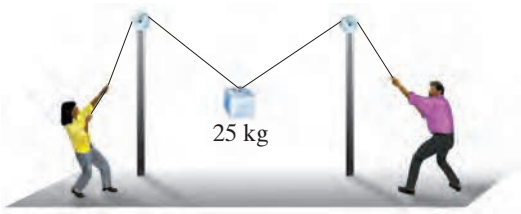

**FIGURE 12–93** Problem 71.

**72.** A cubic crate of side $s = 2.00$ m is top-heavy: its CG is 18 cm above its true center. How steep an incline can the crate rest on without tipping over? [*Hint*: The normal force would act at the lowest corner.]

**73.** A uniform 95-kg flagpole of length 8.4 m is being erected by pulling on a rope attached 2/3 of the way to the top (Fig. 12–94). When the pole is inclined at 35° and the rope makes an angle with the ground of 18°, what is the tension in the rope?

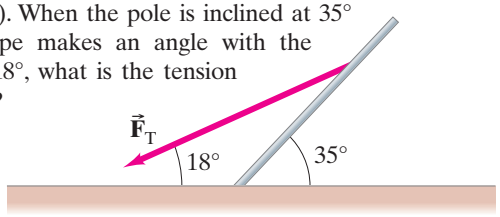

**FIGURE 12–94**
Problem 73.

**74.** Two identical, uniform beams are symmetrically set up against each other (Fig. 12–95) on a floor with which they have a coefficient of friction $\mu_s = 0.45$. What is the minimum angle the beams can make with the floor and still not fall?

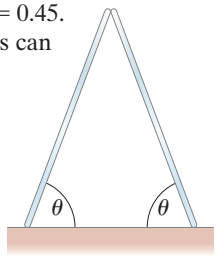

**FIGURE 12–95**
Problem 74.

**75.** A steel rod of radius $R = 15$ cm and length $\ell_0$ stands upright on a firm surface. A 78-kg man climbs atop the rod. (*a*) Determine the percent decrease in the rod's length. (*b*) When a metal is compressed, each atom throughout its bulk moves closer to its neighboring atom by exactly the same fractional amount. If iron atoms in steel are normally $2.0 \times 10^{-10}$ m apart, by what distance did this interatomic spacing have to change in order to produce the normal force required to support the man? [*Note*: Neighboring atoms repel each other, and this repulsion accounts for the observed normal force.]

**76.** A home mechanic wants to raise the 310-kg engine out of a car. The plan is to stretch a rope vertically from the engine to a branch of a tree 6.0 m above, and back to the bumper (Fig. 12–96). When the mechanic climbs up a stepladder and pulls horizontally on the rope at its midpoint, the engine rises out of the car. (*a*) How much force must the mechanic exert to hold the engine 0.50 m above its normal position? (*b*) What is the system's mechanical advantage?

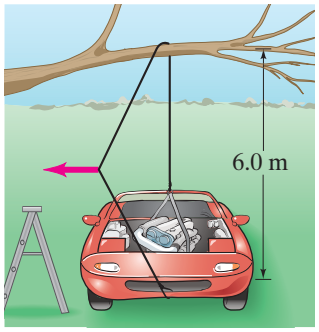

**FIGURE 12–96**
Problem 76.

**77.** A 2.0-m-high box with a 1.0-m-square base is moved across a rough floor as in Fig. 12–97. The uniform box weighs 250 N and has a coefficient of static friction with the floor of 0.60. What minimum force must be exerted on the box to make it slide? What is the maximum height $h$ above the floor that this force can be applied without tipping the box over? Note that if the box tips, the normal force and the friction force will act at the lowest corner.

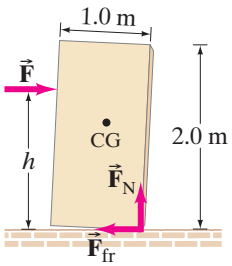

**FIGURE 12–97**
Problem 77.

**78.** Two springs, both having stiffness constant 225 N/m, are attached to a table and to a 0.500-kg uniform thin wooden board (Fig. 12–98). The board is exactly horizontal. What are the natural lengths of each spring? [*Hint*: One of the springs is stretched, the other compressed, from their natural equilibrium lengths.]

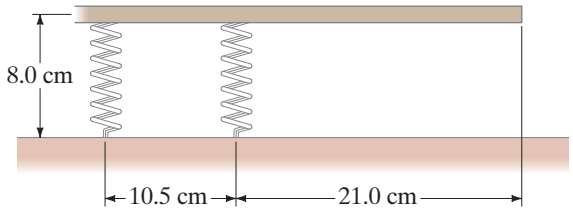

**FIGURE 12–98** Problem 78.

**79.** A tightly stretched horizontal "high wire" is 36 m long. It sags vertically 0.90 m when a 56.0-kg *tightrope walker* stands at its center. What is the tension in the wire? Is it possible to increase the tension in the wire so that there is no sag?

**80.** *Parachutists* whose chutes have failed to open have been known to survive if they land in deep snow. Assume that a 75-kg parachutist hits the snow with an area of impact of 0.30 $m^2$ at a velocity of 55 m/s, and that the ultimate strength of body tissue is $5 \times 10^5$ $N/m^2$. Assume that the person is brought to rest in 1.0 m of snow. Show that the person may escape serious injury.

**81.** A uniform flexible steel cable of weight $mg$ is suspended between two points at the same elevation as shown in Fig. 12–99, where $\theta = 62°$. Determine the tension in the cable (*a*) at its lowest point, and (*b*) at the points of attachment. (*c*) What is the direction of the tension force in each case?

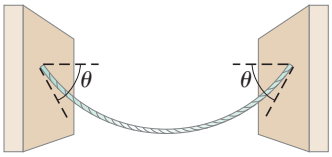

**FIGURE 12–99** Problem 81.

**82.** One rod of the square frame shown in Fig. 12–100 contains a turnbuckle which, when turned, can put the rod under tension or compression. If the turnbuckle puts rod AB under a compressive force $F$, determine the forces produced in the other rods. Ignore the mass of the rods and assume the diagonal rods cross each other freely at the center without friction. [*Hint*: Use the symmetry of the situation.]

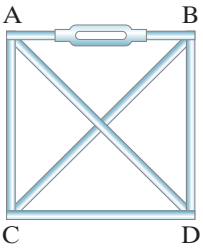

**FIGURE 12–100**
Problem 82.

**83.** A uniform beam of mass $M$ and length $\ell$ is mounted on a hinge at a wall as shown in Fig. 12–101. It is held in a horizontal position by a wire making an angle $\theta$ as shown. A mass $m$ is placed on the beam a distance $x$ from the wall, and this distance can be varied. Determine, as a function of $x$, (*a*) the tension in the wire and (*b*) the components of the force exerted by the beam on the hinge.

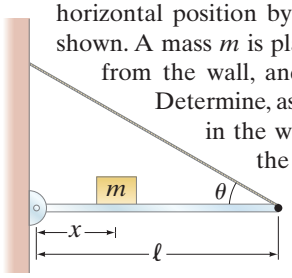

**FIGURE 12–101**
Problem 83.

**84.** If 25 kg is the maximum mass $m$ that a person can hold in a hand when the arm is positioned with a 105° angle at the elbow as shown in Fig. 12–102, what is the maximum force $F_{max}$ that the biceps muscle exerts on the forearm? Assume the forearm and hand have a total mass of 2.0 kg with a CG that is 15 cm from the elbow, and that the biceps muscle attaches 5.0 cm from the elbow.

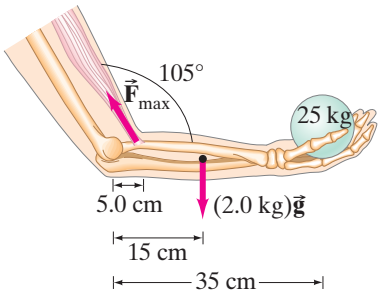

**FIGURE 12–102** Problem 84.

**85.** A uniform 6.0-m-long ladder of mass 16.0 kg leans against a smooth wall (so the force exerted by the wall, $\vec{\mathbf{F}}_W$, is perpendicular to the wall). The ladder makes an angle of 20.0° with the vertical wall, and the ground is rough. Determine the coefficient of static friction at the base of the ladder if the ladder is not to slip when a 76.0-kg person stands three-fourths of the way up the ladder.

**86.** In Fig. 12–103, consider the right-hand (northernmost) section of the Golden Gate Bridge, which has a length $d_1 = 343$ m. Assume the CG of this span is halfway between the tower and anchor. Determine $F_{T1}$ and $F_{T2}$ (which act on the northernmost cable) in terms of $mg$, the weight of the northernmost span, and calculate the tower height $h$ needed for equilibrium. Assume the roadway is supported only by the suspension cables, and neglect the mass of the cables and vertical wires. [*Hint*: $F_{T3}$ does not act on this section.]

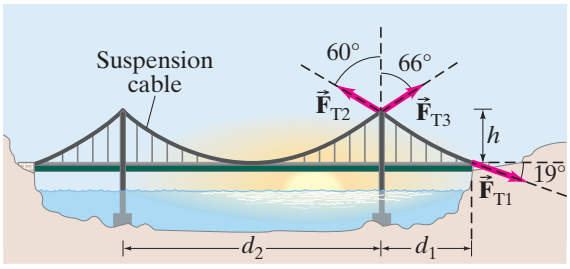

**FIGURE 12–103** Problems 86 and 87.

**87.** Assume that a single-span suspension bridge such as the Golden Gate Bridge has the symmetrical configuration indicated in Fig. 12–103. Assume that the roadway is uniform over the length of the bridge and that each segment of the suspension cable provides the sole support for the roadway directly below it. The ends of the cable are anchored to the ground only, not to the roadway. What must the ratio of $d_2$ to $d_1$ be so that the suspension cable exerts no net horizontal force on the towers? Neglect the mass of the cables and the fact that the roadway isn't precisely horizontal.

**88.** A uniform sphere of weight $mg$ and radius $r_0$ is tethered to a wall by a rope of length $\ell$. The rope is tied to the wall a distance $h$ above the contact point of the sphere, as shown in Fig. 12–104. The rope makes an angle $\theta$ with respect to the wall and is not in line with the ball's center. The coefficient of static friction between the wall and sphere is $\mu$. (*a*) Determine the value of the frictional force on the sphere due to the wall. [*Hint*: A wise choice of axis will make this calculation easy.] (*b*) Suppose the sphere is just on the verge of slipping. Derive an expression for $\mu$ in terms of $h$ and $\theta$.

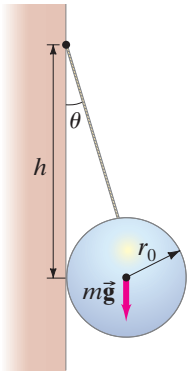

**FIGURE 12–104**
Problem 88.

**89.** A uniform ladder of mass $m$ and length $\ell$ leans at an angle $\theta$ against a wall, Fig. 12–105. The coefficients of static friction between ladder–ground and ladder–wall are $\mu_G$ and $\mu_W$, respectively. The ladder will be on the verge of slipping when both the static friction forces due to the ground and due to the wall take on their maximum values. (*a*) Show that the ladder will be stable if $\theta \geq \theta_{min}$, where the minimum angle $\theta_{min}$ is given by

$$\tan\theta_{min} = \frac{1}{2\mu_G}(1 - \mu_G\mu_W).$$

(*b*) "Leaning ladder problems" are often analyzed under the seemingly unrealistic assumption that the wall is frictionless (see Example 12–6). You wish to investigate the magnitude of error introduced by modeling the wall as frictionless, if in reality it is frictional. Using the relation found in part (*a*), calculate the true value of $\theta_{min}$ for a frictional wall, taking $\mu_G = \mu_W = 0.40$. Then, determine the approximate value of $\theta_{min}$ for the "frictionless wall" model by taking $\mu_G = 0.40$ and $\mu_W = 0$. Finally, determine the percent deviation of the approximate value of $\theta_{min}$ from its true value.

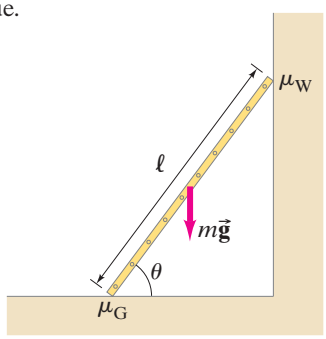

**FIGURE 12–105** Problem 89.

**90.** A 28-kg uniform round table is supported by three vertical legs equal distances apart on the edge. What minimum mass, placed on the table's edge, will cause the table to overturn?

**91.** The CM of a 95,000-kg train locomotive starts across a 260-m-long bridge at time $t = 0$. The bridge is a uniform beam of mass 23,000 kg and the train travels at a constant 80.0 km/h. What are the magnitudes of the vertical forces, $F_A(t)$ and $F_B(t)$, on the two end supports, written as a function of time during the train's passage?

**92.** A 23-kg sphere rests between two smooth planes as shown in Fig. 12–106. Determine the magnitude of the force acting on the sphere exerted by each plane.

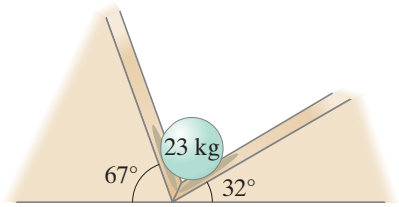

**FIGURE 12–106** Problem 92.

**93.** A uniform 55-kg bar is 2.0 m long and is attached to a wall by a frictionless hinge. The center of mass of the bar is connected to the wall, Fig. 12–107, by a horizontal steel wire (cross-sectional area $0.0050\,\text{m}^2$). When a force $\vec{\mathbf{F}}$ is applied to the end of the bar, and perpendicular to it, the wire stretches 0.10 mm. (*a*) What is the magnitude of $\vec{\mathbf{F}}$? (*b*) Determine the $x$ and $y$ components of the force $\vec{\mathbf{F}}_\text{H}$ exerted on the bar at the hinge.

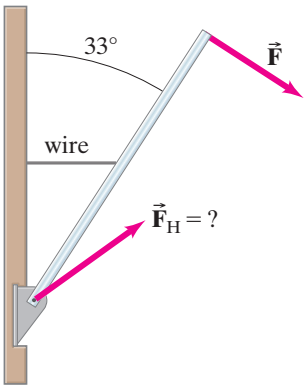

**FIGURE 12–107** Problem 93.

**94.** The forces acting on an 85,000-kg aircraft flying at constant velocity are shown in Fig. 12–108. The engine thrust, $F_\text{T} = 5.0 \times 10^5\,\text{N}$, acts on a line 1.6 m below the CM. Determine the drag force $F_\text{D}$ and the distance above the CM that it acts. Assume $\vec{\mathbf{F}}_\text{D}$ and $\vec{\mathbf{F}}_\text{T}$ are horizontal. ($\vec{\mathbf{F}}_\text{L}$ is the "lift" force on the wing.)

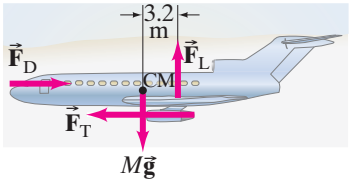

**FIGURE 12–108**
Problem 94.

**95.** Suppose a 65-kg person jumps from a height of 3.0 m down to the ground. (*a*) What is the speed of the person just before landing (Chapter 2)? (*b*) Estimate the average force on the person's feet exerted by the ground to bring the person to rest, if the knees are bent so the person's CG moves a distance $d = 50\,\text{cm}$ during the deceleration period (Fig. 12–109). [*Hint*: This force exerted by the ground $\neq$ net force. You may want to consult Chapters 2, 4, and 7, and be sure to draw a careful free-body diagram of the person.] (*c*) Estimate the decelerating force if the person lands stiff-legged so $d \approx 1.0\,\text{cm}$. (*d*) Estimate the stress in the tibia (a lower leg bone of area $= 3.0 \times 10^{-4}\,\text{m}^2$), and determine whether or not the bone will *fracture* if the landing is made with bent legs ($d = 50\,\text{cm}$). (*e*) Estimate the stress and determine if the tibia will break in a stiff-legged landing ($d = 1.0\,\text{cm}$).

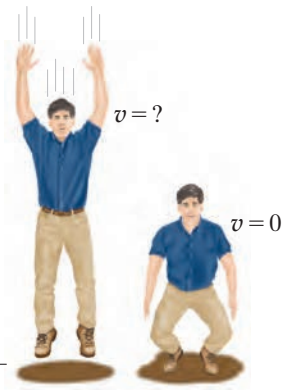

**FIGURE 12–109**
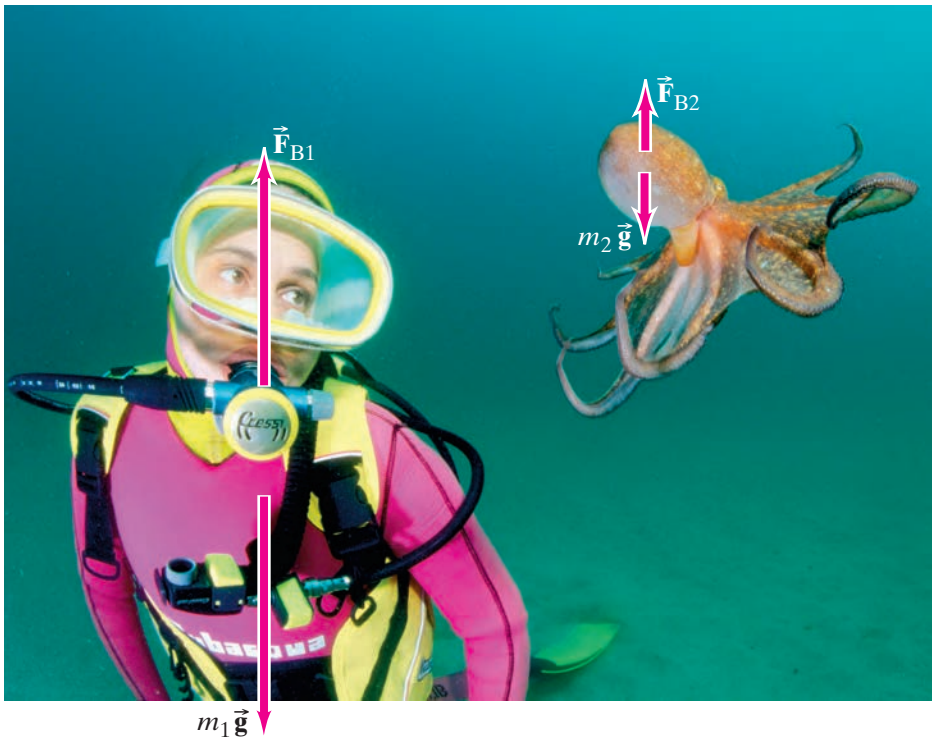
Problem 95.

## ANSWERS TO EXERCISES

**A:** $F_\text{A}$ also has a component to balance the sideways force $F_\text{B}$. So the resultant force will be greater than $F_{\text{A}y} = mg$.



**B:** $F_\text{N} = m_\text{A}\,g + m_\text{B}\,g + Mg$
$= (30\,\text{kg} + 25\,\text{kg} + 4.0\,\text{kg})\,g = 580\,\text{N}$.

**C:** (*a*).

**D:** Static friction at the cement floor ($= F_{Cx}$) is crucial, or else the ladder would slip. At the top, the ladder can move and adjust, so we wouldn't need or expect a strong static friction force there.

**E:** 7.0 kg.

**F:** (*b*).

Underwater divers and sea creatures experience a buoyant force ($\vec{\mathbf{F}}_B$) that closely balances their weight $m\vec{\mathbf{g}}$. The buoyant force is equal to the weight of the volume of fluid displaced (Archimedes' principle) and arises because the pressure increases with depth in the fluid. Sea creatures have a density very close to that of water, so their weight very nearly equals the buoyant force. Humans have a density slightly less than water, so they can float if not weighed down.

When fluids flow, interesting effects occur because the pressure in the fluid is lower where the fluid velocity is higher (Bernoulli's principle).

## CHAPTER-OPENING QUESTIONS—Guess now!

**1.** Which container below has the largest pressure at the bottom? Assume each container holds the same volume of water.

**2.** Two balloons are tied and hang with their nearest edges about 3 cm apart. If you blow between the balloons (not *at* the balloons, but at the opening between them), what will happen?

**(a)** Nothing.
**(b)** The balloons will move closer together.
**(c)** The balloons will move farther apart.

In previous Chapters we considered objects that were solid and assumed they maintain their shape except for a small amount of elastic deformation. We sometimes treated objects as point particles. Now we are going to shift our attention to materials that are very deformable and can flow. Such "fluids" include liquids and gases. We will examine fluids both at rest (fluid statics) and in motion (fluid dynamics).

# 13–1 Phases of Matter

The three common **phases**, or **states**, of matter are solid, liquid, and gas. A simple way to distinguish these three phases is as follows. A **solid** maintains a generally fixed size and shape; usually it requires a large force to change the volume or shape of a solid[†] (although a thin object might bend). A **liquid** does not maintain a fixed shape—it takes on the shape of its container, and it can flow; but like a solid it is not readily compressible, and its volume can be changed significantly only by a very large force. A **gas** has neither a fixed shape nor a fixed volume—it will expand to fill its container. For example, when air is pumped into an automobile tire, the air does not all run to the bottom of the tire as a liquid would; it spreads out to fill the whole volume of the tire.

Because liquids and gases do not maintain a fixed shape, they both have the ability to flow. They are thus referred to collectively as **fluids**.

The division of matter into three phases is not always simple. How, for example, should butter be classified? Furthermore, a fourth phase of matter can be distinguished, the **plasma** phase, which occurs only at very high temperatures and consists of ionized atoms (electrons separated from the nuclei). Some scientists believe that *colloids* (suspensions of tiny particles in a liquid) should also be considered a separate phase of matter. **Liquid crystals**, used in TV, cell phone, and computer screens, can be considered a phase of matter in between solids and liquids. For now, we will be interested in the three ordinary phases of matter.

# 13–2 Density and Specific Gravity

It is sometimes said that iron is "heavier" than wood. This cannot really be true since a large log clearly weighs more than an iron nail. What we should say is that iron is more *dense* than wood.

The **density**, $\rho$, of a substance ($\rho$ is the lowercase Greek letter rho) is defined as its mass per unit volume:

$$\rho = \frac{m}{V}, \tag{13–1}$$

where $m$ is the mass of a sample of the substance and $V$ its volume. Density is a characteristic property of any pure substance. Objects made of a particular pure substance, such as pure gold, can have any size or mass, but the density will be the same for each.

We can use density, Eq. 13–1, to write the mass of an object as

$$m = \rho V,$$

and the weight of an object is thus

$$mg = \rho V g.$$

The SI unit for density is kg/m$^3$. Sometimes densities are given in g/cm$^3$. Note that a density given in g/cm$^3$ must be multiplied by 1000 to give the result in kg/m$^3$ $\left[1\,\text{kg/m}^3 = 1000\,\text{g}/(100\,\text{cm})^3 = 10^3\,\text{g}/10^6\,\text{cm}^3 = 10^{-3}\,\text{g/cm}^3\right]$. For example, the density of aluminum is $\rho = 2.70\,\text{g/cm}^3$, which equals $2700\,\text{kg/m}^3$. The densities of various substances are given in Table 13–1. The Table specifies temperature and atmospheric pressure because they affect density (the effect is slight for liquids and solids). Note that air is about 1000 times less dense than water.

**TABLE 13–1**
**Densities of Substances[‡]**

| Substance | Density, $\rho$ (kg/m$^3$) |
|---|---|
| *Solids* | |
| Aluminum | $2.70 \times 10^3$ |
| Iron and steel | $7.8 \times 10^3$ |
| Copper | $8.9 \times 10^3$ |
| Lead | $11.3 \times 10^3$ |
| Gold | $19.3 \times 10^3$ |
| Concrete | $2.3 \times 10^3$ |
| Granite | $2.7 \times 10^3$ |
| Wood (typical) | $0.3–0.9 \times 10^3$ |
| Glass, common | $2.4–2.8 \times 10^3$ |
| Ice ($H_2O$) | $0.917 \times 10^3$ |
| Bone | $1.7–2.0 \times 10^3$ |
| *Liquids* | |
| Water (4°C) | $1.000 \times 10^3$ |
| Sea water | $1.025 \times 10^3$ |
| Blood, plasma | $1.03 \times 10^3$ |
| Blood, whole | $1.05 \times 10^3$ |
| Mercury | $13.6 \times 10^3$ |
| Alcohol, ethyl | $0.79 \times 10^3$ |
| Gasoline | $0.7–0.8 \times 10^3$ |
| *Gases* | |
| Air | 1.29 |
| Helium | 0.179 |
| Carbon dioxide | 1.98 |
| Water (steam) (100°C) | 0.598 |

[‡]Densities are given at 0°C and 1 atm pressure unless otherwise specified.

**EXAMPLE 13–1** **Mass, given volume and density.** What is the mass of a solid iron wrecking ball of radius 18 cm?

**APPROACH** First we use the standard formula $V = \frac{4}{3}\pi r^3$ (see inside rear cover) to obtain the sphere's volume. Then Eq. 13–1 and Table 13–1 give us the mass $m$.

**SOLUTION** The volume of the sphere is

$$V = \tfrac{4}{3}\pi r^3 = \tfrac{4}{3}(3.14)(0.18\,\text{m})^3 = 0.024\,\text{m}^3.$$

From Table 13–1, the density of iron is $\rho = 7800\,\text{kg/m}^3$, so Eq. 13–1 gives

$$m = \rho V = (7800\,\text{kg/m}^3)(0.024\,\text{m}^3) = 190\,\text{kg}.$$

[†]Section 12–5.

The **specific gravity** of a substance is defined as the ratio of the density of that substance to the density of water at 4.0°C. Because specific gravity (abbreviated SG) is a ratio, it is a simple number without dimensions or units. For example (see Table 13–1), the specific gravity of lead is 11.3 $\left[(11.3 \times 10^3\,\text{kg/m}^3)/(1.00 \times 10^3\,\text{kg/m}^3)\right]$. The SG of alcohol is 0.79.

The concepts of density and specific gravity are especially helpful in the study of fluids because we are not always dealing with a fixed volume or mass.

## 13–3 Pressure in Fluids

Pressure and force are related, but they are not the same thing. **Pressure** is defined as force per unit area, where the force $F$ is understood to be the magnitude of the force acting perpendicular to the surface area $A$:

$$\text{pressure} = P = \frac{F}{A}. \qquad \textbf{(13–2)}$$

Although force is a vector, pressure is a scalar. Pressure has magnitude only. The SI unit of pressure is $\text{N/m}^2$. This unit has the official name **pascal** (Pa), in honor of Blaise Pascal (see Section 13–5); that is, $1\ \text{Pa} = 1\ \text{N/m}^2$. However, for simplicity, we will often use $\text{N/m}^2$. Other units sometimes used are $\text{dynes/cm}^2$ (cgs),[†] and in the British system $\text{lb/in}^2$ (pounds per square inch, abbreviated "psi"). Several other units for pressure are discussed in Sections 13–4 and 13–6, along with conversions between them (see also the Table inside the front cover).

**CAUTION**
*Pressure is a scalar, not a vector*

**EXAMPLE 13–2 Calculating pressure.** A 60-kg person's two feet cover an area of 500 $\text{cm}^2$. (*a*) Determine the pressure exerted by the two feet on the ground. (*b*) If the person stands on one foot, what will be the pressure under that foot?

**APPROACH** Assume the person is at rest. Then the ground pushes up on her with a force equal to her weight $mg$, and she exerts a force $mg$ on the ground where her feet (or foot) contact it. Because $1\ \text{cm}^2 = (10^{-2}\,\text{m})^2 = 10^{-4}\,\text{m}^2$, then $500\ \text{cm}^2 = 0.050\ \text{m}^2$.

**SOLUTION** (*a*) The pressure on the ground exerted by the two feet is

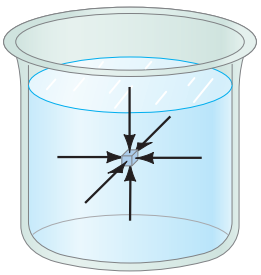
$$P = \frac{F}{A} = \frac{mg}{A} = \frac{(60\,\text{kg})(9.8\,\text{m/s}^2)}{(0.050\,\text{m}^2)} = 12 \times 10^3\,\text{N/m}^2.$$

(*b*) If the person stands on one foot, the force is still equal to the person's weight, but the area will be half as much, so the pressure ($F/A$) will be twice as much: $24 \times 10^3\,\text{N/m}^2$.

Pressure is particularly useful for dealing with fluids. It is an experimental observation that *a fluid exerts pressure in every direction*. This is well known to swimmers and divers who feel the water pressure on all parts of their bodies. At any depth in a fluid at rest, the pressure is the same in all directions at that given depth. To see why, consider a tiny cube of the fluid (Fig. 13–1) which is so small that we can consider it a point and can ignore the force of gravity on it. The pressure on one side of it must equal the pressure on the opposite side. If this weren't true, there would be a net force on the cube and it would start moving. If the fluid is not flowing, then the pressures must be equal.

For a fluid at rest, the force due to fluid pressure always acts *perpendicular* to any solid surface it touches. If there were a component of the force parallel to the surface, as shown in Fig. 13–2, then according to Newton's third law the solid surface would exert a force back on the fluid, which would cause the fluid to flow—in contradiction to our assumption that the fluid is at rest. Thus the force due to the pressure in a fluid at rest is always perpendicular to the surface in contact with the fluid.

[†]Sections 1–4 and 4–4.



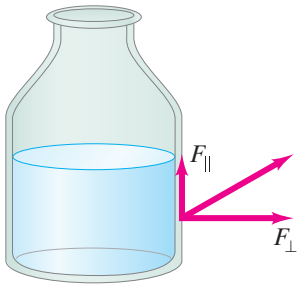


**FIGURE 13–1** Pressure is the same in every direction in a nonmoving fluid at a given depth. If this weren't true, the fluid would be moving (or flowing).

**FIGURE 13–2** If there were a component of force parallel to the solid surface of the container, the liquid would move in response to it. For a liquid at rest, $F_{\parallel} = 0$.

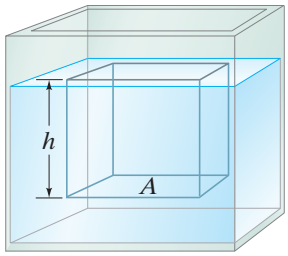

**FIGURE 13–3** Calculating the pressure at a depth $h$ in a liquid, due to the weight of the liquid above.

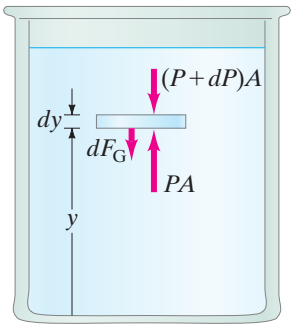
We now calculate quantitatively how the pressure in a liquid of uniform density varies with *depth*. Let us look at a depth $h$ below the surface of the liquid, as shown in Fig. 13–3 (that is, the liquid's top surface is a height $h$ above this level). The pressure due to the liquid at this depth $h$ is due to the weight of the column of liquid above it. Thus the force due to the weight of liquid acting on the area $A$ is $F = mg = (\rho V)g = \rho Ahg$, where $Ah$ is the volume of the liquid above area $A$, $\rho$ is the density of the liquid (assumed to be constant), and $g$ is the acceleration of gravity. The pressure $P$ due to the weight of liquid is then



$$P = \frac{F}{A} = \frac{\rho Ahg}{A}$$

$$P = \rho gh. \qquad \text{[liquid]} \quad \textbf{(13–3)}$$

Note that the area $A$ doesn't affect the pressure at a given depth. The fluid pressure is directly proportional to the density of the liquid and to the depth within the liquid. In general, *the pressure at equal depths within a uniform liquid is the same*.

**EXERCISE A** Return to Chapter-Opening Question 1, page 365, and answer it again now. Try to explain why you may have answered differently the first time.

**FIGURE 13–4** Forces on a flat, slablike volume of fluid for determining the pressure $P$ as a function of height $y$ in the fluid.

Equation 13–3 tells us what the pressure is at a depth $h$ in the liquid, due to the liquid itself. But what if there is additional pressure exerted at the surface of the liquid, such as the pressure of the atmosphere or a piston pushing down? And what if the density of the fluid is not constant? Gases are quite compressible and hence their density can vary significantly with depth. Liquids, too, can be compressed, although we can often ignore the variation in density. (One exception is in the depths of the ocean where the great weight of water above significantly compresses the water and increases its density.) To cover these, and other cases, we now treat the general case of determining how the pressure in a fluid varies with depth.

As shown in Fig. 13–4, let us determine the pressure at any height $y$ above some reference point[†] (such as the ocean floor or the bottom of a tank or swimming pool). Within this fluid, at the height $y$, we consider a tiny, flat, slablike volume of the fluid whose area is $A$ and whose (infinitesimal) thickness is $dy$, as shown. Let the pressure acting upward on its lower surface (at height $y$) be $P$. The pressure acting downward on the top surface of our tiny slab (at height $y + dy$) is designated $P + dP$. The fluid pressure acting on our slab thus exerts a force equal to $PA$ upward on our slab and a force equal to $(P + dP)A$ downward on it. The only other force acting vertically on the slab is the (infinitesimal) force of gravity $dF_G$, which on our slab of mass $dm$ is

$$dF_G = (dm)g = \rho g\, dV = \rho gA\, dy,$$

where $\rho$ is the density of the fluid at the height $y$. Since the fluid is assumed to be at rest, our slab is in equilibrium so the net force on it must be zero. Therefore we have

$$PA - (P + dP)A - \rho gA\, dy = 0,$$

which when simplified becomes

$$\frac{dP}{dy} = -\rho g. \qquad \textbf{(13–4)}$$

This relation tells us how the pressure within the fluid varies with height above any reference point. The minus sign indicates that the pressure decreases with an increase in height; or that the pressure increases with depth (reduced height).

If the pressure at a height $y_1$ in the fluid is $P_1$, and at height $y_2$ it is $P_2$, then we can integrate Eq. 13–4 to obtain

$$\int_{P_1}^{P_2} dP = -\int_{y_1}^{y_2} \rho g\, dy$$

$$P_2 - P_1 = -\int_{y_1}^{y_2} \rho g\, dy, \qquad \textbf{(13–5)}$$

where we assume $\rho$ is a function of height $y$: $\rho = \rho(y)$. This is a general relation,

[†]Now we are measuring $y$ positive upwards, the reverse of what we did to get Eq. 13–3 where we measured the depth (i.e. downward as positive).

and we apply it now to two special cases: (1) pressure in liquids of uniform density and (2) pressure variations in the Earth's atmosphere.

For liquids in which any variation in density can be ignored, $\rho$ = constant and Eq. 13–5 is readily integrated:

$$P_2 - P_1 = -\rho g(y_2 - y_1). \qquad \textbf{(13–6a)}$$

For the everyday situation of a liquid in an open container—such as water in a glass, a swimming pool, a lake, or the ocean—there is a free surface at the top exposed to the atmosphere. It is convenient to measure distances from this top surface. That is, we let $h$ be the *depth* in the liquid where $h = y_2 - y_1$ as shown in Fig. 13–5. If we let $y_2$ be the position of the top surface, then $P_2$ represents the atmospheric pressure, $P_0$, at the top surface. Then, from Eq. 13–6a, the pressure $P\ (= P_1)$ at a depth $h$ in the fluid is

$$P = P_0 + \rho gh. \qquad [h \text{ is depth in liquid}] \quad \textbf{(13–6b)}$$

Note that Eq. 13–6b is simply the liquid pressure (Eq. 13–3) plus the pressure $P_0$ due to the atmosphere above.

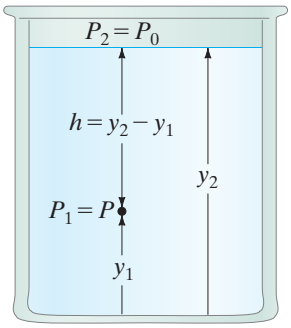


**FIGURE 13–5** Pressure at a depth $h = (y_2 - y_1)$ in a liquid of density $\rho$ is $P = P_0 + \rho gh$, where $P_0$ is the external pressure at the liquid's top surface.

**EXAMPLE 13–3** **Pressure at a faucet.** The surface of the water in a storage tank is 30 m above a water faucet in the kitchen of a house, Fig. 13–6. Calculate the difference in water pressure between the faucet and the surface of the water in the tank.

**APPROACH** Water is practically incompressible, so $\rho$ is constant even for $h = 30$ m when used in Eq. 13–6b. Only $h$ matters; we can ignore the "route" of the pipe and its bends.

**SOLUTION** We assume the atmospheric pressure at the surface of the water in the storage tank is the same as at the faucet. So, the water pressure difference between the faucet and the surface of the water in the tank is

$$\Delta P = \rho gh = (1.0 \times 10^3\,\text{kg/m}^3)(9.8\,\text{m/s}^2)(30\,\text{m}) = 2.9 \times 10^5\,\text{N/m}^2.$$

**NOTE** The height $h$ is sometimes called the **pressure head**. In this Example, the head of water is 30 m at the faucet. The very different diameters of the tank and faucet don't affect the result—only height does.

**PHYSICS APPLIED**
*Water supply*

**CAUTION**
*Pressure depends only on* h; *ignore pipe bends*

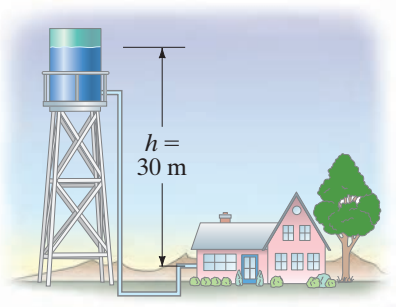

**FIGURE 13–6** Example 13–3.

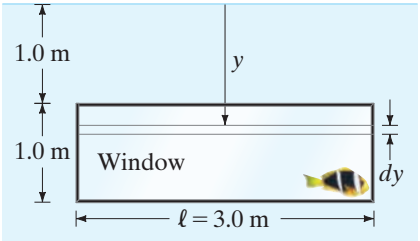
**EXAMPLE 13–4** **Force on aquarium window.** Calculate the force due to water pressure exerted on a $1.0\,\text{m} \times 3.0\,\text{m}$ aquarium viewing window whose top edge is 1.0 m below the water surface, Fig. 13–7.



**APPROACH** At a depth $h$, the pressure due to the water is given by Eq. 13–6b. Divide the window up into thin horizontal strips of length $\ell = 3.0$ m and thickness $dy$, as shown in Fig. 13–7. We choose a coordinate system with $y = 0$ at the surface of the water and $y$ is positive downward. (With this choice, the minus sign in Eq. 13–6a becomes plus, or we use Eq. 13–6b with $y = h$.) The force due to water pressure on each strip is $dF = PdA = \rho g y \ell\, dy$.

**SOLUTION** The total force on the window is given by the integral:

$$\int_{y_1 = 1.0\,\text{m}}^{y_2 = 2.0\,\text{m}} \rho g y \ell\, dy = \tfrac{1}{2}\rho g \ell (y_2^2 - y_1^2)$$
$$= \tfrac{1}{2}(1000\,\text{kg/m}^3)(9.8\,\text{m/s}^2)(3.0\,\text{m})[(2.0\,\text{m})^2 - (1.0\,\text{m})^2] = 44{,}000\,\text{N}.$$

**NOTE** To check our answer, we can do an estimate: multiply the area of the window $(3.0\,\text{m}^2)$ times the pressure at the middle of the window $(h = 1.5\,\text{m})$ using Eq. 13–3, $P = \rho gh = (1000\,\text{kg/m}^3)(9.8\,\text{m/s}^2)(1.5\,\text{m}) \approx 1.5 \times 10^4\,\text{N/m}^2$. So $F = PA \approx (1.5 \times 10^4\,\text{N/m}^2)(3.0\,\text{m})(1.0\,\text{m}) \approx 4.5 \times 10^4\,\text{N}$. Good!

**FIGURE 13–7** Example 13–4.

**EXERCISE B** A dam holds back a lake that is 85 m deep at the dam. If the lake is 20 km long, how much thicker should the dam be than if the lake were smaller, only 1.0 km long?

Now let us apply Eq. 13–4 or 13–5 to gases. The density of gases is normally quite small, so the difference in pressure at different heights can usually be ignored if $y_2 - y_1$ is not large (we used this in Example 13–3). Indeed, for most ordinary containers of gas, we can assume that the pressure is the same throughout. However, if $y_2 - y_1$ is very large, we cannot make this assumption. An interesting example is the air of Earth's atmosphere, whose pressure at sea level is about $1.013 \times 10^5\ \text{N/m}^2$ and decreases gradually with altitude.

PHYSICS APPLIED
*How pressure in the atmosphere decreases with altitude*

## Elevation effect on atmospheric pressure

We can determine the variation in pressure in the Earth's atmosphere as a function of height $y$ above sea level, assuming $g$ is constant and that the density of the air is proportional to the pressure. (This last assumption is not terribly accurate, in part because temperature and other weather effects are important.)

We start with Eq. 13–4 and integrate it from the surface of the Earth where $y = 0$ and $P = P_0$, up to height $y$ at pressure $P$. We are assuming that $\rho$ is proportional to $P$, so we can write

$$\frac{\rho}{\rho_0} = \frac{P}{P_0},$$

where $P_0 = 1.013 \times 10^5\ \text{N/m}^2$ is atmospheric pressure at sea level and $\rho_0 = 1.29\ \text{kg/m}^3$ is the density of air at sea level at 0°C (Table 13–1). (These are "average" values for $P_0$ and $\rho_0$ because they in fact vary with the weather.) From the differential change in pressure with height, Eq. 13–4, we have

$$\frac{dP}{dy} = -\rho g = -P\left(\frac{\rho_0}{P_0}\right)g,$$

so

$$\frac{dP}{P} = -\frac{\rho_0}{P_0}\,g\,dy.$$

We integrate this from $y = 0$ (Earth's surface) where $P = P_0$, to the height $y$ where the pressure is $P$:

$$\int_{P_0}^{P} \frac{dP}{P} = -\frac{\rho_0}{P_0}\,g \int_0^y dy$$

$$\ln\frac{P}{P_0} = -\frac{\rho_0}{P_0}\,gy,$$

since $\ln P - \ln P_0 = \ln(P/P_0)$: see Appendix A–7. Then

$$P = P_0 e^{-(\rho_0 g/P_0)y}. \qquad \textbf{(13–6c)}$$

So, based on our assumptions, we find that the air pressure in our atmosphere decreases approximately exponentially with height above Earth's surface.

The atmosphere does not have a distinct top surface, so there is no natural point from which to measure *depth* in the atmosphere, as we can do for a liquid.

PHYSICS APPLIED
*Altitude where air pressure drops to half*

**EXAMPLE 13–5** **Elevation where $P = \frac{1}{2}$ atm.** At what altitude above sea level is the atmospheric pressure equal to half the pressure at sea level?

**APPROACH** We use Eq. 13–6c setting $P = \frac{1}{2}P_0$ and solve for $y$.

**SOLUTION** The constant $(\rho_0 g/P_0)$ has the value

$$\frac{\rho_0 g}{P_0} = \frac{(1.29\ \text{kg/m}^3)(9.80\ \text{m/s}^2)}{(1.013 \times 10^5\ \text{N/m}^2)} = 1.25 \times 10^{-4}\ \text{m}^{-1}.$$

Then, when we set $P = \frac{1}{2}P_0$ in Eq. 13–6c, we obtain

$$\tfrac{1}{2} = e^{-(1.25\times10^{-4}\ \text{m}^{-1})y}.$$

Now we take natural logarithms of both sides:

$$\ln\tfrac{1}{2} = (-1.25 \times 10^{-4}\ \text{m}^{-1})y.$$

So (recall $\ln\frac{1}{2} = -\ln 2$, Appendix A–7, Eq. iii)

$$y = (\ln 2.00)/(1.25 \times 10^{-4}\ \text{m}^{-1}) = 5550\ \text{m}.$$

At an elevation of about 5500 m (about 18,000 ft), atmospheric pressure is half what it is at sea level. Mountain climbers often use oxygen tanks at very high altitudes.

# 13–4 Atmospheric Pressure and Gauge Pressure

## Atmospheric Pressure

The pressure of the air at a given place on Earth varies slightly according to the weather and your elevation above sea level. At sea level, the pressure of the atmosphere on average is $1.013 \times 10^5\,\text{N/m}^2$ $(\text{or } 14.7\,\text{lb/in.}^2)$. This value lets us define a commonly used unit of pressure, the **atmosphere** (abbreviated atm):

$$1\,\text{atm} = 1.013 \times 10^5\,\text{N/m}^2 = 101.3\,\text{kPa}.$$

Another unit of pressure sometimes used (in meteorology and on weather maps) is the **bar**, which is defined as

$$1\,\text{bar} = 1.000 \times 10^5\,\text{N/m}^2.$$

Thus **standard atmospheric pressure**, at sea level, is slightly more than 1 bar.

The pressure due to the weight of the atmosphere is exerted on all objects immersed in this great sea of air, including our bodies. How does a human body withstand the enormous pressure on its surface? The answer is that living cells maintain an internal pressure that closely equals the external pressure, just as the pressure inside a balloon closely matches the outside pressure of the atmosphere. An automobile tire, because of its rigidity, can maintain internal pressures much greater than the external pressure.

**PHYSICS APPLIED**
*Pressure on living cell*

**CONCEPTUAL EXAMPLE 13–6** **Finger holds water in a straw.** You insert a straw of length $\ell$ into a tall glass of water. You place your finger over the top of the straw, capturing some air above the water but preventing any additional air from getting in or out, and then you lift the straw from the water. You find that the straw retains most of the water (Fig. 13–8a). Does the air in the space between your finger and the top of the water have a pressure $P$ that is greater than, equal to, or less than, the atmospheric pressure $P_0$ outside the straw?

**RESPONSE** Consider the forces on the column of water (Fig. 13–8b). Atmospheric pressure outside the straw pushes upward on the water at the bottom of the straw, gravity pulls the water downward, and the air pressure inside the top of the straw pushes downward on the water. Since the water is in equilibrium, the upward force due to atmospheric pressure $P_0$ must balance the two downward forces. The only way this is possible is for the air pressure $P$ inside the straw at the top to be *less than* the atmosphere pressure outside the straw. (When you initially remove the straw from the water glass, a little water may leave the bottom of the straw, thus increasing the volume of trapped air and reducing its density and pressure.)

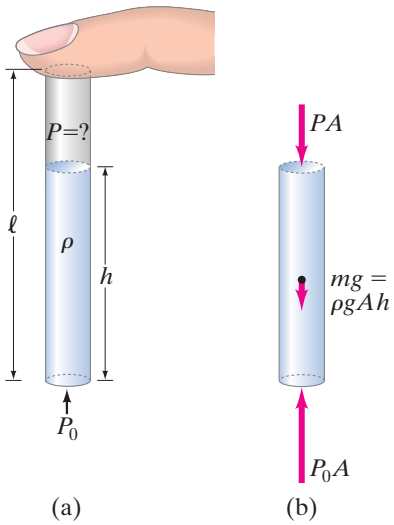


**FIGURE 13–8** Example 13–6.

## Gauge Pressure

It is important to note that tire gauges, and most other pressure gauges, register the pressure above atmospheric pressure. This is called **gauge pressure**. Thus, to get the **absolute pressure**, $P$, we must add the atmospheric pressure, $P_0$, to the gauge pressure, $P_G$:

$$P = P_G + P_0.$$

If a tire gauge registers 220 kPa, the absolute pressure within the tire is 220 kPa + 101 kPa = 321 kPa, equivalent to about 3.2 atm (2.2 atm gauge pressure).

# 13–5 Pascal's Principle

The Earth's atmosphere exerts a pressure on all objects with which it is in contact, including other fluids. External pressure acting on a fluid is transmitted throughout that fluid. For instance, according to Eq. 13–3, the pressure due to the water at a depth of 100 m below the surface of a lake is $P = \rho g\,\Delta h = (1000\,\text{kg/m}^3)(9.8\,\text{m/s}^2)(100\,\text{m}) = 9.8 \times 10^5\,\text{N/m}^2$, or 9.7 atm.

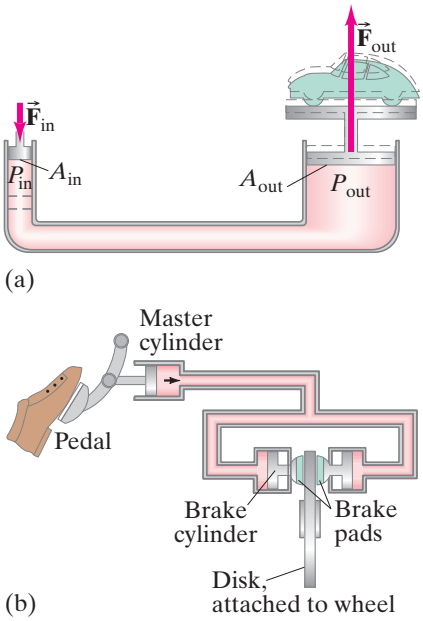

**FIGURE 13–9** Applications of Pascal's principle: (a) hydraulic lift; (b) hydraulic brakes in a car.

However, the total pressure 100 m down in a lake is due to the pressure of water plus the pressure of the air above it. Hence the total pressure (if the lake is near sea level) is 9.7 atm + 1.0 atm = 10.7 atm. This is just one example of a general principle attributed to the French philosopher and scientist Blaise Pascal (1623–1662). **Pascal's principle** states that *if an external pressure is applied to a confined fluid, the pressure at every point within the fluid increases by that amount.*

A number of practical devices make use of Pascal's principle. One example is the hydraulic lift, illustrated in Fig. 13–9a, in which a small input force is used to exert a large output force by making the area of the output piston larger than the area of the input piston. To see how this works, we assume the input and output pistons are at the same height (at least approximately). Then the external input force $F_{in}$, by Pascal's principle, increases the pressure equally throughout the fluid. Therefore, at the same level (see Fig. 13–9a),

$$P_{out} = P_{in}$$

where the input quantities are represented by the subscript "in" and the output by "out." Since $P = F/A$, we write the above equality as

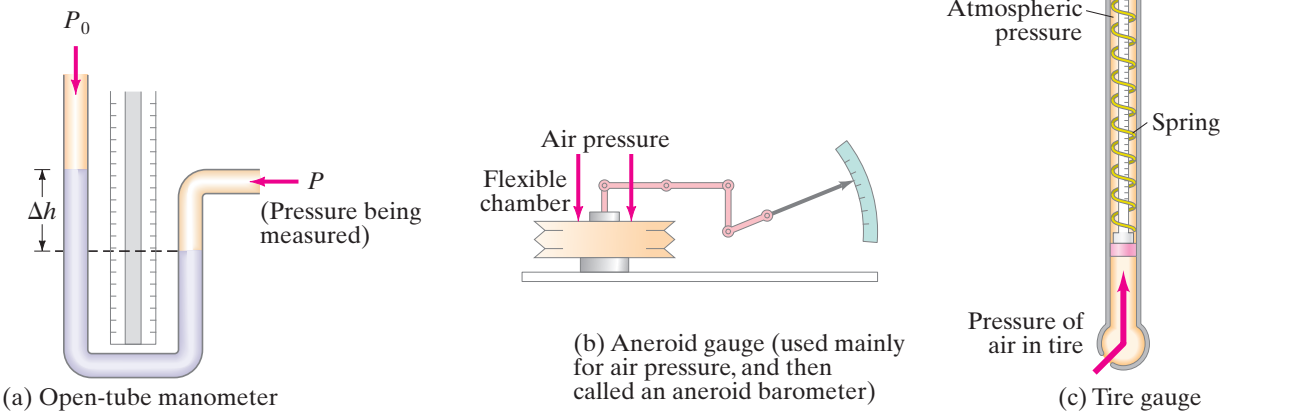
$$\frac{F_{out}}{A_{out}} = \frac{F_{in}}{A_{in}},$$

or

$$\frac{F_{out}}{F_{in}} = \frac{A_{out}}{A_{in}}.$$

The quantity $F_{out}/F_{in}$ is called the **mechanical advantage** of the hydraulic lift, and it is equal to the ratio of the areas. For example, if the area of the output piston is 20 times that of the input cylinder, the force is multiplied by a factor of 20. Thus a force of 200 lb could lift a 4000-lb car.

**PHYSICS APPLIED**
*Hydraulic lift*



**PHYSICS APPLIED**
*Hydraulic brakes*

Figure 13–9b illustrates the brake system of a car. When the driver presses the brake pedal, the pressure in the master cylinder increases. This pressure increase occurs throughout the brake fluid, thus pushing the brake pads against the disk attached to the car's wheel. A leak, though, can be disastrous.

## 13–6 Measurement of Pressure; Gauges and the Barometer

Many devices have been invented to measure pressure, some of which are shown in Fig. 13–10. The simplest is the *open-tube* **manometer** (Fig. 13–10a) which is a U-shaped tube partially filled with a liquid, usually mercury or water. The pressure $P$

**FIGURE 13–10** Pressure gauges: (a) open-tube manometer, (b) aneroid gauge, and (c) common tire pressure gauge.

being measured is related to the difference in height $\Delta h$ of the two levels of the liquid by the relation

$$P = P_0 + \rho g\,\Delta h, \qquad \text{[manometer]}$$

where $P_0$ is atmospheric pressure (acting on the top of the liquid in the left-hand tube), and $\rho$ is the density of the liquid in the U-shaped tube. Note that the quantity $\rho g\,\Delta h$ is the gauge pressure—the amount by which $P$ exceeds atmospheric pressure $P_0$. If the liquid in the left-hand column is lower than that in the right-hand column, $P$ is less than atmospheric pressure (and $\Delta h$ is negative).

Instead of calculating the product $\rho g\,\Delta h$, sometimes only the change in height $\Delta h$ is specified. In fact, pressures are sometimes specified as so many "millimeters of mercury" (mm-Hg), if $\rho$ is for mercury, or "mm of water" (mm-$H_2O$). The unit mm-Hg is equivalent to a pressure of $133\,\text{N/m}^2$, because $\rho g\,\Delta h$ for 1 mm $(= 1.0 \times 10^{-3}\,\text{m})$ of mercury gives

$$\begin{aligned}\rho g\,\Delta h &= (13.6 \times 10^3\,\text{kg/m}^3)(9.80\,\text{m/s}^2)(1.00 \times 10^{-3}\,\text{m}) \\ &= 1.33 \times 10^2\,\text{N/m}^2.\end{aligned}$$

The unit mm-Hg is also called the **torr** in honor of the Italian scientist Evangelista Torricelli (1608–1647), a student of Galileo's who invented the barometer (see Fig. 13–11).

Conversion factors among the various units of pressure (an incredible nuisance!) are given in Table 13–2. It is important that only $\text{N/m}^2 = \text{Pa}$, the proper SI unit, be used in calculations involving other quantities specified in SI units.

**PROBLEM SOLVING**
*Use SI unit in calculations:*
1 Pa = 1 $\text{N/m}^2$

**TABLE 13–2 Conversion Factors Between Different Units of Pressure**

| In Terms of 1 Pa = 1 $\text{N/m}^2$ | 1 atm in Different Units |
|---|---|
| 1 atm = $1.013 \times 10^5\,\text{N/m}^2$ = $1.013 \times 10^5\,\text{Pa} = 101.3\,\text{kPa}$ | 1 atm = $1.013 \times 10^5\,\text{N/m}^2$ |
| 1 bar = $1.000 \times 10^5\,\text{N/m}^2$ | 1 atm = 1.013 bar |
| 1 dyne/$\text{cm}^2$ = $0.1\,\text{N/m}^2$ | 1 atm = $1.013 \times 10^6$ dyne/$\text{cm}^2$ |
| 1 lb/$\text{in.}^2$ = $6.90 \times 10^3\,\text{N/m}^2$ | 1 atm = 14.7 lb/$\text{in.}^2$ |
| 1 lb/$\text{ft}^2$ = $47.9\,\text{N/m}^2$ | 1 atm = $2.12 \times 10^3$ lb/$\text{ft}^2$ |
| 1 cm-Hg = $1.33 \times 10^3\,\text{N/m}^2$ | 1 atm = 76.0 cm-Hg |
| 1 mm-Hg = $133\,\text{N/m}^2$ | 1 atm = 760 mm-Hg |
| 1 torr = $133\,\text{N/m}^2$ | 1 atm = 760 torr |
| 1 mm-$H_2O$ (4°C) = $9.80\,\text{N/m}^2$ | 1 atm = $1.03 \times 10^4$ mm-$H_2O$ (4°C) ≈ 10 m of water |

Another type of pressure gauge is the **aneroid gauge** (Fig. 13–10b) in which the pointer is linked to the flexible ends of an evacuated thin metal chamber. In electronic gauges, the pressure may be applied to a thin metal diaphragm whose resulting deformation is translated into an electrical signal by a transducer. A common tire gauge uses a spring, as shown in Fig. 13–10c.

Atmospheric pressure can be measured by a modified kind of mercury manometer with one end closed, called a mercury **barometer** (Fig. 13–11). The glass tube is completely filled with mercury and then inverted into the bowl of mercury. If the tube is long enough, the level of the mercury will drop, leaving a vacuum at the top of the tube, since atmospheric pressure can support a column of mercury only about 76 cm high (exactly 76.0 cm at standard atmospheric pressure). That is, a column of mercury 76 cm high exerts the same pressure as the atmosphere:†

$$\begin{aligned}P &= \rho g\,\Delta h \\ &= (13.6 \times 10^3\,\text{kg/m}^3)(9.80\,\text{m/s}^2)(0.760\,\text{m}) = 1.013 \times 10^5\,\text{N/m}^2 = 1.00\,\text{atm}.\end{aligned}$$

Household barometers are usually of the aneroid type (Fig. 13–10b), either mechanical (with dial) or electronic.

†This calculation confirms the entry in Table 13–2, 1 atm = 76.0 cm-Hg.

**FIGURE 13–11** A mercury barometer, invented by Torricelli, is shown here when the air pressure is standard atmospheric, 76.0 cm-Hg.

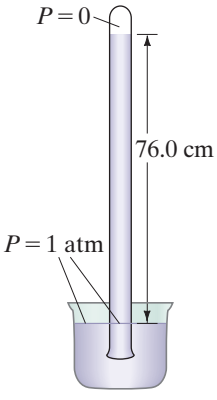


**FIGURE 13–12** A water barometer: a full tube of water (longer than 10 m), closed at the top, is inserted into a tub of water. When the submerged bottom end of the tube is unplugged, some water flows out of the tube into the tub, leaving a vacuum at the top of the tube above the water's upper surface. Why? Because air pressure can support a column of water only 10 m high.

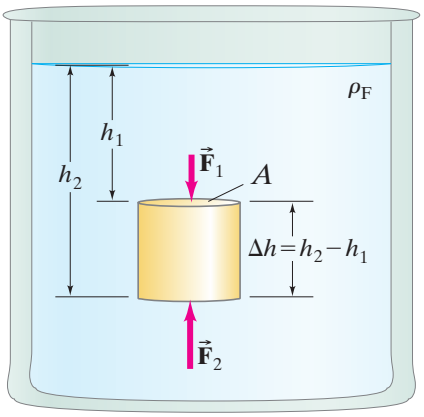
A calculation similar to that just done for Hg will show that atmospheric pressure can maintain a column of water 10.3 m high in a tube whose top is under vacuum (Fig. 13–12). No matter how good a vacuum pump is, water cannot be made to rise more than 10.3 m under normal atmospheric pressure. To pump water out of deep mine shafts with a vacuum pump requires multiple stages for depths greater than 10 m. Galileo studied this problem, and his student Torricelli was the first to explain it. The point is that a pump does not really suck water up a tube—it merely reduces the pressure at the top of the tube. Atmospheric air pressure *pushes* the water up the tube if the top end is at lower pressure (under a vacuum), just as it is air pressure that pushes (or maintains) the mercury 76 cm high in a barometer. [Force pumps, Section 13–14, can push higher.]

**CONCEPTUAL EXAMPLE 13–7** **Suction.** A novice engineer proposes suction cup shoes for space shuttle astronauts working on the exterior of a spacecraft. Having just studied this Chapter, you gently remind him of the fallacy of this plan. What is it?

**RESPONSE** Suction cups work by pushing out the air underneath the cup. What holds the suction cup in place is the air pressure outside it. (This can be a substantial force when on Earth. For example, a 10-cm-diameter suction cup has an area of $7.9 \times 10^{-3}\,\text{m}^2$. The force of the atmosphere on it is $(7.9 \times 10^{-3}\,\text{m}^2)(1.0 \times 10^5\,\text{N/m}^2) \approx 800\,\text{N}$, about 180 lbs!) But in outer space, there is no air pressure to push the suction cup onto the spacecraft.

We sometimes mistakenly think of suction as something we actively do. For example, we intuitively think that we pull the soda up through a straw. Instead, what we do is use our mouth to lower the pressure at the top of the straw, and the atmosphere *pushes* the soda up the straw.



### Vacuum

A "vacuum" ideally means a space devoid of matter. In real life it refers to a reduced pressure, usually much less than atmospheric pressure. (The top of the barometer in Fig. 13–11 would seem a perfect vacuum; but some molecules of mercury evaporate into the gas state, just like water evaporates.)

## 13–7 Buoyancy; Archimedes' Principle

Objects submerged in a fluid appear to weigh less than they do when outside the fluid. For example, a large rock that you would have difficulty lifting off the ground can often be easily lifted from the bottom of a stream. When you lift the rock through the surface of the water, it suddenly seems to be much heavier. Many objects, such as wood, float on the surface of water. These two effects are examples of **buoyancy**. In each example, the force of gravity is acting downward. But in addition, an upward *buoyant force* is exerted by the liquid. The buoyant force on fish and underwater divers (as in the Chapter-Opening photo) almost exactly balances the force of gravity downward, and allows them to "hover" in equilibrium.

**FIGURE 13–13** Determination of the buoyant force.

The buoyant force occurs because the pressure in a fluid increases with depth. Thus the upward pressure on the bottom surface of a submerged object is greater than the downward pressure on its top surface. To see this effect, consider a cylinder of height $\Delta h$ whose top and bottom ends have an area $A$ and which is completely submerged in a fluid of density $\rho_F$, as shown in Fig. 13–13. The fluid exerts a pressure $P_1 = \rho_F g h_1$ at the top surface of the cylinder (Eq. 13–3). The force due to this pressure on top of the cylinder is $F_1 = P_1 A = \rho_F g h_1 A$, and it is directed downward. Similarly, the fluid exerts an upward force on the bottom of the cylinder equal to $F_2 = P_2 A = \rho_F g h_2 A$. The net force on the cylinder exerted by the fluid pressure, which is the **buoyant force**, $\vec{\mathbf{F}}_B$, acts upward and has the magnitude

$$\begin{aligned} F_B &= F_2 - F_1 = \rho_F g A (h_2 - h_1) \\ &= \rho_F g A\, \Delta h \\ &= \rho_F V g \\ &= m_F g, \end{aligned}$$

where $V = A\,\Delta h$ is the volume of the cylinder; the product $\rho_F V$ is the mass of the fluid displaced, and $\rho_F V g = m_F g$ is the weight of fluid which takes up

a volume equal to the volume of the cylinder. Thus the buoyant force on the cylinder is equal to the weight of fluid displaced by the cylinder.

This result is valid no matter what the shape of the object. Its discovery is credited to Archimedes (287?–212 B.C.), and it is called **Archimedes' principle**:

> **the buoyant force on an object immersed in a fluid is equal to the weight of the fluid displaced by that object.**

By "fluid displaced," we mean a volume of fluid equal to the submerged volume of the object (or that part of the object that is submerged). If the object is placed in a glass or tub initially filled to the brim with water, the water that flows over the top represents the water displaced by the object.

We can derive Archimedes' principle in general by the following simple but elegant argument. The irregularly shaped object D shown in Fig. 13–14a is acted on by the force of gravity (its weight, $m\vec{\mathbf{g}}$, downward) and the buoyant force, $\vec{\mathbf{F}}_B$, upward. We wish to determine $F_B$. To do so, we next consider a body (D′ in Fig. 13–14b), this time made of the fluid itself, with the same shape and size as the original object, and located at the same depth. You might think of this body of fluid as being separated from the rest of the fluid by an imaginary membrane. The buoyant force $F_B$ on this body of fluid will be exactly the same as that on the original object since the surrounding fluid, which exerts $F_B$, is in exactly the same configuration. This body of fluid D′ is in equilibrium (the fluid as a whole is at rest). Therefore, $F_B = m'g$, where $m'g$ is the weight of the body of fluid D′. Hence the buoyant force $F_B$ is equal to the weight of the body of fluid whose volume equals the volume of the original submerged object, which is Archimedes' principle.

Archimedes' discovery was made by experiment. What we have done is show that Archimedes' principle can be derived from Newton's laws.

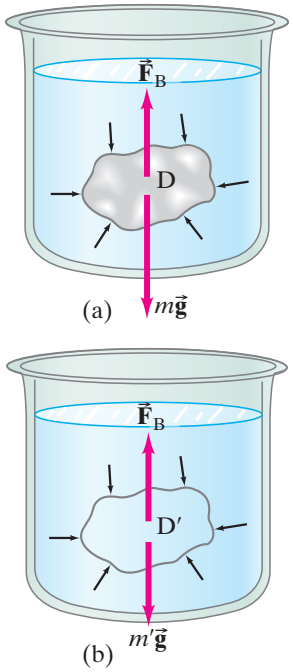


**FIGURE 13–14** Archimedes' principle.

**CONCEPTUAL EXAMPLE 13–8** **Two pails of water.** Consider two identical pails of water filled to the brim. One pail contains only water, the other has a piece of wood floating in it. Which pail has the greater weight?

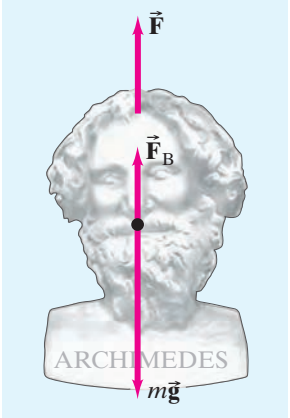
**RESPONSE** Both pails weigh the same. Recall Archimedes' principle: the wood displaces a volume of water with weight equal to the weight of the wood. Some water will have overflowed from the pail, but Archimedes' principle tells us the spilled water has weight equal to the weight of the wood; so that pail will have the same weight as the other pail.

**EXAMPLE 13–9** **Recovering a submerged statue.** A 70-kg ancient statue lies at the bottom of the sea. Its volume is $3.0 \times 10^4\,\text{cm}^3$. How much force is needed to lift it (without acceleration)?

**APPROACH** The force $F$ needed to lift the statue is equal to the statue's weight $mg$ minus the buoyant force $F_B$. Figure 13–15 is the free-body diagram.

**SOLUTION** We apply Newton's second law, $\Sigma F = ma = 0$, which gives $F + F_B - mg = 0$ or

$$F = mg - F_B.$$



The buoyant force on the statue due to the water is equal to the weight of $3.0 \times 10^4\,\text{cm}^3 = 3.0 \times 10^{-2}\,\text{m}^3$ of water (for seawater, $\rho = 1.025 \times 10^3\,\text{kg/m}^3$):

$$F_B = m_{H_2O}g = \rho_{H_2O}Vg = (1.025 \times 10^3\,\text{kg/m}^3)(3.0 \times 10^{-2}\,\text{m}^3)(9.8\,\text{m/s}^2)$$
$$= 3.0 \times 10^2\,\text{N},$$

where we use the chemical symbol for water, $H_2O$, as a subscript. The weight of the statue is $mg = (70\,\text{kg})(9.8\,\text{m/s}^2) = 6.9 \times 10^2\,\text{N}$. Hence the force $F$ needed to lift it is $690\,\text{N} - 300\,\text{N} = 390\,\text{N}$. It feels like the statue has a mass of only $(390\,\text{N})/(9.8\,\text{m/s}^2) = 40\,\text{kg}$.

**NOTE** Here $F = 390\,\text{N}$ is the force needed to lift the statue without acceleration when it is under water. As the statue comes *out* of the water, the force $F$ increases, reaching 690 N when the statue is fully out of the water.

**FIGURE 13–15** Example 13–9. The force needed to lift the statue is $\vec{\mathbf{F}}$.

Archimedes is said to have discovered his principle in his bath while thinking how he might determine whether the king's new crown was pure gold or a fake. Gold has a specific gravity of 19.3, somewhat higher than that of most metals, but a determination of specific gravity or density is not readily done directly because, even if the mass is known, the volume of an irregularly shaped object is not easily calculated. However, if the object is weighed in air $(= w)$ and also "weighed" while it is under water $(= w')$, the density can be determined using Archimedes' principle, as the following Example shows. The quantity $w'$ is called the *apparent weight* in water, and is what a spring scale reads when the object is submerged in water (see Fig. 13–16); $w'$ equals the true weight $(w = mg)$ minus the buoyant force.

**EXAMPLE 13–10** **Archimedes: Is the crown gold?** When a crown of mass 14.7 kg is submerged in water, an accurate scale reads only 13.4 kg. Is the crown made of gold?

**APPROACH** If the crown is gold, its density and specific gravity must be very high, SG = 19.3 (see Table 13–1). We determine the specific gravity of the crown using Archimedes' principle and the two free-body diagrams shown in Fig. 13–16.

**SOLUTION** The apparent weight of the submerged object (the crown) is $w'$ (what the scale reads in Fig. 13–16b), and is the force pulling down on the scale hook. By Newton's third law, $w'$ equals the force $F'_T$ that the scale exerts on the crown in Fig. 13–16b. The sum of the forces on the crown at rest is zero, so $w'$ equals the actual weight $w\ (= mg)$ minus the buoyant force $F_B$:

$$w' = F'_T = w - F_B$$

so

$$w - w' = F_B.$$

Let $V$ be the volume of the completely submerged object (the crown) and $\rho_O$ the object's density (so $\rho_O V$ is its mass), and let $\rho_F$ be the density of the fluid (water). Then $(\rho_F V)g$ is the weight of fluid displaced $(= F_B)$. Now we can write

$$w = mg = \rho_O Vg$$
$$w - w' = F_B = \rho_F Vg. \qquad \text{(Archimedes' principle)}$$

We divide these two equations and obtain

$$\frac{w}{w - w'} = \frac{\rho_O Vg}{\rho_F Vg} = \frac{\rho_O}{\rho_F}.$$

We see that $w/(w - w')$ is equal to the specific gravity of the object (the crown) if the fluid in which it is submerged is water $(\rho_F = 1.00 \times 10^3\ \text{kg/m}^3)$. Thus

$$\frac{\rho_O}{\rho_{H_2O}} = \frac{w}{w - w'} = \frac{(14.7\ \text{kg})g}{(14.7\ \text{kg} - 13.4\ \text{kg})g} = \frac{14.7\ \text{kg}}{1.3\ \text{kg}} = 11.3.$$

This corresponds to a density of $11{,}300\ \text{kg/m}^3$. The crown is not gold, but seems to be made of lead (see Table 13–1).

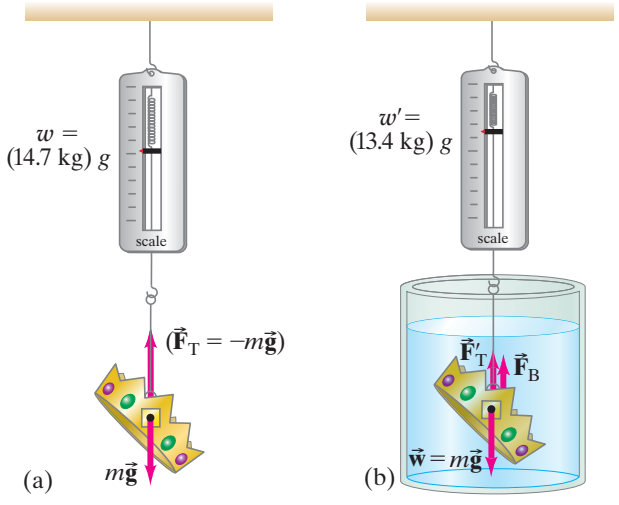


**FIGURE 13–16** (a) A scale reads the mass of an object in air—in this case the crown of Example 13–10. All objects are at rest, so the tension $F_T$ in the connecting cord equals the weight $w$ of the object: $F_T = mg$. We show the free-body diagram of the crown, and $F_T$ is what causes the scale reading (it is equal to the net downward force on the scale, by Newton's third law). (b) Submerged, the crown has an additional force on it, the buoyant force $F_B$. The net force is zero, so $F'_T + F_B = mg\ (= w)$. The scale now reads $m' = 13.4$ kg, where $m'$ is related to the effective weight by $w' = m'g$. Thus $F'_T = w' = w - F_B$.

Archimedes' principle applies equally well to objects that float, such as wood. In general, *an object floats on a fluid if its density* $(\rho_O)$ *is less than that of the fluid* $(\rho_F)$. This is readily seen from Fig. 13–17a, where a submerged log of mass $m_O$ will experience a net upward force and float to the surface if $F_B > m_O g$; that is, if $\rho_F V g > \rho_O V g$ or $\rho_F > \rho_O$. At equilibrium—that is, when floating—the buoyant force on an object has magnitude equal to the weight of the object. For example, a log whose specific gravity is 0.60 and whose volume is 2.0 $m^3$ has a mass

$$m_O = \rho_O V = (0.60 \times 10^3\ \text{kg/m}^3)(2.0\ \text{m}^3) = 1200\ \text{kg}.$$

If the log is fully submerged, it will displace a mass of water

$$m_F = \rho_F V = (1000\ \text{kg/m}^3)(2.0\ \text{m}^3) = 2000\ \text{kg}.$$

Hence the buoyant force on the submerged log $(= m_F g)$ will be greater than its weight, and it will be pushed upward to float on the surface (Fig. 13–17). The log will come to equilibrium when it displaces 1200 kg of water, which means that 1.2 $m^3$ of its volume will be submerged. This 1.2 $m^3$ corresponds to 60% of the volume of the log $(= 1.2/2.0 = 0.60)$, so 60% of the log is submerged.

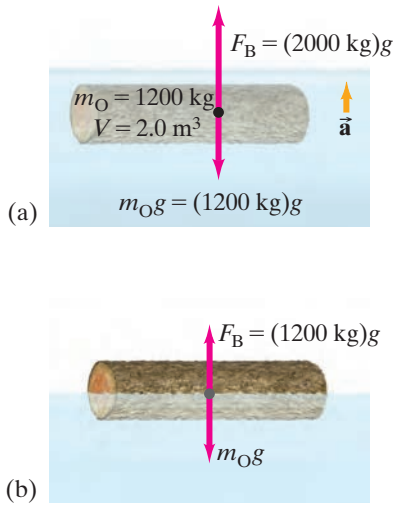
In general when an object floats, we have $F_B = m_O g$, which we can write as (see Fig. 13–18)

$$F_B = m_O g$$
$$\rho_F V_{\text{displ}} g = \rho_O V_O g,$$

where $V_O$ is the full volume of the object and $V_{\text{displ}}$ is the volume of fluid it displaces (= volume submerged). Thus

$$\frac{V_{\text{displ}}}{V_O} = \frac{\rho_O}{\rho_F}.$$

That is, the fraction of the object submerged is given by the ratio of the object's density to that of the fluid. If the fluid is water, this fraction equals the specific gravity of the object.



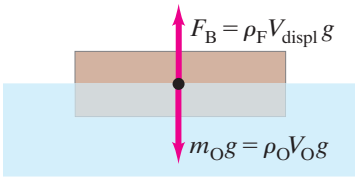


**FIGURE 13–17** (a) The fully submerged log accelerates upward because $F_B > m_O g$. It comes to equilibrium (b) when $\Sigma F = 0$, so $F_B = m_O g = (1200\ \text{kg})g$. Then 1200 kg, or 1.2 $m^3$, of water is displaced.

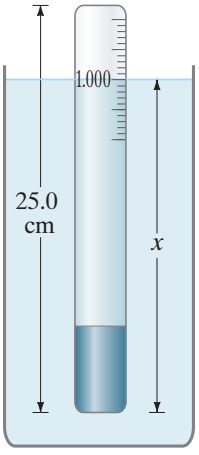
**FIGURE 13–18** An object floating in equilibrium: $F_B = m_O g$.

**EXAMPLE 13–11** **Hydrometer calibration.** A **hydrometer** is a simple instrument used to measure the specific gravity of a liquid by indicating how deeply the instrument sinks in the liquid. A particular hydrometer (Fig. 13–19) consists of a glass tube, weighted at the bottom, which is 25.0 cm long and 2.00 $cm^2$ in cross-sectional area, and has a mass of 45.0 g. How far from the weighted end should the 1.000 mark be placed?

**APPROACH** The hydrometer will float in water if its density $\rho$ is less than $\rho_{H_2O} = 1.000\ \text{g/cm}^3$, the density of water. The fraction of the hydrometer submerged $(V_{\text{displaced}}/V_{\text{total}})$ is equal to the density ratio $\rho/\rho_{H_2O}$.



**SOLUTION** The hydrometer has an overall density

$$\rho = \frac{m}{V} = \frac{45.0\ \text{g}}{(2.00\ \text{cm}^2)(25.0\ \text{cm})} = 0.900\ \text{g/cm}^3.$$

Thus, when placed in water, it will come to equilibrium when 0.900 of its volume is submerged. Since it is of uniform cross section, $(0.900)(25.0\ \text{cm}) = 22.5\ \text{cm}$ of its length will be submerged. The specific gravity of water is defined to be 1.000, so the mark should be placed 22.5 cm from the weighted end.

**NOTE** Hydrometers can be used to measure the density of liquids like car antifreeze coolant, car battery acid (a measure of its charge), wine and beer fermenting, and many others.

**FIGURE 13–19** A hydrometer. Example 13–11.

**EXERCISE C** On the hydrometer of Example 13–11, will the marks above the 1.000 mark represent higher or lower values of density of the liquid in which it is submerged?

**EXERCISE D** Which of the following objects, submerged in water, experiences the largest magnitude of the buoyant force? (*a*) A 1-$m^3$ helium balloon; (*b*) 1 $m^3$ of wood; (*c*) 1 $m^3$ of ice; (*d*) 1 $m^3$ of iron; (*e*) all the same.

**PHYSICS APPLIED**
*Continental drift—plate tectonics*

Archimedes' principle is also useful in geology. According to the theories of plate tectonics and continental drift, the continents float on a fluid "sea" of slightly deformable rock (mantle rock). Some interesting calculations can be done using very simple models, which we consider in the Problems at the end of the Chapter.

Air is a fluid, and it too exerts a buoyant force. Ordinary objects weigh less in air than they do in a vacuum. Because the density of air is so small, the effect for ordinary solids is slight. There are objects, however, that *float* in air—helium-filled balloons, for example, because the density of helium is less than the density of air.

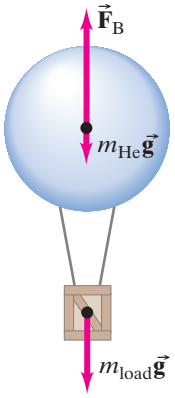


**FIGURE 13–20** Example 13–12.

**EXAMPLE 13–12 Helium balloon.** What volume $V$ of helium is needed if a balloon is to lift a load of 180 kg (including the weight of the empty balloon)?

**APPROACH** The buoyant force on the helium balloon, $F_B$, which is equal to the weight of displaced air, must be at least equal to the weight of the helium plus the weight of the balloon and load (Fig. 13–20), if they are to float upward. Table 13–1 gives the density of helium as $0.179\ \text{kg/m}^3$.

**SOLUTION** The buoyant force must have a minimum value of

$$F_B = (m_{He} + 180\ \text{kg})g.$$

This equation can be written in terms of density using Archimedes' principle:

$$\rho_{air} Vg = (\rho_{He} V + 180\ \text{kg})g.$$

Solving now for $V$, we find

$$V = \frac{180\ \text{kg}}{\rho_{air} - \rho_{He}} = \frac{180\ \text{kg}}{(1.29\ \text{kg/m}^3 - 0.179\ \text{kg/m}^3)} = 160\ \text{m}^3.$$

**NOTE** This is the minimum volume needed near the Earth's surface, where $\rho_{air} = 1.29\ \text{kg/m}^3$. To reach a high altitude, a greater volume would be needed since the density of air decreases with altitude.

**CONCEPTUAL EXAMPLE 13–13 Throwing a rock overboard.** A rowboat carrying a large granite rock floats in a small lake. If the rock (SG $\approx$ 3, Table 13–1) is thrown overboard and sinks, does the lake level drop, rise, or stay the same?

**RESPONSE** Together the boat and rock float, so the buoyant force on them equals their total weight. The boat and rock displace a mass of water whose weight is equal to the weight of boat plus rock. When the rock is thrown into the lake, it displaces only its own volume, which is smaller than the volume of water the rock displaced when in the boat ($\approx \frac{1}{3}$ as much because the rock's density is $\approx$ 3 times greater than water). So less lake water is displaced and the water level of the lake *drops* when the rock is in the lake.

Maybe numbers can help. Suppose the boat and the rock each has a mass of 60 kg. Then the boat carrying the rock displaces 120 kg of water, which is a volume of $0.12\ \text{m}^3$ ($\rho = 1000\ \text{kg/m}^3$ for water, Table 13–1). When the rock is thrown into the lake, the boat alone now displaces $0.06\ \text{m}^3$. The rock displaces only its own volume of $0.02\ \text{m}^3$ ($\rho = m/V \approx 3$ so $V \approx 0.06\ \text{m}^3/3$). Thus a total of $0.08\ \text{m}^3$ of water is displaced. Less water is displaced so the water level of the lake drops.

**EXERCISE E** If you throw a flat 60-kg aluminum plate into water, the plate sinks. But if that aluminum is shaped into a rowboat, it floats. Explain.

## 13–8 Fluids in Motion; Flow Rate and the Equation of Continuity

We now turn to the subject of fluids in motion, which is called **fluid dynamics**, or (especially if the fluid is water) **hydrodynamics**.

We can distinguish two main types of fluid flow. If the flow is smooth, such that neighboring layers of the fluid slide by each other smoothly, the flow is said to be **streamline** or **laminar flow**.† In streamline flow, each particle of the fluid follows a smooth path, called a **streamline**, and these paths do not cross

†The word laminar means "in layers."

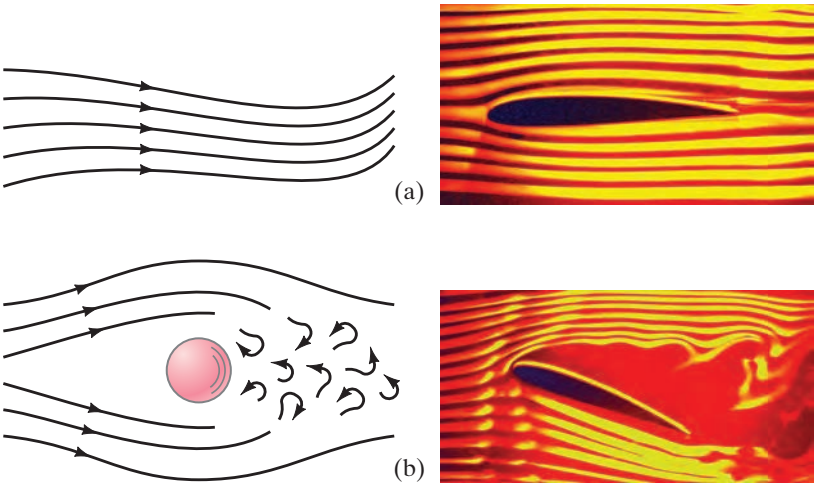

**FIGURE 13–21** (a) Streamline, or laminar, flow; (b) turbulent flow. The photos show airflow around an airfoil or airplane wing (more in Section 13–10).

one another (Fig. 13–21a). Above a certain speed (and depending on the shape of an object immersed in the fluid) the flow becomes turbulent. **Turbulent flow** is characterized by erratic, small, whirlpool-like circles called *eddy currents* or *eddies* (Fig. 13–21b). Eddies absorb a great deal of energy, and although a certain amount of internal friction called **viscosity** is present even during streamline flow, it is much greater when the flow is turbulent. A few tiny drops of ink or food coloring dropped into a moving liquid can quickly reveal whether the flow is streamline or turbulent.

Let us consider the steady laminar flow of a fluid through an enclosed tube or pipe as shown in Fig. 13–22. First we determine how the speed of the fluid changes when the diameter of the tube changes. The mass **flow rate** is defined as the mass $\Delta m$ of fluid that passes a given point per unit time $\Delta t$:

$$\text{mass flow rate} = \frac{\Delta m}{\Delta t}.$$

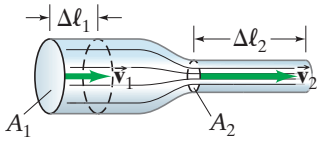

**FIGURE 13–22** Fluid flow through a pipe of varying diameter.

In Fig. 13–22, the volume of fluid passing point 1 (through area $A_1$) in a time $\Delta t$ is $A_1\,\Delta\ell_1$, where $\Delta\ell_1$ is the distance the fluid moves in time $\Delta t$. The velocity[†] of fluid (density $\rho_1$) passing point 1 is $v_1 = \Delta\ell_1/\Delta t$. Then the mass flow rate $\Delta m_1/\Delta t$ through area $A_1$ is

$$\frac{\Delta m_1}{\Delta t} = \frac{\rho_1\,\Delta V_1}{\Delta t} = \frac{\rho_1 A_1\,\Delta\ell_1}{\Delta t} = \rho_1 A_1 v_1,$$

where $\Delta V_1 = A_1\,\Delta\ell_1$ is the volume of mass $\Delta m_1$. Similarly, at point 2 (through area $A_2$), the flow rate is $\rho_2 A_2 v_2$. Since no fluid flows in or out the sides of the tube, the flow rates through $A_1$ and $A_2$ must be equal. Thus

$$\frac{\Delta m_1}{\Delta t} = \frac{\Delta m_2}{\Delta t},$$

and

$$\rho_1 A_1 v_1 = \rho_2 A_2 v_2. \qquad \textbf{(13–7a)}$$

This is called the **equation of continuity**.

If the fluid is incompressible ($\rho$ doesn't change with pressure), which is an excellent approximation for liquids under most circumstances (and sometimes for gases as well), then $\rho_1 = \rho_2$, and the equation of continuity becomes

$$A_1 v_1 = A_2 v_2. \qquad [\rho = \text{constant}] \quad \textbf{(13–7b)}$$

The product $Av$ represents the *volume rate of flow* (volume of fluid passing a given point per second), since $\Delta V/\Delta t = A\,\Delta\ell/\Delta t = Av$, which in SI units is $\text{m}^3/\text{s}$. Equation 13–7b tells us that where the cross-sectional area is large, the velocity is small, and where the area is small, the velocity is large.

[†]If there were no viscosity, the velocity would be the same across a cross section of the tube. Real fluids have viscosity, and this internal friction causes different layers of the fluid to flow at different speeds. In this case $v_1$ and $v_2$ represent the average speeds at each cross section.

That this is reasonable can be seen by looking at a river. A river flows slowly through a meadow where it is broad, but speeds up to torrential speed when passing through a narrow gorge.

**PHYSICS APPLIED**
*Blood flow*

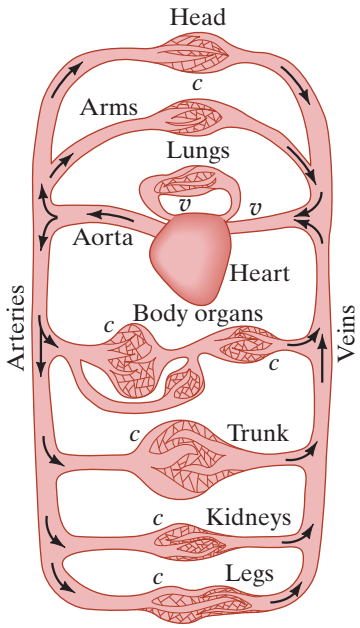

**FIGURE 13–23** Human circulatory system.

**EXAMPLE 13–14** **ESTIMATE** **Blood flow.** In humans, blood flows from the heart into the aorta, from which it passes into the major arteries, Fig. 13–23. These branch into the small arteries (arterioles), which in turn branch into myriads of tiny capillaries. The blood returns to the heart via the veins. The radius of the aorta is about 1.2 cm, and the blood passing through it has a speed of about 40 cm/s. A typical capillary has a radius of about $4 \times 10^{-4}$ cm, and blood flows through it at a speed of about $5 \times 10^{-4}$ m/s. Estimate the number of capillaries that are in the body.

**APPROACH** We assume the density of blood doesn't vary significantly from the aorta to the capillaries. By the equation of continuity, the volume flow rate in the aorta must equal the volume flow rate through *all* the capillaries. The total area of all the capillaries is given by the area of a typical capillary multiplied by the total number $N$ of capillaries.

**SOLUTION** Let $A_1$ be the area of the aorta and $A_2$ be the area of *all* the capillaries through which blood flows. Then $A_2 = N\pi r_{\text{cap}}^2$, where $r_{\text{cap}} \approx 4 \times 10^{-4}$ cm is the estimated average radius of one capillary. From the equation of continuity (Eq. 13–7b), we have

$$\begin{aligned} v_2 A_2 &= v_1 A_1 \\ v_2 N\pi r_{\text{cap}}^2 &= v_1 \pi r_{\text{aorta}}^2 \end{aligned}$$

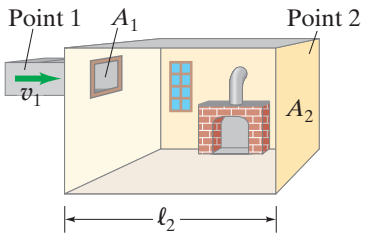
so

$$N = \frac{v_1}{v_2}\frac{r_{\text{aorta}}^2}{r_{\text{cap}}^2} = \left(\frac{0.40\ \text{m/s}}{5 \times 10^{-4}\ \text{m/s}}\right)\left(\frac{1.2 \times 10^{-2}\ \text{m}}{4 \times 10^{-6}\ \text{m}}\right)^2 \approx 7 \times 10^9,$$

or on the order of 10 billion capillaries.

**EXAMPLE 13–15** **Heating duct to a room.** What area must a heating duct have if air moving 3.0 m/s along it can replenish the air every 15 minutes in a room of volume 300 $\text{m}^3$? Assume the air's density remains constant.

**APPROACH** We apply the equation of continuity at constant density, Eq. 13–7b, to the air that flows through the duct (point 1 in Fig. 13–24) and then into the room (point 2). The volume flow rate in the room equals the volume of the room divided by the 15-min replenishing time.



**SOLUTION** Consider the room as a large section of the duct, Fig. 13–24, and think of air equal to the volume of the room as passing by point 2 in $t = 15\ \text{min} = 900\ \text{s}$. Reasoning in the same way we did to obtain Eq. 13–7a (changing $\Delta t$ to $t$), we write $v_2 = \ell_2/t$ so $A_2 v_2 = A_2 \ell_2/t = V_2/t$, where $V_2$ is the volume of the room. Then the equation of continuity becomes $A_1 v_1 = A_2 v_2 = V_2/t$ and

$$A_1 = \frac{V_2}{v_1 t} = \frac{300\ \text{m}^3}{(3.0\ \text{m/s})\,(900\ \text{s})} = 0.11\ \text{m}^2.$$

**NOTE** If the duct is square, then each side has length $\ell = \sqrt{A} = 0.33$ m, or 33 cm. A rectangular duct 20 cm × 55 cm will also do.

**PHYSICS APPLIED**
*Heating duct*

**FIGURE 13–24** Example 13–15.

# 13–9 Bernoulli's Equation

Have you ever wondered why an airplane can fly, or how a sailboat can move against the wind? These are examples of a principle worked out by Daniel Bernoulli (1700–1782) concerning fluids in motion. In essence, **Bernoulli's principle** states that *where the velocity of a fluid is high, the pressure is low, and where the velocity is low, the pressure is high*. For example, if the pressure in the fluid is measured at points 1

and 2 of Fig. 13–22, it will be found that the pressure is lower at point 2, where the velocity is greater, than it is at point 1, where the velocity is smaller. At first glance, this might seem strange; you might expect that the greater speed at point 2 would imply a higher pressure. But this cannot be the case: if the pressure in the fluid at point 2 were higher than at point 1, this higher pressure would slow the fluid down, whereas in fact it has sped up in going from point 1 to point 2. Thus the pressure at point 2 must be less than at point 1, to be consistent with the fact that the fluid accelerates.

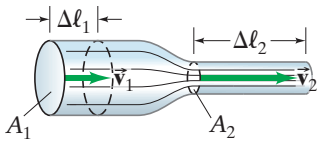


**FIGURE 13–22** (Repeated.) Fluid flow through a pipe of varying diameter.

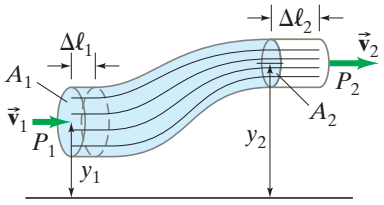
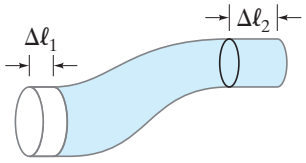
To help clarify any misconceptions, a faster fluid might indeed exert a greater force bouncing off an obstacle placed in its path. But that is not what we mean by the pressure in a fluid. We are examining smooth streamline flow, with no obstacles that interrupt the flow. The fluid pressure is exerted on the walls of a tube or pipe, or on the surface of a material the fluid passes over.



Bernoulli developed an equation that expresses this principle quantitatively. To derive Bernoulli's equation, we assume the flow is steady and laminar, the fluid is incompressible, and the viscosity is small enough to be ignored. To be general, we assume the fluid is flowing in a tube of nonuniform cross section that varies in height above some reference level, Fig. 13–25. We will consider the volume of fluid shown in color and calculate the work done to move it from the position shown in Fig. 13–25a to that shown in Fig. 13–25b. In this process, fluid entering area $A_1$ flows a distance $\Delta\ell_1$ and forces the fluid at area $A_2$ to move a distance $\Delta\ell_2$. The fluid to the left of area $A_1$ exerts a pressure $P_1$ on our section of fluid and does an amount of work

$$W_1 = F_1\,\Delta\ell_1 = P_1 A_1\,\Delta\ell_1,$$



(since $P = F/A$). At point 2 (area $A_2$), the work done on our section of fluid is

$$W_2 = -P_2 A_2\,\Delta\ell_2.$$

**FIGURE 13–25** Fluid flow: for derivation of Bernoulli's equation.

(a)

(b)

The negative sign is present because the force exerted on the fluid is opposite to the displacement. Work is also done on the fluid by the force of gravity. The net effect of the process shown in Fig. 13–25 is to move a mass $m$ of volume $A_1\,\Delta\ell_1$ $(= A_2\,\Delta\ell_2,$ since the fluid is incompressible) from point 1 to point 2, so the work done by gravity is

$$W_3 = -mg(y_2 - y_1),$$

where $y_1$ and $y_2$ are heights of the center of the tube above some (arbitrary) reference level. In the case shown in Fig. 13–25, this term is negative since the motion is uphill against the force of gravity. The net work $W$ done on the fluid is thus

$$W = W_1 + W_2 + W_3$$
$$W = P_1 A_1\,\Delta\ell_1 - P_2 A_2\,\Delta\ell_2 - mgy_2 + mgy_1.$$

According to the work-energy principle (Section 7–4), the net work done on a system is equal to its change in kinetic energy. Hence

$$\tfrac{1}{2}mv_2^2 - \tfrac{1}{2}mv_1^2 = P_1 A_1\,\Delta\ell_1 - P_2 A_2\,\Delta\ell_2 - mgy_2 + mgy_1.$$

The mass $m$ has volume $A_1\,\Delta\ell_1 = A_2\,\Delta\ell_2$ for an incompressible fluid. Thus we can substitute $m = \rho A_1\,\Delta\ell_1 = \rho A_2\,\Delta\ell_2$, and then divide through by $A_1\,\Delta\ell_1 = A_2\,\Delta\ell_2$, to obtain

$$\tfrac{1}{2}\rho v_2^2 - \tfrac{1}{2}\rho v_1^2 = P_1 - P_2 - \rho gy_2 + \rho gy_1,$$

which we rearrange to get

$$P_2 + \tfrac{1}{2}\rho v_2^2 + \rho gy_2 = P_1 + \tfrac{1}{2}\rho v_1^2 + \rho gy_1. \qquad \textbf{(13–8)}$$

*Bernoulli's equation*

This is **Bernoulli's equation**. Since points 1 and 2 can be any two points along a tube of flow, Bernoulli's equation can be written as

$$P + \tfrac{1}{2}\rho v^2 + \rho gy = \text{constant}$$

at every point in the fluid, where $y$ is the height of the center of the tube above a fixed reference level. [Note that if there is no flow $(v_1 = v_2 = 0)$, then Eq. 13–8 reduces to the hydrostatic equation, Eq. 13–6a: $P_1 - P_2 = \rho g(y_2 - y_1)$.]

Bernoulli's equation is an expression of the law of energy conservation, since we derived it from the work-energy principle.

**EXERCISE F** As water in a level pipe passes from a narrow cross section of pipe to a wider cross section, how does the pressure against the walls change?

PHYSICS APPLIED
*Hot-water heating system*

**EXAMPLE 13–16 Flow and pressure in a hot-water heating system.** Water circulates throughout a house in a hot-water heating system. If the water is pumped at a speed of 0.50 m/s through a 4.0-cm-diameter pipe in the basement under a pressure of 3.0 atm, what will be the flow speed and pressure in a 2.6-cm-diameter pipe on the second floor 5.0 m above? Assume the pipes do not divide into branches.

**APPROACH** We use the equation of continuity at constant density to determine the flow speed on the second floor, and then Bernoulli's equation to find the pressure.

**SOLUTION** We take $v_2$ in the equation of continuity, Eq. 13–7, as the flow speed on the second floor, and $v_1$ as the flow speed in the basement. Noting that the areas are proportional to the radii squared $(A = \pi r^2)$, we obtain

$$v_2 = \frac{v_1 A_1}{A_2} = \frac{v_1 \pi r_1^2}{\pi r_2^2} = (0.50\,\text{m/s})\,\frac{(0.020\,\text{m})^2}{(0.013\,\text{m})^2} = 1.2\,\text{m/s}.$$

To find the pressure on the second floor, we use Bernoulli's equation (Eq. 13–8):

$$\begin{aligned} P_2 &= P_1 + \rho g(y_1 - y_2) + \tfrac{1}{2}\rho(v_1^2 - v_2^2) \\ &= (3.0\times10^5\,\text{N/m}^2) + (1.0\times10^3\,\text{kg/m}^3)(9.8\,\text{m/s}^2)(-5.0\,\text{m}) \\ &\quad + \tfrac{1}{2}(1.0\times10^3\,\text{kg/m}^3)[(0.50\,\text{m/s})^2 - (1.2\,\text{m/s})^2] \\ &= (3.0\times10^5\,\text{N/m}^2) - (4.9\times10^4\,\text{N/m}^2) - (6.0\times10^2\,\text{N/m}^2) \\ &= 2.5\times10^5\,\text{N/m}^2 = 2.5\,\text{atm}. \end{aligned}$$

**NOTE** The velocity term contributes very little in this case.

# 13–10 Applications of Bernoulli's Principle: Torricelli, Airplanes, Baseballs, Blood Flow

Bernoulli's equation can be applied to many situations. One example is to calculate the velocity, $v_1$, of a liquid flowing out of a spigot at the bottom of a reservoir, Fig. 13–26. We choose point 2 in Eq. 13–8 to be the top surface of the liquid. Assuming the diameter of the reservoir is large compared to that of the spigot, $v_2$ will be almost zero. Points 1 (the spigot) and 2 (top surface) are open to the atmosphere, so the pressure at both points is equal to atmospheric pressure: $P_1 = P_2$. Then Bernoulli's equation becomes

$$\tfrac{1}{2}\rho v_1^2 + \rho g y_1 = \rho g y_2$$

or

$$v_1 = \sqrt{2g(y_2 - y_1)}. \qquad \textbf{(13–9)}$$

This result is called **Torricelli's theorem**. Although it is seen to be a special case of Bernoulli's equation, it was discovered a century earlier by Evangelista Torricelli (see page 373). Equation 13–9 tells us that the liquid leaves the spigot with the same speed that a freely falling object would attain if falling from the same height. This should not be too surprising since the derivation of Bernoulli's equation relies on the conservation of energy.

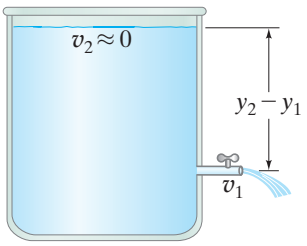


**FIGURE 13–26** Torricelli's theorem: $v_1 = \sqrt{2g(y_2 - y_1)}$.

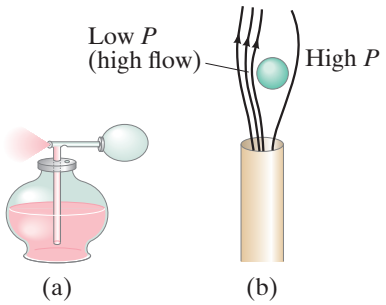
Another special case of Bernoulli's equation arises when a fluid is flowing horizontally with no appreciable change in height; that is, $y_1 = y_2$. Then Eq. 13–8 becomes

$$P_1 + \tfrac{1}{2}\rho v_1^2 = P_2 + \tfrac{1}{2}\rho v_2^2, \qquad \textbf{(13–10)}$$

which tells us quantitatively that the speed is high where the pressure is low, and vice versa. It explains many common phenomena, some of which are illustrated in Figs. 13–27 to 13–33. The pressure in the air blown at high speed across the top of the vertical tube of a perfume atomizer (Fig. 13–27a) is less than the normal air pressure acting on the surface of the liquid in the bowl. Thus atmospheric pressure in the bowl pushes the perfume up the tube because of the lower pressure at the top. A Ping-Pong ball can be made to float above a blowing jet of air (a hair dryer or a vacuum cleaner that can also blow air), Fig. 13–27b; if the ball begins to leave the jet of air, the higher pressure in the still air outside the jet pushes the ball back in.



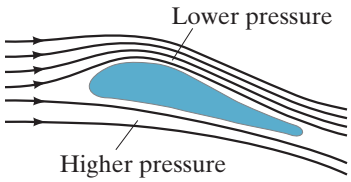


**FIGURE 13–27** Examples of Bernoulli's principle: (a) atomizer, (b) Ping-Pong ball in jet of air.

**EXERCISE G** Return to Chapter-Opening Question 2, page 365, and answer it again now. Try to explain why you may have answered differently the first time. Try it and see.

## Airplane Wings and Dynamic Lift

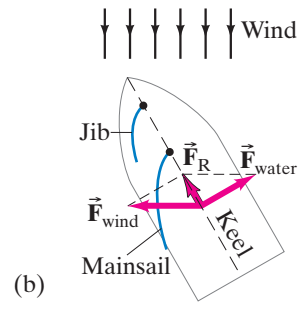
Airplanes experience a "lift" force on their wings, keeping them up in the air, if they are moving at a sufficiently high speed relative to the air and the wing is tilted upward at a small angle (the *attack angle*). See Fig. 13–28, where streamlines of air are shown rushing by the wing (we are in the reference frame of the wing, as if sitting on the wing.) The upward tilt, as well as the rounded upper surface of the wing, causes the streamlines to be forced upward and to be crowded together above the wing. The area for air flowing between any two streamlines is smaller as the streamlines get closer together, so from the equation of continuity $(A_1 v_1 = A_2 v_2)$, the air speed increases above the wing where the streamlines are squished together. (Recall also how the crowded streamlines in a pipe constriction, Fig. 13–22, indicate the velocity is higher in the constriction.) Thus the air speed is greater above the wing than below it, so the pressure above the wing is less than the pressure below the wing (Bernoulli's principle). Hence there is a net upward force on the wing called **dynamic lift**. Experiments show that the speed of air above the wing can even be double the speed of the air below it. (Friction between the air and wing exerts a *drag force*, toward the rear, which must be overcome by the plane's engines.)

**FIGURE 13–28** Lift on an airplane wing. We are in the reference frame of the wing, seeing the air flow by.

**PHYSICS APPLIED**
*Airplanes and dynamic lift*

A flat wing, or one with symmetric cross section, will experience lift as long as the front of the wing is tilted upward (attack angle). The wing shown in Fig. 13–28 can experience lift even if the attack angle is zero, because the rounded upper surface deflects air up, squeezing the streamlines together. Being both rounded and tilted is better. Airplanes can fly upside down, experiencing lift, if the attack angle is sufficient to deflect streamlines up and closer together.

Our picture considers streamlines; but if the attack angle is larger than about 15°, turbulence sets in (Fig. 13–21b) leading to greater drag and less lift, causing the plane to "stall" and then to drop dangerously.



From another point of view, the upward tilt of a wing means the air moving horizontally in front of the wing is deflected downward by the lower surface of the wing; the change in momentum of the rebounding air molecules results in an upward force on the wing (Newton's third law).

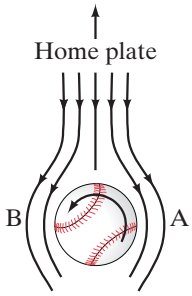
## Sailboats

A sailboat can move "against" the wind, with the aid of the Bernoulli effect, by setting the sails at an angle, as shown in Fig. 13–29. The air traveling rapidly over the bulging front surface of the mainsail exerts a smaller pressure than the relatively still air behind the sail. The result is a net force on the sail, $\vec{\mathbf{F}}_{\text{wind}}$, as shown in Fig. 13–29b. This force would tend to make the boat move sideways if it weren't for the *keel* that extends vertically downward beneath the water: the water exerts a force $(\vec{\mathbf{F}}_{\text{water}})$ on the keel nearly perpendicular to the keel. The resultant of these two forces $(\vec{\mathbf{F}}_{\text{R}})$ is almost directly forward as shown.

**FIGURE 13–29** Sailboat (a) sailing against the wind with (b) analysis.

(a)

(b)



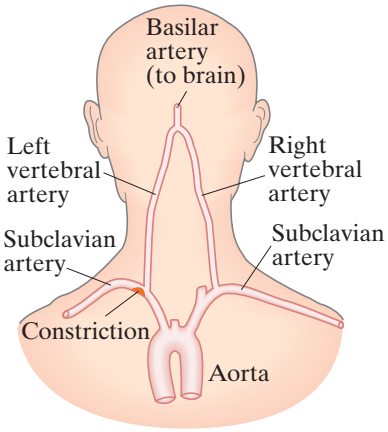


**FIGURE 13–30** Looking down on a pitched baseball heading toward home plate. We are in the reference frame of the baseball, with the air flowing by.

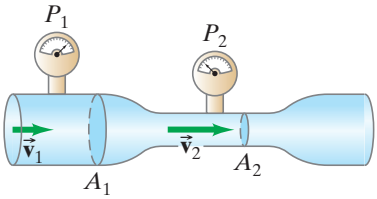
**FIGURE 13–31** Rear of the head and shoulders showing arteries leading to the brain and to the arms. High blood velocity past the constriction in the left subclavian artery causes low pressure in the left vertebral artery, in which a reverse (downward) blood flow can then occur, resulting in a TIA, a loss of blood to the brain.

## Baseball Curve

Why a spinning pitched baseball (soccer ball, tennis ball) curves can also be explained using Bernoulli's principle. It is simplest if we put ourselves in the reference frame of the ball, with the air rushing by, just as we did for the airplane wing. Suppose the ball is rotating counterclockwise as seen from above, Fig. 13–30. A thin layer of air (*boundary layer*) is being dragged around by the ball. We are looking down on the ball, and at point A in Fig. 13–30, this boundary layer tends to slow down the oncoming air. At point B, the air rotating with the ball adds its speed to that of the oncoming air, so the air speed is higher at B than at A. The higher speed at B means the pressure is lower at B than at A, resulting in a net force toward B. The ball's path curves toward the left (as seen by the pitcher).



## Lack of Blood to the Brain—TIA

In medicine, one of many applications of Bernoulli's principle is to explain a TIA, a *transient ischemic attack* (meaning a temporary lack of blood supply to the brain). A person suffering a TIA may experience symptoms such as dizziness, double vision, headache, and weakness of the limbs. A TIA can occur as follows. Blood normally flows up to the brain at the back of the head via the two vertebral arteries—one going up each side of the neck—which meet to form the basilar artery just below the brain, as shown in Fig. 13–31. Each vertebral artery connects to the subclavian artery, as shown, before the blood passes to the arms. When an arm is exercised vigorously, blood flow increases to meet the needs of the arm's muscles. If the subclavian artery on one side of the body is partially blocked, however, as in arteriosclerosis (hardening of the arteries), the blood velocity will have to be higher on that side to supply the needed blood. (Recall the equation of continuity: smaller area means larger velocity for the same flow rate, Eqs. 13–7.) The increased blood velocity past the opening to the vertebral artery results in lower pressure there (Bernoulli's principle). Thus blood rising in the vertebral artery on the "good" side at normal pressure can be *diverted down* into the other vertebral artery because of the low pressure on that side, instead of passing upward to the brain. Hence the blood supply to the brain is reduced, causing dizziness, or worse.

## Other Applications

A **venturi tube** is essentially a pipe with a narrow constriction (the throat). The flowing fluid speeds up as it passes through this constriction, so the pressure is lower in the throat. A **venturi meter**, Fig. 13–32, is used to measure the flow speed of gases and liquids, including blood velocity in arteries. The velocity $v_1$ can be determined by measuring the pressure $P_1$ and $P_2$, the areas $A_1$ and $A_2$, as well as the density of the fluid. (The formula is given in Problem 60.)

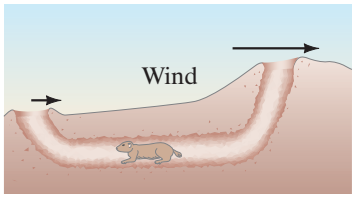


**FIGURE 13–32** Venturi meter.

**PHYSICS APPLIED**
*Smoke up a chimney, and underground air circulation*

Why does smoke go up a chimney? It's partly because hot air rises (it's less dense and therefore buoyant). But Bernoulli's principle also plays a role. When wind blows across the top of a chimney, the pressure is less there than inside the house. Hence, air and smoke are pushed up the chimney by the higher indoor pressure. Even on an apparently still night there is usually enough ambient air flow at the top of a chimney to assist upward flow of smoke.

**FIGURE 13–33** Bernoulli's principle explains air flow in underground burrows.

If gophers, prairie dogs, rabbits, and other animals that live underground are to avoid suffocation, the air must circulate in their burrows. The burrows always have at least two entrances (Fig. 13–33). The speed of air flow across different holes will usually be slightly different. This results in a slight pressure difference, which forces a flow of air through the burrow via Bernoulli's principle. The flow of air is enhanced if one hole is higher than the other (animals often build mounds) since wind speed tends to increase with height.

Bernoulli's equation ignores the effects of friction (viscosity) and the compressibility of the fluid. The energy that is transformed to internal (or potential) energy due to compression and to thermal energy by friction can be taken into account by adding terms to Eq. 13–8. These terms are difficult to calculate theoretically and are normally determined empirically for given situations. They do not significantly alter the explanations for the phenomena described above.

## 13–11 Viscosity

Real fluids have a certain amount of internal friction called **viscosity**, as mentioned in Section 13–8. Viscosity exists in both liquids and gases, and is essentially a frictional force between adjacent layers of fluid as the layers move past one another. In liquids, viscosity is due to the electrical cohesive forces between the molecules. In gases, it arises from collisions between the molecules.

The viscosity of different fluids can be expressed quantitatively by a *coefficient of viscosity*, $\eta$ (the Greek lowercase letter eta), which is defined in the following way. A thin layer of fluid is placed between two flat plates. One plate is stationary and the other is made to move, Fig. 13–34. The fluid directly in contact with each plate is held to the surface by the adhesive force between the molecules of the liquid and those of the plate. Thus the upper surface of the fluid moves with the same speed $v$ as the upper plate, whereas the fluid in contact with the stationary plate remains stationary. The stationary layer of fluid retards the flow of the layer just above it, which in turn retards the flow of the next layer, and so on. Thus the velocity varies continuously from 0 to $v$, as shown. The *increase* in velocity divided by the distance over which this change is made—equal to $v/\ell$—is called the **velocity gradient** $(= \Delta v/\ell = (v - 0)/\ell = v/\ell)$. To move the upper plate requires a force, which you can verify by moving a flat plate across a puddle of syrup on a table. For a given fluid, it is found that the force required, $F$, is proportional to the area of fluid in contact with each plate, $A$, and to the speed, $v$, and is inversely proportional to the separation, $\ell$, of the plates: $F \propto vA/\ell$. For different fluids, the more viscous the fluid, the greater is the required force. The proportionality constant for this equation is defined as the coefficient of viscosity, $\eta$:

$$F = \eta A \frac{v}{\ell}. \qquad \textbf{(13–11)}$$

Solving for $\eta$, we find $\eta = F\ell/vA$. The SI unit for $\eta$ is $\mathrm{N \cdot s/m^2 = Pa \cdot s}$ (pascal · second). In the cgs system, the unit is $\mathrm{dyne \cdot s/cm^2}$, which is called a *poise* (P). Viscosities are often given in centipoise $(1\,\mathrm{cP} = 10^{-2}\,\mathrm{P} = 10^{-3}\,\mathrm{Pa \cdot s})$. Table 13–3 lists the coefficient of viscosity for various fluids. The temperature is also specified, since it has a strong effect; the viscosity of liquids such as motor oil, for example, decreases rapidly as temperature increases.‡

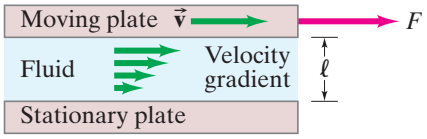

**FIGURE 13–34** Determination of viscosity.

**TABLE 13–3**
**Coefficients of Viscosity**

| Fluid (temperature in °C) | Coefficient of Viscosity, $\eta$ (Pa · s)† |
|---|---|
| Water (0°) | $1.8 \times 10^{-3}$ |
| (20°) | $1.0 \times 10^{-3}$ |
| (100°) | $0.3 \times 10^{-3}$ |
| Whole blood (37°) | $\approx 4 \times 10^{-3}$ |
| Blood plasma (37°) | $\approx 1.5 \times 10^{-3}$ |
| Ethyl alcohol (20°) | $1.2 \times 10^{-3}$ |
| Engine oil (30°) (SAE 10) | $200 \times 10^{-3}$ |
| Glycerine (20°) | $1500 \times 10^{-3}$ |
| Air (20°) | $0.018 \times 10^{-3}$ |
| Hydrogen (0°) | $0.009 \times 10^{-3}$ |
| Water vapor (100°) | $0.013 \times 10^{-3}$ |

†1 Pa · s = 10 poise (P) = 1000 cP.

## *13–12 Flow in Tubes: Poiseuille's Equation, Blood Flow

If a fluid had no viscosity, it could flow through a level tube or pipe without a force being applied. Viscosity acts like a sort of friction (between fluid layers moving at slightly different speeds), so a pressure difference between the ends of a level tube is necessary for the steady flow of any real fluid, be it water or oil in a pipe, or blood in the circulatory system of a human.

‡The Society of Automotive Engineers assigns numbers to represent the viscosity of oils: 30-weight (SAE 30) is more viscous than 10-weight. Multigrade oils, such as 20–50, are designed to maintain viscosity as temperature increases; 20–50 means the oil acts like 20-weight when cool and is like 50-weight when it is hot (engine running temperature). In other words, the viscosity does not drop precipitously as the oil warms up, as a simple 20-weight oil would.

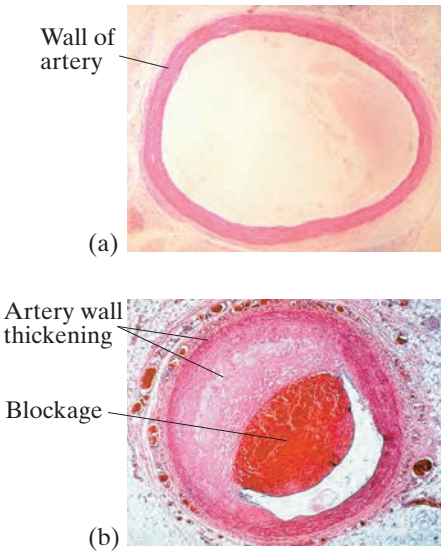

**FIGURE 13–35** A cross section of a human artery that (a) is healthy, (b) is partly blocked as a result of arteriosclerosis.

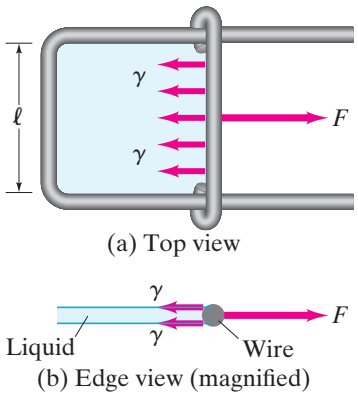
**PHYSICS APPLIED**

*Blood flow and heart disease*

The French scientist J. L. Poiseuille (1799–1869), who was interested in the physics of blood circulation (and after whom the "poise" is named), determined how the variables affect the flow rate of an incompressible fluid undergoing laminar flow in a cylindrical tube. His result, known as **Poiseuille's equation**, is:

$$Q = \frac{\pi R^4 (P_1 - P_2)}{8\eta\ell}, \qquad \textbf{(13–12)}$$

where $R$ is the inside radius of the tube, $\ell$ is the tube length, $P_1 - P_2$ is the pressure difference between the ends, $\eta$ is the coefficient of viscosity, and $Q$ is the volume rate of flow (volume of fluid flowing past a given point per unit time which in SI has units of $m^3/s$). Equation 13–12 applies only to laminar (streamline) flow.



Poiseuille's equation tells us that the flow rate $Q$ is directly proportional to the **pressure gradient**, $(P_1 - P_2)/\ell$, and it is inversely proportional to the viscosity of the fluid. This is just what we might expect. It may be surprising, however, that $Q$ also depends on the *fourth* power of the tube's radius. This means that for the same pressure gradient, if the tube radius is halved, the flow rate is decreased by a factor of 16! Thus the rate of flow, or alternately the pressure required to maintain a given flow rate, is greatly affected by only a small change in tube radius.

An interesting example of this $R^4$ dependence is *blood flow* in the human body. Poiseuille's equation is valid only for the streamline flow of an incompressible fluid. So it cannot be precisely accurate for blood whose flow is not without turbulence and that contains blood cells (whose diameter is almost equal to that of a capillary). Nonetheless, Poiseuille's equation does give a reasonable first approximation. Because the radius of arteries is reduced as a result of arteriosclerosis (thickening and hardening of artery walls, Fig. 13–35) and by cholesterol buildup, the pressure gradient must be increased to maintain the same flow rate. If the radius is reduced by half, the heart would have to increase the pressure by a factor of about $2^4 = 16$ in order to maintain the same blood-flow rate. The heart must work much harder under these conditions, but usually cannot maintain the original flow rate. Thus, high blood pressure is an indication both that the heart is working harder and that the blood-flow rate is reduced.

**FIGURE 13–36** Spherical water droplets, dew on a blade of grass.

**FIGURE 13–37** U-shaped wire apparatus holding a film of liquid to measure surface tension $(\gamma = F/2\ell)$.

# *13–13 Surface Tension and Capillarity

## *Surface Tension

The *surface* of a liquid at rest behaves in an interesting way, almost as if it were a stretched membrane under tension. For example, a drop of water on the end of a dripping faucet, or hanging from a thin branch in the early morning dew (Fig. 13–36), forms into a nearly spherical shape as if it were a tiny balloon filled with water. A steel needle can be made to float on the surface of water even though it is denser than the water. The surface of a liquid acts like it is under tension, and this tension, acting along the surface, arises from the attractive forces between the molecules. This effect is called **surface tension**. More specifically, a quantity called the *surface tension*, $\gamma$ (the Greek letter gamma), is defined as the force $F$ per unit length $\ell$ that acts perpendicular to any line or cut in a liquid surface, tending to pull the surface closed:

$$\gamma = \frac{F}{\ell}. \qquad \textbf{(13–13)}$$

To understand this, consider the U-shaped apparatus shown in Fig. 13–37 which encloses a thin film of liquid (such as a liquid soap film). Because of surface tension, a force $F$ is required to pull the movable wire and thus increase the surface area of the liquid. The liquid contained by the wire apparatus is a thin film having both a top and a bottom surface. Hence the total length of the surface being increased is $2\ell$, and the surface tension is $\gamma = F/2\ell$. A delicate apparatus of this type can be used to measure the surface tension of various liquids. The surface tension of water is 0.072 N/m at 20°C. Table 13–4 gives the values for several substances. Note that temperature has a considerable effect on the surface tension.

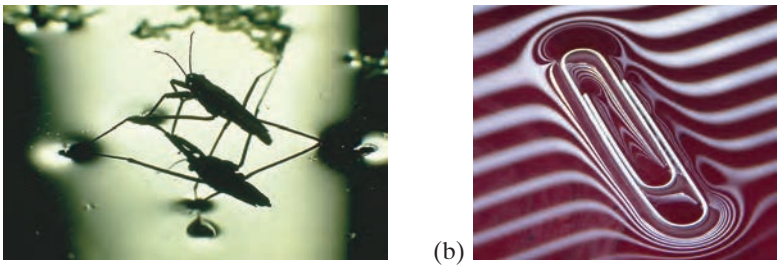


**FIGURE 13–38** (a) Water strider. (b) Paper clip (light coming through window blinds).

Because of surface tension, some insects (Fig. 13–38a) can walk on water, and objects more dense than water, such as a paper clip (Fig. 13–38b), can float on the surface. Figure 13–39a shows how the surface tension can support the weight $w$ of an object. Actually, the object sinks slightly into the fluid, so $w$ is the "effective weight" of that object—its true weight less the buoyant force.

**EXAMPLE 13–17** ESTIMATE **Insect walks on water.** The base of an insect's leg is approximately spherical in shape, with a radius of about $2.0 \times 10^{-5}$ m. The 0.0030-g mass of the insect is supported equally by its six legs. Estimate the angle $\theta$ at which the surface tension force acts (see Fig. 13–39) for an insect on the surface of water. Assume the water temperature is 20°C.

**APPROACH** Since the insect is in equilibrium, the upward surface tension force is equal to the pull of gravity downward on each leg. We ignore the buoyant force for this estimate.

**SOLUTION** For each leg, we assume the surface tension force acts all around a circle of radius $r$, at an angle $\theta$, as shown in Fig. 13–39a. Only the vertical component, $\gamma \cos\theta$, acts to balance the weight $mg$. We approximate the length $\ell$ in Eq. 13–13 as the circumference of the circle, $\ell \approx 2\pi r$. Then the net upward force due to surface tension is $F_y \approx (\gamma \cos\theta)\ell \approx 2\pi r\gamma \cos\theta$. We set this surface tension force equal to one-sixth the weight of the insect since it has six legs:

$$\begin{aligned} 2\pi r\gamma \cos\theta &\approx \tfrac{1}{6}mg \\ (6.28)\,(2.0 \times 10^{-5}\,\text{m})\,(0.072\,\text{N/m})\cos\theta &\approx \tfrac{1}{6}(3.0 \times 10^{-6}\,\text{kg})\,(9.8\,\text{m/s}^2) \\ \cos\theta &\approx 0.54. \end{aligned}$$

So $\theta \approx 57°$.

**NOTE** If $\cos\theta$ had come out greater than 1, the surface tension would not have been great enough to support the insect's weight. If the insect is very light, it will sink less into the water and $\theta$ (Fig. 13–39a) will be larger than calculated above.

**NOTE** Our estimate ignored the buoyant force and ignored any difference between the radius of the insect's "foot" and the radius of the surface depression.

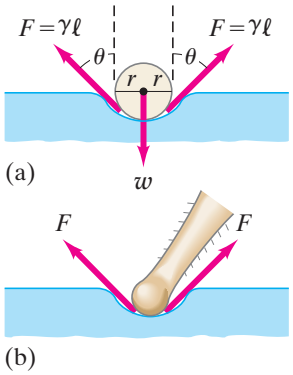
Soaps and detergents lower the surface tension of water. This is desirable for washing and cleaning since the high surface tension of pure water prevents it from penetrating easily between the fibers of material and into tiny crevices. Substances that reduce the surface tension of a liquid are called *surfactants*.

## *Capillarity

Surface tension plays a role in another interesting phenomenon, *capillarity*. It is a common observation that water in a glass container rises up slightly where it touches the glass, Fig. 13–40a. The water is said to "wet" the glass. Mercury, on the other hand, is depressed when it touches the glass, Fig. 13–40b; the mercury does not wet the glass. Whether a liquid wets a solid surface is determined by the relative strength of the cohesive forces between the molecules of the liquid compared to the adhesive forces between the molecules of the liquid and those of the container. **Cohesion** refers to the force between molecules of the same type, whereas **adhesion** refers to the force between molecules of different types.

**TABLE 13–4 Surface Tension of Some Substances**

| Substance | Surface Tension (N/m) |
|---|---|
| Mercury (20°C) | 0.44 |
| Blood, whole (37°C) | 0.058 |
| Blood, plasma (37°C) | 0.073 |
| Alcohol, ethyl (20°C) | 0.023 |
| Water (0°C) | 0.076 |
| (20°C) | 0.072 |
| (100°C) | 0.059 |
| Benzene (20°C) | 0.029 |
| Soap solution (20°C) | ≈0.025 |
| Oxygen (−193°C) | 0.016 |



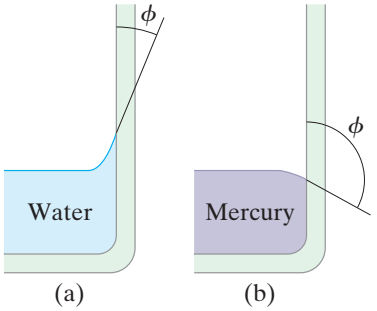


**FIGURE 13–39** Surface tension acting on (a) a sphere, and (b) an insect leg. Example 13–17.

PHYSICS APPLIED
*Soaps and detergents*

**FIGURE 13–40** (a) Water "wets" the surface of glass, whereas (b) mercury does not "wet" the glass.

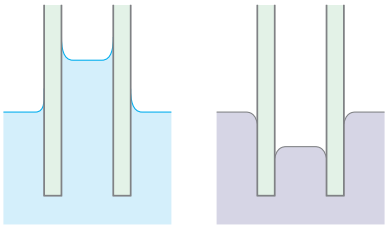

**FIGURE 13–41** Capillarity.

Water wets glass because the water molecules are more strongly attracted to the glass molecules than they are to other water molecules. The opposite is true for mercury: the cohesive forces are stronger than the adhesive forces.

In tubes having very small diameters, liquids are observed to rise or fall relative to the level of the surrounding liquid. This phenomenon is called **capillarity**, or **capillary action**, and such thin tubes are called **capillaries**. Whether the liquid rises or falls (Fig. 13–41) depends on the relative strengths of the adhesive and cohesive forces. Thus water rises in a glass tube, whereas mercury falls. The actual amount of rise (or fall) depends on the surface tension—which is what keeps the liquid surface from breaking apart.

# 13–14 Pumps, and the Heart

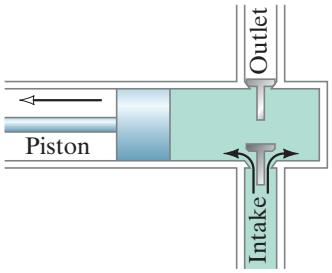
We conclude this Chapter with a brief discussion of pumps, including the heart. Pumps can be classified into categories according to their function. A *vacuum pump* is designed to reduce the pressure (usually of air) in a given vessel. The best vacuum attainable in the laboratory today is on the order of $10^{-14}$ atm.

A *force pump*, on the other hand, is a pump that is intended to increase the pressure—for example, to lift a liquid (such as water from a well) or to push a fluid through a pipe.

Figure 13–42 illustrates the principle behind a simple reciprocating pump. It could be a vacuum pump, in which case the intake is connected to the vessel to be evacuated. A similar mechanism is used in some force pumps, and in this case the fluid is forced under increased pressure through the outlet.

Another type of pump is the centrifugal pump, shown in Fig. 13–43. It, or any force pump, can be used as a *circulating pump*—that is, to circulate a fluid around a closed path, such as the cooling water or lubricating oil in an automobile.

**FIGURE 13–42** One kind of pump (reciprocating type): the intake valve opens and air (or fluid that is being pumped) fills the empty space when the piston moves to the left. When the piston moves to the right (not shown), the outlet valve opens and fluid is forced out.



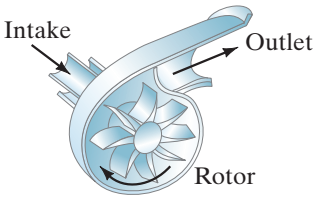


**FIGURE 13–43** Centrifugal pump: the rotating blades force fluid through the outlet pipe; this kind of pump is used in vacuum cleaners and as a water pump in automobiles.

**PHYSICS APPLIED**
*Heart as a pump*

The heart of a human (and of other animals as well) is essentially a circulating pump. The action of a human heart is shown in Fig. 13–44. There are actually two separate paths for blood flow. The longer path takes blood to the parts of the body, via the arteries, bringing oxygen to body tissues and picking up carbon dioxide,

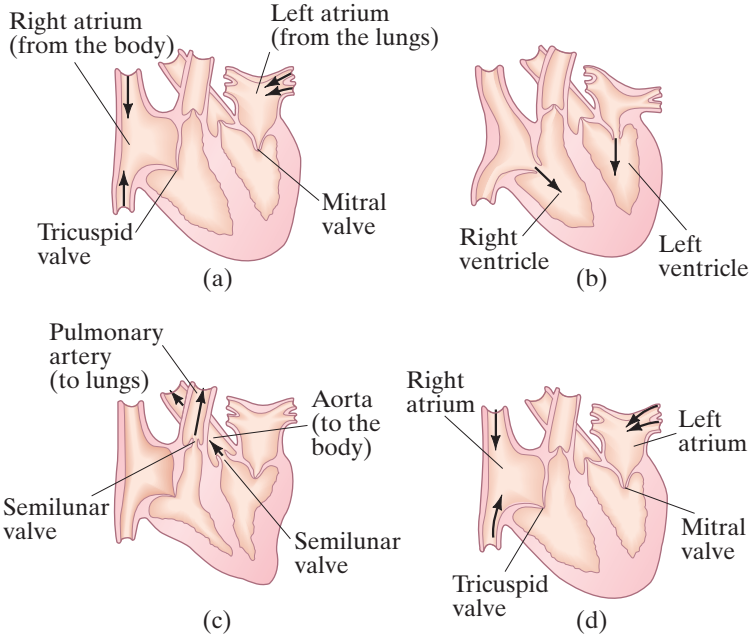

**FIGURE 13–44** Pumping human heart. (a) In the diastole phase, the heart relaxes between beats. Blood moves into the heart; both atria fill rapidly. (b) When the atria contract, the systole or pumping phase begins. The contraction pushes the blood through the mitral and tricuspid valves into the ventricles. (c) The contraction of the ventricles forces the blood through the semilunar valves into the pulmonary artery, which leads to the lungs, and to the aorta (the body's largest artery), which leads to the arteries serving all the body. (d) When the heart relaxes, the semilunar valves close; blood fills the atria, beginning the cycle again.

which it carries back to the heart via veins. This blood is then pumped to the lungs (the second path), where the carbon dioxide is released and oxygen is taken up. The oxygen-laden blood is returned to the heart, where it is again pumped to the tissues of the body.

Blood pressure is measured using one of the types of gauge mentioned earlier (Section 13–6), and it is usually calibrated in mm-Hg. The gauge is attached to a closed, air-filled cuff that is wrapped around the upper arm at the level of the heart, Fig. 13–45. Two values of blood pressure are measured: the maximum pressure when the heart is pumping, called *systolic pressure*; and the pressure when the heart is in the resting part of the cycle, called *diastolic pressure*. Initially, the air pressure in the cuff is increased high above the systolic pressure by a pump, compressing the main (brachial) artery in the arm and briefly cutting off the flow of blood. The cuff pressure is then reduced slowly until blood again begins to flow into the arm; it can be detected by listening with a stethoscope to the characteristic tapping sound[†] of the blood returning to the forearm. At this point, systolic pressure is just equal to the air pressure in the arm cuff which can be read off the gauge. The cuff pressure is subsequently reduced further, and the tapping sound disappears when blood at low pressure can enter the artery. At this point, the gauge indicates the diastolic pressure. Normal systolic pressure is around 120 mm-Hg, whereas normal diastolic pressure is around 70 or 80 mm-Hg. Blood pressure is reported in the form 120/70. This is the technique that many doctors still use. Naturally there are digital devices, as readout and also to detect the turbulence or tapping sound.

**PHYSICS APPLIED**
*Blood pressure*

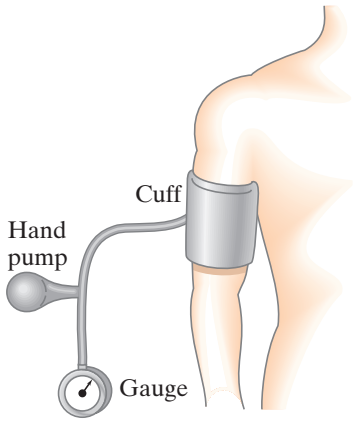

**FIGURE 13–45** Device for measuring blood pressure.

[†]When the blood starts flowing through the constriction caused by the tight cuff, its velocity is high and the flow is turbulent. It is the turbulence that causes the tapping sound.

# Summary

The three common phases of matter are **solid**, **liquid**, and **gas**. Liquids and gases are collectively called **fluids**, meaning they have the ability to flow. The **density** of a material is defined as its mass per unit volume:

$$\rho = \frac{m}{V}. \qquad \textbf{(13–1)}$$

**Specific gravity** (**SG**) is the ratio of the density of the material to the density of water (at 4°C).

**Pressure** is defined as force per unit area:

$$P = \frac{F}{A}. \qquad \textbf{(13–2)}$$

The pressure $P$ at a depth $h$ in a liquid of constant density $\rho$, due to the weight of the liquid, is given by

$$P = \rho g h, \qquad \textbf{(13–3)}$$

where $g$ is the acceleration due to gravity. If $P_0$ = atmospheric pressure at the surface of the liquid, then the **absolute pressure** is $P = P_0 + \rho g h$, and $\rho g h$ represents the **gauge pressure**.

If the density of a fluid is not uniform, the pressure $P$ varies with height $y$ as

$$\frac{dP}{dy} = -\rho g. \qquad \textbf{(13–4)}$$

**Pascal's principle** says that an external pressure applied to a confined fluid is transmitted throughout the fluid.

Pressure is measured using a manometer or other type of gauge. A **barometer** is used to measure atmospheric pressure. **Standard atmospheric pressure** (average at sea level) is $1.013 \times 10^5\ \text{N/m}^2$.

**Archimedes' principle** states that an object submerged wholly or partially in a fluid is buoyed up by a force equal to the weight of fluid it displaces $(F_B = m_F g = \rho_F V_{\text{displ}} g)$.

Fluid flow can be characterized either as **streamline** (also called **laminar**), in which the layers of fluid move smoothly and regularly along paths called **streamlines**, or as **turbulent**, in which case the flow is not smooth and regular but is characterized by irregularly shaped whirlpools.

Fluid flow rate is the mass or volume of fluid that passes a given point per unit time. The **equation of continuity** states that for an incompressible fluid flowing in an enclosed tube, the product of the velocity of flow and the cross-sectional area of the tube remains constant:

$$Av = \text{constant}. \qquad \textbf{(13–7b)}$$

**Bernoulli's principle** tells us that where the velocity of a fluid is high, the pressure in it is low, and where the velocity is low, the pressure is high. For steady laminar flow of an incompressible and nonviscous fluid, **Bernoulli's equation**, which is based on the law of conservation of energy, is

$$P_2 + \tfrac{1}{2}\rho v_2^2 + \rho g y_2 = P_1 + \tfrac{1}{2}\rho v_1^2 + \rho g y_1, \qquad \textbf{(13–8)}$$

for two points along the flow.

**Viscosity** refers to friction within a fluid and is essentially a frictional force between adjacent layers of fluid as they move past one another.

[*Liquid surfaces hold together as if under tension (**surface tension**), allowing drops to form and objects like needles and insects to stay on the surface.]

# Questions

1. If one material has a higher density than another, must the molecules of the first be heavier than those of the second? Explain.
2. Airplane travelers sometimes note that their cosmetics bottles and other containers have leaked during a flight. What might cause this?
3. The three containers in Fig. 13–46 are filled with water to the same height and have the same surface area at the base; hence the water pressure, and the total force on the base of each, is the same. Yet the total weight of water is different in each container. Explain this "hydrostatic paradox."

**FIGURE 13–46**
Question 3.

4. Consider what happens when you push both a pin and the blunt end of a pen against your skin with the same force. Decide what determines whether your skin is cut—the net force applied to it or the pressure. Explain.
5. A small amount of water is boiled in a 1-gallon metal can. The can is removed from the heat and the lid screwed on. As the can cools, it collapses and looks crushed. Explain.
6. When blood pressure is measured, why must the arm cuff be held at the level of the heart?
7. An ice cube floats in a glass of water filled to the brim. What can you say about the density of ice? As the ice melts, will the water overflow? Explain.
8. Will an ice cube float in a glass of alcohol? Why or why not?
9. A submerged can of Coke® will sink, but a can of Diet Coke® will float. (Try it!) Explain.
10. When submerged in water, two objects with different volumes have the same *apparent* weight. When taken out of water, compare their weights in air. Which object has the greater density? Explain.
11. Explain how the tube in Fig. 13–47, known as a **siphon**, can transfer liquid from one container to a lower one even though the liquid must flow uphill for part of its journey. (Note that the tube must be filled with liquid to start with.)

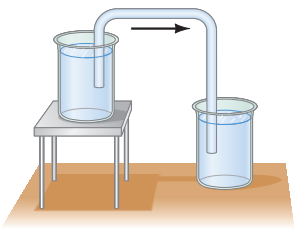

**FIGURE 13–47**
Question 11. A siphon.

12. A barge filled high with sand approaches a low bridge over the river and cannot quite pass under it. Should sand be added to, or removed from, the barge? [*Hint*: Consider Archimedes' principle.]
13. Explain why helium weather balloons, which are used to measure atmospheric conditions at high altitudes, are normally released from the ground while filled to only 10–20% of their maximum volume.
14. A row boat floats in a swimming pool, and the level of the water at the edge of the pool is marked. Consider the following situations and explain whether the *level of the water* will rise, fall, or stay the same. (*a*) The boat is removed from the water. (*b*) The boat in the water holds an iron anchor which is removed from the boat and placed on the shore. (*c*) The iron anchor is removed from the boat and dropped in the pool.
15. Will an empty balloon have precisely the same apparent weight on a scale as a balloon filled with air? Explain.
16. Why do you float higher in salt water than in fresh water?
17. If you dangle two pieces of paper vertically, a few inches apart (Fig. 13–48), and blow between them, how do you think the papers will move? Try it and see. Explain.

**FIGURE 13–48**
Question 17.

18. Why does the stream of water from a faucet become narrower as it falls (Fig. 13–49)?

**FIGURE 13–49**
Question 18. Water coming from a faucet.

19. Children are told to avoid standing too close to a rapidly moving train because they might get sucked under it. Is this possible? Explain.
20. What approximations are made in the derivation of Bernoulli's equation? Qualitatively, how do you think Bernoulli's equation would change if each of these approximations was not made?
21. A tall Styrofoam cup is filled with water. Two holes are punched in the cup near the bottom, and water begins rushing out. If the cup is dropped so it falls freely, will the water continue to flow from the holes? Explain.
22. Why do airplanes normally take off into the wind?
23. Two ships moving in parallel paths close to one another risk colliding. Why?
24. Why does the canvas top of a convertible bulge out when the car is traveling at high speed? [*Hint*: The windshield deflects air upward, pushing streamlines closer together.]
25. Roofs of houses are sometimes "blown" off (or are they pushed off?) during a tornado or hurricane. Explain using Bernoulli's principle.

# MisConceptual Questions

1. You hold a piece of wood in one hand and a piece of iron in the other. Both pieces have the same volume, and you hold them fully under water at the same depth. At the moment you let go of them, which one experiences the greater buoyant force?
   (*a*) The piece of wood.
   (*b*) The piece of iron.
   (*c*) They experience the same buoyant force.
   (*d*) More information is needed.

2. Three containers are filled with water to the same height and have the same surface area at the base, but the total weight of water is different for each (Fig. 13–50). In which container does the water exert the greatest force on the bottom of the container?
   (*a*) Container A.
   (*b*) Container B.
   (*c*) Container C.
   (*d*) All three are equal.

**FIGURE 13–50**
MisConceptual Question 2.

3. A jar is completely filled with water, and then it is sealed with a flexible lid. If you push down on the lid with a force equal to 1000 Pa times the area of the lid, what happens to the water pressure at the bottom of the jar?
   (*a*) It remains unchanged.
   (*b*) It increases by 1000 Pa.
   (*c*) It increases by more than 1000 Pa.
   (*d*) It increases by an amount dependent on the height of the jar.
   (*e*) It increases by less than 1000 Pa.

4. Beaker A is filled to the brim with water. Beaker B is the same size and contains a small block of wood which floats when the beaker is filled with water to the brim. Which beaker weighs more?
   (*a*) Beaker A.
   (*b*) Beaker B.
   (*c*) The same for both.

5. Which of the following objects, submerged in water, experiences the largest magnitude of the buoyant force?
   (*a*) A 1-kg helium balloon.
   (*b*) 1 kg of wood.
   (*c*) 1 kg of ice.
   (*d*) 1 kg of iron.
   (*e*) All the same.

6. Why does an ocean liner float?
   (*a*) It is made of steel, which floats.
   (*b*) Its very big size means it is more buoyant.
   (*c*) It is held up in the water by large styrofoam compartments.
   (*d*) Air: the average density of the ocean liner is less than that of seawater.
   (*e*) Remember the *Titanic*—ocean liners do not float.

7. You put two ice cubes in a glass and fill the glass to the rim with water. As the ice melts, the water level
   (*a*) drops below the rim.
   (*b*) rises and water spills out of the glass.
   (*c*) remains the same.
   (*d*) drops at first, then rises until a little water spills out.

8. A mylar ballon (the kind that doesn't stretch much as more pressure is added) is filled with helium. If the amount of helium in the balloon is now doubled, how will the force needed to hold the balloon down change?
   (*a*) It will stay the same.
   (*b*) It will increase a bit.
   (*c*) It will decrease a bit.

9. Hot air is less dense than cold air. Could a hot-air balloon be flown on the Moon, where there is no atmosphere?
   (*a*) No, there is no air to displace, so no buoyancy force would exist.
   (*b*) Yes, warm air always rises, especially in a weak gravitational field like that of the Moon.
   (*c*) Yes, but the balloon would have to be filled with helium instead of hot air.

10. An object that can float in both water and in oil (whose density is less than that of water) experiences a buoyant force that is
    (*a*) greater when it is floating in oil than when floating in water.
    (*b*) greater when it is floating in water than when floating in oil.
    (*c*) the same when it is floating in water or in oil.

11. A piece of wood is floating in a tub of water. A second piece of wood rests on top of the first piece; it does not touch the water. If the second piece is removed from the first and placed in the water, what happens to the water level in the tub?
    (*a*) The water level cannot be determined without additional information.
    (*b*) The water level drops.
    (*c*) The water level rises.
    (*d*) The water level remains unchanged.

12. Water flows in a horizontal pipe that is narrow but then widens and the speed of the water becomes less. The pressure in the water moving in the pipe is
    (*a*) greater in the wide part.
    (*b*) greater in the narrow part.
    (*c*) the same in both parts.
    (*d*) greater where the speed is higher.
    (*e*) greater where the speed is lower.

13. When a baseball curves to the right (a curveball), air is flowing
    (*a*) faster over the left side than over the right side.
    (*b*) faster over the right side than over the left side.
    (*c*) faster over the top than underneath.
    (*d*) at the same speed all around the baseball, but the ball curves as a result of the way the wind is blowing on the field.

14. How is the smoke drawn up a chimney affected when a wind is blowing outside?
    (*a*) Smoke rises more rapidly in the chimney.
    (*b*) Smoke rises more slowly in the chimney.
    (*c*) Smoke is forced back down the chimney.
    (*d*) Smoke is unaffected.

# Problems

## 13–2 Density and Specific Gravity

**1.** (I) The approximate volume of the granite monolith known as El Capitan in Yosemite National Park (Fig. 13–51) is about $10^8\ m^3$. What is its approximate mass?

**FIGURE 13–51** Problem 1.

**2.** (I) What is the approximate mass of air in a living room $5.6\ m \times 4.6\ m \times 2.4\ m$?

**3.** (I) If you tried to smuggle gold bricks by filling your backpack, whose dimensions are $54\ cm \times 31\ cm \times 22\ cm$, what would its mass be?

**4.** (II) If 4.0 L of antifreeze solution (specific gravity = 0.80) is added to 5.0 L of water to make a 9.0-L mixture, what is the specific gravity of the mixture?

**5.** (II) A bottle has a mass of 32.00 g when empty and 98.44 g when filled with water. When filled with another fluid, the mass is 89.22 g. What is the specific gravity of this other fluid?

**6.** (III) The Earth is not a uniform sphere, but has regions of varying density. Consider a simple model of the Earth divided into three regions—inner core, outer core, and mantle. Let us assume each region has a constant density (the average density of that region in the real Earth):

| Region | Radius (km) | Density $(kg/m^3)$ |
|---|---|---|
| Inner Core | 0–1220 | 13,000 |
| Outer Core | 1220–3480 | 11,100 |
| Mantle | 3480–6380 | 4400 |

(*a*) Use this model to predict the average density of the entire Earth. (*b*) If the radius of the Earth is 6380 km and its mass is $5.98 \times 10^{24}$ kg, determine the actual average density of the Earth and compare it (as a percent difference) with the one you determined in (*a*).

## 13–3 to 13–6 Pressure; Pascal's Principle

**7.** (I) Estimate the pressure exerted on a floor by (*a*) one pointed heel of area $= 0.45\ cm^2$, and (*b*) one wide heel of area $18\ cm^2$, Fig. 13–52. The person wearing the shoes has a mass of 56 kg.

**FIGURE 13–52** Problem 7.

**8.** (I) Estimate the pressure needed to raise a column of water to the same height as a 46-m-tall pine tree.

**9.** (I) (*a*) Calculate the total force of the atmosphere acting on the top of a table that measures $1.7\ m \times 2.6\ m$. (*b*) What is the total force acting upward on the underside of the table?

**10.** (I) What is the difference in blood pressure (mm-Hg) between the top of the head and bottom of the feet of a 1.75-m-tall person standing vertically?

**11.** (II) How high would the level be in an alcohol barometer at normal atmospheric pressure?

**12.** (II) In a movie, Tarzan evades his captors by hiding underwater for many minutes while breathing through a long, thin reed. Assuming the maximum pressure difference his lungs can manage and still breathe is −88 mm-Hg, calculate the deepest he could have been.

**13.** (II) The recommended tire pressure for a particular car is 220 kPa. If the mass of the car is 1250 kg, what area of each tire must be in contact with the road? Assume the car's weight is evenly distributed among all 4 tires.

**14.** (II) The gauge pressure in each of the four tires of an automobile is 240 kPa. If each tire has a "footprint" of $190\ cm^2$ (area touching the ground), estimate the mass of the car.

**15.** (II) (*a*) Determine the total force and the absolute pressure on the bottom of a swimming pool 24.0 m by 8.5 m whose uniform depth is 1.8 m. (*b*) What will be the absolute pressure against the *side* of the pool near the bottom?

**16.** (II) A house at the bottom of a hill is fed by a full tank of water 6.0 m deep and connected to the house by a pipe that is 75 m long at an angle of 61° from the horizontal (Fig. 13–53). (*a*) Determine the water gauge pressure at the house. (*b*) How high could the water shoot if it came vertically out of a broken pipe in front of the house?

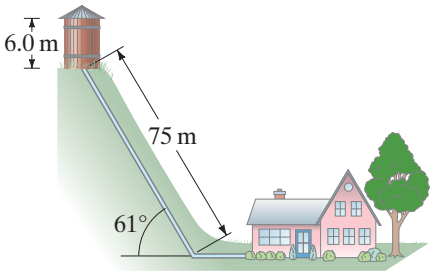

**FIGURE 13–53** Problem 16.

**17.** (II) Water and then oil (which don't mix) are poured into a U-shaped tube, open at both ends. They come to equilibrium as shown in Fig. 13–54. What is the density of the oil? [*Hint*: Pressures at points a and b are equal. Why?]

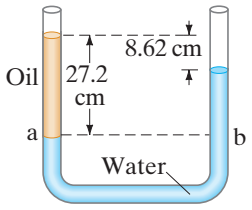

**FIGURE 13–54** Problem 17.

**18.** (II) While exploring a sunken ocean liner, a small robot submarine measured the absolute pressure at the level of the ship to be 413 atmospheres. (*a*) Calculate the depth *D* of the sunken ocean liner. (*b*) Calculate the magnitude of the force due to the water on a viewing port of the submarine at this depth if the viewing port has a surface area of $0.0100\ m^2$.

19. (II) Determine the minimum gauge pressure needed in the water pipe leading into a building if water is to come out of a faucet on the fourteenth floor, 44 m above that pipe.

20. (II) A **hydraulic press** for compacting powdered samples has a large cylinder which is 10.0 cm in diameter, and a small cylinder with a diameter of 2.0 cm (Fig. 13–55). A lever is attached to the small cylinder as shown. The sample, which is placed on the large cylinder, has an area of 4.0 $cm^2$. What is the pressure on the sample if 320 N is applied to the lever?

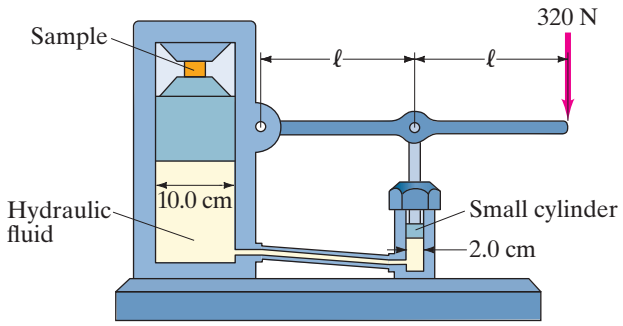

**FIGURE 13–55** Problem 20.

21. (II) An open-tube mercury manometer is used to measure the pressure in an oxygen tank. When the atmospheric pressure is 1040 mbar, what is the absolute pressure (in Pa) in the tank if the height of the mercury in the open tube is (*a*) 18.5 cm higher, (*b*) 7.6 cm lower, than the mercury in the tube connected to the tank? See Fig. 13–10a.

22. (III) A beaker of liquid accelerates from rest, on a horizontal surface, with acceleration $a$ to the right. (*a*) Show that the surface of the liquid makes an angle $\theta = \tan^{-1}(a/g)$ with the horizontal. (*b*) Which edge of the water surface is higher? (*c*) How does the pressure vary with depth below the surface?

23. (III) Water stands at a height $h$ behind a vertical dam of uniform width $b$. (*a*) Use integration to show that the total force of the water on the dam is $F = \frac{1}{2}\rho g h^2 b$. (*b*) Show that the torque about the base of the dam due to this force can be considered to act with a lever arm equal to $h/3$. (*c*) A concrete dam of uniform thickness $t$ and height $h$ is unfortunately "freestanding"—that is, not anchored. What minimum thickness is needed to prevent overturning? Do you need to add in atmospheric pressure for this last part? Explain.

24. (III) Estimate the density of the water 5.4 km deep in the sea. (See Table 12–1 and Section 12–5 regarding bulk modulus.) By what fraction does it differ from the density at the surface?

25. (III) A cylindrical bucket of liquid (density $\rho$) is rotated about its symmetry axis, which is vertical. If the angular velocity is $\omega$, show that the pressure at a distance $r$ from the rotation axis is

$$P = P_0 + \tfrac{1}{2}\rho\omega^2 r^2,$$

where $P_0$ is the pressure at $r = 0$.

## 13–7 Buoyancy and Archimedes' Principle

26. (I) What fraction of a piece of iron will be submerged when it floats in mercury?

27. (II) A geologist finds that a Moon rock whose mass is 8.94 kg has an apparent mass of 6.18 kg when submerged in water. What is the density of the rock?

28. (II) A crane lifts the 21,000-kg steel hull of a sunken ship out of the water. Determine (*a*) the tension in the crane's cable when the hull is fully submerged in the water, and (*b*) the tension when the hull is completely out of the water.

29. (II) A spherical balloon has a radius of 7.15 m and is filled with helium. How large a cargo can it lift, assuming that the skin and structure of the balloon have a mass of 890 kg? Neglect the buoyant force on the cargo volume itself.

30. (II) A partially filled cylindrical container with an interior diameter of 52 mm is floating upright in water. The container is removed from the water and some of the contents removed. When the container is replaced in the water, it floats 28 mm higher than it did before. How much mass was removed from the container?

31. (II) The specific gravity of ice is 0.917, whereas that of seawater is 1.025. What percent of an iceberg is above the surface of the water?

32. (II) Calculate the true mass (in vacuum) of an aluminum sphere whose apparent mass is 4.0000 kg when weighed in air.

33. (II) A 32-kg child decides to make a raft out of empty 1.0-L water bottles and duct tape. Neglecting the mass of the duct tape and plastic in the bottles, what minimum number of water bottles will the child need to be able to stay dry on the raft?

34. (II) Archimedes' principle can be used not only to determine the specific gravity of a solid using a known liquid (Example 13–10). The reverse can be done as well. (*a*) As an example, a 3.80-kg aluminum ball has an apparent mass of 2.10 kg when submerged in a particular liquid: calculate the density of the liquid. (*b*) Determine a formula for finding the density of a liquid using this procedure.

35. (II) An undersea research chamber is spherical with an external diameter of 5.20 m. The mass of the chamber, when occupied, is 74,400 kg. It is anchored to the sea bottom by a cable. What is (*a*) the buoyant force on the chamber, and (*b*) the tension in the cable?

36. (II) A 0.48-kg piece of wood floats in water but is found to sink in alcohol (SG = 0.79), in which it has an apparent mass of 0.047 kg. What is the SG of the wood?

37. (II) A simple model used to determine percent body fat in a human body assumes that a fraction $f$ ($< 1$) of the body's total mass $m$ is composed of fat with a density of 0.90 $g/cm^3$, and that the remaining mass of the body is composed of fat-free tissue and bone with a density of 1.10 $g/cm^3$. If the specific gravity of the entire body's density is measured to be $X$, show that the percent body fat ($= f \times 100$) is given by

$$\%\ \text{Body fat} = \frac{495}{X} - 450.$$

38. (II) On dry land, an athlete weighs 70.2 kg. The same athlete, when submerged in a swimming pool and hanging from a scale, has an "apparent weight" of 3.4 kg. Using Example 13–10 as a guide, (*a*) find the total volume $V$ of the submerged athlete. (*b*) Assume that when submerged, the athlete's body contains a residual volume $V_R = 1.3 \times 10^{-3}\ m^3$ of air (mainly in the lungs). Taking $V - V_R$ to be the actual volume of the athlete's body, find the body's specific gravity, SG. (*c*) What is the athlete's percent body fat assuming it is given by the formula (495/SG) − 450?

39. (II) How many helium-filled balloons would it take to lift a person? Assume the person has a mass of 72 kg and that each helium-filled balloon is spherical with a diameter of 36 cm.

**40.** (II) A cube of side length 10.0 cm and made of unknown material floats at the surface between water and oil. The oil has a density of 810 kg/m$^3$. If the cube floats so that it is 72% in the water and 28% in the oil, what is the mass of the cube and what is the buoyant force on the cube?

**41.** (II) A scuba tank, when fully submerged, displaces 15.7 L of seawater. The tank itself has a mass of 14.0 kg and, when "full," contains 3.00 kg of air. Assuming only its weight and the buoyant force act on the tank, determine the net force (magnitude and direction) on the fully submerged tank at the beginning of a dive (when it is full of air) and at the end of a dive (when it no longer contains any air).

**42.** (III) If an object floats in water, its density can be determined by tying a sinker to it so that both the object and the sinker are submerged. Show that the specific gravity is given by $w/(w_1 - w_2)$, where $w$ is the weight of the object alone in air, $w_1$ is the apparent weight when a sinker is tied to it and the sinker only is submerged, and $w_2$ is the apparent weight when both the object and the sinker are submerged.

**43.** (III) A 3.75-kg block of wood (SG = 0.50) floats on water. What minimum mass of lead, hung from the wood by a string, will cause the block to sink?

## 13–8 to 13–10 Fluid Flow, Bernoulli's Equation

**44.** (I) Calculate the average speed of blood flow in the major arteries of the body, which have a total cross-sectional area of about 2.0 cm$^2$. Use the data of Example 13–14.

**45.** (I) A 12-cm-radius air duct is used to replenish the air of a room 8.2 m × 4.5 m × 3.5 m every 12 min. How fast does the air flow in the duct?

**46.** (I) How fast does water flow from a hole at the bottom of a very wide, 5.1-m-deep storage tank filled with water? Ignore viscosity.

**47.** (II) What is the volume rate of flow of water from a 1.85-cm-diameter faucet if the pressure head is 12.0 m?

**48.** (II) A fish tank has dimensions 36 cm wide by 1.0 m long by 0.60 m high. If the filter should process all the water in the tank once every 2.5 h, what should the flow speed be in the 3.0-cm-diameter input tube for the filter?

**49.** (II) A 180-km/h wind blowing over the flat roof of a house causes the roof to lift off the house. If the house is 6.2 m × 12.4 m in size, estimate the weight of the roof. Assume the roof is not nailed down.

**50.** (II) A $\frac{5}{8}$-in. (inside) diameter garden hose is used to fill a round swimming pool 6.1 m in diameter. How long will it take to fill the pool to a depth of 1.4 m if water flows from the hose at a speed of 0.40 m/s?

**51.** (II) Estimate the air pressure inside a category 5 hurricane, where the wind speed is 300 km/h (Fig. 13–56).

**FIGURE 13–56**
Problem 51.

**52.** (II) A 6.0-cm-diameter horizontal pipe gradually narrows to 4.5 cm. When water flows through this pipe at a certain rate, the gauge pressure in these two sections is 36.5 kPa and 22.6 kPa, respectively. What is the volume rate of flow?

**53.** (II) Show that the power needed to drive a fluid through a pipe with uniform cross-section is equal to the volume rate of flow, $Q$, times the pressure difference, $P_1 - P_2$. Ignore viscosity.

**54.** (II) What is the lift (in newtons) due to Bernoulli's principle on a wing of area 82 m$^2$ if the air passes over the top and bottom surfaces at speeds of 280 m/s and 150 m/s, respectively?

**55.** (II) Water at a gauge pressure of 3.8 atm at street level flows into an office building at a speed of 0.78 m/s through a pipe 5.0 cm in diameter. The pipe tapers down to 2.8 cm in diameter by the top floor, 16 m above (Fig. 13–57), where the faucet has been left open. Calculate the flow velocity and the gauge pressure in the pipe on the top floor. Assume no branch pipes and ignore viscosity.

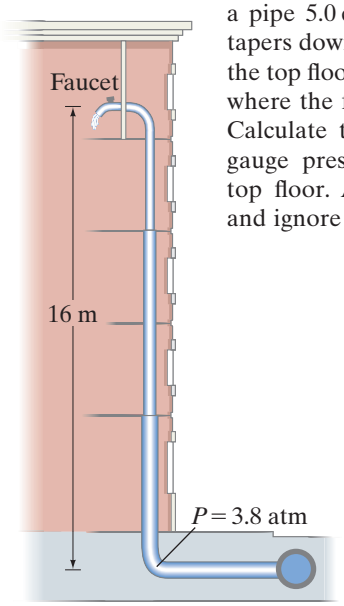

**FIGURE 13–57**
Problem 55.

**56.** (II) In Fig. 13–58, take into account the speed of the top surface of the tank and show that the speed of fluid leaving an opening near the bottom is (compare Eq. 13-9)

$$v_1 = \sqrt{\frac{2gh}{(1 - A_1^2/A_2^2)}},$$

where $h = y_2 - y_1$, and $A_1$ and $A_2$ are the areas of the opening and of the top surface, respectively. Assume $A_1 \ll A_2$ so that the flow remains nearly steady and laminar.

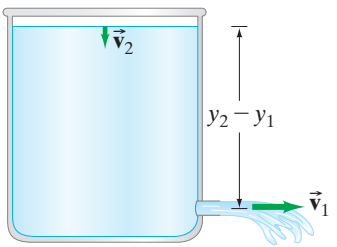

**FIGURE 13–58**
Problems 56, 57, and 58.

**57.** (II) Suppose the top surface of the vessel in Fig. 13–58 is subjected to an external pressure $P_2$ in addition to atmospheric pressure $P_0$. (*a*) Derive a formula for the speed, $v_1$, at which the liquid flows from the opening at the bottom into atmospheric pressure, $P_0$. Assume the velocity of the liquid surface, $v_2$, is approximately zero. (*b*) If $P_2 = 0.85$ atm and $y_2 - y_1 = 2.4$ m, determine $v_1$ for water.

**58.** (III) (*a*) In Fig. 13–58, show that Bernoulli's principle predicts that the level of the liquid, $h = y_2 - y_1$, drops at a rate

$$\frac{dh}{dt} = -\sqrt{\frac{2ghA_1^2}{A_2^2 - A_1^2}},$$

where $A_1$ and $A_2$ are the areas of the opening and the top surface, respectively, assuming $A_1 \ll A_2$, and viscosity is ignored. (*b*) Determine $h$ as a function of time by integrating. Let $h = h_0$ at $t = 0$. (*c*) How long would it take to empty a 10.6-cm-tall cylinder filled with 1.3 L of water if the opening is at the bottom and has a 0.50-cm diameter? Do not assume $v_2 = 0$.

**59.** (III) *Thrust of a rocket.* (*a*) Use Bernoulli's equation and the equation of continuity to show that the emission speed of the propelling gases of a rocket is

$$v = \sqrt{2(P - P_0)/\rho},$$

where $\rho$ is the density of the gas, $P$ is the pressure of the gas inside the rocket, and $P_0$ is atmospheric pressure just outside the exit orifice. Assume that the gas density stays approximately constant, and that the area of the exit orifice, $A_0$, is much smaller than the cross-sectional area, $A$, of the inside of the rocket (take it to be a large cylinder). Assume also that the gas speed is not so high that significant turbulence or nonsteady flow sets in. (*b*) Show that the thrust force on the rocket due to the emitted gases is

$$F = 2A_0(P - P_0).$$

**60.** (III) (*a*) Show that the flow speed measured by a venturi meter (see Fig. 13–32) is given by the relation

$$v_1 = A_2\sqrt{\frac{2(P_1 - P_2)}{\rho(A_1^2 - A_2^2)}}.$$

(*b*) A venturi meter is measuring the flow of water; it has a main diameter of 3.5 cm tapering down to a throat diameter of 1.0 cm. If the pressure difference is measured to be 18 mm-Hg, what is the speed of the water entering the venturi throat?

**61.** (III) A fire hose exerts a force on the person holding it due to the water accelerating as it goes from the thicker hose out through the narrow nozzle. How much force is required to hold a 7.0-cm-diameter hose delivering 480 L/min through a 0.75-cm-diameter nozzle?

## 13–11 Viscosity

**62.** (II) A viscometer consists of two concentric cylinders, 10.20 cm and 10.60 cm in diameter. A liquid fills the space between them to a depth of 15.0 cm. The outer cylinder is fixed, and a torque of $0.024\ \text{m} \cdot \text{N}$ keeps the inner cylinder turning at a steady rotational speed of 57 rev/min. What is the viscosity of the liquid?

**63.** (III) A long vertical hollow tube with an inner diameter of 1.00 cm is filled with SAE 10 motor oil. A 0.900-cm-diameter, 30.0-cm-long 150-g rod is dropped vertically through the oil in the tube. What is the maximum speed attained by the rod as it falls?

## *13–12 Flow in Tubes; Poiseuille's Equation

***64.** (I) A gardener feels it is taking too long to water a garden with a $\frac{3}{8}$-in.-diameter hose. By what factor will the time be cut using a $\frac{5}{8}$-in.-diameter hose instead? Assume nothing else is changed.

***65.** (I) Engine oil (assume SAE 10, Table 13–3) passes through a fine 1.80-mm-diameter tube that is 10.2 cm long. What pressure difference is needed to maintain a flow rate of 5.8 mL/min?

***66.** (II) Calculate the pressure drop per cm along the aorta using the data of Example 13–14 and Table 13–3.

***67.** (II) What diameter must an 18.0-m-long air duct have if the ventilation and heating system is to replenish the air in a room $8.0\ \text{m} \times 14.0\ \text{m} \times 4.0\ \text{m}$ every 15.0 min? Assume the pump can exert a gauge pressure of $0.710 \times 10^{-3}$ atm.

***68.** (II) What must be the pressure difference between the two ends of a 1.6-km section of pipe, 29 cm in diameter, if it is to transport oil $(\rho = 950\ \text{kg/m}^3,\ \eta = 0.20\ \text{Pa} \cdot \text{s})$ at a rate of $650\ \text{cm}^3/\text{s}$?

***69.** (II) Poiseuille's equation does not hold if the flow velocity is high enough that turbulence sets in. The onset of turbulence occurs when the **Reynolds number**, *Re*, exceeds approximately 2000. *Re* is defined as

$$Re = \frac{2\bar{v}r\rho}{\eta},$$

where $\bar{v}$ is the average speed of the fluid, $\rho$ is its density, $\eta$ is its viscosity, and $r$ is the radius of the tube in which the fluid is flowing. (*a*) Determine if blood flow through the aorta is laminar or turbulent when the average speed of blood in the aorta $(r = 1.2\ \text{cm})$ during the resting part of the heart's cycle is about 35 cm/s. (*b*) During exercise, the blood-flow speed approximately doubles. Calculate the Reynolds number in this case, and determine if the flow is laminar or turbulent. NOTE: There is a second **Reynolds** *number* used for assessing flow around a stationary object in a moving fluid (a large rock in a river), or an object moving in a stationary fluid (submarine moving under water or an object falling in air). It is

$$Re' = vL\rho/\eta$$

where $v$ is the speed of the object relative to the fluid, $L$ is the width of the object, and $\rho$ and $\eta$ are density and viscosity of the fluid. If $Re'$ is less than 1, the flow around the object is essentially laminar. If $Re' \gtrsim 1$, the flow behind the object becomes turbulent (called the *wake*), as in Fig. 13-21b.

***70.** (II) If cholesterol buildup reduces the diameter of an artery by 25%, by what % will the blood flow rate be reduced, assuming the same pressure difference?

***71.** (III) A patient is to be given a *blood transfusion*. The blood is to flow through a tube from a raised bottle to a needle inserted in the vein (Fig. 13–59). The inside diameter of the 25-mm-long needle is 0.80 mm, and the required flow rate is $2.0\ \text{cm}^3$ of blood per minute. How high $h$ should the bottle be placed above the needle? Obtain $\rho$ and $\eta$ from the Tables. Assume the blood pressure is 78 torr above atmospheric pressure.

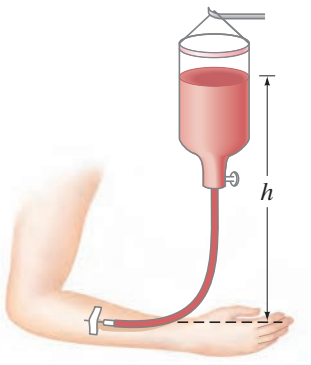

**FIGURE 13–59**
Problems 71, 79, and 104.

### *13–13 Surface Tension and Capillarity

*72. (I) If the force $F$ needed to move the wire in Fig. 13–37 is $3.1 \times 10^{-3}$ N, calculate the surface tension $\gamma$ of the enclosed fluid. Assume $\ell = 0.070$ m.

*73. (I) Calculate the force needed to move the wire in Fig. 13–37 if it holds a soapy solution (Table 13–4) and the wire is 21.5 cm long.

*74. (II) If the base of an insect's leg has a radius of about $3.0 \times 10^{-5}$ m and the insect's mass is 0.016 g, would you expect the six-legged insect to remain on top of the water? Why or why not?

*75. (II) Estimate the diameter of a steel needle that can just barely remain on top of water due to surface tension. (See Figs. 13–38 and 13–39a, and Table 13–1.)

*76. (III) Show that inside a soap bubble, there must be a pressure $\Delta P$ in excess of that outside equal to $\Delta P = 4\gamma/r$, where $r$ is the radius of the bubble and $\gamma$ is the surface tension. [*Hint*: Think of the bubble as two hemispheres in contact with each other, one on the left and one on the right; and remember that there are two surfaces to the bubble, outside and inside. Note that this result applies to any kind of membrane, where $2\gamma$ is the tension per unit length in that membrane.]

*77. (III) A common effect of surface tension is the ability of a liquid to rise up a narrow tube due to capillary action. Show that for a narrow tube of radius $r$ placed in a liquid of density $\rho$ and surface tension $\gamma$, the liquid in the tube will reach a height $h = 2\gamma/\rho g r$ above the level of the liquid outside the tube, where $g$ is the gravitational acceleration. Assume that the liquid "wets" the tube and that the liquid surface is vertical at the contact with the inside of the tube.

### 13–14 Pumps; the Heart

78. (II) A physician judges the health of a heart by measuring the pressure with which it pumps blood, as was shown in Fig. 13–45. If the pressurized cuff is attached around a standing person's calf (about 1 m below the heart) instead of the arm (Fig. 13–45), what error (in mm-Hg) would be introduced in the heart's blood pressure measurement?

## General Problems

79. Intravenous transfusions are often made under gravity, as shown in Fig. 13–59. Assuming the fluid has a density of 1.00 g/cm$^3$, at what height $h$ should the bottle be placed so the liquid pressure is (*a*) 52 mm-Hg, and (*b*) 680 mm-$H_2O$? (*c*) If the blood pressure is 75 mm-Hg above atmospheric pressure, how high should the bottle be placed so that the fluid just barely enters the vein?

80. A 3.2-N force is applied to the plunger of a hypodermic needle. If the diameter of the plunger is 1.3 cm and that of the needle is 0.20 mm, (*a*) with what force does the fluid leave the needle? (*b*) What force on the plunger would be needed to push fluid into a vein where the gauge pressure is 75 mm-Hg? Answer for the instant just before the fluid starts to move.

81. Estimate the difference in air pressure between the top and the bottom of the Empire State Building in New York City. It is 380 m tall and is located at sea level. Express as a fraction of atmospheric pressure at sea level.

82. A bicycle pump is used to inflate a tire. The initial tire (gauge) pressure is 210 kPa (30 psi). At the end of the pumping process, the final pressure is 310 kPa (45 psi). If the diameter of the plunger in the cylinder of the pump is 2.5 cm, what is the range of the force that needs to be applied to the pump handle from beginning to end?

83. A pump supplies water to a 1.59-cm inner diameter hose that tapers down to a 0.953-cm-diameter nozzle. The nozzle is aimed so water comes out at a 45° angle and lands 3.0 m away. The nozzle is 0.60 m above ground level, and the pump output is essentially at ground level. What pressure is supplied by the pump?

84. A hydraulic lift is used to jack a 960-kg car 52 cm off the floor. The diameter of the output piston is 18 cm, and the input force is 380 N. (*a*) What is the area of the input piston? (*b*) What is the work done in lifting the car 52 cm? (*c*) If the input piston moves 13 cm in each stroke, how high does the car move up for each stroke? (*d*) How many strokes are required to jack the car up 52 cm? (*e*) Show that energy is conserved.

85. When you ascend or descend a great deal when driving in a car, your ears "pop," which means that the pressure behind the eardrum is being equalized to that outside. If this did not happen, what would be the approximate force on an eardrum of area 0.20 cm$^2$ if a change in altitude of 1120 m takes place?

86. Airlines are not allowed to reduce the air pressure within the passenger cabin to less than the equivalent of an altitude of 8000 ft (2400 m) to reduce adverse health effects among passengers due to oxygen deprivation. Estimate this minimum pressure (in atm).

87. Giraffes are a wonder of cardiovascular engineering. Calculate the difference in pressure (in atmospheres) that the blood vessels in a giraffe's head must accommodate as the head is lowered from a full upright position to ground level for a drink. The height of an average giraffe is about 6 m.

88. A copper (Cu) weight is placed on top of a 0.40-kg block of wood (density = $0.60 \times 10^3$ kg/m$^3$) floating in water, as shown in Fig. 13–60. What is the mass of the copper if the top of the wood block is exactly at the water's surface?

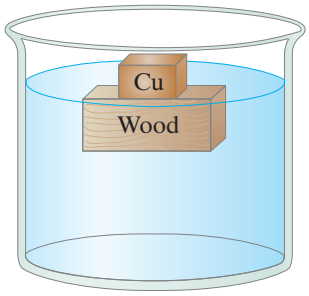

**FIGURE 13–60**
Problem 88.

89. When a person drives or hikes to a higher altitude, and even more during descent, volume changes of trapped air in the middle ear can cause ear discomfort until the middle-ear pressure and exterior pressure are equalized. (*a*) If a rapid descent at a rate of 7.0 m/s or faster commonly causes ear discomfort, what is the maximum rate of increase in atmospheric pressure (that is, $dP/dt$) tolerable to most people? (*b*) In a 350-m-tall building, what will be the fastest possible descent time for an elevator traveling from the top floor to the ground floor, assuming the elevator is properly designed to account for human physiology?

**90.** A tub of water rests on a scale as shown in Fig. 13–61. The weight of the tub plus water is 100 N. A 50-N concrete brick is tied by a cord to a fixed arm and lowered into the water but does not touch the bottom of the tub. What does the scale read now? [*Hint*: Draw two free-body diagrams, one for the brick and a second one for the tub + water + brick.]

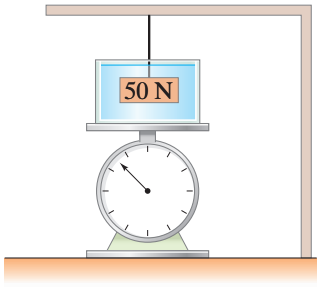

**FIGURE 13–61** Problem 90.

**91.** A simple model (Fig. 13–62) considers a continent as a block $\left(\text{density} \approx 2800\ \text{kg/m}^3\right)$ floating in the mantle rock around it $\left(\text{density} \approx 3300\ \text{kg/m}^3\right)$. Assuming the continent is 35 km thick (the average thickness of the Earth's continental crust), estimate the height of the continent above the surrounding mantle rock.

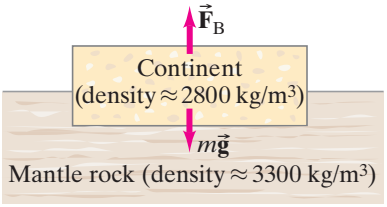

**FIGURE 13–62** Problem 91.

**92.** A ship, carrying fresh water to a desert island in the Caribbean, has a horizontal cross-sectional area of 2240 $\text{m}^2$ at the waterline. When unloaded, the ship rises 8.55 m higher in the sea. How much water $\left(\text{m}^3\right)$ was delivered?

**93.** You are watering your lawn with a hose when you put your finger over the hose opening to increase the distance the water reaches. If you are holding the hose horizontally, and the distance the water reaches increases by a factor of 4, what fraction of the hose opening did you block?

**94.** A raft is made of 12 logs lashed together. Each is 45 cm in diameter and has a length of 6.5 m. How many people can the raft hold before they start getting their feet wet, assuming the average person has a mass of 68 kg? Do *not* neglect the weight of the logs. Assume the specific gravity of wood is 0.60.

**95.** The stream of water from a faucet decreases in diameter as it falls (Fig. 13–63). Derive an equation for the diameter of the stream as a function of the distance $y$ below the faucet, given that the water has speed $v_0$ when it leaves the faucet, whose diameter is $d$.

**FIGURE 13–63** Problem 95. Water coming from a faucet.

**96.** In working out his principle, Pascal showed dramatically how force can be multiplied with fluid pressure. He placed a long, thin tube of radius $r = 0.30\ \text{cm}$ vertically into a wine barrel of radius $R = 21\ \text{cm}$, Fig. 13–64. He found that when the barrel was filled with water and the tube filled to a height of 12 m, the barrel burst. Calculate (*a*) the mass of water in the tube, and (*b*) the net force exerted by the water in the barrel on the lid just before rupture.

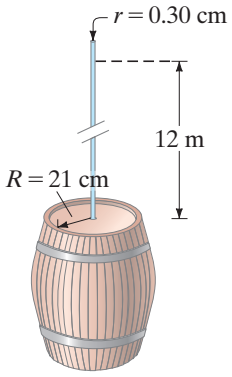

**FIGURE 13–64**
Problem 96. (Not to scale.)

**97.** (*a*) Show that the buoyant force $F_B$ on a partially submerged object such as a ship acts at the center of gravity of the fluid before it was displaced, Fig. 13–65. This point is called the **center of buoyancy**. (*b*) To ensure that a ship is in stable equilibrium, would it be better if its center of buoyancy was above, below, or at the same point as its center of gravity? Explain.

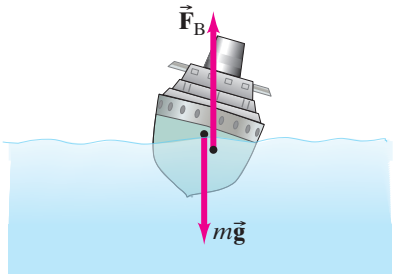

**FIGURE 13–65** Problem 97.

**98.** An aluminum cube, 2.0 cm on a side, and an iron cube, 1.0 cm on a side, are connected by a thin, rigid rod (negligible mass) 55 cm long. The device is immersed in water in two different ways (Fig. 13–66). (*a*) To balance the rod horizontally on your finger underwater, how far from the iron block is your finger? (*b*) You place the rod vertically as shown in Fig. 13–66b, and release it. If the two cubes fall perfectly vertically, estimate their resulting vertical acceleration. (*c*) Describe the likely motion of the two cubes.

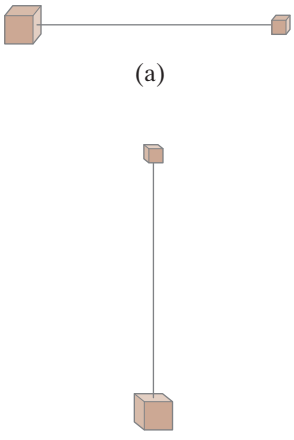

**FIGURE 13–66**
Problem 98.

**99.** Estimate the total mass of the Earth's atmosphere, using the known value of atmospheric pressure at sea level.

**100.** During each heartbeat, approximately 70 $cm^3$ of blood is pushed from the heart at an average pressure of 105 mm-Hg. Calculate the power output of the heart, in watts, assuming 70 beats per minute.

**101.** A hurricane-force wind of 180 km/h blows across the face of a storefront window. Estimate the force on the 3.0 m × 3.0 m window due to the difference in air pressure inside and outside the window. Assume the store is airtight so the inside pressure remains at 1.0 atm. (This is why you should not tightly seal a building in preparation for a hurricane.)

**102.** A drinking fountain shoots water about 12 cm up in the air from a nozzle of diameter 0.60 cm (Fig. 13–67). The pump at the base of the unit (1.1 m below the nozzle) pushes water into a 1.2-cm-diameter supply pipe that goes up to the nozzle. What gauge pressure does the pump have to provide? Ignore the viscosity; your answer will therefore be an underestimate.

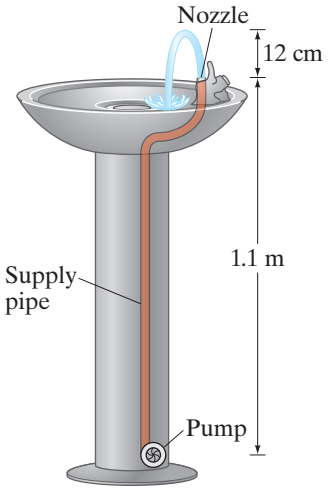

**FIGURE 13–67**
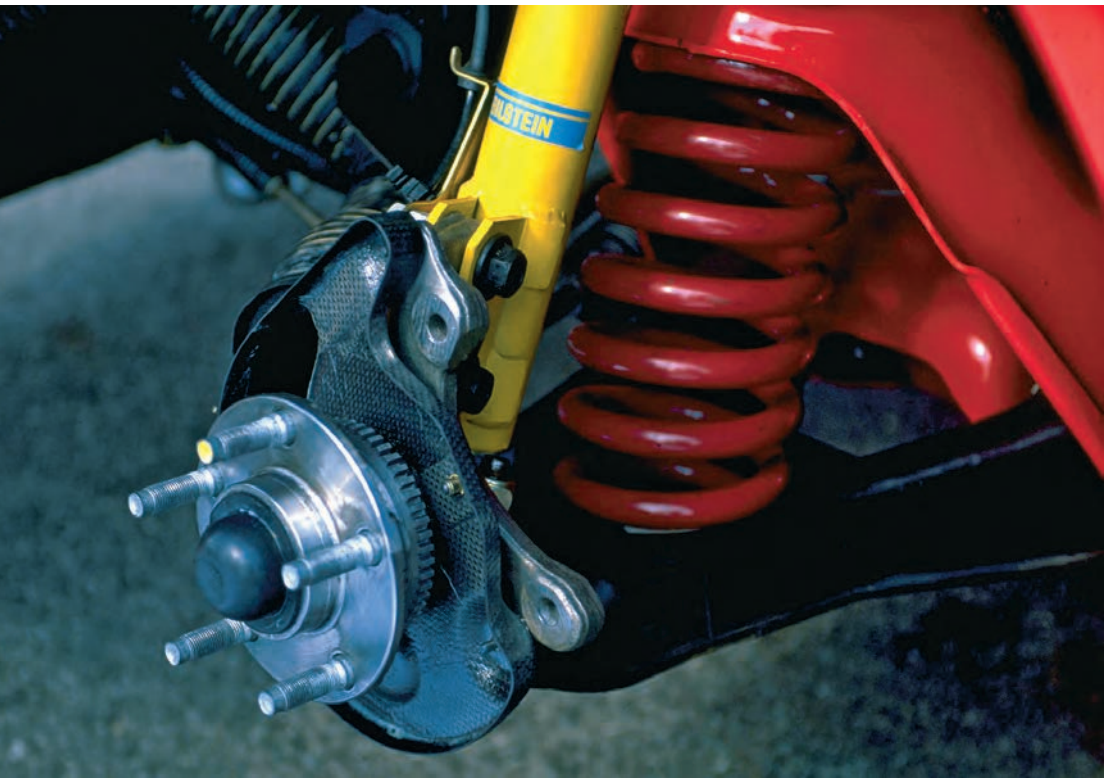
Problem 102.

**103.** Four lawn sprinkler heads are fed by a 1.9-cm-diameter pipe. The water comes out of the heads at an angle of 35° to the horizontal and covers a radius of 5.0 m. (*a*) What is the velocity of the water coming out of each sprinkler head? (Assume zero air resistance.) (*b*) If the output diameter of each head is 3.0 mm, how many liters of water do the four heads deliver per minute? (*c*) How fast is the water flowing inside the 1.9-cm-diameter pipe?

***104.** Blood is placed in a bottle 1.40 m above a 3.8-cm-long needle, of inside diameter 0.40 mm, from which it flows at a rate of 4.1 $cm^3$/min. What is the viscosity of this blood? (See Fig. 13–59 and Problem 71.)



**105.** Three forces act significantly on a freely floating helium-filled balloon: gravity, air resistance (or drag force), and a buoyant force. Consider a spherical helium-filled balloon of radius $r = 15$ cm rising upward through 0°C air, and $m = 2.8$ g is the mass of the (deflated) balloon itself. For all speeds $v$, except the very slowest ones, the flow of air past a rising balloon is turbulent, and the drag force $F_D$ is given by the relation

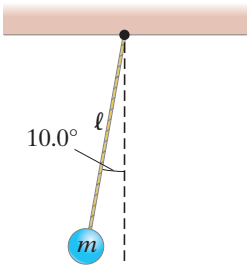
$$F_D = \tfrac{1}{2} C_D \rho_{air} \pi r^2 v^2$$

where the constant $C_D = 0.47$ is the "drag coefficient" for a smooth sphere of radius $r$. If this balloon is released from rest, it will accelerate very quickly (in a few tenths of a second) to its terminal velocity $v_T$, where the buoyant force is cancelled by the drag force and the balloon's total weight. Assuming the balloon's acceleration takes place over a negligible time and distance, how long does it take the released balloon to rise a distance $h = 15$ m?

## ANSWERS TO EXERCISES

**A:** (*d*).
**B:** The same. Pressure depends on depth, not on length.
**C:** Lower.
**D:** (*e*).
**E:** The rowboat is shaped to have a lot of empty, air-filled space, so its "average" density is lower than that of water (unless the boat becomes full of water, in which case it sinks). Steel ships float for the same reason.
**F:** Increases.
**G:** (*b*).

An object attached to a coil spring can exhibit oscillatory motion. Many kinds of oscillatory motion are sinusoidal in time, or nearly so, and are referred to as simple harmonic motion. Real systems generally have at least some friction, causing the motion to be damped. The automobile spring shown here (red) has a shock absorber (yellow) that purposefully dampens the oscillation to make for a smooth ride.



When an external sinusoidal force is exerted on a system able to oscillate, resonance occurs if the driving force is at or near the natural frequency of oscillation of the system.

CHAPTER 14

# Oscillations

**CHAPTER-OPENING QUESTION—Guess now!**
A simple pendulum consists of a mass $m$ (the "bob") hanging on the end of a thin string of length $\ell$ and negligible mass. The bob is pulled sideways so the string makes a 5.0° angle to the vertical. When released, it oscillates back and forth at a frequency $f$. If the pendulum is started at a 10.0° angle instead, its frequency would be

**(a)** twice as great.
**(b)** half as great.
**(c)** the same, or very close to it.
**(d)** not quite twice as great.
**(e)** a bit more than half as great.

Many objects vibrate or oscillate—an object connected to a spring, a tuning fork, a pendulum, a plastic ruler held firmly over the edge of a table and gently struck, the strings of a guitar or piano. Spiders detect prey by the vibrations of their webs; cars oscillate up and down when they hit a bump; buildings and bridges vibrate when heavy trucks pass or the wind is fierce. Indeed, because most solids are elastic (see Section 12–5), they vibrate (at least briefly) when given an impulse. Electrical oscillations occur in radio and television sets. At the atomic level, atoms oscillate within a molecule, and the atoms of a solid oscillate about their relatively fixed positions. Because it is so common in everyday life and occurs in so many areas of physics, oscillatory (or vibrational) motion is of great importance. Mechanical oscillations or vibrations are fully described on the basis of Newtonian mechanics.

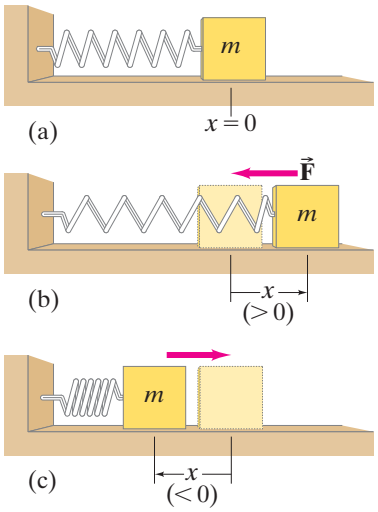

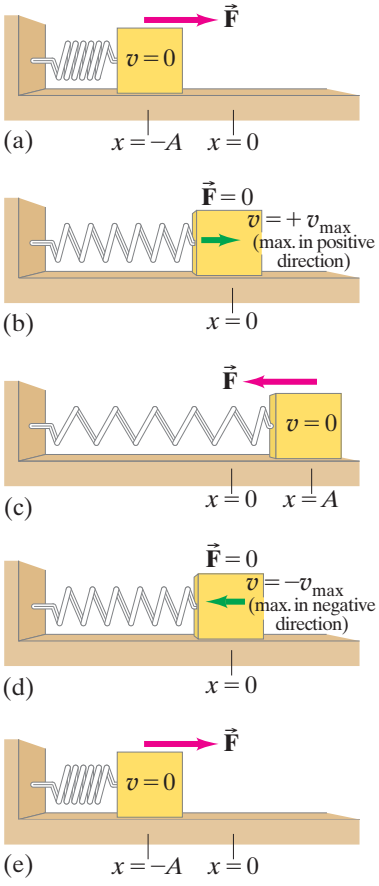

**FIGURE 14–1** An object of mass $m$ oscillating at the end of a uniform spring. The force $\vec{\mathbf{F}}$ on the object at the different positions is shown *above* the object. (The pale yellow box represents the object at the equilibrium position, $x = 0$.)

**FIGURE 14–2** An object oscillating on a frictionless surface, indicating the force on the object and its velocity at different positions of its oscillation cycle.

# 14–1 Oscillations of a Spring

When an object **vibrates** or **oscillates** back and forth, over the same path, each oscillation taking the same amount of time, the motion is **periodic**. The simplest form of periodic motion is represented by an object oscillating on the end of a uniform coil spring. Because many other types of oscillatory motion closely resemble this system, we will look at it in detail. We assume that the mass of the spring can be ignored, and that the spring is mounted horizontally, as shown in Fig. 14–1a. We assume the object of mass $m$ slides without friction on the horizontal surface. Any spring has a natural length at which it exerts no force on the mass $m$. The position of the mass and spring at this point is called the **equilibrium position**. If the mass is moved either to the left, which compresses the spring, or to the right, which stretches it, the spring exerts a force on the mass that acts in the direction of returning the mass to the equilibrium position; hence it is called a *restoring force*. We consider the common situation where we can assume the restoring force $F$ is directly proportional to the displacement $x$ the spring has been stretched (Fig. 14–1b) or compressed (Fig. 14–1c) from the equilibrium position:

$$F = -kx. \qquad \text{[force exerted by spring]} \quad \textbf{(14–1)}$$

Note that the equilibrium position has been chosen at $x = 0$ and the minus sign in Eq. 14–1 indicates that the restoring force is always in the direction opposite to the displacement $x$. For example, if we choose the positive direction to the right in Fig. 14–1, $x$ is positive when the spring is stretched (Fig. 14–1b), but the direction of the restoring force is to the left (negative direction). If the spring is compressed, $x$ is negative (to the left) but the force $F$ acts toward the right (Fig. 14–1c).

Equation 14–1 is often referred to as Hooke's law (Sections 7–3, 8–2 and 12–5), and is accurate only if the spring is not compressed to where the coils are close to touching, or stretched beyond the elastic region (see Fig. 12–18). Hooke's law works not only for springs but for other oscillating solids as well; it thus has wide applicability, even though it is valid only over a certain range of $F$ and $x$ values.

The proportionality constant $k$ in Eq. 14–1 is called the *force constant*, or more commonly the **spring constant** for that particular spring (or *spring stiffness constant*) with units = N/m. To stretch the spring a displacement $x$ from equilibrium $(x = 0)$, an (external) force must be exerted on the free end of the spring with a magnitude at least equal to

$$F_{\text{ext}} = +kx. \qquad \text{[external force on spring]}$$

The greater the value of $k$, the greater the force needed to stretch a spring a given amount. That is, the stiffer the spring, the greater the spring constant $k$.

Note that the force $F$ in Eq. 14–1 is *not* a constant, but varies with position. Therefore the acceleration of the mass $m$ is not constant, so we *cannot* use the equations for constant acceleration developed in Chapter 2 (Eqs. 2–12).

Let us examine what happens when our uniform spring is initially compressed a displacement $x = -A$, as shown in Fig. 14–2a, and then our object of mass $m$ is released on the frictionless surface. The spring exerts a force on the mass that accelerates it toward the equilibrium position. Because the mass has inertia, it passes the equilibrium position with considerable speed. Indeed, as the mass reaches the equilibrium position, the force on it decreases to zero, but its speed at this point is a maximum, $v_{\text{max}}$ (Fig. 14–2b). As the mass moves farther to the right, the force on it acts to slow it down, and it stops for an instant at $x = A$ (Fig. 14–2c). It then begins moving back in the opposite direction, accelerating until it passes the equilibrium point (Fig. 14–2d), and then slows down until it reaches zero speed at the original starting point, $x = -A$ (Fig. 14–2e). It then repeats the motion, moving back and forth symmetrically between $x = A$ and $x = -A$.

**EXERCISE A** A mass is oscillating on a frictionless surface at the end of a horizontal spring. Where, if anywhere, is the acceleration of the mass zero (see Fig. 14–2)? (*a*) At $x = -A$; (*b*) at $x = 0$; (*c*) at $x = +A$; (*d*) at both $x = -A$ and $x = +A$; (*e*) nowhere.

To discuss oscillatory motion, we need to define a few terms. The distance $x$ of the mass from the equilibrium point at any moment is the **displacement** (with a + or − sign). The maximum displacement—the greatest distance from the equilibrium point—is called the **amplitude**, $A$. One **cycle** refers to the complete to-and-fro motion from some initial point back to that same point—say, from $x = -A$ to $x = +A$ and back to $x = -A$. The **period**, $T$, is defined as the time required to complete one cycle. Finally, the **frequency**, $f$, is the number of complete cycles per second. Frequency is generally specified in hertz (Hz), where 1 Hz = 1 cycle per second $(s^{-1})$. Given their definitions, frequency and period are inversely related, as we saw earlier (Eqs. 5–2 and 10–8):

$$f = \frac{1}{T} \quad \text{and} \quad T = \frac{1}{f}. \tag{14–2}$$

For example, if the frequency is 2 cycles per second, then each cycle takes $\frac{1}{2}$ s.

**EXERCISE B** If an oscillating mass has a frequency of 1.25 Hz, it makes 100 oscillations in (*a*) 12.5 s, (*b*) 125 s, (*c*) 80 s, (*d*) 8.0 s.

The oscillation of a spring hung vertically is essentially the same as that of a horizontal spring. But because of gravity, the length of a vertical spring with a mass $m$ on the end will be longer at equilibrium than when that same spring is horizontal; see Fig. 14–3. The spring is in equilibrium when $\Sigma F = 0 = mg - kx_0$, so the spring stretches an extra amount $x_0 = mg/k$ to be in equilibrium. If $x$ is measured from this new equilibrium position, which we now call $x = 0$, Eq. 14–1 can be used directly with the same value of $k$.

**CAUTION**
*For vertical spring, measure displacement (x or y) from the vertical equilibrium position*

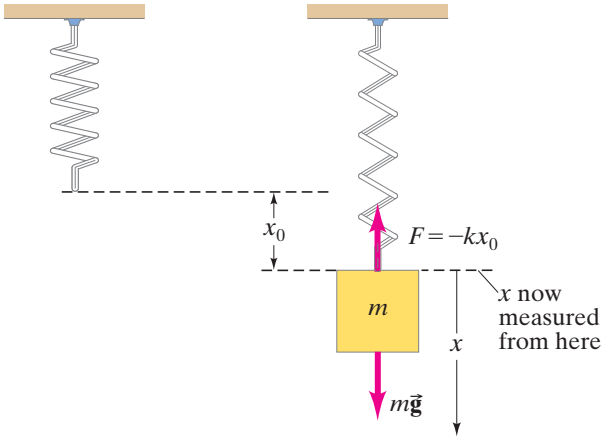

**FIGURE 14–3**
(a) Free spring, hung vertically.
(b) Mass $m$ attached to spring in new equilibrium position, which occurs when $\Sigma F = 0 = mg - kx_0$.

**EXAMPLE 14–1** **Car springs.** When a family of four with a total mass of $m = 200$ kg step into their 1200-kg car, the car's springs compress 3.0 cm (see Chapter-Opening photo, page 399). (*a*) What is the spring constant of the car's springs, assuming they act as a single spring? (*b*) How far will the car lower if loaded with 300 kg rather than 200 kg?

**APPROACH** We use Hooke's law: the weight of the people, $mg$, causes a 3.0-cm displacement.

**SOLUTION** (*a*) The added force of $mg = (200\text{ kg})(9.8\text{ m/s}^2) = 1960$ N causes the springs to compress $3.0 \times 10^{-2}$ m. Therefore (Eq. 14–1), the spring constant is

$$k = \frac{F}{x} = \frac{1960\text{ N}}{3.0 \times 10^{-2}\text{ m}} = 6.5 \times 10^4\text{ N/m}.$$

(*b*) If the car is loaded with 300 kg, Hooke's law gives

$$x = \frac{F}{k} = \frac{(300\text{ kg})(9.8\text{ m/s}^2)}{(6.5 \times 10^4\text{ N/m})} = 4.5 \times 10^{-2}\text{ m},$$

or 4.5 cm.

**NOTE** In (*b*), we could have obtained $x$ without solving for $k$: since $x$ is proportional to $F$, if 200 kg compresses the spring 3.0 cm, then 1.5 times the force will compress the spring 1.5 times as much, or 4.5 cm.

## 14–2 Simple Harmonic Motion

Any oscillating system for which the net restoring force is directly proportional to the negative of the displacement (as in Eq. 14–1, $F = -kx$) is said to exhibit **simple harmonic motion** (SHM). Such a system is often called a **simple harmonic oscillator** (SHO). [The word "harmonic" refers to the motion being sinusoidal: see below. It is "simple" when the motion is sinusoidal of a single frequency. This can happen only if friction or other forces are not acting.]

We saw in Section 12–5 that most solid materials stretch or compress according to Eq. 14–1 as long as the displacement is not too great. Because of this, many natural oscillations are simple harmonic or sufficiently close to it that they can be treated using this SHM model.

**CONCEPTUAL EXAMPLE 14–2** **Is the motion simple harmonic?** Which of the following forces would cause an object to move in simple harmonic motion? (*a*) $F = -0.5x^2$, (*b*) $F = -2.3y$, (*c*) $F = 8.6x$, (*d*) $F = -4\theta$.

**RESPONSE** Both (*b*) and (*d*) will give simple harmonic motion because they give the force as minus a constant times a displacement. The displacement need not be $x$, but the minus sign is required to restore the system to equilibrium, which is why (*c*) does not produce SHM. Nor does (*a*) because $x$ is squared.

Let us now determine the position $x$ as a function of time for a mass attached to the end of a simple spring with spring constant $k$. To do so, we make use of Newton's second law, $F = ma$. Since the acceleration $a = d^2x/dt^2$ (Chapter 2), we have

$$ma = \Sigma F$$
$$m\frac{d^2x}{dt^2} = -kx,$$

where $m$ is the mass[†] which is oscillating. We rearrange this to obtain

$$\frac{d^2x}{dt^2} + \frac{k}{m}x = 0, \qquad \text{[SHM]} \quad \textbf{(14–3)}$$

which is known as the **equation of motion** for the simple harmonic oscillator. Mathematically, this is a *second-order differential equation* because it involves second derivatives. We want to determine what function of time, $x(t)$, satisfies this equation. We might guess the form of the solution by noting that if a pen is attached to an oscillating mass (Fig. 14–4) and a sheet of paper is moved at a steady rate beneath it, the pen would trace the curve shown. The shape of this curve looks a lot like it might be **sinusoidal** (such as cosine or sine) as a function of time, and its height is the amplitude $A$. Let us then guess that the general solution to Eq. 14–3 can be written in a form such as

$$x = A\cos(\omega t + \phi), \qquad \textbf{(14–4)}$$

where $\omega$ is a constant to be determined (units rad/s) and we include the constant $\phi$ in the argument to be general.[‡] Let us now put this trial solution into Eq. 14–3 and see if it really works. We need to differentiate the $x = x(t)$ twice:

$$\frac{dx}{dt} = \frac{d}{dt}[A\cos(\omega t + \phi)] = -\omega A\sin(\omega t + \phi)$$
$$\frac{d^2x}{dt^2} = -\omega^2 A\cos(\omega t + \phi).$$

We next put this equation for $d^2x/dt^2$ into Eq. 14–3 along with Eq. 14–4 for $x$

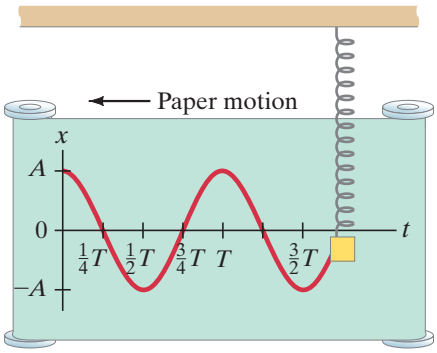

**FIGURE 14–4** Sinusoidal nature of SHM: position as a function of time. In this case, $x = A\cos(2\pi t/T)$.

[†]We are assuming an ideal massless spring, but the spring itself also oscillates and a part of its mass should be included. Approximately one-third the mass of the spring, $M_s$, should be included, so for a mass $m$ oscillating on the end of a spring, the total mass $M$ is $M = m + \frac{1}{3}M_s$ in our equation. Often $M_s$ is small enough to be ignored.

[‡]Another possible way to write the solution is the combination $x = a\cos\omega t + b\sin\omega t$, where $a$ and $b$ are constants. This is equivalent to Eq. 14–4 as can be seen using the trigonometric identity $\cos(A \pm B) = \cos A\cos B \mp \sin A\sin B$.

to see if Eq. 14–4 was a good guess:

$$\frac{d^2x}{dt^2} + \frac{k}{m}x = 0$$

$$-\omega^2 A\cos(\omega t + \phi) + \frac{k}{m}A\cos(\omega t + \phi) = 0$$

or

$$\left(\frac{k}{m} - \omega^2\right)A\cos(\omega t + \phi) = 0.$$

The left side of this equation must equal zero for *all* times $t$, because it is zero on the right side. This equation is satisfied for any time $t$ if $(k/m - \omega^2) = 0$. So our solution, Eq. 14–4, does indeed satisfy the equation of motion (Eq. 14–3) for any time $t$, but only if

$$\omega^2 = \frac{k}{m}. \qquad \textbf{(14–5)}$$

Equation 14–4 is the general solution to Eq. 14–3, and we also know the value of the constant $\omega$, i.e., $\omega = \sqrt{k/m}$. The solution is sinusoidal and it contains two arbitrary constants $A$ and $\phi$, which we should expect because the second derivative in Eq. 14–3 implies that two integrations are needed, each yielding a constant. They are "arbitrary" only in a calculus sense, in that they can be anything and still satisfy the differential equation, Eq. 14–3. In real physical situations, however, $A$ and $\phi$ are determined by the **initial conditions**. Suppose, for example, that the mass is started at its maximum displacement $A$ and is released from rest. This is, in fact, what is shown in Fig. 14–4, and for this case $x = A\cos\omega t$. Let us confirm it: we are given $v = 0$ at $t = 0$, where

$$v = \frac{dx}{dt} = \frac{d}{dt}[A\cos(\omega t + \phi)] = -\omega A\sin(\omega t + \phi) = 0. \qquad [\text{at } t = 0]$$

For $v$ to be zero at $t = 0$, then $\sin(\omega t + \phi) = \sin(0 + \phi)$ can be zero if $\phi = 0$ ($\phi$ could also be $\pi$, $2\pi$, etc.), and when $\phi = 0$, then

$$x = A\cos\omega t,$$

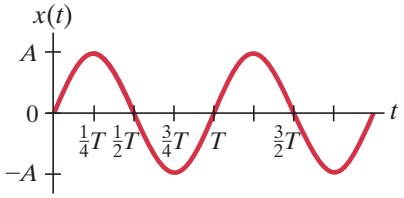
as we expected. We see immediately that $A$ is the amplitude of the motion, and it is determined initially by how far you pull the mass $m$ from equilibrium before releasing it.

Consider another interesting case: at $t = 0$ the mass $m$ is at $x = 0$ and is struck, giving it an initial velocity toward increasing values of $x$. Given $x = 0$ at $t = 0$, we can write $x = A\cos(\omega t + \phi) = A\cos\phi = 0$, which can happen only if $\phi = \pm\pi/2$ (or $\pm 90°$). Whether $\phi = +\pi/2$ or $-\pi/2$ depends on $v = dx/dt = -\omega A\sin(\omega t + \phi) = -\omega A\sin\phi$ at $t = 0$, which we are given as positive ($v > 0$ at $t = 0$); hence $\phi = -\pi/2$ because $\sin(-90°) = -1$. Thus our solution for this case is

$$x = A\cos\left(\omega t - \frac{\pi}{2}\right)$$
$$= A\sin\omega t,$$

where we used $\cos(\theta - \pi/2) = \sin\theta$ (see Appendix A, Fig. A–5). The solution in this case is a pure sine function, Fig. 14–5, where $A$ is still the amplitude.

Many other situations are possible, such as that shown in Fig. 14–6. The constant $\phi$ is called the **phase angle**, or **phase constant**, and it tells us how long after (or before) $t = 0$ the peak at $x = A$ is reached. Notice that the value of $\phi$ does not affect the shape of the $x(t)$ curve, but only affects the displacement at some arbitrary time, $t = 0$. Simple harmonic motion is thus always *sinusoidal*. Simple harmonic motion can in fact be *defined* as motion that is purely sinusoidal.



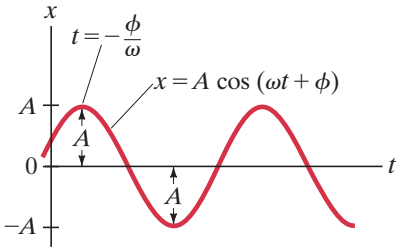


**FIGURE 14–5** In this case of SHM, the mass $m$ starts at $t = 0$ at the equilibrium position $x = 0$, and has initial velocity toward positive values of $x$ ($v > 0$ at $t = 0$).

**FIGURE 14–6** A plot of $x = A\cos(\omega t + \phi)$ when $\phi < 0$. Note: $A\cos(\omega t + \phi) = A$ only when $\cos\theta = 1$, which occurs (first) when $\theta = 0$, in which case $t = -\phi/\omega$ as shown.

Since our oscillating mass repeats its motion after a time equal to its period $T$, it must be at the same position and moving in the same direction at $t = T$ as it was at $t = 0$. Since a sine or cosine function repeats itself after every $2\pi$ radians, then from Eq. 14–4, we must have

$$\omega T = 2\pi.$$

Hence

$$\omega = \frac{2\pi}{T} = 2\pi f,$$

where $f$ is the frequency of the motion. Strictly speaking, we call $\omega$ the **angular frequency** (units are rad/s) to distinguish it from the frequency $f$ (units are $s^{-1}$ = Hz); sometimes the word "angular" is dropped, so the symbol $\omega$ or $f$ needs to be specified. Because $\omega = 2\pi f = 2\pi/T$, we can write Eq. 14–4 as

$$x = A\cos\left(\frac{2\pi t}{T} + \phi\right) \qquad \textbf{(14–6a)}$$

or

$$x = A\cos(2\pi f t + \phi). \qquad \textbf{(14–6b)}$$

**CAUTION**

*t is a variable (time); T is a constant for a given situation*

Notice in Eq. 14–6a that when $t = T$ (a time equal to one period), we have the cosine of $2\pi + \phi$ (or $360° + \phi$), which is the same as the cosine at $t = 0$. This makes sense because the motion repeats itself after a time $t = T$.

Because $\omega = 2\pi f = \sqrt{k/m}$ (Eq. 14–5), then

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}, \qquad \textbf{(14–7a)}$$

$$T = 2\pi\sqrt{\frac{m}{k}}. \qquad \textbf{(14–7b)}$$

Note that the *frequency and period do not depend on the amplitude*. Changing the amplitude of a simple harmonic oscillator does not affect its frequency. Equation 14–7a tells us that the greater the mass, the lower the frequency; and the stiffer the spring, the higher the frequency. This makes sense since a greater mass means more inertia and therefore a slower response (or acceleration); and larger $k$ means greater force and therefore quicker response. The frequency $f$ (Eq. 14–7a) at which a SHO oscillates naturally is called its **natural frequency** (to distinguish it from a frequency at which it might be forced to oscillate by an outside force, as discussed in Section 14–8).

The simple harmonic oscillator is important in physics because whenever we have a net restoring force proportional to the displacement $(F = -kx)$, which is at least a good approximation for a variety of systems, then the motion is simple harmonic—that is, sinusoidal.

**PHYSICS APPLIED**

*Car springs*

**EXAMPLE 14–3** **Car springs again.** Determine the period and frequency of the car in Example 14–1a after hitting a bump. Assume the shock absorbers are poor, so the car really oscillates up and down.

**APPROACH** We put $m = 1400\,\text{kg}$ and $k = 6.5 \times 10^4\,\text{N/m}$ from Example 14–1a into Eqs. 14–7.

**SOLUTION** From Eq. 14–7b,

$$T = 2\pi\sqrt{\frac{m}{k}} = 2\pi\sqrt{\frac{1400\,\text{kg}}{6.5 \times 10^4\,\text{N/m}}} = 0.92\,\text{s},$$

or slightly less than a second. The frequency $f = 1/T = 1.1\,\text{Hz}$.

**EXERCISE C** By how much should the mass on the end of a spring be changed to halve the frequency of its oscillations? (*a*) No change; (*b*) doubled; (*c*) quadrupled; (*d*) halved; (*e*) quartered.

**EXAMPLE 14–4** **ESTIMATE** **Spider web.** A spider of mass 0.30 g waits in its web of negligible mass (Fig. 14–7). A slight movement causes the web to vibrate with a frequency of about 15 Hz. (*a*) Estimate the value of the spring stiffness constant $k$ for the web. (*b*) At what frequency would you expect the web to vibrate if an insect of mass 0.10 g is trapped in addition to the spider?

**APPROACH** We can only make a rough estimate because a spider's web is in 3 dimensions and so is complicated and may vibrate with a mixture of frequencies. We use SHM as an approximate model.

**SOLUTION** (*a*) The frequency of SHM is given by Eq. 14–7a,

$$f = \frac{1}{2\pi}\sqrt{\frac{k}{m}}.$$

We solve for $k$:

$$k = (2\pi f)^2 m$$
$$= (2\pi)^2(15\,\text{s}^{-1})^2(3.0\times10^{-4}\,\text{kg}) = 2.7\,\text{N/m}.$$

(*b*) The total mass is now $0.10\,\text{g} + 0.30\,\text{g} = 4.0\times10^{-4}\,\text{kg}$. We could substitute $m = 4.0\times10^{-4}\,\text{kg}$ into Eq. 14–7a. Instead, we notice that the frequency decreases with the square root of the mass. Since the new mass is 4/3 times the first mass, the frequency changes by a factor of $1/\sqrt{4/3} = \sqrt{3/4}$. Thus $f = (15\,\text{Hz})(\sqrt{3/4}) \approx 13\,\text{Hz}$, and is only an approximation.

**NOTE** Check this result by direct substitution of $k$, found in part (*a*), and the new mass $m$ into Eq. 14–7a.

**FIGURE 14–7** Example 14–4. A spider waits for its prey (on the left).

**EXERCISE D** The position of a SHO is given by $x = (0.80\,\text{m})\cos(3.14t - 0.25)$. The frequency is (*a*) 3.14 Hz, (*b*) 1.0 Hz, (*c*) 0.50 Hz, (*d*) 9.88 Hz, (*e*) 19.8 Hz.

Let us continue our analysis of a simple harmonic oscillator. The velocity and acceleration of the oscillating mass can be obtained by differentiation of Eq. 14–4, $x = A\cos(\omega t + \phi)$:

$$v = \frac{dx}{dt} = -\omega A\sin(\omega t + \phi) \qquad \textbf{(14–8a)}$$

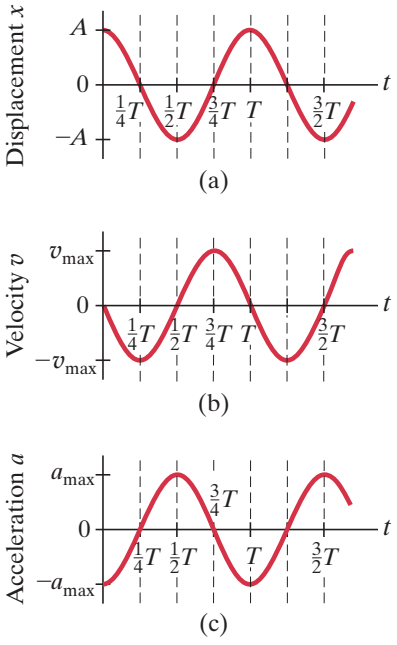
$$a = \frac{d^2x}{dt^2} = \frac{dv}{dt} = -\omega^2 A\cos(\omega t + \phi). \qquad \textbf{(14–8b)}$$

The velocity and acceleration of a SHO also vary sinusoidally. In Fig. 14–8 we plot the displacement, velocity, and acceleration of a SHO as a function of time for the case when $\phi = 0$. The speed reaches its maximum

$$v_{\text{max}} = \omega A = \sqrt{\frac{k}{m}}A \qquad \textbf{(14–9a)}$$

when the oscillating object is passing through its equilibrium point, $x = 0$, as seen in Fig. 14–8a and b. And the speed is zero at points of maximum displacement, $x = \pm A$. This is in accord with our discussion of Fig. 14–2. Similarly, the acceleration has its maximum value

$$a_{\text{max}} = \omega^2 A = \frac{k}{m}A \qquad \textbf{(14–9b)}$$



which occurs when $x = \pm A$; and $a$ is zero at $x = 0$, as we expect, because $ma = F$ is proportional to $x$ ($F = -kx$).

For the general case when $\phi \neq 0$, we can relate the constants $A$ and $\phi$ to the initial values of $x$, $v$, and $a$ by setting $t = 0$ in Eqs. 14–4, 14–8, and 14–9:

$$x_0 = x(t=0) = A\cos\phi$$
$$v_0 = v(t=0) = -\omega A\sin\phi = -v_{\text{max}}\sin\phi$$
$$a_0 = a(t=0) = -\omega^2 A\cos\phi = -a_{\text{max}}\cos\phi.$$

Note that $v_0$ is not the same as $v_{\text{max}}$, and $a_0$ is not the same as $a_{\text{max}}$.

**FIGURE 14–8** Graphs showing (a) displacement $x$ as a function of time $t$: $x = A\cos\omega t$; (b) velocity as a function of time: $v = -v_{\text{max}}\sin\omega t$, where $v_{\text{max}} = A\sqrt{k/m}$; (c) acceleration as a function of time: $a = -a_{\text{max}}\cos\omega t$, where $a_{\text{max}} = Ak/m$.

**EXAMPLE 14–5** **ESTIMATE** **A vibrating floor.** A large motor in a factory causes the floor to vibrate at a frequency of 10 Hz. The amplitude of the floor's motion near the motor is about 3.0 mm. Estimate the maximum acceleration of the floor near the motor.

**APPROACH** Assuming the motion of the floor is roughly SHM we can make an estimate for the maximum acceleration using Eq. 14–9b.

**SOLUTION** Given $\omega = 2\pi f = (2\pi)(10\,\text{s}^{-1}) = 62.8\,\text{rad/s}$, then Eq. 14–9b gives

$$a_{\text{max}} = \omega^2 A = (62.8\,\text{rad/s})^2(0.0030\,\text{m}) = 12\,\text{m/s}^2.$$

**PHYSICS APPLIED**
*Unwanted floor vibrations*

**NOTE** The maximum acceleration is a little over $g$, so when the floor accelerates down, objects sitting on the floor will actually lose contact momentarily, which will cause noise and serious wear.

**EXAMPLE 14–6** **Starting with $x = A\cos\omega t$.** The displacement of an object is described by the following equation, where $x$ is in meters and $t$ is in seconds:

$$x = (0.30\,\text{m})\cos(8.0\,t\ \text{rad}).$$

Determine the oscillating object's (*a*) amplitude, (*b*) frequency, (*c*) period, (*d*) maximum speed, and (*e*) maximum acceleration.

**APPROACH** We start by comparing the given equation for $x$ with Eq. 14–6b, $x = A\cos(2\pi ft)$, with $\phi = 0$.

**SOLUTION** From $x = A\cos(2\pi ft)$, we see by inspection that (*a*) the amplitude $A = 0.30\,\text{m}$, and (*b*) $2\pi f = 8.0\,\text{rad/s}$; so $f = (8.0\,\text{rad/s}\,/2\pi\,\text{rad}) = 1.27\,\text{s}^{-1} = 1.27\,\text{Hz}$. (*c*) Then $T = 1/f = 0.79\,\text{s}$. (*d*) The maximum speed (Eq. 14–9a) is

$$v_{\text{max}} = \omega A = 2\pi f A$$
$$= (2\pi)(1.27\,\text{s}^{-1})(0.30\,\text{m}) = 2.4\,\text{m/s}.$$

(*e*) The maximum acceleration is given by Eq. 14–9b:

$$a_{\text{max}} = \omega^2 A = (2\pi f)^2 A$$
$$= (2\pi)^2(1.27\,\text{s}^{-1})^2(0.30\,\text{m}) = 19\,\text{m/s}^2.$$

**EXAMPLE 14–7** **Loudspeaker.** The cone of a loudspeaker (Fig. 14–9) oscillates in SHM at a frequency of 262 Hz ("middle C"). The amplitude at the central part of the cone is $A = 1.5 \times 10^{-4}\,\text{m}$, and at $t = 0$, $x = A$. (*a*) What equation describes the motion of the center of the cone? (*b*) What are the velocity and acceleration as a function of time? (*c*) What is the position of the cone at $t = 1.00\,\text{ms}$ $(= 1.00 \times 10^{-3}\,\text{s})$?

**FIGURE 14–9** Example 14–7. Loudspeaker cone.

**APPROACH** The motion begins $(t = 0)$ with the cone at its maximum displacement $(x = A$ at $t = 0)$. So we use the cosine function, $x = A\cos\omega t$, with $\phi = 0$.

**SOLUTION** (*a*) The amplitude $A = 1.5 \times 10^{-4}\,\text{m}$ and

$$\omega = 2\pi f = (6.28\,\text{rad})(262\,\text{s}^{-1}) = 1650\,\text{rad/s}.$$

The motion is described as

$$x = A\cos\omega t = (1.5 \times 10^{-4}\,\text{m})\cos(1650\,t\ \text{rad}),$$

where $t$ is in seconds.

(*b*) The maximum velocity, from Eq. 14–9a, is

$$v_{\text{max}} = \omega A = (1650\,\text{rad/s})(1.5 \times 10^{-4}\,\text{m}) = 0.25\,\text{m/s},$$

so

$$v = -(0.25\,\text{m/s})\sin(1650\,t\ \text{rad}).$$

From Eq. 14–9b the maximum acceleration is $a_{\text{max}} = \omega^2 A = (1650\,\text{rad/s})^2(1.5 \times 10^{-4}\,\text{m}) = 410\,\text{m/s}^2$, which is more than 40 $g$'s. Then

$$a = -(410\,\text{m/s}^2)\cos(1650\,t\ \text{rad}).$$

(*c*) At $t = 1.00 \times 10^{-3}\,\text{s}$,

$$x = A\cos\omega t = (1.5\times10^{-4}\,\text{m})\cos[(1650\,\text{rad/s})(1.00\times10^{-3}\,\text{s})]$$
$$= (1.5\times10^{-4}\,\text{m})\cos(1.65\,\text{rad}) = -1.2\times10^{-5}\,\text{m}.$$

**NOTE** Be sure your calculator is set in RAD mode, not DEG mode, for these $\cos\omega t$ calculations.

**CAUTION**
*Always be sure your calculator is in the correct mode for angles*

**EXAMPLE 14–8** **Spring calculations.** A spring stretches 0.150 m when a 0.300-kg mass is gently suspended from it as in Fig. 14–3b. The spring is then set up horizontally with the 0.300-kg mass resting on a frictionless table as in Fig. 14–2. The mass is pulled so that the spring is stretched 0.100 m from the equilibrium point, and released from rest. Determine: (*a*) the spring stiffness constant $k$ and angular frequency $\omega$; (*b*) the amplitude of the horizontal oscillation $A$; (*c*) the magnitude of the maximum velocity $v_{\text{max}}$; (*d*) the magnitude of the maximum acceleration $a_{\text{max}}$ of the mass; (*e*) the period $T$ and frequency $f$; (*f*) the displacement $x$ as a function of time; and (*g*) the velocity at $t = 0.150\,\text{s}$.

**APPROACH** When the 0.300-kg mass hangs at rest from the spring as in Fig. 14–3b, we apply Newton's second law for the vertical forces: $\Sigma F = 0 = mg - kx_0$, so $k = mg/x_0$. For the horizontal oscillations, the amplitude is given, and the other quantities can be found from Eqs. 14–4, 14–5, 14–7, and 14–9. We choose $x$ positive to the right.

**SOLUTION** (*a*) The spring stretches 0.150 m due to the 0.300-kg load, so

$$k = \frac{F}{x_0} = \frac{mg}{x_0} = \frac{(0.300\,\text{kg})(9.80\,\text{m/s}^2)}{0.150\,\text{m}} = 19.6\,\text{N/m}.$$

From Eq. 14–5,

$$\omega = \sqrt{\frac{k}{m}} = \sqrt{\frac{19.6\,\text{N/m}}{0.300\,\text{kg}}} = 8.08\,\text{rad/s}.$$

(*b*) The spring is now horizontal (on a table). It is stretched 0.100 m from equilibrium and is given no initial speed, so $A = 0.100\,\text{m}$.

(*c*) From Eq. 14–9a, the maximum velocity has magnitude

$$v_{\text{max}} = \omega A = (8.08\,\text{rad/s})(0.100\,\text{m}) = 0.808\,\text{m/s}.$$

(*d*) Since $F = ma$, the maximum acceleration occurs where the force is greatest—that is, when $x = \pm A = \pm 0.100\,\text{m}$. Thus its magnitude is

$$a_{\text{max}} = \frac{F}{m} = \frac{kA}{m} = \frac{(19.6\,\text{N/m})(0.100\,\text{m})}{0.300\,\text{kg}} = 6.53\,\text{m/s}^2.$$

[This result could also have been obtained directly from Eq. 14–9b, but it is often useful to go back to basics as we did here.]

(*e*) Equations 14–7b and 14–2 give

$$T = 2\pi\sqrt{\frac{m}{k}} = 2\pi\sqrt{\frac{0.300\,\text{kg}}{19.6\,\text{N/m}}} = 0.777\,\text{s}$$
$$f = \frac{1}{T} = 1.29\,\text{Hz}.$$

(*f*) The motion begins at a point of maximum stretch. If we take $x$ positive to the right in Fig. 14–2, then at $t = 0$, $x = +A = 0.100\,\text{m}$. So we need a sinusoidal curve that has its maximum value at $t = 0$, which is a cosine:

$$x = A\cos\omega t,$$
$$= (0.100\,\text{m})\cos(8.08\,t\ \text{rad}),$$

where $t$ is in seconds and $x$ is in meters.

(*g*) The velocity at any time $t$ is $dx/dt$ (see also part *c*):

$$v = \frac{dx}{dt} = -\omega A\sin\omega t = -(0.808\,\text{m/s})\sin(8.08\,t\ \text{rad}).$$

At $t = 0.150\,\text{s}$, $v = -(0.808\,\text{m/s})\sin(1.21\,\text{rad}) = -0.756\,\text{m/s}$, and the object is moving to the left (the minus sign).

**EXAMPLE 14–9** **Spring is started with a push.** Suppose the spring of Example 14–8 is compressed 0.100 m from equilibrium $(x_0 = -0.100\,\text{m})$ and is given a shove to create an initial velocity in the $+x$ direction of $v_0 = 0.400$ m/s. Determine $(a)$ the phase angle $\phi$, $(b)$ the amplitude $A$, and $(c)$ the displacement $x$ as a function of time, $x(t)$.

**APPROACH** We use Eq. 14–8a, at $t = 0$, to write $v_0 = -\omega A \sin\phi$, and Eq. 14–4 to write $x_0 = A\cos\phi$. Combining these, we can obtain $\phi$. We obtain $A$ by using Eq. 14–4 again at $t = 0$. From Example 14–8, $\omega = 8.08$ rad/s.

**SOLUTION** $(a)$ We combine Eqs. 14–8a and 14–4 at $t = 0$ and solve for the tangent:

$$\tan\phi = \frac{\sin\phi}{\cos\phi} = \frac{(v_0/(-\omega A))}{(x_0/A)} = -\frac{v_0}{\omega x_0} = -\frac{0.400\,\text{m/s}}{(8.08\,\text{rad/s})(-0.100\,\text{m})} = 0.495.$$

A calculator gives the angle as 26.3°, but we note from this equation that both the sine and cosine $(x_0 < 0)$ are negative at $t = 0$, so our angle is in the third quadrant. Hence

$$\phi = 26.3° + 180° = 206.3° = 3.60\,\text{rad}.$$

$(b)$ Again using Eq. 14–4 at $t = 0$, as given in the Approach above,

$$A = \frac{x_0}{\cos\phi} = \frac{(-0.100\,\text{m})}{\cos(3.60\,\text{rad})} = 0.112\,\text{m}.$$

$(c)$ $x = A\cos(\omega t + \phi) = (0.112\,\text{m})\cos(8.08\,t\ \text{rad} + 3.60\,\text{rad})$.

# 14–3 Energy in the Simple Harmonic Oscillator

When forces are not constant, such as here with simple harmonic motion, it is often convenient and useful to use the energy approach, as we saw in Chapters 7 and 8.

For a simple harmonic oscillator, such as a mass $m$ oscillating on the end of a massless spring, the restoring force is given by

$$F = -kx.$$

The potential energy function, as we saw in Chapter 8, is given by

$$U = -\int F\,dx = \tfrac{1}{2}kx^2,$$

where we set the constant of integration equal to zero so $U = 0$ at $x = 0$ (the equilibrium position).

The total mechanical energy is the sum of the kinetic and potential energies,

$$E = \tfrac{1}{2}mv^2 + \tfrac{1}{2}kx^2,$$

where $v$ is the velocity of the mass $m$ at a distance $x$ from the equilibrium position. SHM can occur only if friction is negligible, so that the total mechanical energy $E$ remains constant. As the mass oscillates back and forth, the energy continuously changes from potential energy to kinetic energy, and back again (Fig. 14–10). At the extreme points, $x = -A$ and $x = +A$ (Figs. 14–10a, c), all the energy is stored in the spring as potential energy (and is the same whether the spring is compressed or stretched to the full amplitude). At these extreme points, the mass stops for an instant as it changes direction, so $v = 0$ and:

$$E = \tfrac{1}{2}m(0)^2 + \tfrac{1}{2}kA^2 = \tfrac{1}{2}kA^2. \qquad \textbf{(14–10a)}$$

Thus, the **total mechanical energy of a simple harmonic oscillator is proportional to the square of the amplitude**. At the equilibrium point, $x = 0$, all the energy is kinetic:

$$E = \tfrac{1}{2}mv^2 + \tfrac{1}{2}k(0)^2 = \tfrac{1}{2}mv_{\text{max}}^2, \qquad \textbf{(14–10b)}$$

where $v_{\text{max}}$ is the maximum velocity during the motion (which occurs at $x = 0$). Note that $v_{\text{max}} \neq v_0$.

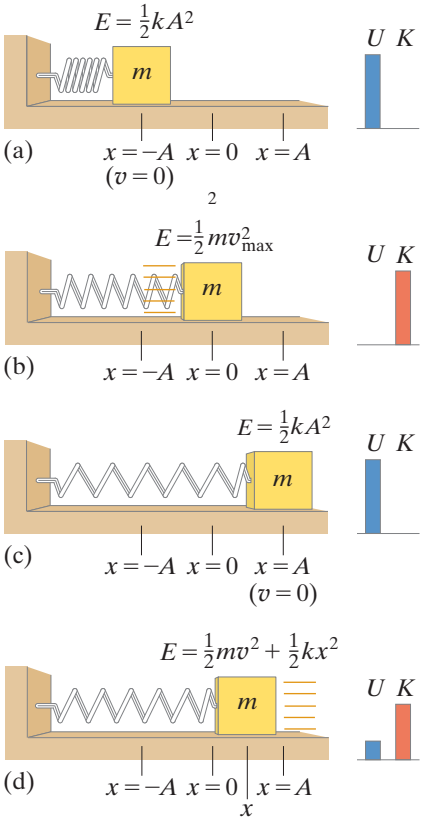


**FIGURE 14–10** Energy changes from potential energy to kinetic energy and back again as the spring oscillates. Energy bar graphs (on the right) are described in Section 8–4 (Fig. 8–7).

At intermediate points (Fig. 14–10d), the energy is part kinetic and part potential. Energy conservation tells us

$$E = \tfrac{1}{2}mv^2 + \tfrac{1}{2}kx^2 \qquad \textbf{(14–10c)}$$

Let us check Eqs. 14–10a and b by inserting Eqs. 14–8a and 14–4 into Eq. 14–10c:

$$E = \tfrac{1}{2}m\omega^2A^2\sin^2(\omega t + \phi) + \tfrac{1}{2}kA^2\cos^2(\omega t + \phi).$$

Using Eq. 14–5, $\omega^2 = k/m$, we have $m\omega^2 = k$, so

$$E = \tfrac{1}{2}kA^2\left[\sin^2(\omega t + \phi) + \cos^2(\omega t + \phi)\right].$$

Equation 14–9a tells us $kA^2 = mv_{\text{max}}^2$, and recalling the trigonometric identity $\sin^2(\omega t + \phi) + \cos^2(\omega t + \phi) = 1$, we obtain Eqs. 14–10a and b:

$$E = \tfrac{1}{2}kA^2 = \tfrac{1}{2}mv_{\text{max}}^2.$$

We can now obtain an equation for the velocity $v$ as a function of $x$ by solving for $v$ in Eq. 14–10c, $v = \pm\sqrt{(2E - kx^2)/m}$, and then substituting (from Eq. 14–10a) $E = \frac{1}{2}kA^2$, to find

$$v = \pm\sqrt{\frac{k}{m}(A^2 - x^2)}. \qquad \textbf{(14–11a)}$$

Because $v_{\text{max}} = A\sqrt{k/m}$ (as in Eq. 14–9a), then

$$v = \pm v_{\text{max}}\sqrt{1 - \frac{x^2}{A^2}}. \qquad \textbf{(14–11b)}$$

Again we see that $v$ is a maximum at $x = 0$, and is zero at $x = \pm A$.

The potential energy, $U = \frac{1}{2}kx^2$, is plotted in Fig. 14–11 (see also Section 8–9). The upper horizontal line represents a particular value of the total energy $E = \frac{1}{2}kA^2$. The distance between the $E$ line and the $U$ curve represents the kinetic energy, $K$, and the motion is restricted to $x$ values between $-A$ and $+A$. These results are consistent with our full solution of the previous Section.

Energy conservation is a convenient way to obtain $v$, for example, if $x$ is given (or vice versa), without having to deal with time $t$.

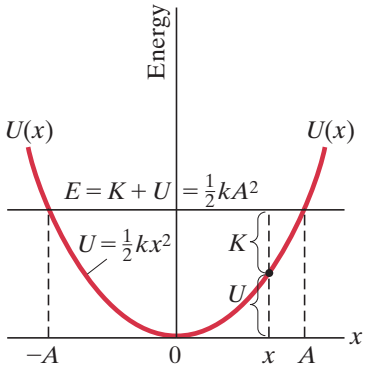

**FIGURE 14–11** Graph of potential energy, $U = \frac{1}{2}kx^2$, as a function of $x$. $K + U = E =$ constant for any point $x$ where $-A \le x \le A$. Values of $K$ and $U$ are indicated towards the right for an arbitrary position $x$.

**EXAMPLE 14–10** **Energy calculations.** For the simple harmonic oscillator of Example 14–8, determine (*a*) the total energy, (*b*) the kinetic and potential energies as a function of time, (*c*) the velocity when the mass is 0.050 m from equilibrium, (*d*) the kinetic and potential energies at half amplitude $(x = \pm A/2)$.

**APPROACH** We use conservation of energy for a spring–mass system, Eqs. 14–10 and 14–11.

**SOLUTION** (*a*) From Example 14–8, $k = 19.6\,\text{N/m}$ and $A = 0.100\,\text{m}$, so the total energy $E$ from Eq. 14–10a is

$$E = \tfrac{1}{2}kA^2 = \tfrac{1}{2}(19.6\,\text{N/m})(0.100\,\text{m})^2 = 0.0980\,\text{J}.$$

(*b*) We have, from parts (*f*) and (*g*) of Example 14–8, $x = (0.100\,\text{m})\cos(8.08\,t\ \text{rad})$ and $v = -(0.808\,\text{m/s})\sin(8.08\,t\ \text{rad})$, so

$$U = \tfrac{1}{2}kx^2 = \tfrac{1}{2}(19.6\,\text{N/m})(0.100\,\text{m})^2\cos^2(8.08\,t\ \text{rad}) = (0.0980\,\text{J})\cos^2(8.08\,t\ \text{rad})$$

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}(0.300\,\text{kg})(0.808\,\text{m/s})^2\sin^2(8.08\,t\ \text{rad}) = (0.0980\,\text{J})\sin^2(8.08\,t\ \text{rad}).$$

Note that $U + K = E$ because $\sin^2\theta + \cos^2\theta = 1$.

(*c*) We use Eq. 14–11b and find

$$v = v_{\text{max}}\sqrt{1 - x^2/A^2} = (0.808\,\text{m/s})\sqrt{1 - \left(\tfrac{1}{2}\right)^2} = 0.700\,\text{m/s}.$$

(*d*) At $x = A/2 = 0.050\,\text{m}$, we have

$$U = \tfrac{1}{2}kx^2 = \tfrac{1}{2}(19.6\,\text{N/m})(0.050\,\text{m})^2 = 2.5 \times 10^{-2}\,\text{J}$$

$$K = E - U = 7.3 \times 10^{-2}\,\text{J}.$$

**CONCEPTUAL EXAMPLE 14–11** **Doubling the amplitude.** Suppose the spring in Fig. 14–10 is stretched twice as far (to $x = 2A$). What happens to (*a*) the energy of the system, (*b*) the maximum velocity of the oscillating mass, (*c*) the maximum acceleration of the mass?

**RESPONSE** (*a*) From Eq. 14–10a, the total energy is proportional to the square of the amplitude $A$, so stretching it twice as far quadruples the energy $(2^2 = 4)$. You may protest, "I did work stretching the spring from $x = 0$ to $x = A$. Don't I do the same work stretching it from $A$ to $2A$?" No. The force you exert is proportional to the displacement $x$, so for the second displacement, from $x = A$ to $2A$, you do more work than for the first displacement $(x = 0$ to $A)$.

(*b*) From Eqs. 14–10a and b, we can see that when the amplitude is doubled, the maximum velocity must be doubled $(v_{\max} \propto \sqrt{E} \propto A)$.

(*c*) Since the force is twice as great when we stretch the spring twice as far, the acceleration is also twice as great: $a \propto F \propto x$.

**EXERCISE E** Suppose the spring in Fig. 14–10 is compressed to $x = -A$, but is given a push to the right so that the initial speed of the mass $m$ is $v_0$. What effect does this push have on (*a*) the energy of the system, (*b*) the maximum velocity, (*c*) the maximum acceleration?

# 14–4 Simple Harmonic Motion Related to Uniform Circular Motion

Simple harmonic motion has a simple relationship to a particle rotating in a circle with uniform speed. Consider a mass $m$ rotating in a circle of radius $A$ with speed $v_M$ on top of a table as shown in Fig. 14–12. As viewed from above, the motion is a circle. But a person who looks at the motion from the edge of the table sees an oscillatory motion back and forth, and this corresponds precisely to SHM as we shall now see. What the person sees, and what we are interested in, is the projection of the circular motion onto the $x$ axis, Fig. 14–12. To see that this motion is analogous to SHM, let us calculate the $x$ component of the velocity $v_M$ which is labeled $v$ in Fig. 14–12. The two right triangles indicated in Fig. 14–12 are similar, so

$$\frac{v}{v_M} = \frac{\sqrt{A^2 - x^2}}{A}$$

or

$$v = v_M \sqrt{1 - \frac{x^2}{A^2}}.$$

This is exactly the equation for the speed of a mass oscillating with SHM, Eq. 14–11b, where $v_M = v_{\max}$. Furthermore, we can see from Fig. 14–12 that if the angular displacement at $t = 0$ is $\phi$, then after a time $t$ the particle will have rotated through an angle $\theta = \omega t$, and so

$$x = A\cos(\theta + \phi) = A\cos(\omega t + \phi).$$

But what is $\omega$ here? The linear velocity $v_M$ of our particle undergoing rotational motion is related to $\omega$ by $v_M = \omega A$, where $A$ is the radius of the circle (see Eq. 10–4, $v = R\omega$). To make one revolution requires a time $T$, so we also have $v_M = 2\pi A/T$ where $2\pi A$ is the circle's circumference. Hence

$$\omega = \frac{v_M}{A} = \frac{2\pi A/T}{A} = 2\pi/T = 2\pi f$$

where $T$ is the time required for one rotation and $f$ is the frequency of rotation. This corresponds precisely to the back-and-forth motion of a simple harmonic oscillator. Thus, the projection on the $x$ axis of a particle rotating in a circle has the same motion as a mass undergoing SHM. Indeed, we can say that the projection of circular motion onto a straight line is simple harmonic motion.

The projection of uniform circular motion onto the $y$ axis is also simple harmonic. Thus uniform circular motion can be thought of as two simple harmonic motions operating at right angles.

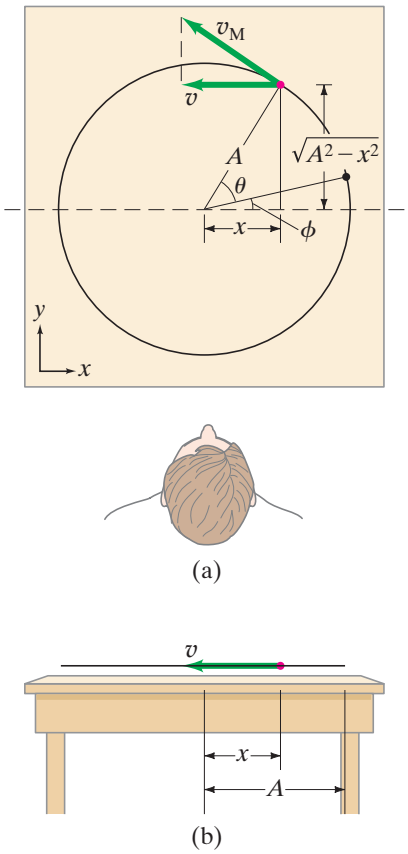

**FIGURE 14–12** Analysis of simple harmonic motion as a side view (b) of circular motion (a).

# 14–5 The Simple Pendulum

A **simple pendulum** consists of a small object (the pendulum bob) suspended from the end of a lightweight cord, Fig. 14–13. We assume that the cord does not stretch and that its mass can be ignored relative to that of the bob. The motion of a simple pendulum moving back and forth with negligible friction resembles simple harmonic motion: the pendulum bob oscillates along the arc of a circle with equal amplitude on either side of its equilibrium point, and as it passes through the equilibrium point (where it would hang vertically) it has its maximum speed. But is it really undergoing SHM? That is, is the restoring force proportional to its displacement? Let us find out.

The displacement $s$ of the pendulum along the arc is given by $s = \ell\theta$, where $\theta$ is the angle (in radians) that the cord makes with the vertical and $\ell$ is the length of the cord (Fig. 14–14). If the restoring force is proportional to $s$ or to $\theta$, the motion will be simple harmonic. The restoring force is the net force on the bob, which equals the component of the weight ($mg$) tangent to the arc:

$$F = -mg\sin\theta,$$

where $g$ is the acceleration due to gravity. The minus sign here, as in Eq. 14–1, means the force is in the direction opposite to the angular displacement $\theta$. Since $F$ is proportional to the sine of $\theta$ and not to $\theta$ itself, the motion is *not* SHM. However, if $\theta$ is small, then $\sin\theta$ is very nearly equal to $\theta$ when the angle is specified in radians. This can be seen by looking at the series expansion[†] of $\sin\theta$, or simply by noting in Fig. 14–14 that the arc length $s\ (= \ell\theta)$ is nearly the same length as the chord $(= \ell\sin\theta)$ indicated by the horizontal straight dashed line, *if $\theta$ is small*. For angles less than 15°, the difference between $\theta$ (in radians) and $\sin\theta$ is less than 1%—see Table 14–1. Thus, to a very good approximation for small angles,

$$F = -mg\sin\theta \approx -mg\theta.$$

Substituting $s = \ell\theta$, or $\theta = s/\ell$, we have

$$F \approx -\frac{mg}{\ell}s.$$

Thus, for small displacements, the motion can be modeled as being approximately simple harmonic, because this approximate equation fits Hooke's law, $F = -kx$, where in place of $x$ we have arc length $s$. The effective force constant is $k = mg/\ell$. Thus we can write

$$\theta = \theta_{\max}\cos(\omega t + \phi)$$

where $\theta_{\max}$ is the maximum angular displacement and $\omega = 2\pi f = 2\pi/T$. To obtain $\omega$ we use Eq. 14–5, where for $k$ we substitute $mg/\ell$: that is,[‡] $\omega = \sqrt{k/m} = \sqrt{(mg/\ell)/m}$, or

$$\omega = \sqrt{\frac{g}{\ell}}. \qquad [\theta \text{ small}] \quad \textbf{(14–12a)}$$

Then the frequency $f$ and period $T$ are

$$f = \frac{\omega}{2\pi} = \frac{1}{2\pi}\sqrt{\frac{g}{\ell}}, \qquad [\theta \text{ small}] \quad \textbf{(14–12b)}$$

$$T = \frac{1}{f} = 2\pi\sqrt{\frac{\ell}{g}}. \qquad [\theta \text{ small}] \quad \textbf{(14–12c)}$$

The mass $m$ of the pendulum bob does not appear in these formulas for $T$ and $f$. Thus we have the surprising result that the period and frequency of a simple pendulum do not depend on the mass of the pendulum bob. You may have noticed this if you pushed a small child and then a large one on the same swing.

[†] $\sin\theta = \theta - \frac{\theta^3}{3!} + \frac{\theta^5}{5!} - \frac{\theta^7}{7!} + \cdots$ (Appendix A).

[‡] We are using the symbol $\omega$ differently here; it is not $d\theta/dt$ as in rotational motion. In this Section $\theta$ is the angle of the pendulum at any instant (Fig. 14–14), but we use $\omega$ now to represent *not* the rate this angle $\theta$ changes, but rather a constant related to the period of oscillation, $\omega = 2\pi f = \sqrt{g/\ell}$.

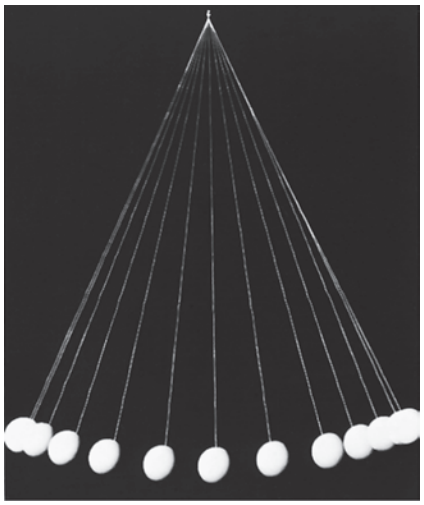

**FIGURE 14–13** Strobe-light photo of an oscillating pendulum photographed at equal time intervals.

**FIGURE 14–14** Simple pendulum, and a free-body diagram.

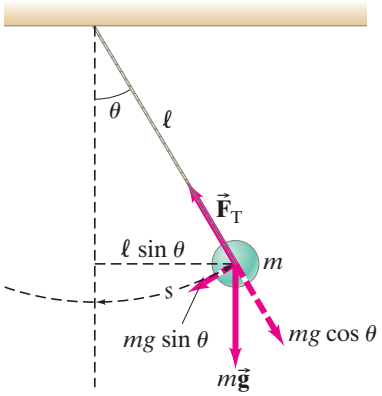

**TABLE 14–1 Sin $\theta$ at Small Angles**

| $\theta$ (degrees) | $\theta$ (radians) | $\sin\theta$ | % Difference |
|---|---|---|---|
| 0 | 0 | 0 | 0 |
| 1° | 0.01745 | 0.01745 | 0.005% |
| 5° | 0.08727 | 0.08716 | 0.1% |
| 10° | 0.17453 | 0.17365 | 0.5% |
| 15° | 0.26180 | 0.25882 | 1.1% |

**PHYSICS APPLIED**
*Pendulum clock*

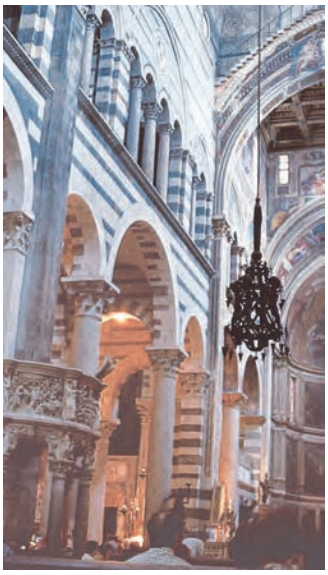

**FIGURE 14–15** The swinging motion of this elaborate lamp, hanging by a very long cord from the ceiling of the cathedral at Pisa, Italy, is said to have been observed by Galileo and to have inspired him to the conclusion that the period of a pendulum does not depend on amplitude.

We also see from Eq. 14–12c that the period of a pendulum does not depend on the amplitude (like any SHM, Section 14–2), as long as the amplitude $\theta$ is small. Galileo is said to have first noted this fact while watching a swinging lamp in the cathedral at Pisa (Fig. 14–15). This discovery led to the invention of the pendulum clock, the first really precise timepiece, which became the standard for centuries.

Because a pendulum does not undergo *precisely* SHM, the period does depend slightly on the amplitude, the more so for large amplitudes. The accuracy of a pendulum clock would be affected, after many swings, by the decrease in amplitude due to friction. But a mainspring in a pendulum clock (or the falling weight in a grandfather clock) supplies energy to compensate for the friction and to maintain the amplitude constant, so that the timing remains precise.

**EXERCISE F** Return to the Chapter-Opening Question, page 399, and answer it again now. Try to explain why you may have answered differently the first time.

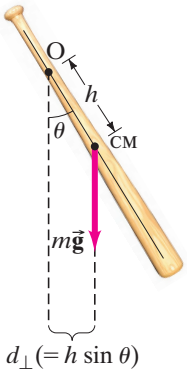
**EXERCISE G** If a simple pendulum is taken from sea level to the top of a high mountain and started at the same angle of 5°, it would oscillate at the top of the mountain (*a*) slightly slower; (*b*) slightly faster; (*c*) at exactly the same frequency; (*d*) not at all—it would stop; (*e*) none of these.

**EXAMPLE 14–12** **Measuring *g*.** A geologist uses a simple pendulum that has a length of 37.10 cm and a frequency of 0.8190 Hz at a particular location on the Earth. What is the acceleration due to gravity at this location?

**APPROACH** We can use the length $\ell$ and frequency $f$ of the pendulum in Eq. 14–12b, which contains our unknown, $g$.

**SOLUTION** We solve Eq. 14–12b for $g$ and obtain

$$g = (2\pi f)^2\ell = (2\pi)^2(0.8190\,\text{s}^{-1})^2(0.3710\,\text{m}) = 9.824\,\text{m/s}^2.$$



# *14–6 The Physical Pendulum and the Torsion Pendulum

## *Physical Pendulum

The term physical pendulum refers to any real extended object which oscillates back and forth, in contrast to the rather idealized simple pendulum where all the mass is assumed concentrated in the tiny pendulum bob. An example of a physical pendulum is a baseball bat suspended from the point O, as shown in Fig. 14–16. We can write the force of gravity as acting at the center of gravity or center of mass (CM) of the object located a distance $h$ from the pivot point O. The physical pendulum is best analyzed using the equations of rotational motion. The torque on a physical pendulum, calculated about point O, is

$$\tau = -mgh\sin\theta.$$

**FIGURE 14–16** A physical pendulum suspended from point O.

Newton's second law for rotational motion, Eq. 10–14, states that

$$\Sigma\tau = I\alpha = I\frac{d^2\theta}{dt^2},$$

where $I$ is the moment of inertia of the object about the pivot point and $\alpha = d^2\theta/dt^2$ is the angular acceleration. Thus we have

$$I\frac{d^2\theta}{dt^2} = -mgh\sin\theta$$

or

$$\frac{d^2\theta}{dt^2} + \frac{mgh}{I}\sin\theta = 0,$$

where $I$ is calculated about an axis through point O (Fig. 14–16).

For small angular amplitude, $\sin\theta \approx \theta$, so we have

$$\frac{d^2\theta}{dt^2} + \left(\frac{mgh}{I}\right)\theta = 0. \qquad \text{[small angular displacement]} \quad \textbf{(14–13)}$$

This is just the equation for SHM, Eq. 14–3, except that $\theta$ replaces $x$ and $mgh/I$ replaces $k/m$. Thus, for small angular displacements, a physical pendulum undergoes SHM, given by

$$\theta = \theta_{\max}\cos(\omega t + \phi),$$

where $\theta_{\max}$ is the maximum angular displacement and $\omega = 2\pi/T$. The period, $T$, is (see Eq. 14–7b, replacing $m/k$ with $I/mgh$):

$$T = 2\pi\sqrt{\frac{I}{mgh}}. \qquad \text{[small angular displacement]} \quad \textbf{(14–14)}$$

**EXAMPLE 14–13** **Moment of inertia measurement.** An easy way to measure the moment of inertia of an object about any axis is to measure the period of oscillation about that axis. (*a*) Suppose a nonuniform 1.0-kg stick can be balanced at a point 42 cm from one end. If it is pivoted about the end closest to that point ( = CM), Fig. 14–17, it oscillates with a period of 1.6 s. What is its moment of inertia about this end? (*b*) What is its moment of inertia about an axis perpendicular to the stick through its center of mass?

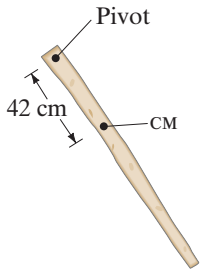


**FIGURE 14–17** Example 14–13.

**APPROACH** We put the given values into Eq. 14–14 and solve for $I$. The distance from the pivot point at the rod's end to the CM is $h = 42$ cm. For (*b*) we use the parallel-axis theorem (Section 10–7).

**SOLUTION** (*a*) Given $T = 1.6$ s, and $h = 0.42$ m, Eq. 14–14 gives

$$I = mghT^2/4\pi^2 = 0.27\ \text{kg}\cdot\text{m}^2.$$

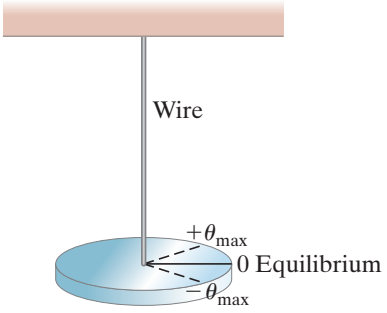
(*b*) We use the parallel-axis theorem, Eq. 10–17. The CM is where the stick balanced, 42 cm from the end, so

$$I_{CM} = I - mh^2 = 0.27\ \text{kg}\cdot\text{m}^2 - (1.0\ \text{kg})(0.42\ \text{m})^2 = 0.09\ \text{kg}\cdot\text{m}^2.$$

**NOTE** An object does not oscillate about its CM, so we cannot measure $I_{CM}$ directly. But the parallel-axis theorem provides a convenient method to determine $I_{CM}$.

## *Torsion Pendulum

Another type of oscillatory motion is by a **torsion pendulum**, in which a disk (Fig. 14–18) or a bar (as in Cavendish's apparatus, Fig. 6–3) is suspended from a wire. The twisting (torsion) of the wire serves as the elastic force. The motion here will be SHM since the restoring torque is very closely proportional to the negative of the angular displacement,



$$\tau = -k\theta,$$

where $k$ is a constant that depends on the wire stiffness under rotation. Then, since $\tau = I\alpha = -k\theta$ corresponds to $F = ma = -kx$, so for a torsion pendulum

$$\omega = \sqrt{k/I}.$$

There is no small angle restriction here, as there is for the physical pendulum (where gravity acts), as long as the wire responds linearly in accordance with Hooke's law.

**FIGURE 14–18** A torsion pendulum. The disk oscillates in SHM between $\theta_{\max}$ and $-\theta_{\max}$.

# 14–7 Damped Harmonic Motion

The amplitude of any real oscillating spring or swinging pendulum slowly decreases in time until the oscillations stop altogether. Figure 14–19 shows a typical graph of the displacement as a function of time. This is called **damped harmonic motion**. The damping[†] is generally due to the resistance of air and to friction within the oscillating system. The energy that is dissipated to thermal energy results in a decreased amplitude of oscillation.

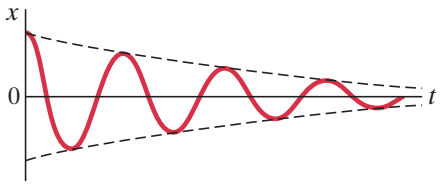


**FIGURE 14–19** Damped harmonic motion. The solid red curve represents a cosine times a decreasing exponential (the dashed lines).

Since natural oscillating systems are damped in general, why do we even talk about (undamped) simple harmonic motion? The answer is that SHM is much easier to deal with mathematically. And if the damping is not large, the oscillations can be thought of as simple harmonic motion on which the damping is superposed, as represented by the dashed lines in Fig. 14–19. Although damping does alter the frequency of vibration, the effect can be small if the damping is small. Let us look at this in more detail.

The damping force can depend on the speed of the oscillating object, and opposes the motion. In some simple cases the damping force (Section 5–6) can be approximated as being directly proportional to the speed:

$$F_{\text{damping}} = -bv,$$

where $b$ is a constant. For a mass oscillating on the end of a spring, the restoring force of the spring is $F = -kx$; so Newton's second law $(ma = \Sigma F)$ becomes

$$ma = -kx - bv.$$

We bring all terms to the left side of the equation and substitute $v = dx/dt$ and $a = d^2x/dt^2$ to obtain

$$m\frac{d^2x}{dt^2} + b\frac{dx}{dt} + kx = 0, \qquad \textbf{(14–15)}$$

which is the *equation of motion* for damped harmonic motion. To solve this equation, we guess at a solution and then check to see if it works. If the damping constant $b$ is small, $x$ as a function of $t$ is as plotted in Fig. 14–19, which looks like a cosine function times a factor (represented by the dashed lines) that decreases in time. A simple function that does this is the exponential, $e^{-\gamma t}$, and a solution that might satisfy Eq. 14–15 is

$$x = Ae^{-\gamma t}\cos\omega' t, \qquad \textbf{(14–16)}$$

where $A$, $\gamma$, and $\omega'$ are assumed to be constants, and $x = A$ at $t = 0$. If we substitute Eq. 14–16 into Eq. 14–15 (we do this in the optional subsection at the end of this Section, page 417), we find that Eq. 14–16 is indeed a solution if $\gamma$ and $\omega'$ have the values

$$\gamma = \frac{b}{2m} \qquad \textbf{(14–17)}$$

$$\omega' = \sqrt{\frac{k}{m} - \frac{b^2}{4m^2}}. \qquad \textbf{(14–18)}$$

We have called the angular frequency $\omega'$ (and not $\omega$) because it is not the same as the $\omega$ for SHM without damping $(\omega = \sqrt{k/m})$.

[†]To "damp" means to diminish, restrain, or extinguish, as to "dampen one's spirits."

Thus $x$ as a function of time $t$ for a (lightly) damped harmonic oscillator is

$$x = Ae^{(-b/2m)t}\cos\omega' t. \qquad \textbf{(14–19)}$$

Of course a phase constant, $\phi$, can be added to the argument of the cosine in Eq. 14–19. As it stands with $\phi = 0$, it is clear that the constant $A$ in Eq. 14–19 is simply the initial displacement, $x = A$ at $t = 0$. The frequency $f'$ is

$$f' = \frac{\omega'}{2\pi} = \frac{1}{2\pi}\sqrt{\frac{k}{m} - \frac{b^2}{4m^2}}. \qquad \textbf{(14–20)}$$

The frequency is lower, and the period longer, than for undamped SHM. (In many practical cases of light damping, however, $\omega'$ differs only slightly from $\omega = \sqrt{k/m}$.) This makes sense since we expect damping to slow down the motion. Equation 14–20 reduces to Eq. 14–7a, as it should, when there is no damping $(b = 0)$. The constant $\gamma = b/2m$ is a measure of how quickly the oscillations decrease toward zero (Fig. 14–19). The time $\tau = 2m/b$ is the time taken for the oscillations to drop to $1/e$ of the original amplitude, and is sometimes referred to as the **relaxation time** of the oscillations. Note that the larger $b$ is, the more quickly the oscillations die away.

The solution, Eq. 14–19, is not valid if $b$ is so large that

$$b^2 > 4mk$$

because then $\omega'$ (Eq. 14–18) would become imaginary. In this case the system does not oscillate at all but returns directly to its equilibrium position: the damping is so large that the motion no longer resembles simple harmonic motion.

Three common cases of *heavily damped* systems are shown in Fig. 14–20. Curve B represents an **underdamped** situation, in which the system makes several oscillations before coming to rest $(b^2 < 4mk)$; it corresponds to a more heavily damped version of Fig. 14–19. Curve D represents the **overdamped** situation, when the damping is so large $(b^2 > 4mk)$ that there is no oscillation and the system takes a long time to come to rest (equilibrium). Curve C represents **critical damping**: $(b^2 = 4mk)$; in this case the displacement approaches zero in the shortest time. These terms all derive from the use of practical damped systems such as door-closing mechanisms and **shock absorbers** in a car (Fig. 14–21), which are usually designed to give critical damping. But as they wear out, underdamping occurs: the door of a room slams and a car bounces up and down several times when it hits a bump.

In many systems, the oscillatory motion is what counts, as in clocks and musical instruments, and damping may need to be minimized. In other systems, oscillations are the problem, such as a car's springs, so a proper amount of damping (i.e., critical) is desired. Well-designed damping is needed for all kinds of applications. Large buildings, especially in California, are now built (or retrofitted) with huge **dampers** to reduce possible earthquake damage (Fig. 14–22).

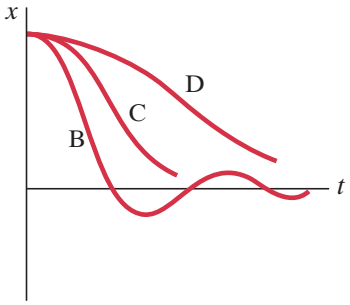

**FIGURE 14–20** Underdamped (B), critically damped (C), and overdamped (D) motion.

**FIGURE 14–21** Automobile spring with shock absorber which provides damping so that a car won't bounce up and down endlessly. See Chapter-Opening photograph, page 399.

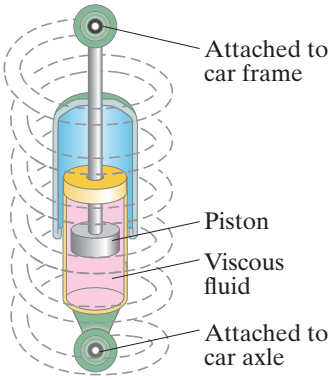

**FIGURE 14–22** These huge dampers placed in a building look a lot like huge automobile shock absorbers, and they serve a similar purpose—to reduce the amplitude and the acceleration of movement when the shock of an earthquake hits.

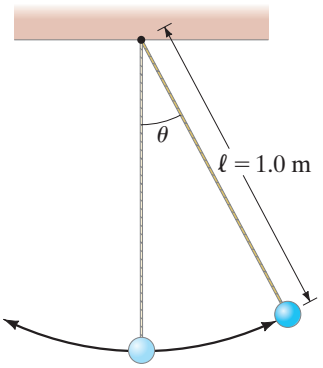

**FIGURE 14–23** Example 14–14.

**EXAMPLE 14–14 Simple pendulum with damping** A simple pendulum has a length $\ell = 1.0\,\text{m}$ (Fig. 14–23). It is set swinging with small-amplitude oscillations. After 5.0 minutes, the amplitude is only 50% of what it was initially. (*a*) What is the value of $\gamma$ for the motion? (*b*) By what factor does the frequency, $f'$, differ from $f$, the undamped frequency?

**APPROACH** Lightly damped harmonic motion is described by (see Eqs. 14–16, 14–17, and 14–18)

$$x = Ae^{-\gamma t}\cos\omega' t, \quad \text{where} \quad \gamma = \frac{b}{2m} \quad \text{and} \quad \omega' = \sqrt{\frac{k}{m} - \frac{b^2}{4m^2}},$$

for damped motion of a mass on the end of a spring. For the simple pendulum without damping, we saw in Section 14–5 that, for small $\theta$,

$$F = -mg\theta.$$

We start with $F = ma$, where $a$ can be written in terms of the angular acceleration $\alpha = d^2\theta/dt^2$; that is, $a = \ell\alpha = \ell\, d^2\theta/dt^2$ so $F = ma = m\ell\, d^2\theta/dt^2$. Then, $F = ma$ means $ma - F = 0$ where $F = -mg\theta$, so (cancelling out $m$)

$$\ell\frac{d^2\theta}{dt^2} + g\theta = 0.$$

We introduce a damping term, $b(d\theta/dt)$, assuming the damping force is proportional to *angular* speed, $d\theta/dt$ (instead of plain $v$ as before):

$$\ell\frac{d^2\theta}{dt^2} + b\frac{d\theta}{dt} + g\theta = 0,$$

which is the same as Eq. 14–15 with $\theta$ replacing $x$, and $\ell$ and $g$ replacing $m$ and $k$.

**SOLUTION** (*a*) We compare Eq. 14–15 with our equation just above and see that Eq. 14–16, $x = Ae^{-\gamma t}\cos\omega' t$, becomes an equation for $\theta$,

$$\theta = Ae^{-\gamma t}\cos\omega' t,$$

where

$$\gamma = \frac{b}{2\ell} \quad \text{and} \quad \omega' = \sqrt{\frac{g}{\ell} - \frac{b^2}{4\ell^2}}.$$

At $t = 0$,

$$\theta_0 = Ae^{-\gamma\cdot 0}\cos\omega'\cdot 0 = A.$$

Then at $t = 5.0\,\text{min} = 300\,\text{s}$, the amplitude $\theta$ has fallen to $0.50A$, so

$$0.50A = Ae^{-\gamma(300\,\text{s})}.$$

We solve this for $\gamma$ and obtain $\gamma = \ln 2.0/(300\,\text{s}) = 2.3\times10^{-3}\,\text{s}^{-1}$. This means the oscillations fall to $1/e$ of their initial amplitude in a time $t = 1/\gamma = 1/(2.3\times10^{-3}\,\text{s}) = 430\,\text{s}$ or about 7 minutes.

(*b*) We have $\ell = 1.0\,\text{m}$, so $b = 2\gamma\ell = 2(2.3\times10^{-3}\,\text{s}^{-1})(1.0\,\text{m}) = 4.6\times10^{-3}\,\text{m/s}$. Thus $(b^2/4\ell^2)$ is very much less than $g/\ell$ $(= 9.8\,\text{s}^{-2})$, and the angular frequency of the motion remains almost the same as that of the undamped motion. Specifically (see Eq. 14–20),

$$f' = \frac{1}{2\pi}\sqrt{\frac{g}{\ell}}\left[1 - \frac{\ell}{g}\left(\frac{b^2}{4\ell^2}\right)\right]^{\frac{1}{2}} \approx \frac{1}{2\pi}\sqrt{\frac{g}{\ell}}\left[1 - \frac{1}{2}\frac{\ell}{g}\left(\frac{b^2}{4\ell^2}\right)\right]$$

where we have used the binomial expansion (see Appendix A–2). Then, with $f = (1/2\pi)\sqrt{g/\ell}$ (Eq. 14–12b),

$$\frac{f - f'}{f} \approx \frac{1}{2}\frac{\ell}{g}\left(\frac{b^2}{4\ell^2}\right) = 2.7\times10^{-7}.$$

So $f'$ differs from $f$ by less than one part in a million.

### *Showing $x = Ae^{-\gamma t}\cos\omega' t$ Is a Solution

We start with Eq. 14–16, to see if it is a solution to Eq. 14–15. First we take the first and second derivatives

$$\frac{dx}{dt} = -\gamma Ae^{-\gamma t}\cos\omega' t - \omega' Ae^{-\gamma t}\sin\omega' t$$

$$\frac{d^2x}{dt^2} = \gamma^2 Ae^{-\gamma t}\cos\omega' t + \gamma A\omega' e^{-\gamma t}\sin\omega' t + \omega'\gamma Ae^{-\gamma t}\sin\omega' t - \omega'^2 Ae^{-\gamma t}\cos\omega' t.$$

We next substitute these relations back into Eq. 14–15 and reorganize to obtain

$$Ae^{-\gamma t}\left[(m\gamma^2 - m\omega'^2 - b\gamma + k)\cos\omega' t + (2\omega'\gamma m - b\omega')\sin\omega' t\right] = 0. \qquad \textbf{(i)}$$

The left side of this equation must equal zero for all times $t$, because it is zero on the right. But this can only be so for certain values of $\gamma$ and $\omega'$. We choose two values of $t$ that will make their evaluation easy. At $t = 0$, $\sin\omega' t = 0$, so the above relation reduces to $A(m\gamma^2 - m\omega'^2 - b\gamma + k) = 0$, which means[†] that

$$m\gamma^2 - m\omega'^2 - b\gamma + k = 0. \qquad \textbf{(ii)}$$

Then at $t = \pi/2\omega'$, $\cos\omega' t = 0$, so Eq. (i) can be valid only if

$$2\gamma m - b = 0, \quad \text{or} \quad \gamma = \frac{b}{2m}. \qquad [= \text{Eq. 14–17}]$$

From Eq. (ii)

$$\omega' = \sqrt{\gamma^2 - \frac{b\gamma}{m} + \frac{k}{m}} = \sqrt{\frac{k}{m} - \frac{b^2}{4m^2}}. \qquad [= \text{Eq. 14–18}]$$

We see Eq. 14–16 is a solution to the equation of motion for damped harmonic motion as long as $\gamma$ and $\omega'$ satisfy Eqs. 14–17 and 14–18.

## 14–8 Forced Oscillations; Resonance

When an oscillating system is set into motion, it oscillates at its natural frequency $f = 1/2\pi\sqrt{k/m}$, Eq. 14–7a (or, for a simple pendulum, Eq. 14–12b). However, a system may have an external force applied to it that has its own particular frequency. Then we have a **forced oscillation**.

For example, we might pull the mass on the spring of Fig. 14–1 back and forth at an externally applied frequency $f$. The mass then oscillates at the external frequency $f$ of the external force, even if this frequency is different from the **natural frequency** of the spring, which we will now denote by $f_0$, where (see Eq. 14–7a)

$$f_0 = \frac{1}{2\pi}\sqrt{\frac{k}{m}}.$$

For a forced oscillation with only light damping, the amplitude of oscillation is found to depend on the difference between $f$ and $f_0$, and is a maximum when the frequency of the external force equals the natural frequency of the system—that is, when $f = f_0$. The amplitude is plotted in Fig. 14–24 as a function of the external frequency $f$. Curve B represents light damping and curve C heavy damping. When the external driving frequency $f$ is near the natural frequency, $f \approx f_0$, the amplitude can become large if the damping is small. This effect of increased amplitude at $f = f_0$ is known as **resonance**. The natural oscillation frequency $f_0$ of a system is also called its **resonant frequency**.

A simple illustration of resonance is pushing a child on a swing. A swing, like any pendulum, has a natural frequency of oscillation. If you push on the swing at a random frequency, the swing bounces around and reaches no great amplitude. But if you push with a frequency equal to the natural frequency of the swing, the amplitude increases greatly. At resonance, relatively little effort is required to obtain and maintain a large amplitude.

The great tenor Enrico Caruso was said to be able to shatter a crystal goblet by singing a note of just the right frequency at full voice. This is an example of resonance, for the sound waves emitted by the voice act as a forced oscillation on the glass. At resonance, the resulting oscillation of the goblet may be large enough in amplitude that the glass exceeds its elastic limit and breaks (Fig. 14–25).

[†]It would also be satisfied by $A = 0$, but this gives the trivial and uninteresting solution $x = 0$ for all $t$—that is, no oscillation.

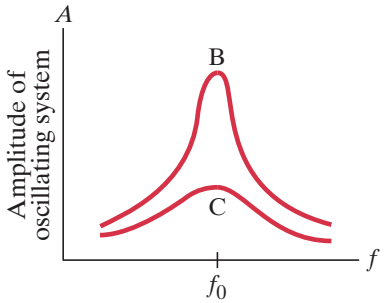

**FIGURE 14–24** Amplitude as a function of driving frequency $f$, showing resonance for lightly damped (B) and heavily damped (C) systems.

**PHYSICS APPLIED**

*Child on a swing*

**FIGURE 14–25** A goblet breaks as it vibrates in resonance to a trumpet call.

(a)

(b)

**FIGURE 14–26** (a) Large-amplitude oscillations of the Tacoma Narrows Bridge, due to gusty winds, led to its collapse (1940). (b) Collapse of a freeway in California, due to resonance in the soft ground below, caused by the 1989 earthquake.

Since material objects are, in general, elastic, resonance is an important phenomenon in a variety of situations. It is particularly important in structural engineering, although the effects are not always foreseen. For example, it has been reported that a railway bridge collapsed because a nick in one of the wheels of a crossing train set up a resonant oscillation in the bridge. Marching soldiers break step when crossing a bridge to avoid the possibility that their normal rhythmic march might match a resonant frequency of the bridge. The famous collapse of the Tacoma Narrows Bridge (Fig. 14–26a) in 1940 occurred (at least in part) as a result of winds gusting at just the right frequency, driving the span into large-amplitude oscillatory motion. The Oakland freeway collapse in the 1989 California earthquake (Fig. 14–26b) involved resonant oscillation of a section built on mudfill that readily transmitted that frequency.

Resonance can be useful, too, and we will meet important examples later, such as in musical instruments and tuning a radio. We will also see that vibrating objects often have not one, but many resonant frequencies.

## Equation of Motion and Its Solution

We now look at the equation of motion for a forced oscillation and its solution. Suppose the external force is sinusoidal and can be represented by

$$F_{\text{ext}} = F_0 \cos \omega t,$$

where $\omega = 2\pi f$ is the angular frequency applied externally to the oscillator. Then the equation of motion (with damping) is

$$ma = -kx - bv + F_0 \cos \omega t,$$

or

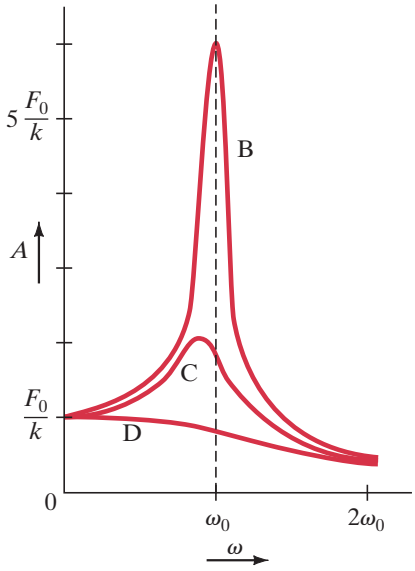
$$m\frac{d^2x}{dt^2} + b\frac{dx}{dt} + kx = F_0 \cos \omega t. \qquad \textbf{(14–21)}$$

The external force, on the right of the equation, is the only term that does not involve $x$ or one of its derivatives. Problem 72 asks you to show that

$$x = A \sin(\omega t + \phi) \qquad \textbf{(14–22)}$$

is a solution to Eq. 14–21, by direct substitution, where

$$A = \frac{F_0}{m\sqrt{(\omega^2 - \omega_0^2)^2 + b^2\omega^2/m^2}} \qquad \textbf{(14–23)}$$



and

$$\phi = \tan^{-1}\frac{\omega_0^2 - \omega^2}{\omega(b/m)}. \qquad \textbf{(14–24)}$$

Actually, the general solution to Eq. 14–21 is Eq. 14–22 plus another term of the form of Eq. 14–19 for the natural damped motion of an oscillator. This second term approaches zero in time, so let us concentrate on the long-term steady state solution, Eq. 14–22.

The amplitude of forced harmonic motion, $A$, depends strongly on the difference between the applied and the natural frequency. A plot of $A$ (Eq. 14–23) as a function of the applied frequency, $\omega$, is shown in Fig. 14–27 (a more detailed version of Fig. 14–24) for three specific values of the damping constant $b$. Curve B $\left(b = \frac{1}{6}m\omega_0\right)$ represents light damping, curve C $\left(b = \frac{1}{2}m\omega_0\right)$ fairly heavy damping, and curve D $\left(b = \sqrt{2}m\omega_0\right)$ overdamped motion. The amplitude can become large when the driving frequency is near the natural frequency, $\omega \approx \omega_0$, as long as the damping is not too large. When the damping is small, the increase in amplitude near $\omega = \omega_0$ is very large and, as we saw, is known as *resonance*. The natural oscillating frequency $f_0\,(=\omega_0/2\pi)$ of a system is its *resonant frequency*.[†]

**FIGURE 14–27** Amplitude of a forced harmonic oscillator as a function of $\omega$. Curves B, C, and D correspond to light, heavy, and overdamped systems, respectively $\left(Q = m\omega_0/b = 6, 2, 0.71\right)$.

[†]Sometimes the resonant frequency is defined as the actual value of $\omega$ at which the amplitude has its maximum value, and this depends somewhat on the damping constant. Except for very heavy damping, this value is quite close to $\omega_0$.

If $b = 0$, resonance occurs at $\omega = \omega_0$ and the resonant peak (of $A$) becomes infinite; in such a case, energy is being continuously transferred into the system and none is dissipated. For real systems, $b$ is never precisely zero, and the resonant peak is finite. The peak does not occur precisely at $\omega = \omega_0$ (because of the term $b^2\omega^2/m^2$ in the denominator of Eq. 14–23), although it is quite close to $\omega_0$ unless the damping is very large. If the damping is large, there is little or no peak (curve D in Fig. 14–27).

### Q Value

The height and narrowness of a resonant peak is often specified by its **quality factor** or **Q value**, defined as

$$Q = \frac{m\omega_0}{b}. \tag{14–25}$$

In Fig. 14–27, curve B has $Q = 6$, curve C has $Q = 2$, and curve D has $Q = 1/\sqrt{2}$. The smaller the damping constant $b$, the larger the $Q$ value becomes, and the higher the resonance peak. The $Q$ value is also a measure of the width of the peak. To see why, let us consider a graph like Fig. 14–27 but instead of the amplitude $A$ on the vertical axis, we put $A^2$. The graphs will look a lot like Fig. 14–27, but now they will essentially be graphs of energy vs. $\omega$ (recall Eq. 14–10a, $E \propto A^2$). On these energy graphs, let $\omega_1$ and $\omega_2$ be the frequencies where the square of the amplitude $A^2$ has *half* its maximum value. Then $\Delta\omega = \omega_1 - \omega_2$, which is called the *width* of the resonance peak (or **full width at half maximum**, or FWHM), is related to $Q$ by

$$\frac{\Delta\omega}{\omega_0} = \frac{1}{Q}. \tag{14–26}$$

This relation is accurate only for weak damping. The larger the $Q$ value, the narrower will be the resonance peak relative to its height. Thus a large $Q$ value, representing a system of high quality, has a *high*, *narrow* resonance peak. To show the validity of Eq. 14–26, square Eq. 14–23 for $A$ and determine $\omega_1$ and $\omega_2$ when $A^2$ is $\frac{1}{2}A^2_{\text{max}}$. Or wait and do it in Problem 73.

## Summary

An oscillating (or vibrating) object undergoes **simple harmonic motion** (SHM) if the restoring force is proportional to the displacement,

$$F = -kx. \tag{14–1}$$

The maximum displacement from equilibrium is called the **amplitude**.

The **period**, $T$, is the time required for one complete cycle (back and forth), and the **frequency**, $f$, is the number of cycles per second; they are related by

$$f = \frac{1}{T}. \tag{14–2}$$

The period of oscillation for a mass $m$ on the end of an ideal massless spring is given by

$$T = 2\pi\sqrt{\frac{m}{k}}. \tag{14–7b}$$

SHM is **sinusoidal**, which means that the displacement as a function of time follows a sine or cosine curve. The general solution can be written

$$x = A\cos(\omega t + \phi) \tag{14–4}$$

where $A$ is the amplitude, $\phi$ is the **phase angle**, and

$$\omega = 2\pi f = \sqrt{\frac{k}{m}}. \tag{14–5}$$

The values of $A$ and $\phi$ depend on the **initial conditions** ($x$ and $v$ at $t = 0$).

During SHM, the total energy

$$E = \tfrac{1}{2}mv^2 + \tfrac{1}{2}kx^2$$

is continually changing from potential to kinetic and back again.

A **simple pendulum** of length $\ell$ approximates SHM if its amplitude is small and friction can be ignored. For small amplitudes, its period is given by

$$T = 2\pi\sqrt{\frac{\ell}{g}}, \tag{14–12c}$$

where $g$ is the acceleration of gravity.

When friction is present (for all real springs and pendulums), the motion is said to be **damped**. The maximum displacement decreases in time, and the mechanical energy is eventually all transformed to thermal energy. If the friction is very large, so no oscillations occur, the system is said to be **overdamped**. If the friction is small enough that oscillations occur, the system is **underdamped**, and the displacement is given by

$$x = Ae^{-\gamma t}\cos\omega' t, \tag{14–16}$$

where $\gamma$ and $\omega'$ are constants. For a **critically damped** system, no oscillations occur and equilibrium is reached in the shortest time.

If a varying force of frequency $f$ is applied to a system capable of oscillating, the amplitude of oscillation can be very large if the frequency of the applied force is near the **natural** (or **resonant**) **frequency** of the oscillator. This is called **resonance**.

# Questions

1. Give some examples of everyday vibrating objects. Which exhibit SHM, at least approximately?
2. Is the acceleration of a simple harmonic oscillator ever zero? If so, where?
3. Real springs have mass. Will the true period and frequency be larger or smaller than given by the equations for a mass oscillating on the end of an idealized massless spring? Explain.
4. How could you double the maximum speed of a simple harmonic oscillator (SHO)?
5. A 5.0-kg trout is attached to the hook of a vertical spring scale, and then is tugged and released. Describe the scale reading as a function of time.
6. If a pendulum clock is accurate at sea level, will it gain or lose time when taken to high altitude? Why?
7. A tire swing hanging from a branch reaches nearly to the ground (Fig. 14–28). How could you estimate the height of the branch using only a stopwatch?

**FIGURE 14–28**
Question 7.

8. For a simple harmonic oscillator, when (if ever) are the displacement and velocity vectors in the same direction? When are the displacement and acceleration vectors in the same direction?
9. Two equal masses are attached to separate identical springs next to one another. One mass is pulled so its spring stretches 20 cm and the other is pulled so its spring stretches only 10 cm. The masses are released simultaneously. Which mass reaches the equilibrium point first? Explain.
10. Does a car bounce on its springs more rapidly when it is empty or when it is fully loaded?
11. What happens to the period of a playground swing if you rise up from sitting and stand on the swing seat? Explain.
12. * A thin uniform rod of mass $m$ is suspended from one end and oscillates with a frequency $f$. If a small sphere of mass $2m$ is attached to the other end, does the frequency increase or decrease? Explain.
13. What is the approximate natural period of your walking step?
14. A tuning fork of natural frequency 264 Hz sits on a table at the front of a room. At the back of the room, two tuning forks, one of natural frequency 260 Hz and one of 420 Hz are initially silent, but when the tuning fork at the front of the room is set into vibration, the 260-Hz fork spontaneously begins to vibrate but the 420-Hz fork does not. Explain.
15. Why can you make water slosh back and forth in a pan only if you shake the pan at a certain frequency?
16. Give several everyday examples of resonance.
17. Sometimes a car develops a pronounced *rattle* or vibration at a particular speed, especially if the road has regularly spaced bumps, as between slabs of concrete. Which of the following is a factor and, if so, how: underdamping, overdamping, critical damping, and forced resonance?
18. Over the years, buildings have been able to be built out of lighter and lighter materials. How has this affected the natural oscillation frequencies of buildings and the problems of resonance due to passing trucks, airplanes, or by wind and other natural sources of vibration?

# MisConceptual Questions

1. A mass on a spring in SHM (Fig. 14–1) has amplitude $A$ and period $T$. At what point in the motion is the velocity zero and the acceleration zero simultaneously?
   (*a*) $x = A$.
   (*b*) $x > 0$ but $x < A$.
   (*c*) $x = 0$.
   (*d*) $x < 0$.
   (*e*) None of the above.
2. An object oscillates back and forth on the end of a spring. Which of the following statements are true at some time during the course of the motion?
   (*a*) The object can have zero velocity and nonzero acceleration simultaneously.
   (*b*) The object can have zero velocity and zero acceleration simultaneously.
   (*c*) The object can have zero acceleration and nonzero velocity simultaneously.
   (*d*) The object can have nonzero velocity and nonzero acceleration simultaneously.
3. An object of mass $M$ oscillates on the end of a spring. To double the period, replace the object with one of mass:
   (*a*) $2M$.
   (*b*) $M/2$.
   (*c*) $4M$.
   (*d*) $M/4$.
   (*e*) None of the above.
4. An object of mass $m$ rests on a frictionless surface and is attached to a horizontal ideal spring with spring constant $k$. The system oscillates with amplitude $A$. The oscillation frequency of this system can be increased by
   (*a*) decreasing $k$.
   (*b*) decreasing $m$.
   (*c*) increasing $A$.
   (*d*) More than one of the above.
   (*e*) None of the above will work.

5. A block fastened to the end of a horizontal spring rests on a frictionless surface. When the block is pulled back a distance $A$ from equilibrium, the spring–block system has energy $E$. If the block is pulled back a distance $2A$ from equilibrium, what is the energy of the spring–block system now?
(*a*) Still $E$, by energy conservation.
(*b*) Work was done on the block, increasing the energy to $2E$.
(*c*) Work was done by the block, decreasing the energy to $\frac{1}{2}E$.
(*d*) Work was done by the block, decreasing the energy to $\frac{1}{4}E$.
(*e*) Work was done on the block, increasing the energy to $4E$.

6. A 100-g mass hangs from a long cord forming a pendulum. The mass is pulled a short distance to one side and released from rest. The time to swing over and back is carefully measured to be 2.0 s. If the 100-g mass is replaced by a 200-g mass, which is then pulled over the same distance and released from rest, the time will be
(*a*) 1.0 s.
(*b*) 1.41 s.
(*c*) 2.0 s.
(*d*) 2.82 s.
(*e*) 4.0 s.

7. A mass $m$ oscillates at the end of a spring with spring constant $k_1$. A second spring has the same amplitude but is twice as stiff $(k_2 = 2k_1)$ and the mass oscillating at its end is $2m$. Which quantities are the same for the two systems? (Choose all that apply.)
(*a*) The total energy.
(*b*) The period.
(*c*) The maximum speed of the mass.
(*d*) The maximum acceleration of the mass.
(*e*) None of the above.

8. When you use the approximation $\sin\theta \approx \theta$ for a pendulum, you must specify the angle $\theta$ in
(*a*) radians only.
(*b*) degrees only.
(*c*) revolutions or radians.
(*d*) degrees or radians.

9. At a playground, two young children are on identical swings. One child appears to be about twice as heavy as the other. If you pull them back together the same distance and release them to start them swinging, what will you notice about the oscillations of the two children?
(*a*) The heavier child swings with a period twice that of the lighter one.
(*b*) The lighter child swings with a period twice that of the heavier one.
(*c*) Both children swing with the same period.

10. A *grandfather clock* is "losing" time because its *pendulum* moves too slowly. Assume that the pendulum is a massive bob at the end of a string. The motion of this pendulum can be sped up by (list all that work):
(*a*) shortening the string.
(*b*) lengthening the string.
(*c*) increasing the mass of the bob.
(*d*) decreasing the mass of the bob.

11. Two simple pendulums swing at a small angle with the same period. The mass of one bob is twice the mass of the other. What can you say about the length of the pendulum with the heavier bob?
(*a*) It must be longer.
(*b*) It must be be shorter.
(*c*) It can be either longer or shorter as long as the amplitudes are adjusted appropriately.
(*d*) The lengths should be the same.

# Problems

## 14–1 and 14–2 Simple Harmonic Motion

1. (I) If a particle undergoes SHM with amplitude 0.27 m, what is the total distance it travels in one period?

2. (I) The springs of a 1700-kg car compress 5.0 mm when its 72-kg driver gets into the driver's seat. If the car goes over a bump, what will be the frequency of oscillations? Ignore damping.

3. (I) (*a*) What is the equation describing the motion of a mass on the end of a spring which is stretched 7.8 cm from equilibrium and then released from rest, and whose period is 0.66 s? (*b*) What will be its displacement after 1.8 s?

4. (I) An elastic cord is 61 cm long when a weight of 68 N hangs from it but is 85 cm long when a weight of 210 N hangs from it. What is the "spring" constant $k$ of this elastic cord?

5. (II) Estimate the spring constant in a child's pogo stick if the child has a mass of 32 kg and bounces once every 1.6 seconds.

6. (II) A fisherman's scale stretches 3.2 cm when a 2.4-kg fish hangs from it. (*a*) What is the spring constant and (*b*) what will be the amplitude and frequency of oscillation if the fish is pulled down 2.1 cm more and released so that it oscillates up and down?

7. (II) A small fly of mass 0.28 g is caught in a spider's web. The web oscillates predominantly with a frequency of 4.0 Hz. (*a*) Estimate the value of the effective force constant $k$ for the web. (*b*) At what frequency would you expect the web to oscillate if an insect of mass 0.46 g is trapped?

8. (II) Construct a Table indicating the position $x$ of the mass in Fig. 14–2 at times $t = 0, \frac{1}{4}T, \frac{1}{2}T, \frac{3}{4}T, T,$ and $\frac{5}{4}T$, where $T$ is the period of oscillation. On a graph of $x$ vs. $t$, plot these six points. Now connect these points with a smooth curve. Based on these simple considerations, does your curve resemble that of a cosine or sine wave?

9. (II) A mass $m$ at the end of a spring oscillates with a frequency of 0.83 Hz. When an additional 830-g mass is added to $m$, the frequency is 0.60 Hz. What is the value of $m$?

10. (II) A wood block of mass 52 g floats on a lake, bobbing up and down at a frequency of 3.5 Hz. (*a*) Estimate the effective force constant of this motion. (*b*) A partially filled water bottle of mass 0.28 kg and almost the same size and shape of the wood block is tossed into the water. At what frequency would you expect the bottle to bob up and down? Assume SHM.

**11.** (II) A 1.45-kg mass stretches a vertical spring 0.245 m. If the spring is stretched an additional 0.130 m and released, how long does it take to reach the (new) equilibrium position again?

**12.** (II) An object of unknown mass $m$ is hung from a vertical spring of unknown spring constant $k$, and the object is observed to be at rest when the spring has extended by 14 cm. The object is then given a slight push and executes SHM. Determine the period $T$ of this oscillation.

**13.** (II) Figure 14–29 shows two examples of SHM, labeled A and B. For each, what is (*a*) the amplitude, (*b*) the frequency, and (*c*) the period? (*d*) Write the equations for both A and B in the form of a sine or cosine.

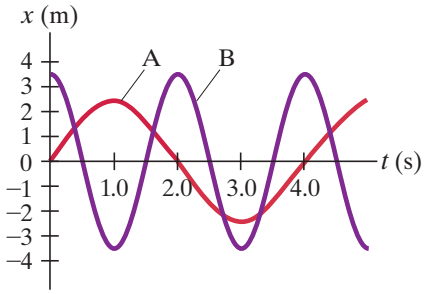


**FIGURE 14–29** Problem 13.

**14.** (II) The graph of displacement vs. time for a small mass $m$ at the end of a spring is shown in Fig. 14–30. At $t = 0$, $x = 0.43$ cm. (*a*) If $m = 7.7$ g, find the spring constant, $k$. (*b*) Write the equation for displacement $x$ as a function of time.

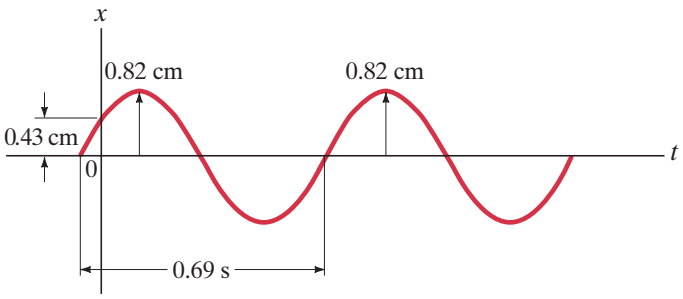

**FIGURE 14–30** Problem 14.

**15.** (II) A 0.350-kg mass oscillates on the end of a thin vertical spring (spring constant 265 N/m) with an amplitude of 28.0 cm. The mass passes through the equilibrium point ($y = 0$) with positive velocity at $t = 0$. (*a*) What equation describes this motion as a function of time? (*b*) At what times will the length of the spring be longest and shortest?

**16.** (II) Determine the phase constant $\phi$ in Eq. 14–4 if, at $t = 0$, the oscillating mass is at (*a*) $x = -A$, (*b*) $x = 0$, (*c*) $x = A$, (*d*) $x = \frac{1}{2}A$, (*e*) $x = -\frac{1}{2}A$, (*f*) $x = A/\sqrt{2}$.

**17.** (II) A tuning fork oscillates at a frequency of 441 Hz and the tip of each prong moves 1.8 mm to either side of center. Calculate (*a*) the maximum speed and (*b*) the maximum acceleration of the tip of a prong.

**18.** (II) The position of a SHO as a function of time is given by $x = 3.8\cos(5\pi t/4 + \pi/6)$ where $t$ is in seconds and $x$ in meters. Find (*a*) the period and frequency, (*b*) the position and velocity at $t = 0$, and (*c*) the velocity and acceleration at $t = 2.5$ s.

**19.** (II) A 1.60-kg object oscillates at the end of a vertically hanging light spring once every 0.68 s. (*a*) Write down the equation giving its position $y$ (+ upward) as a function of time $t$. Assume the spring was initially compressed 16 cm from the equilibrium position (where $y = 0$), and then ($t = 0$) was released. (*b*) How long will it take the object to get to the equilibrium position for the first time? (*c*) What will be its maximum speed? (*d*) What will be its maximum acceleration, and where will it first be attained?

**20.** (II) Consider two objects, A and B, both undergoing SHM, but with different frequencies, as described by the equations $x_A = (2.0\,\text{m})\sin(4.0\,t)$ and $x_B = (5.0\,\text{m})\sin(3.0\,t)$, where $t$ is in seconds. After $t = 0$, find the next three times $t$ at which both objects simultaneously pass through the origin.

**21.** (II) A block of mass $m$ is supported by two identical parallel vertical springs, each with spring stiffness constant $k$ (Fig. 14–31). What will be the frequency of vertical oscillation?

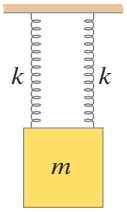

**FIGURE 14–31** Problem 21.

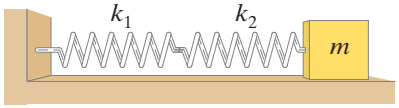
**22.** (II) A *bungee jumper* with mass 65.0 kg jumps from a high bridge. After arriving at his lowest point, he oscillates up and down, reaching a low point five more times in 28.0 s. He eventually comes to rest 25.0 m below the level of the bridge. Estimate the spring constant and the unstretched length of the bungee cord assuming SHM. Assume very little damping.

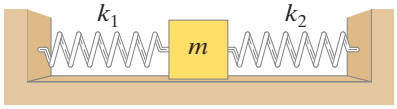
**23.** (III) A uniform 1.25-m-long stick of mass $M$ can rotate easily about a hinge at one end and is held horizontal by a spring with spring constant $k$ attached at the other end (Fig. 14–32). If that end of the stick oscillates up and down slightly, what is its frequency? [*Hint*: Write a torque equation about the hinge.]

**24.** (III) A mass $m$ is at rest on the end of a spring of spring constant $k$. At $t = 0$ it is given an impulse $J$ by a hammer. Write the formula for the subsequent motion in terms of $m$, $k$, $J$, and $t$.



**25.** (III) A mass $m$ is connected to two springs, with spring constants $k_1$ and $k_2$, in two different ways as shown in Fig. 14–33a and b. Show that the period for the configuration shown in part (a) is given by

$$T = 2\pi\sqrt{m\left(\frac{1}{k_1} + \frac{1}{k_2}\right)}$$



and for that in part (b) is given by

$$T = 2\pi\sqrt{\frac{m}{k_1 + k_2}}.$$

Ignore friction.

(a)

(b)

**FIGURE 14–33** Problem 25.

## 14–3 Energy in SHM

**26.** (I) A 1.50-kg mass on a particular spring oscillates with amplitude 10.0 cm. The spring is replaced by another resulting in oscillation with twice the energy for the same amplitude. How do the spring constants compare?

**27.** (I) A 1.28-kg mass oscillates according to the equation $x = 0.650\cos 7.40\,t$ where $x$ is in meters and $t$ in seconds. Determine (*a*) the amplitude, (*b*) the frequency, (*c*) the total energy, and (*d*) the kinetic energy and potential energy when $x = 0.260$ m.

**28.** (I) A 5.5-kg mass is found to cause a spring to stretch a distance of 25 cm when hung vertically from it. If this mass is displaced a further 12 cm and released, find its velocity when it returns to its equilibrium position.

**29.** (I) If one oscillation has 3.0 times the energy of a second one of equal frequency and mass, what is the ratio of their amplitudes?

**30.** (II) (*a*) At what displacement of a SHO is the energy half kinetic and half potential? (*b*) What fraction of the total energy of a SHO is kinetic and what fraction potential when the displacement is one third the amplitude?

**31.** (II) Draw a graph like Fig. 14–11 for a horizontal spring whose spring constant is 95 N/m and which has a mass of 75 g on the end of it. Assume the spring was started with an initial amplitude of 2.0 cm. Neglect the mass of the spring and any friction with the horizontal surface. Use your graph to estimate (*a*) the potential energy, (*b*) the kinetic energy, and (*c*) the speed of the mass, for $x = 1.5$ cm.

**32.** (II) A 0.25-kg mass at the end of a spring oscillates 3.2 times per second with an amplitude of 0.15 m. Determine (*a*) the speed when it passes the equilibrium point, (*b*) the speed when it is 0.10 m from equilibrium, (*c*) the total energy of the system, and (*d*) the equation describing the motion of the mass, assuming that at $t = 0$, $x$ was a maximum.

**33.** (II) A mass of 210 g oscillates on a horizontal frictionless surface at a frequency of 2.5 Hz and with amplitude of 4.5 cm. (*a*) What is the effective spring constant for this motion? (*b*) How much energy is involved in this motion?

**34.** (II) An object with mass 2.7 kg is executing simple harmonic motion, attached to a spring with spring constant $k = 310$ N/m. When the object is 0.020 m from its equilibrium position, it is moving with a speed of 0.60 m/s. (*a*) Calculate the amplitude of the motion. (*b*) Calculate the maximum speed attained by the object.

**35.** (II) A mass resting on a horizontal, frictionless surface is attached to one end of a spring; the other end of the spring is fixed to a wall. It takes 3.2 J of work to compress the spring by 0.13 m. The mass is then released from rest and experiences a maximum acceleration of 12 m/s$^2$. Find the value of (*a*) the spring constant and (*b*) the mass.

**36.** (II) Agent Arlene devised the following method of measuring the muzzle velocity of a rifle (Fig. 14–34). She fires a bullet into a 4.148-kg wooden block resting on a smooth surface, and attached to a spring of spring constant $k = 162.7$ N/m. The bullet, whose mass is 7.450 g, remains embedded in the wooden block. She measures the maximum distance that the block compresses the spring to be 9.460 cm. What is the speed $v$ of the bullet?

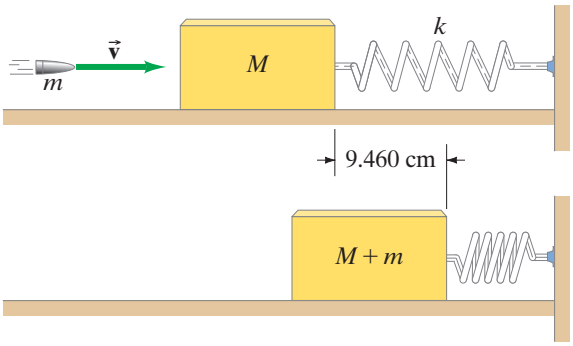


**FIGURE 14–34** Problem 36.

**37.** (II) At $t = 0$, an 885-g mass at rest on the end of a horizontal spring ($k = 184$ N/m) is struck by a hammer which gives it an initial speed of 2.12 m/s. Determine (*a*) the period and frequency of the motion, (*b*) the amplitude, (*c*) the maximum acceleration, (*d*) the position as a function of time, (*e*) the total energy, and (*f*) the kinetic energy when $x = 0.40\,A$ where $A$ is the amplitude.

**38.** (II) Obtain the displacement $x$ as a function of time for the simple harmonic oscillator using the conservation of energy, Eqs. 14–10. [*Hint*: Integrate Eq. 14–11a with $v = dx/dt$. See Appendix B.]

**39.** (III) A *pinball machine* uses a spring launcher that is compressed 6.0 cm to launch a ball up a 22° ramp. Assume that the pinball is a solid uniform sphere of radius $r = 1.0$ cm and mass $m = 25$ g. If it is rolling without slipping (Section 10–9) at a speed of 3.0 m/s when it leaves the launcher, what is the spring constant of the spring launcher?

## 14–5 Simple Pendulum

**40.** (I) How long must a simple pendulum be if it is to make exactly one swing per second? (That is, one complete oscillation takes exactly 2.0 s.)

**41.** (I) A pendulum has a period of 2.15 s on Earth. What is its period on Mars, where the acceleration of gravity is about 0.37 that on Earth?

**42.** (I) A pendulum makes 23 oscillations in exactly 50 s. What is its (*a*) period and (*b*) frequency?

**43.** (II) A musician wishes to construct a *metronome* based on a simple pendulum design where a "beat" is sounded when the bob reaches each opposite extreme of its swing. How long must the pendulum be so that this metronome is set for 104 bpm (bpm = beats per minute)?

**44.** (II) A simple pendulum is swinging with amplitude equal to 8.5°. With what angle should it swing if its total energy is to be doubled?

**45.** (II) A simple pendulum is 0.30 m long. At $t = 0$ it is released from rest starting at an angle of 15°. Ignoring friction, what will be the angular position of the pendulum at (*a*) $t = 0.35$ s, (*b*) $t = 3.45$ s, and (*c*) $t = 6.00$ s?

**46.** (II) What is the period of a simple pendulum 47 cm long (*a*) on the Earth, and (*b*) when it is in a freely falling elevator?

**47.** (II) Your grandfather clock's pendulum has a length of 0.9930 m. If the clock loses 18 s per day, how should you adjust the length of the pendulum?

**48.** (II) Derive a formula for the maximum speed $v_{max}$ of a simple pendulum bob in terms of $g$, the length $\ell$, and the maximum angle of swing $\theta_{max}$.

**49.** (II) A clock pendulum oscillates at a frequency of 2.5 Hz. At $t = 0$, it is released from rest starting at an angle of 12° to the vertical. Ignoring friction, what will be the position (angle in radians) of the pendulum at (*a*) $t = 0.25$ s, (*b*) $t = 1.60$ s, and (*c*) $t = 500$ s?

**50.** (III) A simple pendulum oscillates with an amplitude of 10.0°. What fraction of a period does it spend between +8.0° and −8.0°? Assume SHM.

## *14–6 Physical Pendulum and Torsion Pendulum

***51.** (II) The balance wheel of a *mechanical (analog) watch* is a thin ring of radius 0.95 cm attached to a coil spring (roughly like Fig. 14–35). It oscillates with a frequency of 1.55 Hz. If a torque of $1.1 \times 10^{-5}$ m · N causes the wheel to rotate 45°, calculate the mass of the balance wheel.

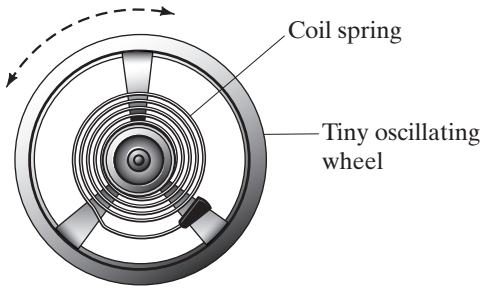

**FIGURE 14–35** Problem 51.

***52.** (II) (*a*) Determine the equation of motion and its solution ($\theta$ as a function of time) for a torsion pendulum, Fig. 14–18, and show that the motion is simple harmonic. (*b*) Show that the period $T$ is $T = 2\pi\sqrt{I/k}$. [The balance wheel of a mechanical watch is an example of a torsion pendulum in which the restoring torque is applied by a coil spring, Fig. 14–35.]

***53.** (II) A pendulum consists of a tiny bob of mass $M$ and a thin uniform rod of mass $m$ and length $\ell$. (*a*) Determine a formula for the period using the small angle approximation. (*b*) What would be the fractional error if you use the formula for a simple pendulum, Eq. 14–12c? (*c*) What ratio of $m/M$ would produce a 10% error?

***54.** (II) A meter stick is hung at its center from a thin wire (Fig. 14–36a). It is twisted and oscillates with a period of 5.0 s. The meter stick is sawed off to a length of 70.0 cm and is again balanced at its center and set in oscillation (Fig. 14–36b). With what period does it oscillate?

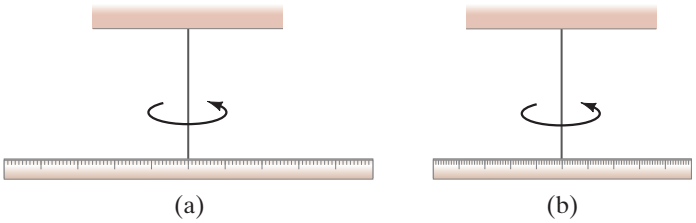

**FIGURE 14–36** Problem 54.

***55.** (II) The *human leg* can be compared to a *physical pendulum*, with a "natural" swinging period at which walking is easiest. Consider the leg as two rods joined rigidly together at the knee; the axis for the leg is the hip joint. The length of each rod is about the same: assume 55 cm. Let the upper rod have a mass of 7.0 kg and the lower rod a mass of 4.0 kg. (*a*) Calculate the natural swinging period of the system. (*b*) Check your answer by standing on a chair and measuring the time for one or more complete back-and-forth swings of your leg. The effect of a shorter leg is a shorter swinging period, enabling a faster *natural stride*.

***56.** (II) A student wants to use a meter stick as a pendulum. She plans to drill a small hole through the meter stick and suspend it from a smooth pin attached to the wall (Fig. 14–37). Where in the meter stick should she drill the hole to obtain the shortest possible period? How short an oscillation period can she obtain with a meter stick in this way?

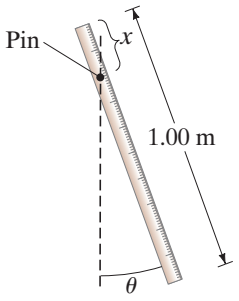

**FIGURE 14–37** Problem 56.

***57.** (II) A plywood disk of radius 20.0 cm and mass 2.20 kg has a small hole drilled through it, 2.00 cm from its edge (Fig. 14–38). The disk is hung from the wall by means of a metal pin through the hole, and is used as a pendulum. What is the period of this pendulum for small oscillations?

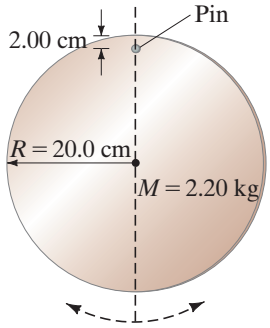

**FIGURE 14–38** Problem 57.

***58.** (II) An aluminum disk, 15.4 cm in diameter and 375 g in mass, is mounted on a vertical shaft with very low friction (Fig. 14–39). One end of a flat coil spring is attached to the disk, the other end to the base of the apparatus. The disk is set into rotational oscillation and the frequency is 0.331 Hz. What is the torsional spring constant $k$ ($\tau = -k\theta$)?

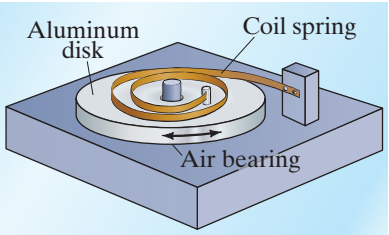

**FIGURE 14–39** Problem 58.

## 14–7 Damping

**59.** (II) Estimate how the damping constant changes when a car's shock absorbers get old and the car bounces three times after going over a speed bump.

**60.** (II) A 0.735-kg block oscillates on the end of a spring whose spring constant is $k = 41.0\ \text{N/m}$. The mass moves in a fluid which offers a resistive force $F = -bv$, where $b = 0.662\ \text{N}\cdot\text{s/m}$. (*a*) What is the period of the motion? (*b*) What is the fractional decrease in amplitude per cycle? (*c*) Write the displacement as a function of time if at $t = 0$, $x = 0$, and at $t = 1.00\ \text{s}$, $x = 0.120\ \text{m}$.

**61.** (II) A damped harmonic oscillator loses 8.0% of its mechanical energy per cycle. (*a*) By what percentage does its frequency differ from the natural frequency $f_0 = (1/2\pi)\sqrt{k/m}$? (*b*) After how many periods will the amplitude have decreased to $1/e$ of its original value?

***62.** (II) A physical pendulum consists of an 85-cm-long uniform wooden rod of mass 280 g hung from a nail near one end (Fig. 14–40). The motion is damped because of friction in the pivot; the damping force is approximately proportional to $d\theta/dt$. The rod is set in oscillation by displacing it 15° from its equilibrium position and releasing it. After 8.0 s, the amplitude of the oscillation has been reduced to 5.5°. If the angular displacement can be written as $\theta = Ae^{-\gamma t}\cos\omega' t$, find (*a*) $\gamma$, (*b*) the approximate period of the motion, and (*c*) how long it takes for the amplitude to be reduced to $\frac{1}{2}$ of its original value.

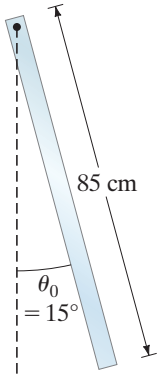

**FIGURE 14–40**
Problem 62.

**63.** (II) A vertical spring of spring constant 115 N/m supports a mass of 58 g. The mass oscillates in a tube of liquid. If the mass is initially given an amplitude of 5.0 cm, the mass is observed to have an amplitude of 2.0 cm after 3.5 s. Estimate the damping constant $b$. Neglect buoyant forces.

**64.** (III) A glider on an air track is connected by springs to either end of the track (Fig. 14–41). Both springs have the same spring constant, $k$, and the glider has mass $M$. (*a*) Determine the frequency of the oscillation, assuming no damping, if $k = 125\ \text{N/m}$ and $M = 215\ \text{g}$. (*b*) It is observed that after 68 oscillations, the amplitude of the oscillation has dropped to one-half of its initial value. Estimate the value of $\gamma$, using Eq. 14–16. (*c*) How long does it take the amplitude to decrease to one-quarter of its initial value?

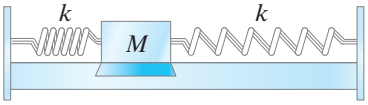

**FIGURE 14–41** Problem 64.

**65.** (III) (*a*) Show that the total mechanical energy, $E = \frac{1}{2}mv^2 + \frac{1}{2}kx^2$, for a lightly damped harmonic oscillator as a function of time, is

$$E = \tfrac{1}{2}kA^2e^{-(b/m)t} = E_0e^{-(b/m)t},$$

where $E_0$ is the total mechanical energy at $t = 0$. (Assume $\omega' \gg b/2m$.) (*b*) Show that the fractional energy lost per period is

$$\frac{\Delta E}{E} = \frac{2\pi b}{m\omega_0} = \frac{2\pi}{Q},$$

where $\omega_0 = \sqrt{k/m}$ and $Q = m\omega_0/b$ is called the **quality factor** or ***Q* value** of the system. A larger $Q$ value means the system can undergo oscillations for a longer time.

**66.** (III) Consider a simple pendulum (point mass bob) 0.50 m long with a $Q$ of 350 (as defined in Problem 65). (*a*) How long does it take for the amplitude (assumed small) to decrease by two-thirds? (*b*) If the amplitude is 2.0 cm and the bob has mass 0.27 kg, what is the initial energy loss rate of the pendulum in watts?

## 14–8 Forced Oscillations; Resonance

**67.** (II) An 1150-kg automobile has springs with $k = 14{,}000\ \text{N/m}$. One of the tires is not properly balanced; it has a little extra mass on one side compared to the other, causing the car to shake at certain speeds. If the tire radius is 42 cm, at what speed will the wheel shake most?

**68.** (III) (*a*) For a forced oscillation at resonance $(\omega = \omega_0)$, what is the value of the phase angle $\phi$ in Eq. 14–22? (*b*) What, then, is the displacement at a time when the driving force $F_{\text{ext}}$ is a maximum, and at a time when $F_{\text{ext}} = 0$? (*c*) What is the phase difference (in degrees) between the driving force and the displacement in this case?

**69.** (III) Differentiate Eq. 14–23 to show that the resonant amplitude peaks at

$$\omega = \sqrt{\omega_0^2 - \frac{b^2}{2m^2}}.$$

**70.** (III) The amplitude of a driven harmonic oscillator reaches a value of $23.7F_0/k$ at a resonant frequency of 418 Hz. What is the $Q$ value of this system?

**71.** (III) Construct an accurate resonance curve, from $\omega = 0$ to $\omega = 2\omega_0$, for $Q = 5.0$, (*a*) for amplitude $A$, and (*b*) for $A^2$ $(\propto E)$.

**72.** (III) By direct substitution, show that Eq. 14–22, with Eqs. 14–23 and 14–24, is a solution of the equation of motion (Eq. 14–21) for the forced oscillator. [*Hint*: To find $\sin\phi$ and $\cos\phi$ from $\tan\phi$, draw a right triangle.]

**73.** (III) Derive Eq. 14–26. Assume $b$ is small, but not zero.

**74.** (III) *Power transferred to driven oscillator.* (*a*) Show that the power input to a forced oscillator due to the external force $F_{\text{ext}} = F_0\cos\omega t$ is (see Eq. 14–21 through Eq. 14–24):

$$P = F_{\text{ext}}v = \frac{F_0^2\,\omega\cos\phi\,\cos^2\omega t - \frac{1}{2}F_0^2\,\omega\sin\phi\,\sin 2\omega t}{m\sqrt{(\omega^2 - \omega_0^2)^2 + \omega^2b^2/m^2}}.$$

(*b*) Show that the average power input, averaged over one (or many) full cycles, is

$$\overline{P} = \frac{\omega F_0^2\cos\phi}{2m\sqrt{(\omega^2 - \omega_0^2)^2 + \omega^2b^2/m^2}} = \tfrac{1}{2}F_0\,v_{\text{max}}\cos\phi,$$

where $v_{\text{max}}$ is the maximum value of $dx/dt$. (*c*) Also show:

$$\overline{P} = \frac{bF_0^2\,(\omega^2/2m^2)}{(\omega^2 - \omega_0^2)^2 + \omega^2b^2/m^2}.$$

(*d*) Plot $\overline{P}$ versus $\omega$ from $\omega = 0$ to $\omega = 2\omega_0$ for $Q = 6.0$. Note that although the amplitude is not zero at $\omega = 0$, $\overline{P}$ is zero at $\omega = 0$.

# General Problems

**75.** An energy-absorbing car bumper has a spring constant of 410 kN/m. Find the maximum compression of the bumper if the car, with mass 1300 kg, collides with a wall at a speed of 2.0 m/s (approximately 5 mi/h).

**76.** A 62-kg person jumps from a window to a fire net 20.0 m directly below, which stretches the net 1.4 m. Assume that the net behaves like a simple spring. (*a*) Calculate how much it would stretch if the same person were lying in it. (*b*) How much would it stretch if the person jumped from 38 m?

**77.** A simple pendulum oscillates with frequency $f$. What is its frequency if the entire pendulum accelerates at $0.35\,g$ (*a*) upward, and (*b*) downward?

**78.** The length of a simple pendulum is 0.72 m, the pendulum bob has a mass of 295 g, and it is released at an angle of 12° to the vertical. Assume SHM. (*a*) With what frequency does it oscillate? (*b*) What is the pendulum bob's speed when it passes through the lowest point of the swing? (*c*) What is the total energy stored in this oscillation assuming no losses?

**79.** A 250-g mass attached to a spring oscillates with a frequency of 3.0 Hz. At time $t = 4.10\,\text{s}$, the mass is at $x = -7.0\,\text{cm}$ and is moving to the right at 1.80 m/s. Find an expression for $x$ as a function of time.

**80.** A block with mass $M = 6.0\,\text{kg}$ rests on a frictionless table and is attached by a horizontal spring $(k = 130\,\text{N/m})$ to a wall. A second block, of mass $m = 1.25\,\text{kg}$, rests on top of $M$. The coefficient of static friction between the two blocks is 0.30. What is the maximum possible amplitude of oscillation such that $m$ will not slip off $M$?

**81.** (*a*) A crane has hoisted a 1550-kg car at the junkyard. The crane's steel cable is 20.0 m long and has a diameter of 6.4 mm. If the car starts bouncing at the end of the cable, what is the period of the bouncing? [*Hint*: Refer to Table 12–1.] (*b*) What amplitude of bouncing will likely cause the cable to snap? (See Table 12–2, and assume Hooke's law holds all the way up to the breaking point.)

**82.** A 0.650-kg mass oscillates according to the equation $x = 0.25 \sin(4.70\,t)$ where $x$ is in meters and $t$ is in seconds. Determine (*a*) the amplitude, (*b*) the frequency, (*c*) the period, (*d*) the total energy, and (*e*) the kinetic energy and potential energy when $x$ is 15 cm.

**83.** *Tall buildings* are designed to *sway* in the wind. In a 100-km/h wind, suppose the top of a 110-story building oscillates horizontally with an amplitude of 15 cm at its natural frequency, which corresponds to a period of 7.0 s. Assuming SHM, find the maximum horizontal velocity and acceleration experienced by an employee as she sits working at her desk located on the top floor. Compare the maximum acceleration (as a percentage) with the acceleration due to gravity.

**84.** An oxygen atom at a particular site within a DNA molecule can be made to execute simple harmonic motion when illuminated by infrared light. The oxygen atom is bound with a spring-like chemical bond to a phosphorus atom, which is rigidly attached to the DNA backbone. The oscillation of the oxygen atom occurs with frequency $f = 3.7 \times 10^{13}\,\text{Hz}$. If the oxygen atom at this site is chemically replaced with a sulfur atom, the spring constant of the bond is unchanged (sulfur is just below oxygen in the Periodic Table). Predict the frequency after the sulfur substitution.

**85.** A "seconds" pendulum has a period of exactly 2.000 s. That is, each one-way swing takes 1.000 s. What is the length of a seconds pendulum in Austin, Texas, where $g = 9.793\,\text{m/s}^2$? If the pendulum is moved to Paris, where $g = 9.809\,\text{m/s}^2$, by how many millimeters must we lengthen the pendulum? What is the length of a seconds pendulum on the Moon, where $g = 1.62\,\text{m/s}^2$?

**86.** A 280-kg wooden raft floats on a lake. When a 68-kg man stands on the raft, it sinks 3.5 cm deeper into the water. When he steps off, the raft oscillates for a while. (*a*) What is the frequency of oscillation? (*b*) What is the total energy of oscillation (ignoring damping)?

**87.** A diving board oscillates with simple harmonic motion of frequency 3.0 cycles per second. What is the maximum amplitude with which the end of the board can oscillate in order that a pebble placed there (Fig. 14–42) does not lose contact with the board during the oscillation?
