

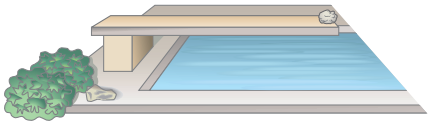

**FIGURE 14–42** Problem 87.

**88.** A 950-kg car strikes a huge spring at a speed of 25 m/s (Fig. 14–43), compressing the spring 4.0 m. (*a*) What is the spring stiffness constant of the spring? (*b*) How long is the car in contact with the spring before it bounces off in the opposite direction?

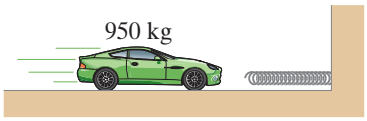

**FIGURE 14–43** Problem 88.

**89.** A 1.80-kg table is supported on four springs. A 0.60-kg chunk of modeling clay is held above the table and dropped so that it hits the center of the table with a speed of 1.65 m/s (Fig. 14–44). The clay makes an inelastic collision with the table, and the table and clay oscillate up and down. After a long time the table comes to rest 6.0 cm below its original position. (*a*) What is the effective spring constant of all four springs taken together? (*b*) With what maximum amplitude does the platform oscillate?

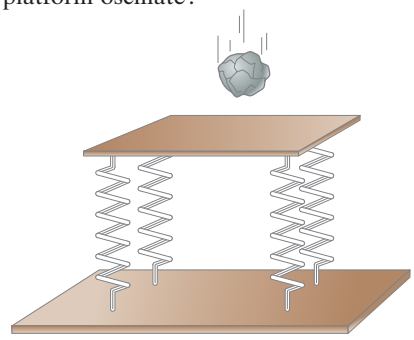

**FIGURE 14–44** Problem 89.

**90.** Estimate the effective spring constant of a trampoline. [*Hint*: Go and jump, or watch, and give your data.]

**91.** A particular unbalanced wheel of a car shakes when the car moves at 90.0 km/h. The wheel plus tire has mass 17.0 kg and diameter 0.58 m. By how much will the springs of this car compress when it is loaded with 280 kg? (Assume the 280 kg is split evenly among all four springs, which are identical.)

**92.** Carbon dioxide is a linear molecule. The carbon–oxygen bonds in this molecule act very much like springs. Figure 14–45 shows one possible way the oxygen atoms in this molecule can oscillate: the oxygen atoms oscillate symmetrically in and out, while the central carbon atom remains at rest. Hence each oxygen atom acts like a simple harmonic oscillator with a mass equal to the mass of an oxygen atom. It is observed that this oscillation occurs with a frequency of $f = 2.83 \times 10^{13}$ Hz. What is the spring constant of the C—O bond?

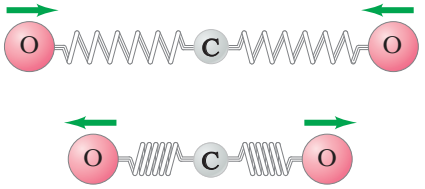

**FIGURE 14–45** Problem 92, the $CO_2$ molecule.

**93.** A mass attached to the end of a spring is stretched a distance $x_0$ from equilibrium and released. At what distance from equilibrium will it have (*a*) velocity equal to half its maximum velocity, and (*b*) acceleration equal to half its maximum acceleration?

**94.** A thin, straight, uniform rod of length $\ell = 1.00$ m and mass $m = 185$ g hangs from a pivot at one end. (*a*) What is its period for small-amplitude oscillations? (*b*) What is the length of a simple pendulum that will have the same period?

**95.** Imagine that a 10-cm-diameter circular hole was drilled all the way through the center of the Earth (Fig. 14–46). At one end of the hole, you drop an apple into the hole. Show that, if you assume that the Earth has a constant density, the subsequent motion of the apple is simple harmonic. How long will the apple take to return? Assume that we can ignore all frictional effects. [*Hint*: See Appendix E.]

**FIGURE 14–46** Problem 95.

**96.** We usually neglect the *mass of a spring* if it is small compared to the mass attached to it. But in some applications, the mass of the spring must be taken into account. Consider a spring of unstretched length $\ell$ and mass $M_S$ uniformly distributed along the length of the spring. A mass $m$ is attached to the end of the spring. One end of the spring is fixed and the mass $m$ is allowed to vibrate horizontally without friction (Fig. 14–47). Each point on the spring moves with a velocity proportional to the distance from that point to the fixed end. For example, if the mass on the end moves with speed $v_0$, the midpoint of the spring moves with speed $v_0/2$. Show that the kinetic energy of the mass plus spring when the mass $m$ is moving with velocity $v$ is

$$K = \tfrac{1}{2}Mv^2$$

where $M = m + \frac{1}{3}M_S$ is the "effective mass" of the system. [*Hint*: Let $D$ be the total length of the stretched spring. Then the velocity of an infinitesimal length $dx$ of spring, of mass $dM$, located at $x$ is $v(x) = v_0(x/D)$. Note also that $dM = dx\,(M_S/D)$.]

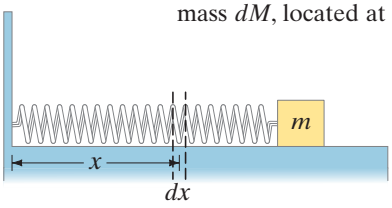

**FIGURE 14–47** Problem 96.

**97.** A mass $m$ is gently placed on the end of a freely hanging spring. The mass then falls 27.0 cm before it stops and begins to rise. What is the frequency of the oscillation?

**98.** Describe a procedure to measure the spring constant $k$ of a car's springs. Assume that the owner's manual gives the car's mass $M$ and that the shock absorbers are worn out so that the springs are underdamped.

**99.** In Section 14–5, the oscillation of a simple pendulum (Fig. 14–48) is viewed as linear motion along the arc length $x$ and analyzed via $F = ma$. Alternatively, the pendulum's movement can be regarded as rotational motion about its point of support and analyzed using $\tau = I\alpha$. Carry out this alternative analysis and show that

$$\theta(t) = \theta_{\max}\cos\left(\sqrt{\frac{g}{\ell}}\,t + \phi\right),$$

where $\theta(t)$ is the angular displacement of the pendulum from the vertical at time $t$, as long as its maximum value is less than about 15°.

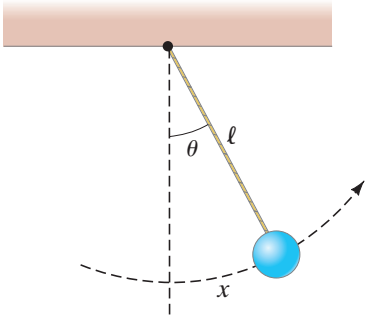

**FIGURE 14–48** Problem 99.

## ANSWERS TO EXERCISES

**A:** (*b*).
**B:** (*c*).
**C:** (*c*).
**D:** (*c*).
**E:** All are larger.
**F:** (*c*).
**G:** (*a*).

Waves—such as these water waves—spread outward from a source. The source in this case is a small spot of water oscillating up and down briefly where a rock, or piece of wood or bark, was thrown in (left photo). Other kinds of waves include waves on a cord or string, which also are produced by a vibration. Waves move away from their source, but we also study waves that seem to stand still ("standing waves"). Waves reflect, and they can interfere with each other when they pass through any point at the same time.

**CHAPTER-OPENING QUESTION—Guess now!**

You drop a rock into a pond, and water waves spread out in circles.

**(a)** The waves carry water outward, away from where the rock hit. That moving water carries energy outward.

**(b)** The waves only make the water move up and down. No energy is carried outward from where the rock hit.

**(c)** The waves only make the water move up and down, but the waves do carry energy outward, away from where the rock hit.

When you throw a stone into a lake or pool of water, circular waves form and move outward, as shown in the photos above. Waves will also travel along a rope or cord that is stretched out flat on a table if you vibrate one end back and forth as shown in Fig. 15–1. Water waves and waves on a cord are two common examples of **mechanical waves**, which propagate as oscillations of matter. We will discuss other kinds of waves in later Chapters, including electromagnetic waves and light.

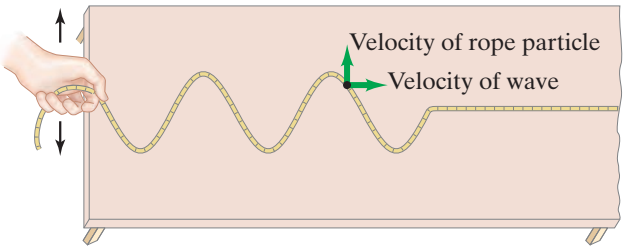

**FIGURE 15–1** Wave traveling on a rope or cord. The wave travels to the right along the rope. Particles of the rope oscillate back and forth on the tabletop.

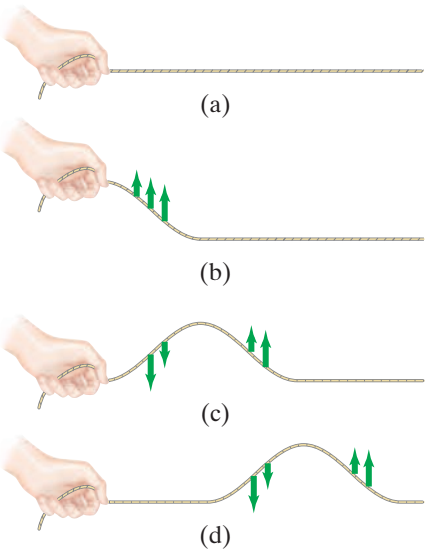
If you have ever watched ocean waves moving toward shore before they break, you may have wondered if the waves were carrying water from far out at sea onto the beach. They don't.[†] Water waves move with a recognizable velocity. But each particle (or molecule) of the water itself merely oscillates about an equilibrium point. This is clearly demonstrated by observing leaves on a pond as waves move by. The leaves (or a cork) are not carried forward by the waves, but oscillate more or less up and down about an equilibrium point because this is the motion of the water itself.

**CONCEPTUAL EXAMPLE 15–1** **Wave vs. particle velocity.** Is the velocity of a wave moving along a rope the same as the velocity of a particle of the rope? See Fig. 15–1.

**RESPONSE** No. The two velocities are different, both in magnitude and direction. The wave on the rope of Fig. 15–1 moves to the right along the tabletop, but each piece of the rope only vibrates to and fro, perpendicular to the traveling wave. (The rope does not travel in the direction that the wave on it does, and the rope does not fall off the edge of the table.)

Waves can move over large distances, but the medium (the water or the rope) itself has only a limited movement, oscillating about an equilibrium point as in simple harmonic motion. Thus, although a wave is not itself matter, the wave pattern can travel in matter. A wave consists of oscillations that move without carrying matter with them.

Waves carry energy from one place to another. Energy is given to a water wave, for example, by a rock thrown into the water, or by wind far out at sea. The energy is transported by waves in all directions and eventually they reach the shore. The oscillating hand in Fig. 15–1 transfers energy to the rope, and that energy is transported down the rope and can be transferred to an object at the other end. All forms of traveling waves transport energy.



**EXERCISE A** Return to the Chapter-Opening Question, page 428, and answer it again now. Try to explain why you may have answered differently the first time.

# 15–1 Characteristics of Wave Motion

Let us look a little more closely at how a wave is formed and how it comes to "travel." We first look at a single wave bump, or **pulse**. A single pulse can be formed on a cord by a quick up-and-down motion of the hand, Fig. 15–2. The hand pulls up on one end of the cord. Because the end section is attached to adjacent sections, these also feel an upward force and they too begin to move upward. As each succeeding section of cord moves upward, the crest of the wave moves outward along the cord. Meanwhile, the end section of cord has been returned to its original position by the hand. As each succeeding section of cord reaches its peak position, it too is pulled back down again by tension from the adjacent section of cord. Thus the source of a traveling wave pulse is a disturbance (or vibration), and cohesive forces between adjacent sections of cord cause the pulse to travel.

[†]Do not be confused by the "breaking" of ocean waves, which occurs when a wave interacts with the ground in shallow water and hence is no longer a simple wave.

**FIGURE 15–2** A wave pulse is generated by a hand holding the end of a cord and moving up and down once. Motion of the wave pulse is to the right. Arrows indicate velocity of cord particles.

Waves in other media are created and propagate outward in a similar fashion. A dramatic example of a wave pulse is a tsunami or tidal wave that is created by an earthquake in the Earth's crust under the ocean. The bang you hear when a door slams is a sound wave pulse.

A **continuous** or **periodic wave**, such as that shown in Fig. 15–1, has as its source a disturbance that is continuous and oscillating; that is, the source is a *vibration* or *oscillation*. In Fig. 15–1, a hand oscillates one end of the rope. Water waves may be produced by any vibrating object at the surface, such as your hand; or the water itself is made to vibrate when wind blows across it or a rock is thrown into it. A vibrating tuning fork or drum membrane gives rise to sound waves in air. We will see later that oscillating electric charges give rise to light waves. Indeed, almost any vibrating object sends out waves.

The source of any wave, then, is a vibration. And it is a *vibration* that propagates outward and thus constitutes the wave. If the source vibrates sinusoidally in SHM, then the wave itself—if the medium is elastic—will have a *sinusoidal* shape both in space and in time. (1) In space: if you take a picture of the wave in space at a given instant of time, the wave will have the shape of a sine or cosine as a function of position. (2) In time: if you look at the motion of the medium at one place over a long period of time—for example, if you look between two closely spaced posts of a pier or out of a ship's porthole as water waves pass by—the up-and-down motion of that small segment of water will be simple harmonic motion. The water moves up and down sinusoidally in time.

Some of the important quantities used to describe a periodic sinusoidal wave are shown in Fig. 15–3. The high points on a wave are called **crests**; the low points, **troughs**. The **amplitude**, $A$, is the maximum height of a crest, or depth of a trough, relative to the normal (or equilibrium) level. The total swing from a crest to a trough is twice the amplitude $(= 2A)$. The distance between two successive crests is the **wavelength**, $\lambda$ (the Greek letter lambda). The wavelength is also equal to the distance between *any* two successive identical points on the wave. The **frequency**, $f$, is the number of crests—or complete cycles—that pass a given point per unit time. The **period**, $T$, equals $1/f$ and is the time elapsed between two successive crests passing by the same point in space.

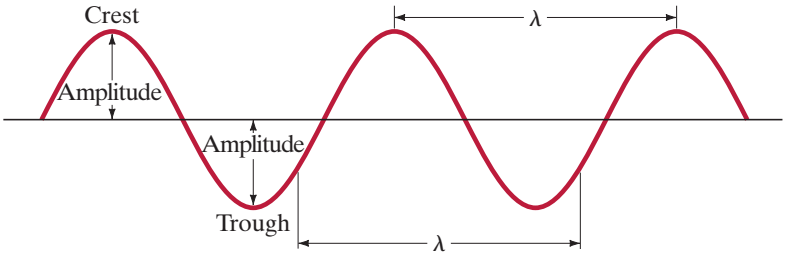


**FIGURE 15–3** Characteristics of a single-frequency continuous wave moving through space.

The **wave speed**, $v$, is the speed at which wave crests (or any other fixed point on the wave shape) move forward. The wave speed must be distinguished from the speed of a particle of the medium itself as we saw in Example 15–1.

A wave crest travels a distance of one wavelength, $\lambda$, in a time equal to one period, $T$. (That is what we mean by the period $T$.) Thus the wave speed is $v = \lambda/T$. Then, since $1/T = f$,

$$v = \lambda f. \qquad \textbf{(15–1)}$$

For example, suppose a wave has a wavelength of 5 m and a frequency of 3 Hz. Since three crests pass a given point per second, and the crests are 5 m apart, the first crest (or any other part of the wave) must travel a distance of 15 m during the 1 s. So the wave speed is 15 m/s, as Eq. 15–1 predicts.

**EXERCISE B** You notice a water wave pass by the end of a pier, with about 0.5 s between crests. Therefore (*a*) the frequency is 0.5 Hz; (*b*) the speed is 0.5 m/s; (*c*) the wavelength is 0.5 m; (*d*) the period is 0.5 s.

# 15–2 Types of Waves: Transverse and Longitudinal

When a wave travels down a cord—say, from left to right as in Fig. 15–1—the particles of the cord vibrate back and forth in a direction transverse (that is, perpendicular) to the motion of the wave itself. Such a wave is called a **transverse wave** (Fig. 15–4a). There exists another type of wave known as a **longitudinal wave**. In a longitudinal wave, the vibration of the particles of the medium is *along* the direction of the wave's motion. Longitudinal waves are readily formed on a stretched spring or Slinky by alternately compressing and expanding one end. This is shown in Fig. 15–4b, and can be compared to the transverse wave in Fig. 15–4a.

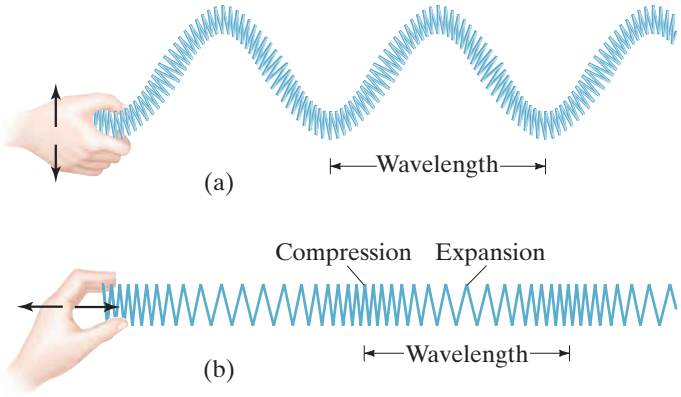

**FIGURE 15–4** (a) A transverse wave, and (b) a longitudinal wave, on a Slinky.

A series of compressions and expansions travel along the spring in Fig. 15–4b. The **compressions** are those areas where the coils are momentarily close together. **Expansions** (sometimes called **rarefactions**) are regions where the coils are momentarily far apart. Compressions and expansions correspond to the crests and troughs of a transverse wave.

An important example of a longitudinal wave is a sound wave in air. A vibrating drumhead, for instance, alternately compresses and expands the air in contact with it, producing a longitudinal wave that travels outward in the air, as shown in Fig. 15–5.

As in the case of transverse waves, each section of the medium in which a longitudinal wave passes oscillates over a very small distance, whereas the wave itself can travel large distances. Wavelength, frequency, and wave speed all have meaning for a longitudinal wave. The wavelength is the distance between successive compressions (or between successive expansions), and frequency is the number of compressions that pass a given point per second. The wave speed is the speed with which each compression appears to move; it is equal to the product of wavelength and frequency, $v = \lambda f$ (Eq. 15–1).

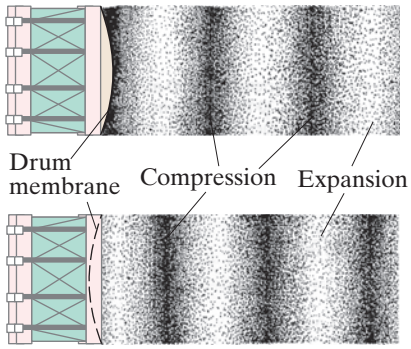

**FIGURE 15–5** Production of a sound wave, which is longitudinal, shown at two moments in time about a half period $(\frac{1}{2}T)$ apart. (An "expansion" is often called a *rarefaction* of the air.) The dots represent air molecules.

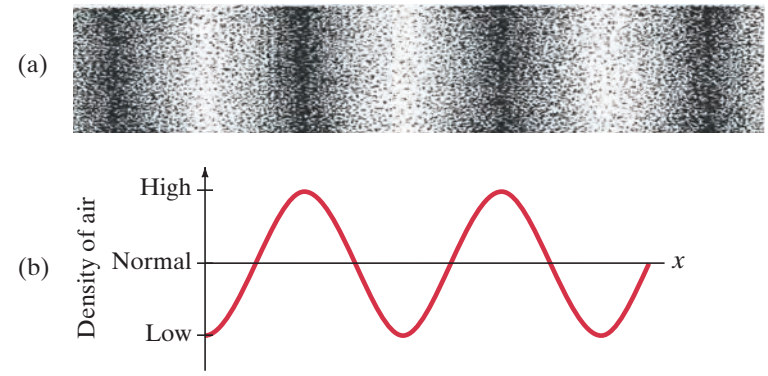

**FIGURE 15–6** (a) A longitudinal wave with (b) its graphical representation at a particular instant in time.

A longitudinal wave can be represented graphically by plotting the density of air molecules (or coils of a Slinky) versus position at a given instant, as shown in Fig. 15–6. Such a graphical representation helps make it clearer what is happening. Note that the graph looks much like a transverse wave.

## Speed of Transverse Waves

The speed of a wave depends on the properties of the medium in which it travels. The speed of a transverse wave on a stretched string or cord, for example, depends on the tension in the cord, $F_T$, and on the mass per unit length of the cord, $\mu$ (the Greek letter mu). If $m$ is the mass of a length $\ell$ of wire, then $\mu = m/\ell$. For waves of small amplitude, the wave speed is

$$v = \sqrt{\frac{F_T}{\mu}}. \qquad \left[\begin{array}{l}\text{transverse}\\ \text{wave on a cord}\end{array}\right] \quad \textbf{(15–2)}$$

This formula makes sense qualitatively on the basis of Newtonian mechanics. That is, we do expect the tension to be in the numerator and the mass per unit length in the denominator. Why? Because when the tension is greater, we expect the speed to be greater since each segment of cord is in tighter contact with its neighbor. And, the greater the mass per unit length, the more inertia the cord has and the more slowly the wave would be expected to propagate. (*Propagate* = travel, spread out.)

**EXERCISE C** A wave starts at the left end of a long cord (see Fig. 15–1) when someone shakes the cord back and forth at the rate of 2.0 Hz. The wave is observed to move to the right at 4.0 m/s. If the frequency is increased from 2.0 to 3.0 Hz, the new speed of the wave is (*a*) 1.0 m/s, (*b*) 2.0 m/s, (*c*) 4.0 m/s, (*d*) 8.0 m/s, (*e*) 16.0 m/s.

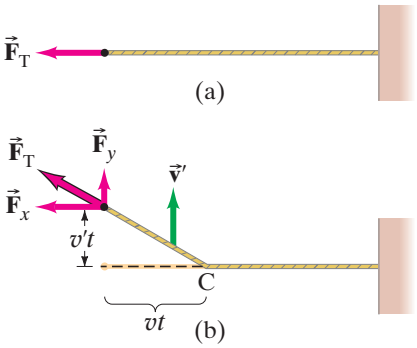

**FIGURE 15–7** Diagram of simple wave pulse on a cord for derivation of Eq. 15–2. (Diagram is not to scale: we assume $v' \ll v$, and $F_x \approx F_T$. The upward angle of the cord is exaggerated for visibility.)

We can make a simple *derivation* of Eq. 15–2 using a simple model of a cord under a tension $F_T$ as shown in Fig. 15–7a. The cord is initially pulled quickly upward at a speed $v'$ by the force $F_y$. As shown in Fig. 15–7b all points of the cord to the left of point C move upward at the speed $v'$, and those to the right are still at rest. The speed of propagation, $v$, of this wave pulse is the speed of point C, the leading edge of the pulse. Point C moves to the right a distance $vt$ in a time $t$, whereas the end of the cord moves upward a distance $v't$. By similar triangles we have the approximate relation

$$\frac{F_T}{F_y} = \frac{vt}{v't} = \frac{v}{v'},$$

which works for small amplitudes so that $F_x \approx F_T$, meaning that $v't \ll vt$. As we saw in Chapter 9, the impulse given to an object is equal to its change in momentum. During the time $t$ the total upward impulse is $F_y t = (v'/v)F_T t$. The change in momentum of the cord, $\Delta p$, is the mass of cord moving upward times its speed $v'$. Since the upward moving segment of cord has mass equal to the mass per unit length $\mu$ times its length $vt$ we have $\Delta p = (\mu vt)v'$, and so

$$F_y t = \Delta p$$
$$\frac{v'}{v} F_T t = (\mu vt)v'.$$

Solving for $v$ we find $v = \sqrt{F_T/\mu}$ which is Eq. 15–2. Although it was derived for a

special case, it is valid for any wave shape since other shapes can be considered to be made up of many tiny such lengths. But it is valid only for small displacements (as was our derivation). Experiment is in accord with this result derived from Newtonian mechanics.

**EXAMPLE 15–2** **Wave along a wire.** A wave whose wavelength is 0.30 m is traveling down a 300-m-long wire whose total mass is 15 kg. If the wire is under a tension of 1000 N, what are the speed and frequency of this wave?

**APPROACH** We assume the speed of this wave on a wire is given by Eq. 15–2. We get the frequency from Eq. 15–1, $f = v/\lambda$.

**SOLUTION** From Eq. 15–2, the speed is

$$v = \sqrt{\frac{1000\,\text{N}}{(15\,\text{kg})/(300\,\text{m})}} = \sqrt{\frac{1000\,\text{N}}{(0.050\,\text{kg/m})}} = 140\,\text{m/s}.$$

The frequency is

$$f = \frac{v}{\lambda} = \frac{140\,\text{m/s}}{0.30\,\text{m}} = 470\,\text{Hz}.$$

**NOTE** A higher tension would increase both $v$ and $f$, whereas a thicker, denser wire would reduce $v$ and $f$.

**EXAMPLE 15–3** **Pulse on a wire.** An 80.0-m-long, 2.10-mm-diameter copper wire is stretched between two poles. A bird lands at the center point of the wire, sending a small wave pulse out in both directions. The pulses reflect at the ends and arrive back at the bird's location 0.750 seconds after it landed. Determine the tension in the wire.

**APPROACH** From Eq. 15–2, the tension is given by $F_T = \mu v^2$. The speed $v$ is distance divided by the time. The mass per unit length $\mu$ is calculated from the density of copper and the dimensions of the wire.

**SOLUTION** Each wave pulse travels 40.0 m to the pole and back again (= 80.0 m) in 0.750 s. Thus their speed is $v = (80.0\,\text{m})/(0.750\,\text{s}) = 107\,\text{m/s}$. We take the density of copper (Table 13–1) as $8.90 \times 10^3\,\text{kg/m}^3$. The volume of copper in the wire is the cross-sectional area $(\pi r^2)$ times the length $\ell$, and the mass of the wire is the density times the volume: $m = \rho(\pi r^2)\ell$ for a wire of radius $r$ and length $\ell$. Then $\mu = m/\ell$ is

$$\mu = \rho\pi r^2\ell/\ell = \rho\pi r^2 = (8.90 \times 10^3\,\text{kg/m}^3)\pi(1.05 \times 10^{-3}\,\text{m})^2 = 0.0308\,\text{kg/m}.$$

Thus, the tension is $F_T = \mu v^2 = (0.0308\,\text{kg/m})\,(107\,\text{m/s})^2 = 353\,\text{N}$.

## Speed of Longitudinal Waves

The speed of a longitudinal wave has a form similar to that for a transverse wave on a cord (Eq. 15–2); that is,

$$v = \sqrt{\frac{\text{elastic force factor}}{\text{inertia factor}}}.$$

In particular, for a longitudinal wave traveling down a long solid rod,

$$v = \sqrt{\frac{E}{\rho}}, \qquad \left[\begin{array}{l}\text{longitudinal}\\ \text{wave in a long rod}\end{array}\right] \quad \textbf{(15–3)}$$

where $E$ is the elastic modulus (Section 12–5) of the material and $\rho$ is its density. For a longitudinal wave traveling in a liquid or gas,

$$v = \sqrt{\frac{B}{\rho}}, \qquad \left[\begin{array}{l}\text{longitudinal wave}\\ \text{in a fluid}\end{array}\right] \quad \textbf{(15–4)}$$

where $B$ is the bulk modulus (Section 12–5) and $\rho$ again is the density. We will derive this, starting on the next page.

**PHYSICS APPLIED**
*Space perception by animals, using sound waves*

**EXAMPLE 15–4 Echolocation.** Echolocation is a form of perception used by animals such as bats, dolphins and toothed whales. The animal emits a pulse of sound (a longitudinal wave) which, after reflection from objects, returns and is detected by the animal. Echolocation waves can have frequencies of about 100,000 Hz. (*a*) Estimate the wavelength of a sea animal's echolocation wave. (*b*) If an obstacle is 100 m from the animal, how long after the animal emits a wave is its reflection detected?

**APPROACH** We first compute the speed of longitudinal (sound) waves in sea water, using Eq. 15–4 and Tables 12–1 and 13–1. The wavelength is $\lambda = v/f$.

**SOLUTION** (*a*) The speed of longitudinal waves in sea water, which is slightly more dense than pure water, is

$$v = \sqrt{\frac{B}{\rho}} = \sqrt{\frac{2.0 \times 10^9\,\text{N/m}^2}{1.025 \times 10^3\,\text{kg/m}^3}} = 1.4 \times 10^3\,\text{m/s}.$$

Then, using Eq. 15–1, we find

$$\lambda = \frac{v}{f} = \frac{(1.4 \times 10^3\,\text{m/s})}{(1.0 \times 10^5\,\text{Hz})} = 14\,\text{mm}.$$

(*b*) The time required for the round-trip between the animal and the object is

$$t = \frac{\text{distance}}{\text{speed}} = \frac{2(100\,\text{m})}{1.4 \times 10^3\,\text{m/s}} = 0.14\,\text{s}.$$

A pretty fast response for this underwater "radar".

**NOTE** We shall see later that waves can be used to "resolve" (or detect) objects whose size is comparable to or larger than the wavelength. Thus, a dolphin can resolve objects on the order of a centimeter or larger in size.

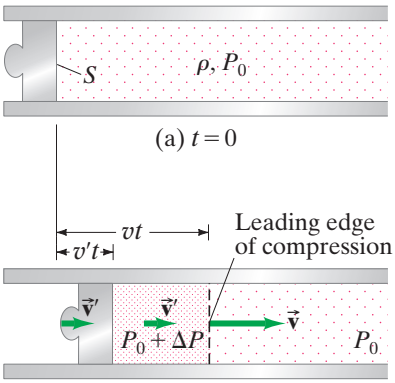

**FIGURE 15–8** Determining the speed of a one-dimensional longitudinal wave in a fluid contained in a long narrow tube.

## *Deriving Speed of Wave in a Fluid

We now derive Eq. 15–4. Consider a wave pulse traveling in a fluid in a long tube, so that the wave motion is one dimensional. The tube is fitted with a piston at the end and is filled with a fluid which, at $t = 0$, is of uniform density $\rho$ and at uniform pressure $P_0$, Fig. 15–8a. At this moment the piston is abruptly made to start moving to the right with speed $v'$, compressing the fluid in front of it. In the (short) time $t$ the piston moves a distance $v't$. The compressed fluid itself also moves with speed $v'$, but the leading edge of the compressed region moves to the right at the characteristic speed $v$ of compression waves in that fluid; we assume the wave speed $v$ is much larger than the piston speed $v'$. The leading edge of the compression (which at $t = 0$ was at the piston face) thus moves a distance $vt$ in time $t$ as shown in Fig. 15–8b. Let the pressure in the compressed fluid be $P_0 + \Delta P$, which is $\Delta P$ higher than in the uncompressed fluid. To move the piston to the right requires an external force $(P_0 + \Delta P)S$ acting to the right, where $S$ is the cross-sectional area of the tube. ($S$ for "surface area"; we save $A$ for amplitude.) The *net* force on the compressed region of the fluid is

$$F_{\text{net}} = (P_0 + \Delta P)S - P_0 S = S\,\Delta P$$

since the uncompressed fluid exerts a force $P_0 S$ to the left at the leading edge. Hence the impulse $(= F_{\text{net}}\,t)$ given to the compressed fluid, which equals its change in momentum, is

$$F_{\text{net}}\,t = \Delta m v'$$
$$S\,\Delta P\,t = (\rho S v t)v',$$

where $\Delta m = \rho V = \rho S v t$ represents the mass of fluid which is given the speed $v'$ (the compressed fluid of area $S$ moves a distance $vt$, Fig. 15–8, so the volume moved is $V = Svt$). Hence we have

$$\Delta P = \rho v v'.$$

From the definition of the bulk modulus, $B$ (Eq. 12–7):

$$B = -\frac{\Delta P}{\Delta V/V_0} = -\frac{\rho v v'}{\Delta V/V_0},$$

where $\Delta V/V_0$ is the fractional change in volume due to compression. The original volume (i.e., before compression) of the compressed fluid is $V_0 = Svt$ (see Fig. 15–8), and it has been compressed by an amount $\Delta V = -Sv't$ (Fig. 15–8b). Thus

$$B = -\frac{\rho v v'}{\Delta V/V_0} = -\frac{\rho v v' V_0}{\Delta V} = -\rho v v'\left(\frac{Svt}{-Sv't}\right) = \rho v^2.$$

Solving this for $v$ gives

$$v = \sqrt{\frac{B}{\rho}},$$

which is what we set out to show, Eq. 15–4.

The derivation of Eq. 15–3 follows similar lines, but takes into account the expansion of the sides of a rod when the end of the rod is compressed.

### Other Waves

PHYSICS APPLIED
*Earthquake waves*

Both transverse and longitudinal waves are produced when an **earthquake** occurs. The transverse waves that travel through the body of the Earth are called S waves (S for shear), and the longitudinal waves are called P waves (P for pressure) or *compression* waves. Both longitudinal and transverse waves can travel through a solid since the atoms or molecules can vibrate about their relatively fixed positions in any direction. But only longitudinal waves can propagate through a fluid, because any transverse motion would not experience any restoring force since a fluid is readily deformable. This fact was used by geophysicists to infer that a portion of the Earth's core must be liquid: after an earthquake, longitudinal waves are detected diametrically across the Earth, but not transverse waves.

Besides these two types of waves that can pass through the body of the Earth (or other substance), there can also be **surface waves** that travel along the boundary between two materials, such as earth and air.

A wave on water is actually a surface wave that moves on the boundary between water and air. The motion of each particle of water at the surface is circular or elliptical (Fig. 15–9), so it is a combination of horizontal and vertical motions. Below the surface, there is also horizontal and vertical motion, as shown. At the bottom, the motion is only horizontal.

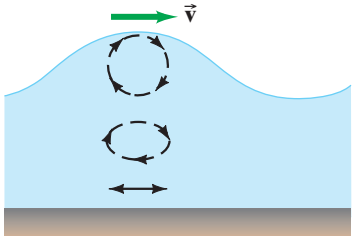

**FIGURE 15–9** A shallow water wave is an example of a *surface wave*, which is a combination of vertical and horizontal motions.

When an ocean wave approaches shore, the water drags at the bottom and is slowed down, while the crests move ahead at higher speed (Fig. 15–10) and "spill" over the top.

Surface waves are also set up on the Earth when an earthquake occurs. The waves that travel along the surface are mainly responsible for the damage caused by earthquakes.

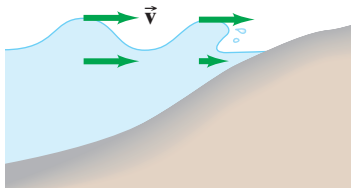

**FIGURE 15–10** How a water wave breaks. The green arrows represent the local velocity of water molecules.

Waves which travel along a line in one dimension, such as transverse waves on a stretched string, or longitudinal waves in a rod or fluid-filled tube, are *linear* or *one-dimensional waves*. Surface waves, such as the water waves shown at the start of this Chapter, page 428, are *two-dimensional waves*. Finally, waves that move out from a source in all directions, such as sound from a loudspeaker or earthquake waves through the Earth, are *three-dimensional waves*.

## 15–3 Energy Transported by Waves

Waves transport energy from one place to another. As waves travel through a medium, the energy is transferred as vibrational energy from particle to particle of the medium. For a sinusoidal wave of frequency $f$, the particles move in simple harmonic motion (Chapter 14) as a wave passes, and each particle has energy $E = \frac{1}{2}kA^2$ where $A$ is the amplitude (maximum displacement) of its motion, either transversely or longitudinally (Eq. 14–10a).

Using Eq. 14–10a for the energy of a particle undergoing SHM, $E = \frac{1}{2}kA^2$, as well as Eq. 14–7a for $k$, we can write $k = 4\pi^2 mf^2$, where $m$ is the mass of a particle (or small volume) of the medium. Then in terms of the frequency $f$ and amplitude $A$,

$$E = \tfrac{1}{2}kA^2 = 2\pi^2 mf^2A^2.$$

For a simple wave of frequency $f$ traveling in an elastic medium, a mass $m$ of the medium is $m = \rho V$, where $\rho$ is the density of the medium and $V$ is the volume of a small slice of the medium. The volume $V = S\ell$ where $S$ is the cross-sectional area through which the wave travels (Fig. 15–11), and we can write $\ell$ as the distance the wave travels in a time $t$ as $\ell = vt$, where $v$ is the speed of the wave. Thus $m = \rho V = \rho S\ell = \rho Svt$ and

$$E = 2\pi^2 \rho Svtf^2A^2. \qquad \textbf{(15–5)}$$

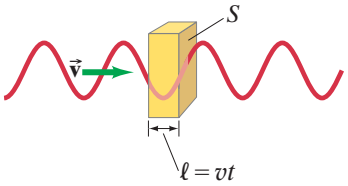

**FIGURE 15–11** Calculating the energy carried by a wave moving with speed $v$.

From this equation we have the important result that **the energy transported by a wave is proportional to the square of the amplitude, and also to the square of the frequency**. The average *rate* of energy transferred is the average power $P$:

$$\overline{P} = \frac{E}{t} = 2\pi^2 \rho Svf^2A^2. \qquad \textbf{(15–6)}$$

Finally, the **intensity**, $I$, of a wave is defined as the average power (energy per unit time) transported across unit area perpendicular to the direction of energy flow:

$$I = \frac{\overline{P}}{S} = 2\pi^2 v\rho f^2A^2. \qquad \textbf{(15–7a)}$$

The intensity too is proportional to amplitude $A$ squared,

$$I \propto A^2, \qquad \textbf{(15–7b)}$$

and its SI unit is watts per square meter $(\mathrm{W/m^2})$.

If a wave flows out from the source in all directions, it is a three-dimensional wave. Examples are sound traveling in the open air, earthquake waves, and light waves. If the medium is isotropic (same in all directions), the wave from a point source is a *spherical wave* (Fig. 15–12). As the wave moves outward, the energy it carries is spread over a larger and larger area since the surface area of a sphere of radius $r$ is $4\pi r^2$. Thus the intensity of a wave is

$$I = \frac{\overline{P}}{S} = \frac{\overline{P}}{4\pi r^2}.$$

If the power output $\overline{P}$ of the source is constant, then the intensity decreases as the inverse square of the distance from the source:

$$I \propto \frac{1}{r^2}. \qquad \text{[spherical wave]} \quad \textbf{(15–8a)}$$

This is often called the **inverse square law**, or "one over $r^2$ law."

If we consider two points at distances $r_1$ and $r_2$ from the source, as in Fig. 15–12, then $I_1 = \overline{P}/4\pi r_1^2$ and $I_2 = \overline{P}/4\pi r_2^2$, so

$$\frac{I_2}{I_1} = \frac{r_1^2}{r_2^2}. \qquad \textbf{(15–8b)}$$

Thus, for example, when the distance doubles $(r_2/r_1 = 2)$, then the intensity is reduced to $\frac{1}{4}$ of its earlier value: $I_2/I_1 = (\frac{1}{2})^2 = \frac{1}{4}$.

The amplitude of a wave also decreases with distance. Since the intensity is proportional to the square of the amplitude (Eq. 15–7), $I \propto A^2$, the amplitude $A$ must decrease as $1/r$ (so that $I \propto A^2$ will be proportional to $1/r^2$, as in Eq. 15–8a). Hence

$$A \propto \frac{1}{r}.$$

For two different distances from the source, $r_1$ and $r_2$, then

$$\frac{A_2}{A_1} = \frac{r_1}{r_2}.$$

When the wave is twice as far from the source, the amplitude is half as large, and so on (ignoring damping due to friction).

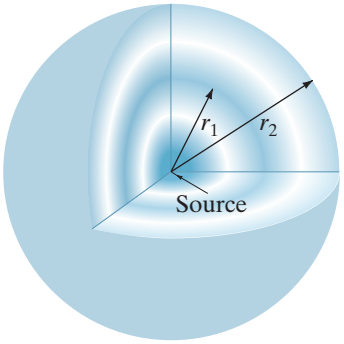

**FIGURE 15–12** A wave traveling uniformly outward in three dimensions from a source is spherical. Two crests (or compressions) are shown, of radii $r_1$ and $r_2$.

**EXAMPLE 15–5** **Earthquake intensity.** The intensity of an earthquake P wave traveling through the Earth and detected 100 km from the source is $1.0 \times 10^6\ \text{W/m}^2$. What is the intensity of that wave if detected 400 km from the source?

**APPROACH** We assume the wave is spherical, so the intensity decreases as the square of the distance from the source.

**SOLUTION** At 400 km the distance is 4 times greater than at 100 km, so the intensity will be $(\frac{1}{4})^2 = \frac{1}{16}$ of its value at 100 km, or $(1.0 \times 10^6\ \text{W/m}^2)/16 = 6.3 \times 10^4\ \text{W/m}^2$.

**NOTE** Using Eq. 15–8b directly gives

$$I_2 = I_1 r_1^2/r_2^2 = (1.0 \times 10^6\ \text{W/m}^2)(100\ \text{km})^2/(400\ \text{km})^2 = 6.3 \times 10^4\ \text{W/m}^2.$$

The situation is different for a one-dimensional wave, such as a transverse wave on a string or a longitudinal wave pulse traveling down a thin uniform metal rod. The area remains constant, so the amplitude $A$ also remains constant (ignoring friction). Thus the amplitude and the intensity do not decrease with distance.

In practice, frictional damping is generally present, and some of the energy is transformed into thermal energy. Thus the amplitude and intensity of a one-dimensional wave will decrease with distance from the source. For a three-dimensional wave, the decrease will be greater than that discussed above, more than $1/r^2$, although the effect may often be small.

## 15–4 Mathematical Representation of a Traveling Wave

Consider a one-dimensional wave traveling along the $x$ axis. It could be a transverse wave on a cord or a longitudinal wave traveling in a solid rod or in a fluid-filled tube. Let us assume the wave shape is sinusoidal and has a particular wavelength $\lambda$ and frequency $f$. At $t = 0$, suppose the wave shape is given by

$$D(x) = A \sin \frac{2\pi}{\lambda} x, \qquad \textbf{(15–9)}$$

as shown by the solid curve in Fig. 15–13. $D(x)$ is the **displacement** of the wave (either longitudinal or transverse) at position $x$, and $A$ is the **amplitude** (maximum displacement) of the wave. Equation 15–9 works because it repeats itself every wavelength: the displacement is the same at $x = 0$, $x = \lambda$, $x = 2\lambda$, and so on because $\sin 4\pi = \sin 2\pi = \sin 0$.

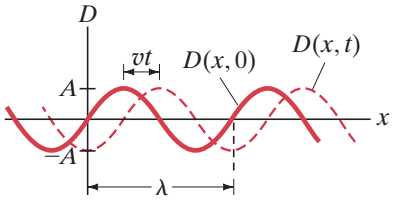

**FIGURE 15–13** A traveling wave. In time $t$, the wave moves a distance $vt$. The solid line represents the wave at $t = 0$. The dashed line is $D(x, t)$, the wave displacement as a function of $x$ at time $t$.

Suppose the wave is moving to the right with speed $v$. After a time $t$, each part of the wave (indeed, the whole wave "shape") has moved to the right a distance $vt$; see the dashed curve in Fig. 15–13. Consider any point on the wave at $t = 0$: say, a crest at some position $x$. After a time $t$, that crest will have traveled a distance $vt$ so its new position is a distance $vt$ larger than its old position. To describe this crest (or other point on the wave shape), the argument of the sine function must have the same numerical value; so we replace $x$ in Eq. 15–9 by $(x - vt)$, and write the displacement as $D(x, t)$ since it depends on both $x$ and $t$:

$$D(x, t) = A \sin\left[\frac{2\pi}{\lambda}(x - vt)\right]. \quad \begin{bmatrix}\text{1-D wave moving} \\ \text{in } +x \text{ direction}\end{bmatrix} \qquad \textbf{(15–10a)}$$

Said another way: if you are riding on a crest, as $t$ increases, $x$ must increase at the same rate so that the value of $(x - vt)$ remains constant.

Equation 15–10a gives the displacement $D(x, t)$ of a wave traveling at speed $v$ along the $x$ axis to the right (increasing $x$) at any point $x$ at any time $t$.

The function $D(x,t)$ describes a curve that represents the actual shape of the wave in space at time $t$. Since $v = \lambda f$ (Eq. 15–1) we can write Eq. 15–10a in other ways that are often convenient:

$$D(x,t) = A\sin\left(\frac{2\pi x}{\lambda} - \frac{2\pi t}{T}\right), \qquad \textbf{(15–10b)}$$

where $T = 1/f = \lambda/v$ is the period; and more simply as

$$D(x,t) = A\sin(kx - \omega t), \qquad \textbf{(15–10c)}$$

where $\omega = 2\pi f = 2\pi/T$ is the angular frequency and

$$k = \frac{2\pi}{\lambda} \qquad \textbf{(15–11)}$$

**CAUTION**

*Don't confuse wave number k with spring constant k*

is called the **wave number**. (Do not confuse the wave number $k$ with the spring constant $k$; they are very different quantities.) All three forms, Eqs. 15–10a, b, and c, are equivalent; Eq. 15–10c is the simplest to write and is perhaps the most common. The quantity $(kx - \omega t)$, and its equivalent in the other two equations, is called the **phase** of the wave. The speed of the wave $v$ is often referred to as the **phase velocity**, since it describes the velocity of the phase (or shape) of the wave, and it can be written in terms of $\omega$ and $k$:

$$v = \lambda f = \left(\frac{2\pi}{k}\right)\left(\frac{\omega}{2\pi}\right) = \frac{\omega}{k}. \qquad \textbf{(15–12)}$$

Equations 15–10 apply for a wave moving to the right along the $x$ axis. For a wave traveling along the $x$ axis to the *left*, toward decreasing values of $x$, $v$ becomes $-v$. So

$$D(x,t) = A\sin\left[\frac{2\pi}{\lambda}(x + vt)\right] \qquad \left[\begin{array}{l}\text{1-D wave moving}\\ \text{in } -x \text{ direction}\end{array}\right] \qquad \textbf{(15–13a)}$$

$$= A\sin\left(\frac{2\pi x}{\lambda} + \frac{2\pi t}{T}\right) \qquad \textbf{(15–13b)}$$

$$= A\sin(kx + \omega t). \qquad \textbf{(15–13c)}$$

Let us look at Eq. 15–13c (or, just as well, at Eq. 15–10c). At $t = 0$ we have

$$D(x,0) = A\sin kx,$$

which is what we started with, a sinusoidal wave shape. If we look at the wave shape in space at a particular later time $t_1$, then we have

$$D(x,t_1) = A\sin(kx + \omega t_1).$$

That is, if we took a picture of the wave at $t = t_1$, we would still see a sine wave in space but shifted by an amount $\omega t_1$. On the other hand, if we consider a fixed point in space, say $x = 0$ in Eq. 15–13c, we can see how the wave varies in time:

$$D(0,t) = A\sin\omega t.$$

This is the equation for simple harmonic motion (Section 14–2). For any other fixed value of $x$, say $x = x_1$, $D = A\sin(\omega t + kx_1)$ which differs only by a constant $kx_1$. Thus, at any point in space, the displacement undergoes the oscillations of simple harmonic motion in time. Equations 15–10 and 15–13 combine both these aspects to give us the representation for a **traveling sinusoidal wave** (also called a **harmonic wave**).

The argument of the sine in Eqs. 15–10 and 15–13 can in general contain a **phase constant** or **phase angle**, $\phi$, which for Eq. 15–10c is

$$D(x,t) = A\sin(kx - \omega t + \phi),$$

to adjust for the position of the wave at $t = 0$, $x = 0$, just as in Section 14–2 (see Fig. 14–6). If the displacement is zero at $t = 0$, $x = 0$, as in Fig. 14–5 (or Fig. 15–13), then $\phi = 0$.

**EXERCISE D** A wave is given by $D(x,t) = (5.0\,\text{mm})\sin(2.0x - 20.0t)$ where $x$ is in meters and $t$ is in seconds. What is the speed of the wave? (*a*) 10 m/s, (*b*) 0.10 m/s, (*c*) 40 m/s, (*d*) 0.005 m/s, (*e*) $2.5 \times 10^{-4}$ m/s.

**EXAMPLE 15–6** **A traveling wave.** The left-hand end of a long horizontal stretched cord oscillates transversely in SHM with frequency $f = 25$ Hz and amplitude 2.6 cm. The cord is under a tension of 140 N and has a linear density $\mu = 0.12$ kg/m. At $t = 0$, the end of the cord has a positive displacement of 1.6 cm and is falling (Fig. 15–14). Determine ($a$) the wavelength of waves produced, ($b$) the equation for the traveling wave, and (c) the speed $v'$ of a particle of cord at $x = 1.00$ m.

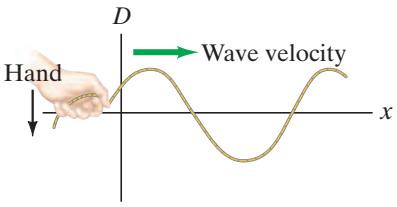

**FIGURE 15–14** Example 15–6. The wave at $t = 0$ (the hand is falling). Not to scale.

**APPROACH** We first find the speed of the transverse wave from Eq. 15–2; then we calculate $\lambda = v/f$. In ($b$), we need to find the phase $\phi$ using the initial conditions.

**SOLUTION** ($a$) The wave speed (or phase velocity) is, from Eq. 15–2,

$$v = \sqrt{\frac{F_T}{\mu}} = \sqrt{\frac{140\text{ N}}{0.12\text{ kg/m}}} = 34\text{ m/s}.$$

Then

$$\lambda = \frac{v}{f} = \frac{34\text{ m/s}}{25\text{ Hz}} = 1.4\text{ m}.$$

($b$) At the left-hand end of the cord $x = 0$. The phase of the wave at $t = 0$ is not zero in general as was assumed in Eqs. 15–9, 10, and 13. The general form for a wave traveling to the right is

$$D(x, t) = A\sin(kx - \omega t + \phi),$$

where $\phi$ is the phase angle. In our case, the amplitude $A = 2.6$ cm; and at $t = 0$, $x = 0$, we are given $D = 1.6$ cm. Thus

$$1.6\text{ cm} = (2.6\text{ cm})\sin\phi,$$

so $\phi = \sin^{-1}(1.6/2.6) = 38° = 0.66$ rad. We also have $\omega = 2\pi f = (2\pi\text{ rad})(25\text{ s}^{-1}) = 157$ rad/s and $k = 2\pi/\lambda = 2\pi\text{ rad}/1.4\text{ m} = 4.5$ rad/m. Hence

$$D = (0.026\text{ m})\sin[(4.5\text{ rad/m})x - (157\text{ rad/s})t + 0.66\text{ rad}]$$

which we can write more simply without detailed units as

$$D = 0.026\sin(4.5x - 157t + 0.66),$$

and we specify clearly that $D$ and $x$ are in meters, $t$ in seconds, and trig functions using rads.

(c) The velocity $v'$ of a particle of cord at $x = 1.00$ m as a function of time is

$$v' = \frac{d}{dt}[(0.026\text{ m})\sin(4.5 - (157\text{ rad/s})t + 0.66)]$$
$$= -(0.026\text{ m})(157\text{ s}^{-1})\cos(4.5 - (157\text{ rad/s})t + 0.66).$$

The speed of this particle varies from zero at times when the cosine = 0, to a maximum (when cos = 1) of (0.026)(157) m/s = 4.1 m/s (vertically). The wave speed, on the other hand, is a constant 34 m/s horizontally.

## *A General Wave (non-sinusoidal)

Now let us consider a general wave (or wave pulse) of any shape. If frictional losses are small, experiment shows that the wave maintains its shape as it travels. Thus we can make the same arguments as we did right after Eq. 15–9. Suppose our wave has some shape at $t = 0$, given by

$$D(x, 0) = D(x)$$

where $D(x)$ is the displacement of the wave at $x$ and is not necessarily sinusoidal. At some later time, if the wave is traveling to the right along the $x$ axis, the wave will have the same shape but all parts will have moved a distance $vt$ where $v$ is the phase velocity of the wave. Hence we replace $x$ by $x - vt$ to obtain the displacement at time $t$:

$$D(x, t) = D(x - vt). \qquad \textbf{(15–14)}$$

Similarly, if the wave moves to the left, we replace $x$ by $x + vt$, so

$$D(x, t) = D(x + vt). \qquad \textbf{(15–15)}$$

Thus, any wave traveling along the $x$ axis has the form of Eq. 15–14 or 15–15.

# *15–5 The Wave Equation

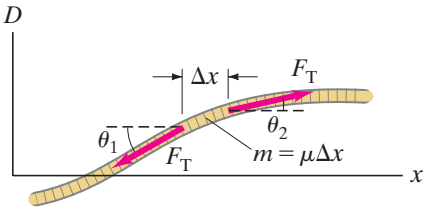

**FIGURE 15–15** Deriving the wave equation from Newton's second law: a segment of string under tension $F_T$.

Many types of waves satisfy an important general equation that is the equivalent of Newton's second law of motion for particles. This "equation of motion for a wave" is called the **wave equation**, and we derive it now for a one-dimensional wave traveling on a stretched horizontal string.

We assume the amplitude of the wave is small compared to the wavelength so that each point on the string can be assumed to move only vertically and the tension in the string, $F_T$, does not vary during a vibration. We apply Newton's second law, $\Sigma F = ma$, to the vertical motion of a tiny section of the string as shown in Fig. 15–15. The amplitude of the wave is small, so the angles $\theta_1$ and $\theta_2$ that the string makes with the horizontal are small. The length of this section is then approximately $\Delta x$, and its mass is $\mu\,\Delta x$, where $\mu$ is the mass per unit length of the string. The net vertical force on this section of string is $F_T \sin\theta_2 - F_T \sin\theta_1$ (see Fig. 15–15). So Newton's second law applied to the vertical direction gives

$$\Sigma F = ma$$

$$F_T \sin\theta_2 - F_T \sin\theta_1 = (\mu\,\Delta x)\frac{\partial^2 D}{\partial t^2}. \qquad \textbf{(i)}$$

We have written the acceleration as $a = \partial^2 D/\partial t^2$ and $m = \mu\,\Delta x$. We use the partial derivative notation because the displacement $D$ is a function of both $x$ and $t$: that is, $D = D(x, t)$. On the left of Eq. (i) the angles $\theta_1$ and $\theta_2$ are assumed small, so $\sin\theta \approx \tan\theta$ and $\tan\theta$ is equal to the slope $s$ of the string at each point:

$$\sin\theta \approx \tan\theta = \frac{\partial D}{\partial x} = s.$$

Thus our equation (i) becomes

$$F_T(s_2 - s_1) = \mu\,\Delta x\frac{\partial^2 D}{\partial t^2}$$

or

$$F_T\frac{\Delta s}{\Delta x} = \mu\frac{\partial^2 D}{\partial t^2}, \qquad \textbf{(ii)}$$

where $\Delta s = s_2 - s_1$ is the difference in the slope between the two ends of our tiny section. Now we take the limit of $\Delta x \to 0$, so that

$$F_T \lim_{\Delta x\to 0}\frac{\Delta s}{\Delta x} = F_T\frac{\partial s}{\partial x}$$

$$= F_T\frac{\partial}{\partial x}\left(\frac{\partial D}{\partial x}\right) = F_T\frac{\partial^2 D}{\partial x^2}$$

since the slope $s = \partial D/\partial x$, as we wrote above. Substituting this into the equation labeled (ii) above gives

$$F_T\frac{\partial^2 D}{\partial x^2} = \mu\frac{\partial^2 D}{\partial t^2}$$

or

$$\frac{\partial^2 D}{\partial x^2} = \frac{\mu}{F_T}\frac{\partial^2 D}{\partial t^2}.$$

We saw earlier in this Chapter (Eq. 15–2) that the speed of waves on a string is given by $v = \sqrt{F_T/\mu}$, so we can write this last equation as

$$\frac{\partial^2 D}{\partial x^2} = \frac{1}{v^2}\frac{\partial^2 D}{\partial t^2}. \qquad \textbf{(15–16)}$$

This is the **one-dimensional wave equation**, and it can describe not only small amplitude waves on a stretched string, but also small amplitude longitudinal waves (such as sound waves) in gases, liquids, and elastic solids, in which case $D$ can refer to the pressure variations. In this case, the wave equation is a direct consequence of Newton's second law applied to a continuous elastic medium.

The wave equation also describes electromagnetic waves for which $D$ refers to the electric or magnetic field, as we shall see in Chapter 31. Equation 15–16 applies to waves traveling in one dimension only. For waves spreading out in three dimensions, the wave equation is the same, with the addition of $\partial^2 D/\partial y^2$ and $\partial^2 D/\partial z^2$ to the left side of Eq. 15–16.

The wave equation is a *linear* equation: the displacement $D$ appears singly in each term. There are no terms that contain $D^2$, or $D(\partial D/\partial x)$, or the like in which $D$ appears more than once. Thus, if $D_1(x, t)$ and $D_2(x, t)$ are two different solutions of the wave equation, then the linear combination

$$D_3(x, t) = aD_1(x, t) + bD_2(x, t),$$

where $a$ and $b$ are constants, is also a solution. This is readily seen by direct substitution into the wave equation. This is the essence of the *superposition principle*, which we discuss in the next Section. Basically it says that if two waves pass through the same region of space at the same time, the actual displacement is the sum of the separate displacements. For waves on a string, or for sound waves, this is valid only for small-amplitude waves. If the amplitude is not small enough, the equations for wave propagation may become nonlinear and the principle of superposition would not hold and more complicated effects may occur.

**EXAMPLE 15–7** **Wave equation solution.** Verify that the sinusoidal wave of Eq. 15–10c, $D(x, t) = A \sin(kx - \omega t)$, satisfies the wave equation.

**APPROACH** We substitute Eq. 15–10c into the wave equation, Eq. 15–16.

**SOLUTION** We take the derivative of Eq. 15–10c twice with respect to $t$:

$$\frac{\partial D}{\partial t} = -\omega A \cos(kx - \omega t)$$

$$\frac{\partial^2 D}{\partial t^2} = -\omega^2 A \sin(kx - \omega t).$$

With respect to $x$, the derivatives are

$$\frac{\partial D}{\partial x} = kA \cos(kx - \omega t)$$

$$\frac{\partial^2 D}{\partial x^2} = -k^2 A \sin(kx - \omega t).$$

If we now divide the second derivatives we get

$$\frac{\partial^2 D/\partial t^2}{\partial^2 D/\partial x^2} = \frac{-\omega^2 A \sin(kx - \omega t)}{-k^2 A \sin(kx - \omega t)} = \frac{\omega^2}{k^2}.$$

From Eq. 15–12 we have $\omega^2/k^2 = v^2$, so we see that Eq. 15–10 does satisfy the wave equation (Eq. 15–16).

## 15–6 The Principle of Superposition

When two or more waves pass through the same region of space at the same time, it is found that for many waves *the actual displacement is the vector* (or *algebraic*) *sum of the separate displacements*. This is called the **principle of superposition**. It is valid for mechanical waves as long as the displacements are not too large and there is a linear relationship between the displacement and the restoring force of the oscillating medium.[†] If the amplitude of a mechanical wave, for example, is so large that it goes beyond the elastic region of the medium, and Hooke's law is no longer operative, the superposition principle is no longer accurate.[‡] For the most part, we will consider systems for which the superposition principle can be assumed to hold.

[†]For electromagnetic waves in vacuum, Chapter 31, the superposition principle always holds.

[‡]Intermodulation distortion in audio equipment is an example of the superposition principle not holding when two frequencies do not combine linearly in the electronics.

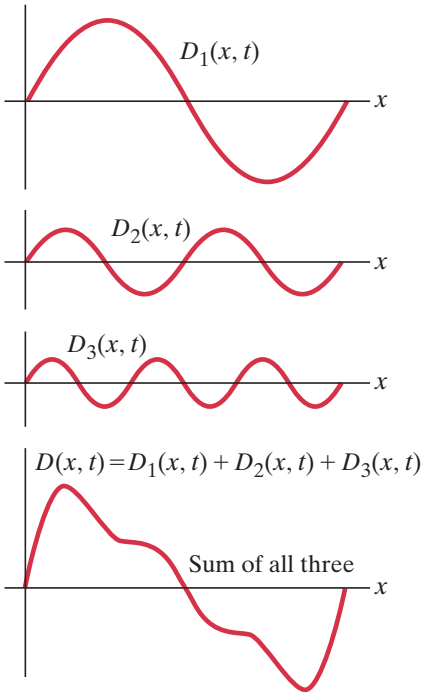

**FIGURE 15–16** The superposition principle for one-dimensional waves. The composite wave formed from three sinusoidal waves of different amplitudes and frequencies $(f_0, 2f_0, 3f_0)$ is shown at the bottom at a certain instant in time. The displacement of the composite wave at each point in space, at any time, is the algebraic sum of the displacements of the component waves. Amplitudes are shown exaggerated; for the superposition principle to hold, they must be small compared to the wavelengths.

One result of the superposition principle is that if two waves pass through the same region of space, they continue to move independently of one another. You may have noticed, for example, that the ripples on the surface of water (two-dimensional waves) that form from two rocks striking the water at different places will pass right through each other.

Figure 15–16 shows an example of the superposition principle. In this case there are three sinusoidal waves present on a stretched string, each of different amplitude and frequency. At any time, such as at the instant shown, the actual displacement at any position $x$ is the algebraic sum of the displacements of the three waves at that position. The actual wave is not a simple sinusoidal wave and is called a *composite* (or *complex*) *wave*. (Amplitudes are exaggerated in Fig. 15–16.)

It can be shown that any complex wave can be considered as being composed of many simple sinusoidal waves of different amplitudes, wavelengths, and frequencies. This is known as *Fourier's theorem*. A complex periodic wave of period $T$ can be represented as a sum of pure sinusoidal terms whose frequencies are integral multiples of $f = 1/T$. If the wave is not periodic, the sum becomes an integral (called a *Fourier integral*). Although we will not go into the details here, we see the importance of considering sinusoidal waves (and simple harmonic motion): because any other wave shape can be considered a sum of such pure sinusoidal waves.

**CONCEPTUAL EXAMPLE 15–8** **Making a square wave.** At $t = 0$, three waves are given by $D_1 = A\cos kx$, $D_2 = -\frac{1}{3}A\cos 3kx$, and $D_3 = \frac{1}{5}A\cos 5kx$, where $k = 10\,\text{m}^{-1}$ and $A = 1.0\,\text{mm} = 1.0 \times 10^{-3}\,\text{m}$. Plot the sum of the three waves from $x = -0.4\,\text{m}$ to $+0.4\,\text{m}$. (These three waves are the first three Fourier components of a "square wave.")

**RESPONSE** The first wave, $D_1$, has amplitude of 1.0 mm and wavelength $\lambda = 2\pi/k = (2\pi/10)\,\text{m} = 0.628\,\text{m}$. The second wave, $D_2$, has amplitude of 0.33 mm and wavelength $\lambda = 2\pi/3k = (2\pi/30)\,\text{m} = 0.209\,\text{m}$. The third wave, $D_3$, has amplitude of 0.20 mm and wavelength $\lambda = 2\pi/5k = (2\pi/50)\,\text{m} = 0.126\,\text{m}$. Each wave is plotted in Fig. 15–17a. The sum of the three waves is shown in Fig. 15–17b. The sum begins to resemble a "square wave," shown in blue in Fig. 15–17b.

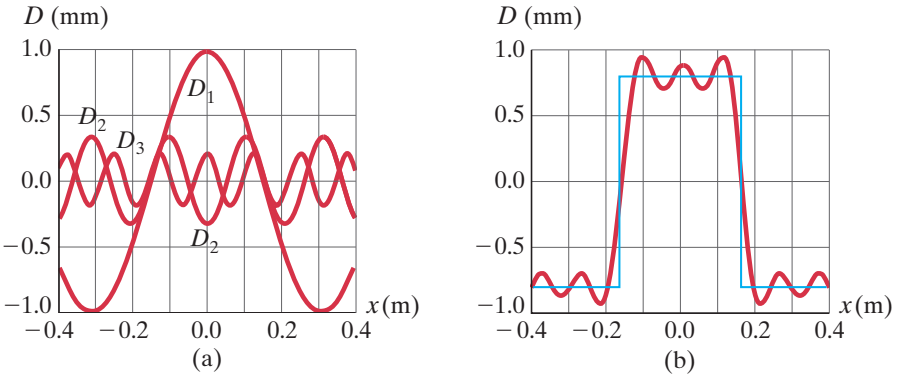

**FIGURE 15–17** Example 15–8. Making a square wave.

**PHYSICS APPLIED**
*Square wave (useful in electronics)*

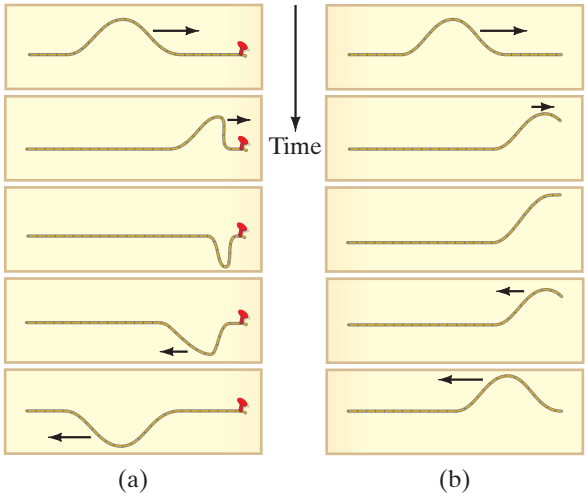
When the restoring force is not precisely proportional to the displacement for mechanical waves in some continuous medium, the speed of sinusoidal waves depends on the frequency. The variation of speed with frequency is called **dispersion**. The different sinusoidal waves that compose a complex wave will travel with slightly different speeds in such a case. Consequently, a complex wave will change shape as it travels if the medium is "dispersive." A pure sine wave will not change shape under these conditions, however, except by the influence of friction or dissipative forces. If there is no dispersion (or friction), even a complex linear wave does not change shape.

**PHYSICS APPLIED**
*When wave speed depends on frequency, a composite wave changes shape over time*

# 15–7 Reflection and Transmission

When a wave strikes an obstacle, or comes to the end of the medium in which it is traveling, at least a part of the wave is reflected. You have probably seen water waves reflect off a rock or the side of a swimming pool. And you may have heard a shout reflected from a distant cliff—which we call an "echo."

A wave pulse traveling along a cord is reflected as shown in Fig. 15–18 (time increasing going downward in both a and b). The reflected pulse returns inverted as in Fig. 15–18a if the end of the cord is fixed; it returns right side up if the end is free as in Fig. 15–18b. When the end is fixed to a support, as in Fig. 15–18a, the pulse reaching that fixed end exerts a force (upward) on the support. The support exerts an equal but opposite force downward on the cord (Newton's third law). This downward force on the cord is what causes the inverted reflected pulse.



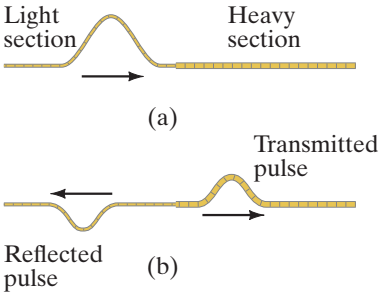


**FIGURE 15–18** Reflection of a wave pulse traveling along a cord lying on a table. (Time increases going down.) (a) The end of the cord is fixed to a peg. (b) The end of the cord is free to move.

Consider next a pulse that travels along a cord which consists of a light section and a heavy section, as shown in Fig. 15–19. When the wave pulse reaches the boundary between the two sections, part of the pulse is reflected and part is transmitted, as shown. The heavier the second section of the cord, the less the energy that is transmitted. Indeed, when the second section is a wall or rigid support, very little is transmitted and most is reflected, as in Fig. 15–18a. For a sinusoidal wave, the *frequency of the transmitted wave does not change* as it crosses the boundary (the boundary point oscillates at that frequency). Thus if the transmitted wave has a lower speed, its wavelength is also less $(\lambda = v/f)$.

**FIGURE 15–19** When a wave pulse traveling to the right along a thin cord (a) reaches a discontinuity where the cord becomes thicker and heavier, then part is reflected and part is transmitted (b).

For a two or three dimensional wave, such as a water wave, we are concerned with **wave fronts**, by which we mean all the points along the wave forming the wave crest (what we usually refer to simply as a "wave" at the seashore). A line drawn in the direction of wave motion, perpendicular to the wave front, is called a **ray**, as shown in Fig. 15–20. Wave fronts far from the source have lost almost all their curvature (Fig. 15–20b) and are nearly straight, as ocean waves often are. They are then called **plane waves**.

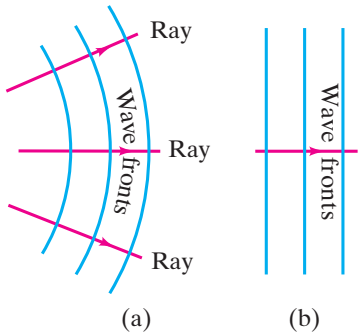

**FIGURE 15–20** Rays, signifying the direction of wave motion, are always perpendicular to the wave fronts (wave crests). (a) Circular or spherical waves near the source. (b) Far from the source, the wave fronts are nearly straight or flat, and are called plane waves.

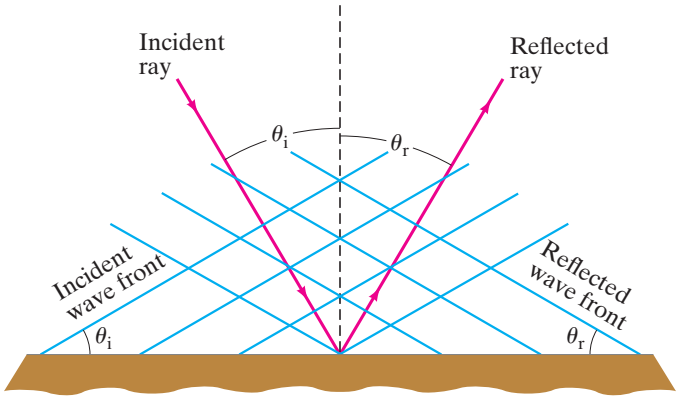

**FIGURE 15–21**
Law of reflection: $\theta_r = \theta_i$.

For reflection of a two- or three-dimensional plane wave, as shown in Fig. 15–21, the angle that the incoming or *incident wave* makes with the reflecting surface is equal to the angle made by the reflected wave. This is the **law of reflection**:

**the angle of reflection equals the angle of incidence.**

The **angle of incidence** is defined as the angle ($\theta_i$) the incident ray makes with the perpendicular to the reflecting surface (or the wave front makes with a tangent to the surface). The **angle of reflection** is the corresponding angle ($\theta_r$) for the reflected wave.

## 15–8 Interference

**Interference** refers to what happens when two waves pass through the same region of space at the same time. Consider, for example, the two wave pulses on a cord traveling toward each other as shown in Fig. 15–22 (time increases downward in both a and b). In Fig. 15–22a the two pulses have the same amplitude, but one is a crest and the other a trough; in Fig. 15–22b they are both crests. In both cases, the waves meet and pass right by each other. However, in the region where they overlap, the resultant displacement is the *algebraic sum of their separate displacements* (a crest is considered positive and a trough negative). This is another example of the principle of superposition. In Fig. 15–22a, the two waves have opposite displacements at the instant they pass one another, and they add to zero. The result is called **destructive interference**. In Fig. 15–22b, at the instant the two pulses overlap, they produce a resultant displacement that is greater than the displacement of either separate pulse, and the result is **constructive interference**.

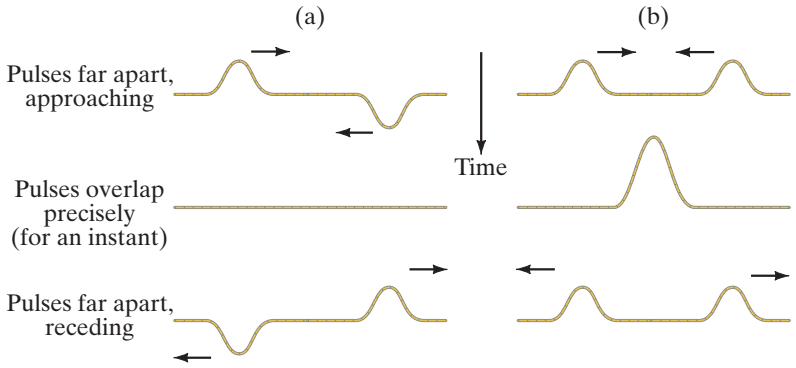

**FIGURE 15–22** Two wave pulses pass each other. Where they overlap, interference occurs: (a) destructive, and (b) constructive. Read (a) and (b) downward (increasing time).

You may wonder where the energy is at the moment of destructive interference in Fig. 15–22a; the cord may be straight at this instant, but the central parts of it are still moving up or down (kinetic energy).

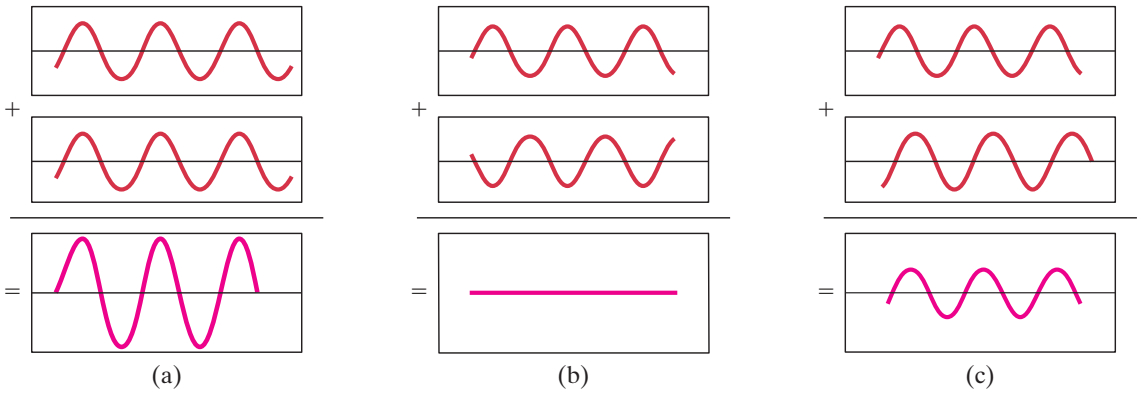

**FIGURE 15–23** (a) Interference of water waves. (b) Constructive interference occurs where one wave's maximum (a crest) meets the other's maximum. Destructive interference ("flat water") occurs where one wave's maximum (a crest) meets the other's minimum (a trough).

When two rocks are thrown into a pond simultaneously, the two sets of circular waves that move outward interfere with one another as shown in Fig. 15–23a. In some areas of overlap, crests of one wave repeatedly meet crests of the other (and troughs meet troughs), Fig. 15–23b. Constructive interference is occurring at these points, and the water continuously oscillates up and down with greater amplitude than either wave separately. In other areas, destructive interference occurs where the water does not move up and down at all over time. This is where crests of one wave meet troughs of the other, and vice versa. Figure 15–24a shows the displacement of two identical waves graphically as a function of time, as well as their sum, for the case of constructive interference. For any two such waves, we use the term **phase** to describe the relative positions of their crests. When the crests and troughs are aligned as in Fig. 15–24a, for constructive interference, the two waves are **in phase**. At points where destructive interference occurs (Fig. 15–24b), crests of one wave repeatedly meet troughs of the other wave and the two waves are said to be completely **out of phase** or, more precisely, out of phase by one-half wavelength (or $\pi$ radians, or 180°).[†] That is, the crests of one wave occur a half wavelength behind the crests of the other wave. The relative phase of the two water waves in Fig. 15–23 in most areas is intermediate between these two extremes, resulting in *partially* destructive interference, as illustrated in Fig. 15–24c. If the amplitudes of two interfering waves are not equal, fully destructive interference (as in Fig. 15–24b) does not occur.

[†]One wavelength, or one full oscillation, corresponds to 360° or $2\pi$ radians.

**FIGURE 15–24** Graphs showing two identical waves, and their sum, as a function of time at three locations. In (a) the two waves interfere constructively, in (b) destructively, and in (c) partially destructively.

# 15–9 Standing Waves; Resonance

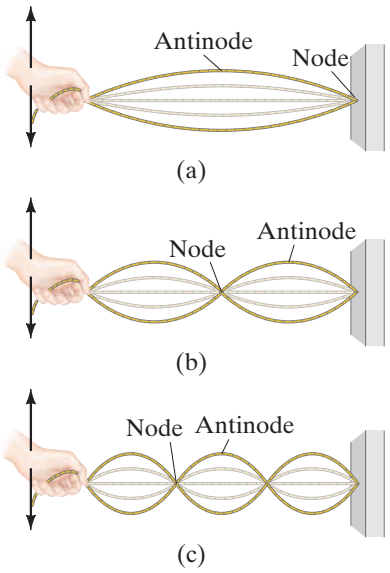

**FIGURE 15–25** Standing waves corresponding to three resonant frequencies.

If you shake one end of a cord and the other end is kept fixed, a continuous wave will travel down to the fixed end and be reflected back, inverted, as we saw in Fig. 15–18a. As you continue to oscillate the cord, waves will travel in both directions, and the wave traveling along the cord, away from your hand, will interfere with the reflected wave coming back. Usually there will be quite a jumble. But if you oscillate the cord at just the right frequency, the two traveling waves will interfere in such a way that a large-amplitude **standing wave** will be produced, Fig. 15–25. It is called a "standing wave" because it does not appear to be traveling. The cord simply appears to have segments that oscillate up and down in a fixed pattern. The points of destructive interference, where the cord remains still at all times, are called **nodes**. Points of constructive interference, where the cord oscillates with maximum amplitude, are called **antinodes**. The nodes and antinodes remain in fixed positions for a particular frequency.

Standing waves can occur at more than one frequency. The lowest frequency of oscillation that produces a standing wave gives rise to the pattern shown in Fig. 15–25a. The standing waves shown in Figs. 15–25b and 15–25c are produced at precisely twice and three times the lowest frequency, respectively, assuming the tension in the cord is the same. The cord can also oscillate with four loops (four antinodes) at four times the lowest frequency, and so on.

The frequencies at which standing waves are produced are the **natural frequencies** or **resonant frequencies** of the cord, and the different standing wave patterns shown in Fig. 15–25 are different "resonant modes of vibration." A standing wave on a cord is the result of the interference of two waves traveling in opposite directions. A standing wave can also be considered a vibrating object at resonance. Standing waves represent the same phenomenon as the resonance of an oscillating spring or pendulum, which we discussed in Section 14–8. However, a spring or pendulum has only one resonant frequency, whereas the cord has an infinite number of resonant frequencies, each of which is a whole-number multiple of the lowest resonant frequency.

Consider a string stretched between two supports that is plucked like a guitar or violin string, Fig. 15–26a. Waves of a great variety of frequencies will travel in both directions along the string, will be reflected at the ends, and will travel back in the opposite direction. Most of these waves interfere with each other and quickly die out. However, those waves that correspond to the resonant frequencies of the string will persist. The ends of the string, since they are fixed, will be nodes. There may be other nodes as well. Some of the possible *resonant modes of vibration* (standing waves) are shown in Fig. 15–26b. Generally, the motion will be a combination of these different resonant modes, but only those frequencies that correspond to a resonant frequency will be present.

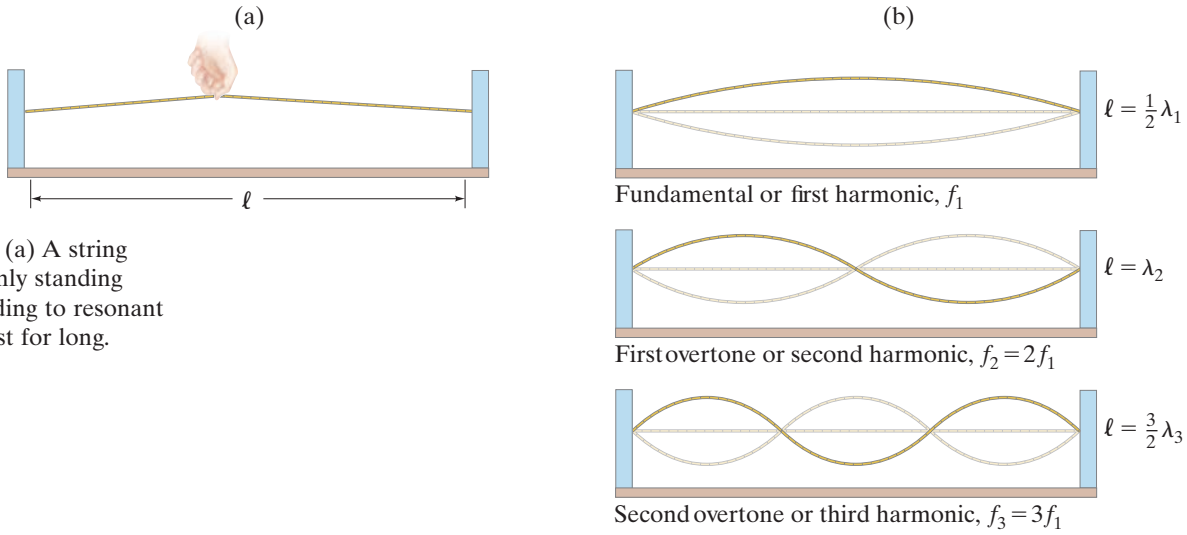

**FIGURE 15–26** (a) A string is plucked. (b) Only standing waves corresponding to resonant frequencies persist for long.

To determine the resonant frequencies, we first note that the wavelengths of the standing waves bear a simple relationship to the length $\ell$ of the string. The lowest frequency, called the **fundamental frequency**, corresponds to one antinode (or loop). And as can be seen in Fig. 15–26b, the whole length corresponds to one-half wavelength. Thus $\ell = \frac{1}{2}\lambda_1$, where $\lambda_1$ stands for the wavelength of the fundamental frequency. The other natural frequencies are called **overtones**; for a vibrating string they are whole-number (integral) multiples of the fundamental, and then are also called **harmonics**, with the fundamental being referred to as the **first harmonic**.[†] The next mode of vibration after the fundamental has two loops and is called the **second harmonic** (or first overtone), Fig. 15–26b. The length of the string $\ell$ at the second harmonic corresponds to one complete wavelength: $\ell = \lambda_2$. For the third and fourth harmonics, $\ell = \frac{3}{2}\lambda_3$, and $\ell = 2\lambda_4$, respectively, and so on. In general, we can write

$$\ell = \frac{n\lambda_n}{2}, \qquad \text{where } n = 1, 2, 3, \cdots.$$

The integer $n$ labels the number of the harmonic: $n = 1$ for the fundamental, $n = 2$ for the second harmonic, and so on. We solve for $\lambda_n$ and find

$$\lambda_n = \frac{2\ell}{n}, \qquad n = 1, 2, 3, \cdots. \qquad \begin{bmatrix}\text{string fixed}\\ \text{at both ends}\end{bmatrix} \qquad \textbf{(15–17a)}$$

To find the frequency $f$ of each vibration we use Eq. 15–1, $f = v/\lambda$, and see that

$$f_n = \frac{v}{\lambda_n} = n\frac{v}{2\ell} = nf_1, \qquad n = 1, 2, 3, \cdots, \qquad \textbf{(15–17b)}$$

where $f_1 = v/\lambda_1 = v/2\ell$ is the fundamental frequency. We see that each resonant frequency is an *integer multiple of the fundamental frequency*.

Because a standing wave is equivalent to two traveling waves moving in opposite directions, the concept of wave speed still makes sense and is given by Eq. 15–2 in terms of the tension $F_T$ in the string and its mass per unit length ($\mu = m/\ell$). That is, $v = \sqrt{F_T/\mu}$ for waves traveling in both directions.

**EXAMPLE 15–9** **Piano string.** A piano string is 1.10 m long and has mass 9.00 g. (*a*) How much tension must the string be under if it is to vibrate at a fundamental frequency of 131 Hz? (*b*) What are the frequencies of the first four harmonics?

**APPROACH** To determine the tension, we need to find the wave speed using Eq. 15–1 ($v = \lambda f$), and then use Eq. 15–2, solving it for $F_T$.

**SOLUTION** (*a*) The wavelength of the fundamental is $\lambda = 2\ell = 2.20\,\text{m}$ (Eq. 15–17a with $n = 1$). The speed of the wave on the string is $v = \lambda f = (2.20\,\text{m})(131\,\text{s}^{-1}) = 288\,\text{m/s}$. Then we have (Eq. 15–2)

$$F_T = \mu v^2 = \frac{m}{\ell}v^2 = \left(\frac{9.00\times10^{-3}\,\text{kg}}{1.10\,\text{m}}\right)(288\,\text{m/s})^2 = 679\,\text{N}.$$

(*b*) The first harmonic (the fundamental) has a frequency $f_1 = 131\,\text{Hz}$. The frequencies of the second, third, and fourth harmonics are two, three, and four times the fundamental frequency: 262, 393, and 524 Hz, respectively.

**NOTE** The speed of the wave on the string is *not* the same as the speed of the sound wave that the piano string produces in the air (as we shall see in Chapter 16).

A standing wave does appear to be standing in place (and a traveling wave appears to move). The term "standing" wave is also meaningful from the point of view of energy. Since the string is at rest at the nodes, no energy flows past these points. Hence the energy is not transmitted down the string but "stands" in place in the string.

Standing waves are produced not only on strings, but on any object that is struck, such as a drum membrane or an object made of metal or wood. The resonant frequencies depend on the dimensions of the object, just as for a string they depend on its length. Large objects have lower resonant frequencies than small objects. All musical instruments, from stringed instruments to wind instruments (in which a column of air vibrates as a standing wave) to drums and other percussion instruments, depend on standing waves to produce their particular musical sounds, as we shall see in Chapter 16.

[†]The term "harmonic" comes from music, because such integral multiples of frequencies "harmonize."

## Mathematical Representation of a Standing Wave

As we saw, a standing wave can be considered to consist of two traveling waves that move in opposite directions. These can be written (see Eqs. 15–10c and 15–13c)

$$D_1(x,t) = A\sin(kx - \omega t) \quad \text{and} \quad D_2(x,t) = A\sin(kx + \omega t)$$

since, assuming no damping, the amplitudes are equal as are the frequencies and wavelengths. The sum of these two traveling waves produces a standing wave which can be written mathematically as

$$D = D_1 + D_2 = A\big[\sin(kx - \omega t) + \sin(kx + \omega t)\big].$$

From the trigonometric identity $\sin\theta_1 + \sin\theta_2 = 2\sin\frac{1}{2}(\theta_1 + \theta_2)\cos\frac{1}{2}(\theta_1 - \theta_2)$, Appendix A–9, we can rewrite this as

$$D = 2A\sin kx\cos\omega t. \qquad \textbf{(15–18)}$$

If we let $x = 0$ at the left-hand end of the string, then the right-hand end is at $x = \ell$ where $\ell$ is the length of the string. Since the string is fixed at its two ends (Fig. 15–26), $D(x,t)$ must be zero at $x = 0$ and at $x = \ell$. Equation 15–18 already satisfies the first condition ($D = 0$ at $x = 0$) and satisfies the second condition if $\sin k\ell = 0$ which means

$$k\ell = \pi, 2\pi, 3\pi, \cdots, n\pi, \cdots$$

where $n$ = an integer. Since $k = 2\pi/\lambda$, then $\lambda = 2\pi/k = 2\pi\ell/n\pi = 2\ell/n$, which is just Eq. 15–17a.

Equation 15–18, with the condition $\lambda = 2\ell/n$, is the mathematical representation of a standing wave. We see that a particle at any position $x$ vibrates in simple harmonic motion (because of the factor $\cos\omega t$). All particles of the string vibrate with the same frequency $f = \omega/2\pi$, but the amplitude depends on $x$ and equals $2A\sin kx$. (Compare this to a traveling wave for which all particles vibrate with the same amplitude.) The amplitude has a maximum, equal to $2A$, when $kx = \pi/2, 3\pi/2, 5\pi/2$, and so on—that is, at

$$x = \frac{\lambda}{4}, \quad \text{and for overtones also at} \quad \frac{3\lambda}{4}, \frac{5\lambda}{4}, \ldots.$$

These are the positions of the antinodes, as we saw in Fig. 15–26.

**EXAMPLE 15–10** **Wave forms.** Two waves traveling in opposite directions on a string fixed at $x = 0$ are described by the functions

$$D_1 = (0.20\,\text{m})\sin(2.0x - 4.0t) \quad \text{and} \quad D_2 = (0.20\,\text{m})\sin(2.0x + 4.0t)$$

(where $x$ is in m, $t$ is in s), and they produce a standing wave pattern. Determine: (*a*) the function for the standing wave, (*b*) the amplitude at $x = 0.45$ m, (*c*) the length $\ell$ of the string, (*d*) the maximum amplitude and where it occurs.

**APPROACH** We use the principle of superposition to add the two waves. The given waves have the form we used to obtain Eq. 15–18, which we thus can use.

**SOLUTION** (*a*) The two waves are of the form $D = A\sin(kx \pm \omega t)$, so

$$k = 2.0\,\text{rad/m} \quad \text{and} \quad \omega = 4.0\,\text{rad/s}.$$

These combine to form a standing wave of the form of Eq. 15–18:

$$D = 2A\sin kx\cos\omega t = (0.40\,\text{m})\sin(2.0x)\cos(4.0t),$$

where $x$ is in meters and $t$ in seconds, and in trig functions we have rads.

(*b*) At $x = 0.45$ m,

$$D = (0.40\,\text{m})\sin(0.90\,\text{rad})\cos(4.0t) = (0.31\,\text{m})\cos(4.0t).$$

The amplitude at this point is 0.31 m and occurs when $\cos(4.0t) = 1$.

(*c*) These waves make a standing wave pattern, so both ends of the string must be nodes. Nodes occur every half wavelength, which for our string is (see Eq. 15–11)

$$\frac{\lambda}{2} = \frac{1}{2}\frac{2\pi}{k} = \frac{\pi}{2.0}\,\text{m} = 1.57\,\text{m}.$$

If the string includes only one loop (first harmonic), its length is $\ell = 1.57$ m. But without more information, it could be twice as long, $\ell = 3.14$ m, or any integral number times 1.57 m, and still provide a standing wave pattern, Fig. 15–27.

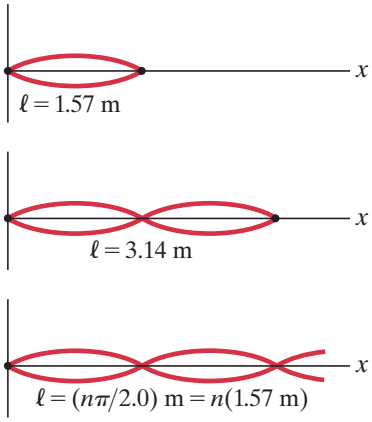

**FIGURE 15–27** Example 15–10: possible lengths for the string.

(*d*) The nodes occur at $x = 0$, $x = 1.57\,\text{m}$, and, if the string is longer than $\ell = 1.57\,\text{m}$, at $x = 3.14\,\text{m}$, 4.71 m, and so on. The maximum amplitude (antinode) is $2A = 0.40\,\text{m}$ [see part (*b*)] and occurs midway between the nodes. For $\ell = 1.57\,\text{m}$, there is only one antinode, at $x = 0.79\,\text{m}$.

## 15–10 Refraction†

When any wave strikes a boundary, some of the energy is reflected and some is transmitted or absorbed. When a two- or three-dimensional wave traveling in one medium crosses a boundary into a medium where its speed is different, the transmitted wave may move in a different direction than the incident wave, as shown in Fig. 15–28. This phenomenon is known as **refraction**. One example is a water wave; the speed decreases in shallow water and the waves refract, as shown in Fig. 15–29. [When the wave speed changes gradually as in Fig. 15–29, without a sharp boundary, the waves change direction (refract) gradually.]

In Fig. 15–28, the speed of the wave in medium 2 is less than in medium 1. In this case, the wave front bends so that it travels more nearly parallel to the boundary. That is, the *angle of refraction*, $\theta_r$, is less than the *angle of incidence*, $\theta_i$. To see why this is so, and to help us get a quantitative relation between $\theta_r$ and $\theta_i$, let us think of each wave front as a row of soldiers. The soldiers are marching from firm ground (medium 1) into mud (medium 2) and hence are slowed down after the boundary. The soldiers that reach the mud first are slowed down first, and the row bends as shown in Fig. 15–30a. Let us consider the wave front (or row of soldiers) labeled A in Fig. 15–30b. In the same time $t$ that point $A_1$ moves a distance $\ell_1 = v_1 t$, we see that point $A_2$ moves a distance $\ell_2 = v_2 t$. The two right triangles in Fig. 15–30b, shaded yellow and green, have side $a$ in common. Thus

$$\sin\theta_1 = \frac{\ell_1}{a} = \frac{v_1 t}{a}$$

since $a$ is the hypotenuse, and

$$\sin\theta_2 = \frac{\ell_2}{a} = \frac{v_2 t}{a}.$$

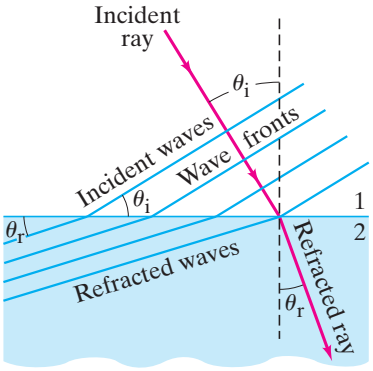
Dividing these two equations, we obtain the **law of refraction**:

$$\frac{\sin\theta_2}{\sin\theta_1} = \frac{v_2}{v_1}. \qquad \textbf{(15–19)}$$

Since $\theta_1$ is the angle of incidence $(\theta_i)$, and $\theta_2$ is the angle of refraction $(\theta_r)$, Eq. 15–19 gives the quantitative relation between the two. If the wave were going in the opposite direction, the geometry would not change; only $\theta_1$ and $\theta_2$ would change roles: $\theta_2$ would be the angle of incidence and $\theta_1$ the angle of refraction. Thus, if the wave travels into a medium where it can move faster, it will bend the opposite way, $\theta_r > \theta_i$. We see from Eq. 15–19 that if the speed increases, the angle increases, and vice versa.

Earthquake waves refract within the Earth as they travel through rock layers of different densities (which have different speeds) just as water waves do. Light waves refract as well, and when we discuss light, we shall find Eq. 15–19 very useful.

†This Section and the next are covered in more detail in Chapters 32 to 35 on optics.



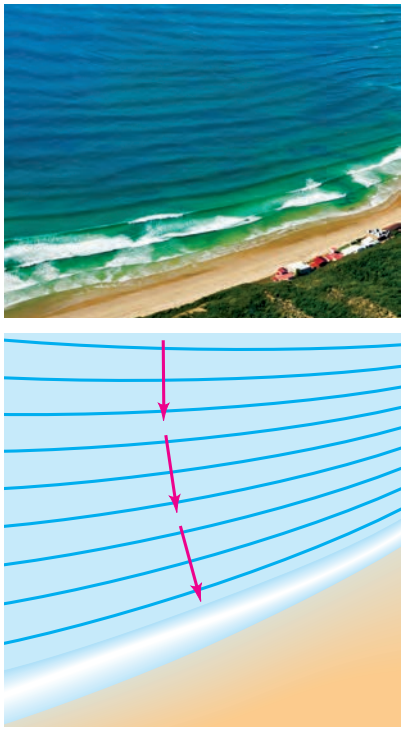


**FIGURE 15–28** Refraction of waves passing a boundary.

**FIGURE 15–29** Water waves refract gradually as they approach the shore, because their speed decreases. There is no distinct boundary, as in Fig. 15–28, because the wave speed changes gradually.

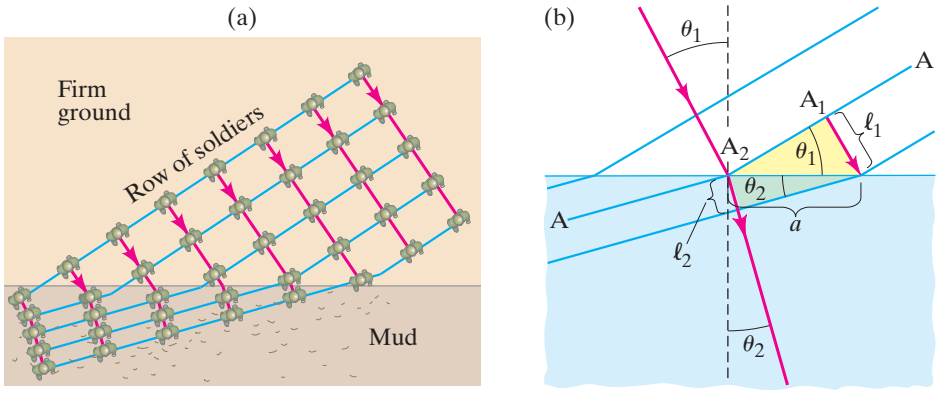

**FIGURE 15–30** (a) Marching soldier analogy to derive (b) the law of refraction for waves.

PHYSICS APPLIED
*Earthquake wave refraction*

**EXAMPLE 15–11 Refraction of an earthquake wave.** An earthquake P wave (page 435) passes across a boundary in rock where its speed increases from 6.5 km/s to 8.0 km/s. If it strikes this boundary at 30°, what is the angle of refraction?

**APPROACH** We apply the law of refraction, Eq. 15–19, $\sin\theta_2/\sin\theta_1 = v_2/v_1$.

**SOLUTION** Since $\sin 30° = 0.50$, Eq. 15–19 yields

$$\sin\theta_2 = \frac{(8.0\,\text{m/s})}{(6.5\,\text{m/s})}(0.50) = 0.62.$$

So $\theta_2 = \sin^{-1}(0.62) = 38°$.

**NOTE** Be careful with angles of incidence and refraction. As we discussed in Section 15–7 (Fig. 15–21), these angles are between the wave front and the boundary line, or—equivalently—between the ray (direction of wave motion) and the line perpendicular to the boundary. Inspect Fig. 15–30b carefully.

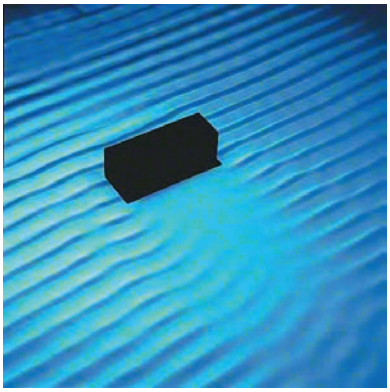

**FIGURE 15–31** Wave diffraction. The waves are coming from the upper left. Note how the waves, as they pass the obstacle, bend around it, into the "shadow region" behind the obstacle.

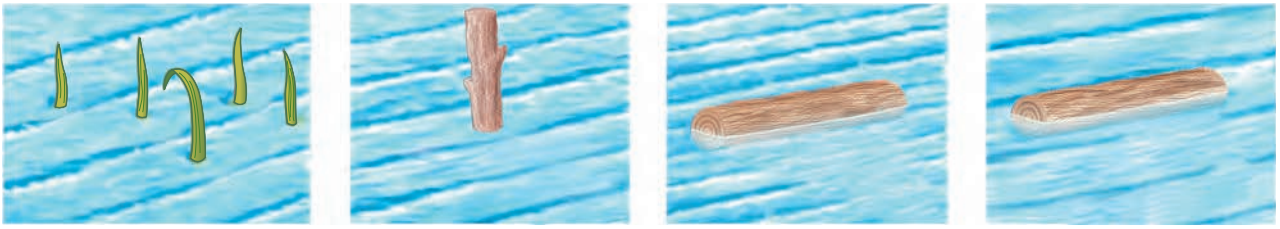
## 15–11 Diffraction

Waves spread as they travel. When they encounter an obstacle, they bend around it somewhat and pass into the region behind it, as shown in Fig. 15–31 for water waves. This phenomenon is called **diffraction**.



The amount of diffraction depends on the wavelength of the wave and on the size of the obstacle, as shown in Fig. 15–32. If the wavelength is much larger than the object, as with the grass blades of Fig. 15–32a, the wave bends around them almost as if they are not there. For larger objects, parts (b) and (c), there is more of a "shadow" region behind the obstacle where we might not expect the waves to penetrate—but they do, at least a little. Then notice in part (d), where the obstacle is the same as in part (c) but the wavelength is longer, that there is more diffraction into the shadow region. As a rule of thumb, *only if the wavelength is smaller than the size of the object will there be a significant shadow region*. This rule applies to *reflection* from an obstacle as well. Very little of a wave is reflected unless the wavelength is smaller than the size of the obstacle.

A rough guide to the amount of diffraction is

$$\theta(\text{radians}) \approx \frac{\lambda}{\ell},$$

where $\theta$ is roughly the angular spread of waves after they have passed through an opening of width $\ell$ or around an obstacle of width $\ell$.

**FIGURE 15–32** Water waves coming from upper left, pass objects of various sizes. Note that the longer the wavelength compared to the size of the object, the more diffraction there is into the "shadow region."

(a) Water waves passing blades of grass

(b) Stick in water

(c) Short-wavelength waves passing log

(d) Long-wavelength waves passing log

That waves can bend around obstacles, and thus can carry energy to areas behind obstacles, is very different from energy carried by material particles. A clear example is the following: if you are standing around a corner on one side of a building, you cannot be hit by a baseball thrown from the other side, but you can hear a shout or other sound because the sound waves diffract around the edges of the building.

**CONCEPTUAL EXAMPLE 15–12** **Cell phones.** Cellular phones operate by radio waves with frequencies of about 1 or 2 GHz (1 gigahertz = $10^9$ Hz). These waves cannot penetrate objects that conduct electricity, such as a sheet of metal or a tree trunk.† The sound quality is best if the transmitting antenna is within clear view of the handset. Yet it is possible to carry on a phone conversation even if the tower is blocked by trees, or if the handset is inside a car. Why?

**RESPONSE** If the radio waves have a frequency of about 2 GHz, and the speed of propagation is equal to the speed of light, $3 \times 10^8$ m/s (Section 1–4), then the wavelength is $\lambda = v/f = (3 \times 10^8 \text{ m/s})/(2 \times 10^9 \text{ Hz}) = 0.15$ m. The waves can diffract readily around objects 15 cm in diameter or smaller.

†Inside the bark are layers of ion-containing water carrying nutrients up to the leaves. The ions are electrically charged and so act as an electrical conductor. Dry wood is not an electrical conductor, but a good insulator.

# Summary

Vibrating objects act as sources of **waves** that travel outward from the source. Waves on water and on a cord are examples. The wave may be a **pulse** (a single crest) or it may be continuous (many crests and troughs).

The **wavelength** of a continuous sinusoidal wave is the distance between two successive crests.

The **frequency** is the number of full wavelengths (or crests) that pass a given point per unit time.

The **amplitude** of a wave is the maximum height of a crest, or depth of a trough, relative to the normal (or equilibrium) level.

The **wave speed** (how fast a crest moves) is equal to the product of wavelength and frequency,

$$v = \lambda f. \qquad \textbf{(15–1)}$$

In a **transverse wave**, the oscillations are perpendicular to the direction in which the wave travels. An example is a wave on a cord.

In a **longitudinal wave**, the oscillations are along (parallel to) the line of travel; sound is an example.

The speed of both longitudinal and transverse waves in matter is proportional to the square root of an elastic force factor divided by an inertia factor (or density).

After an earthquake, both transverse and longitudinal waves (called S and P) propagate through the Earth, plus there are **surface waves**.

Waves carry energy from place to place without matter being carried. The **intensity** $I$ of a wave is the energy per unit time transported across unit area (in watts/m$^2$) and is proportional to the *square of the amplitude, A,* of the wave: $I \propto A^2$.

For a wave traveling uniformly outward in three dimensions from a point source, the intensity decreases inversely with the square of the distance from the source (ignoring damping):

$$I \propto \frac{1}{r^2}, \qquad \textbf{(15–8a)}$$

which is referred to as an **inverse square law**. The amplitude $A(\propto \sqrt{I})$ decreases linearly with distance from the source.

A one-dimensional transverse wave traveling in a medium to the right along the $x$ axis ($x$ increasing) can be represented by a formula for the displacement of the medium from equilibrium at any point $x$ as a function of time as

$$D(x,t) = A \sin\left[\left(\frac{2\pi}{\lambda}\right)(x - vt)\right] \qquad \textbf{(15–10a)}$$

$$= A \sin(kx - \omega t) \qquad \textbf{(15–10c)}$$

where

$$k = \frac{2\pi}{\lambda} \qquad \textbf{(15–11)}$$

is the **wave number**, and $\omega = 2\pi f$ is the *angular frequency*. The **phase velocity** $v$ is

$$v = \lambda f = \omega/k. \qquad \textbf{(15–12)}$$

If a wave is traveling toward decreasing values of $x$, to the left along the $x$ axis, then

$$D(x,t) = A \sin(kx + \omega t). \qquad \textbf{(15–13c)}$$

[*Waves can be described by the **wave equation**, which in one dimension is

$$\partial^2 D/\partial x^2 = (1/v^2)\,\partial^2 D/\partial t^2. \qquad \textbf{(15–16)}]$$

When two or more waves pass through the same region of space at the same time, the displacement at any given point will be the vector sum of the displacements of the separate waves. This is the **principle of superposition**. It is valid for mechanical waves if the amplitudes are small enough that the restoring force of the medium is proportional to displacement. A *complex wave* is one made up of two or more frequencies.

Waves reflect off objects in their path. When the **wave front** of a two- or three-dimensional wave strikes an object, the **angle of reflection** equals the **angle of incidence**, which is the **law of reflection**. When a wave strikes a boundary between two materials in which it can travel, part of the wave is reflected and part is transmitted.

When two waves pass through the same region of space at the same time, they **interfere**. The resultant displacement at any point and time is the sum of their separate displacements (the superposition principle). This can result in **constructive interference**, **destructive interference**, or something in between depending on the amplitudes and relative phases of the waves.

Waves traveling on a cord of fixed length interfere with waves that have reflected off the end and are traveling back in the opposite direction. At certain frequencies, **standing waves** can be produced in which the waves seem to be standing still rather than traveling. The cord (or other medium) is vibrating as a whole. This is a resonance phenomenon, and the frequencies at which standing waves occur are called **resonant frequencies**. Points of destructive interference (no oscillation) are called **nodes**. Points of constructive interference (maximum amplitude of vibration) are called **antinodes**. On a cord of length $\ell$ fixed at both ends, the wavelengths of standing waves are given by

$$\lambda_n = 2\ell/n \qquad \textbf{(15–17a)}$$

where $n$ is an integer.

Waves change direction, or **refract**, when traveling from one medium into a second medium where their speed is different. Waves spread, or **diffract**, as they travel and encounter obstacles. A rough guide to the amount of diffraction is $\theta \approx \lambda/\ell$, where $\lambda$ is the wavelength of the wave, and $\ell$ the width of an opening or obstacle. There is a significant "shadow region" only if the wavelength $\lambda$ is smaller than the size of the obstacle.

# Questions

1. Is the frequency of a simple periodic wave equal to the frequency of its source? Why or why not?
2. Explain the difference between the speed of a transverse wave traveling along a cord and the speed of a tiny piece of the cord.
3. You are finding it a challenge to climb from one boat up onto a higher boat in heavy waves. If the climb varies from 2.5 m to 4.3 m, what is the amplitude of the wave? Assume the centers of the two boats are a half wavelength apart.
4. What kind of waves do you think will travel along a horizontal metal rod if you strike its end (*a*) vertically from above and (*b*) horizontally parallel to its length?
5. Since the density of air decreases with an increase in temperature, but the bulk modulus $B$ is nearly independent of temperature, how would you expect the speed of sound waves in air to vary with temperature?
6. Describe how you could estimate the speed of water waves across the surface of a pond.
7. The speed of sound in most solids is somewhat greater than in air, yet the density of solids is much greater ($10^3$ to $10^4$ times). Explain.
8. Give two reasons why circular water waves decrease in amplitude as they travel away from the source.
9. Two linear waves have the same amplitude and speed, and otherwise are identical, except one has half the wavelength of the other. Which transmits more energy? By what factor?
10. Will any function of $(x - vt)$—see Eq. 15–14—represent a wave motion? Why or why not? If not, give an example.
11. When a sinusoidal wave crosses the boundary between two sections of cord as in Fig. 15–19, the frequency does not change (although the wavelength and speed do change). Explain why.
12. If a sinusoidal wave on a two-section cord (Fig. 15–19) is inverted upon reflection, does the transmitted wave have a longer or shorter wavelength?
13. Is energy always conserved when two waves interfere? Explain.
14. If a string is vibrating as a standing wave in three segments, are there any places you could touch it with a knife blade without disturbing the motion?
15. If a rope has a free end, a pulse sent down the rope behaves differently on reflection than if the rope has that end fixed in position. What is this difference, and why does it occur?
16. How did geophysicists determine that part of the Earth's interior is liquid? (See Section 15–2.)
17. "In a round bowl of water, waves move from the center to the rim, or from the rim to the center, depending on whether you strike at the center or at the rim." So wrote Dante Alighieri 700 years ago in his great poem *Paradiso* (Canto 14), the last part of his famous *Divine Comedy*. Try this experiment and discuss your results.
18. Can the amplitude of the standing waves in Fig. 15–25 be greater than the amplitude of the vibrations that cause them (up and down motion of the hand)?
19. When a standing wave exists on a string, the vibrations of incident and reflected waves cancel at the nodes. Does this mean that energy was destroyed? Explain.
20. When a cord is vibrated as in Fig. 15–25 by hand or by a mechanical oscillator, the "nodes" are not quite true nodes (at rest). Explain. [*Hint*: Consider damping and energy flow from hand or oscillator.]

*21. AM *radio signals* can usually be heard behind a hill, but FM often cannot. That is, AM signals bend more than FM. Explain. (Radio signals, as we shall discuss in Chapter 31, are carried by electromagnetic waves whose wavelength for AM is typically 200 to 600 m and for FM about 3 m.)

*22. If we knew that energy was being transmitted from one place to another, how might we determine whether the energy was being carried by particles (material objects) or by waves?

# MisConceptual Questions

1. A transverse wave is traveling down a cord. Which of the following is true about the transverse motion of a small piece of the cord?
   (*a*) The speed of the wave must be the same as the speed of a small piece of the cord.
   (*b*) The frequency of the wave must be the same as the frequency of a small piece of the cord.
   (*c*) The amplitude of the wave must be the same as the amplitude of a small piece of the cord.
   (*d*) All of the above are true.
   (*e*) Both (*b*) and (*c*) are true.
2. Two waves are traveling toward each other along a rope. When they meet, the waves
   (*a*) pass through each other.
   (*b*) bounce off of each other.
   (*c*) disappear.
3. Which of the following increases the speed of waves in a stretched elastic cord?
   (*a*) Increasing the wave amplitude.
   (*b*) Increasing the wave frequency.
   (*c*) Increasing the wavelength.
   (*d*) Stretching the elastic cord further.
4. Consider a wave on a string moving to the right, as shown in Fig. 15–33. What is the direction of the velocity of a particle of string at point B?
   (*a*) →
   (*b*) ↘
   (*c*) ↓
   (*d*) ↑
   (*e*) $\vec{\mathbf{v}} = 0$, so no direction.

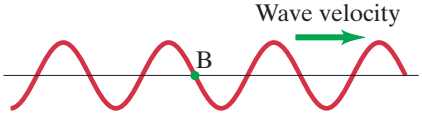


**FIGURE 15–33**
MisConceptual Question 4.

5. What happens when two waves, such as waves on a lake, come from different directions and run into each other?
(*a*) They cancel each other out and disappear.
(*b*) If they are the same size, they cancel each other out and disappear. If one wave is larger than the other, the smaller one disappears and the larger one shrinks but continues.
(*c*) They get larger where they run into each other; then they continue in a direction between the direction of the two original waves and larger than either original wave.
(*d*) They may have various patterns where they overlap, but each wave continues with its original pattern away from the region of overlap.
(*e*) Waves cannot run into each other; they always come from the same direction and so are parallel.

6. A student fixes one end of a Slinky on a table. She holds the other end in her hand, stretches it to a length $\ell$, and then moves it back and forth to send a transverse wave down the Slinky. If she next moves her hand faster while keeping the length of the Slinky the same, how does the wavelength along the Slinky change?
(*a*) It increases. (*b*) It stays the same. (*c*) It decreases.

7. A standing wave on a string is the result of
(*a*) two waves of different frequency but equal amplitude, traveling in the same direction.
(*b*) two equal amplitude, equal frequency waves traveling in opposite directions.
(*c*) two equal amplitude, equal frequency waves traveling in the same direction.
(*d*) two waves of different frequency but equal amplitude traveling in opposite directions.
(*e*) two waves of different amplitude but equal wavelength traveling in the same direction.

8. A wave traveling along a thin cord will pass onto a heavier section of cord as shown in Fig. 15–34.

**FIGURE 15–34** MisConceptual Question 8.

Which quantities will change?
(*a*) Amplitude.
(*b*) Frequency.
(*c*) Wavelength.
(*d*) Wave speed.
(*e*) All of the above.

9. A wave transports
(*a*) energy but not matter.
(*b*) matter but not energy.
(*c*) both energy and matter.

10. When both the frequency and the amplitude of a wave are doubled, the energy carried by the wave
(*a*) is unchanged.
(*b*) increases by a factor of 2.
(*c*) increases by a factor of 4.
(*d*) increases by a factor of 8.
(*e*) increases by a factor of 16.
(*f*) None of the above.

11. A wave is traveling along a cord stretched with tension $F_T$. To double the speed of the wave, the tension must be
(*a*) increased by a factor of 2.
(*b*) decreased by a factor of 2.
(*c*) increased by a factor of $\sqrt{2}$.
(*d*) decreased by a factor of $\sqrt{2}$.
(*e*) increased by a factor of 4.
(*f*) decreased by a factor of 4.
(*g*) None of the above.

# Problems

## 15–1 and 15–2 Characteristics of Waves

1. (I) A fisherman notices that water wave crests pass the bow of his anchored boat every 3.0 s. He measures the distance between two crests to be 7.5 m. How fast are the waves traveling?

2. (I) A sound wave in air has a frequency of 265 Hz and travels with a speed of 343 m/s. How far apart are the wave crests (compressions)?

3. (I) Calculate the speed of longitudinal waves in (*a*) water, (*b*) granite, and (*c*) steel, using Tables in Chapters 12 and 13.

4. (I) AM radio signals have frequencies between 550 kHz and 1600 kHz (kilohertz) and travel with a speed of $3.0 \times 10^8$ m/s. What are the wavelengths of these signals? On FM the frequencies range from 88 MHz to 108 MHz (megahertz) and travel at the same speed. What are their wavelengths?

5. (II) Determine the wavelength of a 6200-Hz longitudinal wave traveling along an iron rod. Use Tables 12–1 and 13–1.

6. (II) A cord of mass 0.65 kg is stretched between two supports 7.2 m apart. If the tension in the cord is 120 N, how long will it take a pulse to travel from one support to the other?

7. (II) A 0.40-kg cord is stretched between two supports 8.7 m apart. When one support is struck by a hammer, a transverse wave travels down the cord and reaches the other support in 0.85 s. What is the tension in the cord?

8. (II) A sailor strikes the side of his ship just below the surface of the sea. He hears the echo of the wave reflected from the ocean floor directly below 2.4 s later. How deep is the ocean at this point? (Use Tables 12–1 and 13–1.)

9. (II) A ski gondola [pronounced gon′do-la] is connected to the top of a hill by a steel cable of length 710 m and diameter 1.5 cm. As the gondola comes to the end of its run, it bumps into the terminal and sends a transverse wave pulse along the cable. It is observed that it took 17 s for the pulse to return. (*a*) What is the speed of the pulse? (*b*) What is the tension in the cable?

10. (II) P and S waves from an earthquake travel at different speeds, and this difference helps locate the earthquake "epicenter" (where the slippage took place). (*a*) Assuming typical speeds of 8.5 km/s and 5.5 km/s for P and S waves, respectively, how far away did the earthquake occur if a particular seismic station detects the arrival of these two types of waves 1.5 min apart? (*b*) Is one seismic station sufficient to determine the position of the epicenter? Explain.

**11.** (II) The wave on a string shown in Fig. 15–35 is moving to the right with a speed of 1.10 m/s. (*a*) Draw the shape of the string 1.00 s later and indicate which parts of the string are moving up and which down at that instant. (*b*) Estimate the vertical speed of point A on the string at the instant shown in Fig. 15–35.

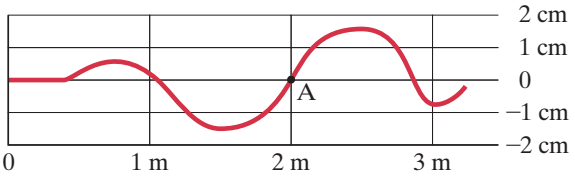

**FIGURE 15–35** Problem 11.

**12.** (II) A 4.4-kg ball hangs from a steel wire 1.00 mm in diameter and 5.00 m long. What would be the speed of a transverse wave in the steel wire?

**13.** (II) Two children are sending signals along a nylon cord tied between tin cans 18 m apart. How long does it take the longitudinal vibrations in the string to go from one child to the other? Nylon has density $\rho = 1.15 \times 10^3\ \text{kg/m}^3$.

**14.** (III) A uniform cord of length $\ell$ and mass $m$ is hung vertically from a support. (*a*) Show that the speed of transverse waves in this cord is $\sqrt{gh}$, where $h$ is the height above the lower end. (*b*) How long does it take for a pulse to travel upward from one end to the other?

## 15–3 Energy Transported by Waves

**15.** (I) Sound waves are produced by a 15-watt output loudspeaker. Compare the intensity of the sound wave heard by a listener 12 m away to the wave intensity heard by a listener 24 m away. Assume spherical waves.

**16.** (I) Two earthquake waves of the same frequency travel through the same portion of the Earth, but one is carrying 3.5 times the energy. What is the ratio of the amplitudes of the two waves?

**17.** (II) What is the ratio of (*a*) the intensities, and (*b*) the amplitudes, of an earthquake P wave passing through the Earth and detected at two points 15 km and 55 km from the source?

**18.** (II) The intensity of an earthquake wave passing through the Earth is measured to be $2.4 \times 10^6\ \text{J/m}^2 \cdot \text{s}$ at a distance of 48 km from the source. (*a*) What was its intensity when it passed a point only 1.0 km from the source? (*b*) At what rate did energy pass through an area of $2.0\ \text{m}^2$ at 1.0 km?

**19.** (II) A thin steel wire of diameter 1.0 mm is connected to an oscillator and is under a tension of 7.5 N. The frequency of the oscillator is 60.0 Hz and it is observed that the amplitude of the wave on the steel wire is 0.40 cm. (*a*) What is the power output of the oscillator, assuming that the wave is not reflected back? (*b*) If the power output stays constant but the frequency is doubled, what is the amplitude of the wave?

**20.** (II) Show that the intensity of a wave (Eq. 15–7a) is equal to the energy density (energy per unit volume) in the wave times the wave speed.

**21.** (II) (*a*) Show that the average rate with which energy is transported along a cord by a transverse wave of frequency $f$ and amplitude $A$ is

$$\overline{P} = 2\pi^2 \mu v f^2 A^2,$$

where $v$ is the speed of the wave and $\mu$ is the mass per unit length of the cord. (*b*) If the cord is under a tension $F_T = 135\ \text{N}$ and has mass per unit length 0.10 kg/m, what power is required to transmit 120-Hz transverse waves of amplitude 2.4 cm?

**22.** (III) Show that if damping is ignored, the amplitude $A$ of circular waves on the surface of water decreases as the square root of the distance $r$ from the source: $A \propto 1/\sqrt{r}$.

## 15–4 Mathematical Representation of Traveling Wave

**23.** (I) A transverse wave on a wire is given by $D(x, t) = 0.015 \sin(35x - 1200t)$ where $D$ and $x$ are in meters and $t$ is in seconds. (*a*) Write an expression for a wave with the same amplitude, wavelength, and frequency but traveling in the opposite direction. (*b*) What is the speed of either wave?

**24.** (II) Suppose at $t = 0$, a wave shape is represented by $D = A \sin(2\pi x/\lambda + \phi)$; that is, it differs from Eq. 15–9 by a constant phase factor $\phi$. What will be the equation for such a wave as a function of $x$ and $t$ if it travels to the left along the $x$ axis?

**25.** (II) A transverse traveling wave on a cord is represented by $D = 0.22 \sin(5.6x + 34t)$ where $D$ and $x$ are in meters and $t$ is in seconds. For this wave determine (*a*) the wavelength, (*b*) frequency, (*c*) amplitude, (*d*) wave velocity (magnitude and direction), and (*e*) maximum and minimum speeds of particles of the cord at $x = 0$.

**26.** (II) Consider the point $x = 1.00\ \text{m}$ on the cord of Example 15–6. Determine (*a*) the maximum acceleration of this point. (*b*) What is the speed and acceleration of this point at $t = 2.15\ \text{s}$?

**27.** (II) A transverse wave pulse travels to the right along a string with a speed $v = 2.0\ \text{m/s}$. At $t = 0$ the shape of the pulse is given by the function

$$D = 0.45 \cos(2.6x + 1.2),$$

where $D$ and $x$ are in meters. (*a*) Plot $D$ vs. $x$ at $t = 0$. (*b*) Determine a formula for the wave pulse at any time $t$ assuming there are no frictional losses. (*c*) Plot $D(x, t)$ vs. $x$ at $t = 1.0\ \text{s}$. (*d*) Repeat parts (*b*) and (*c*) assuming the pulse is traveling to the left. Plot all 3 graphs on the same axes for easy comparison.

**28.** (II) A transverse wave with a frequency of 220 Hz and a wavelength of 10.0 cm is traveling along a cord. The maximum speed of particles on the cord is 0.10 the wave speed. What is the amplitude of the wave?

**29.** (II) A 572-Hz longitudinal wave in air has a speed of 345 m/s. (*a*) What is the wavelength? (*b*) How much time is required for the phase to change by 90° at a given point in space? (*c*) At a particular instant, what is the phase difference (in degrees) between two points 4.4 cm apart?

**30.** (II) Write the equation for the wave in Problem 29 traveling to the right, if its amplitude is 0.020 cm, and $D = -0.020$ cm, at $t = 0$ and $x = 0$.

**31.** (II) A sinusoidal wave traveling on a cord in the negative $x$ direction has amplitude 1.00 cm, wavelength 3.00 cm, and frequency 245 Hz. At $t = 0$, the particle of string at $x = 0$ is displaced a distance $D = 0.80$ cm above the origin and is moving upward. (*a*) Sketch the shape of the wave at $t = 0$ and (*b*) determine the function of $x$ and $t$ that describes the wave.

**32.** (III) A transverse wave on a cord is given by $D(x, t) = 0.12 \sin(3.0x - 15.0t)$, where $D$ and $x$ are in meters and $t$ is in seconds. (*a*) What are the period and frequency of this wave? (*b*) At $t = 0.20$ s, what are the displacement, velocity, and acceleration of a point on the cord where $x = 0.60$ m? (*c*) What are the maximum values of the speed and acceleration of a particle of the cord? (*d*) Determine the velocity of a particle of the cord as a function of $x$ at $t = 0$. (*e*) What is the velocity of a particle of cord at $x = 0.60$ m as a function of time?

## *15–5 The Wave Equation

***33.** (I) Show by direct substitution that $D = A\cos(\omega t - kx)$ is a solution of the wave equation.

***34.** (II) Determine if the function $D = A \sin kx \cos \omega t$ is a solution of the wave equation.

***35.** (II) Show by direct substitution that the following functions satisfy the wave equation: (*a*) $D(x, t) = A \ln(x + vt)$; (*b*) $D(x, t) = (x - vt)^4$.

***36.** (II) Show that the wave forms of Eqs. 15–13c and 15–15 satisfy the wave equation, Eq. 15–16.

***37.** (II) Let two linear waves be represented by $D_1 = f_1(x, t)$ and $D_2 = f_2(x, t)$. If both these waves satisfy the wave equation (Eq. 15–16), show that any combination $D = C_1 D_1 + C_2 D_2$ does as well, where $C_1$ and $C_2$ are constants.

***38.** (II) Does the function $D(x, t) = e^{-(kx-\omega t)^2}$ satisfy the wave equation? Why or why not?

***39.** (II) In deriving Eq. 15–2, $v = \sqrt{F_T/\mu}$, for the speed of a transverse wave on a string, it was assumed that the wave's amplitude $A$ is much less than its wavelength $\lambda$. Assuming a sinusoidal wave shape $D = A \sin(kx - \omega t)$, show via the partial derivative $v' = \partial D/\partial t$ that the assumption $A \ll \lambda$ implies that the maximum transverse speed $v'_{max}$ of the string itself is much less than the wave speed. If $A = \lambda/100$ determine the ratio $v'_{max}/v$.

## 15–7 Reflection and Transmission

**40.** (II) Consider a sine wave traveling down the stretched two-part cord of Fig. 15–19. Determine a formula (*a*) for the ratio of the speeds of the wave in the two sections, $v_H/v_L$, and (*b*) for the ratio of the wavelengths in the two sections. (The frequency is the same in both sections. Why?) (*c*) Is the wavelength larger in the heavier cord or the lighter?

**41.** (II) A cord has two sections with linear densities of 0.10 kg/m and 0.20 kg/m, Fig. 15–36. An incident wave, given by $D = (0.050\text{ m})\sin(7.5x - 12.0t)$, where $x$ is in meters and $t$ in seconds, travels along the lighter cord. (*a*) What is the wavelength on the lighter section of the cord? (*b*) What is the tension in the cord? (*c*) What is the wavelength when the wave travels on the heavier section?

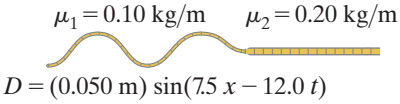

**FIGURE 15–36**
Problem 41.

**42.** (III) A cord stretched to a tension $F_T$ consists of two sections (as in Fig. 15–19) whose linear densities are $\mu_1$ and $\mu_2$. Take $x = 0$ to be the point (a tiny knot) where they are joined, with $\mu_1$ referring to that section of cord to the left and $\mu_2$ that to the right. A sinusoidal wave, $D = A\sin[k_1(x - v_1 t)]$, starts at the left end of the cord. When it reaches the knot, part of it is *reflected* and part is *transmitted*. Let the equation of the reflected wave be $D_R = A_R \sin[k_1(x + v_1 t)]$ and that for the transmitted wave be $D_T = A_T \sin[k_2(x - v_2 t)]$. Since the frequency must be the same in both sections, we have $\omega_1 = \omega_2$ or $k_1 v_1 = k_2 v_2$. (*a*) Because the cord is continuous, a point an infinitesimal distance to the left of the knot has the same displacement at any moment (due to incident plus reflected waves) as a point just to the right of the knot (due to the transmitted wave). Thus show that $A = A_T + A_R$. (*b*) Assuming that the slope (derivative of $D$ with respect to $x$ at a fixed $t$) of the cord just to the left of the knot is the same as the slope just to the right of the knot, show that the amplitude of the reflected wave is given by

$$A_R = \left(\frac{v_1 - v_2}{v_1 + v_2}\right)A = \left(\frac{k_2 - k_1}{k_2 + k_1}\right)A.$$

(*c*) What is $A_T$ in terms of $A$?

## 15–8 Interference

**43.** (I) The two pulses shown in Fig. 15–37 are moving toward each other. (*a*) Sketch the shape of the string at the moment they directly overlap. (*b*) Sketch the shape of the string a few moments later. (*c*) In Fig. 15–37, at the moment the pulses pass each other, the string is straight. What has happened to the energy at this moment?

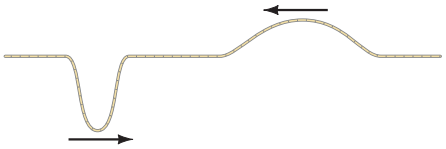

**FIGURE 15–37**
Problem 43.

**44.** (II) Suppose two linear waves of equal amplitude and frequency have a phase difference $\phi$ as they travel in the same medium. They can be represented by

$$D_1 = A\sin(kx - \omega t)$$
$$D_2 = A\sin(kx - \omega t + \phi).$$

(*a*) Use the trigonometric identity $\sin\theta_1 + \sin\theta_2 = 2\sin\frac{1}{2}(\theta_1 + \theta_2)\cos\frac{1}{2}(\theta_1 - \theta_2)$ to show that the resultant wave is given by

$$D = \left(2A\cos\frac{\phi}{2}\right)\sin\left(kx - \omega t + \frac{\phi}{2}\right).$$

(*b*) What is the amplitude of this resultant wave? Is the wave purely sinusoidal, or not? (*c*) Show that constructive interference occurs if $\phi = 0, 2\pi, 4\pi$, and so on, and destructive interference occurs if $\phi = \pi, 3\pi, 5\pi$, etc. (*d*) Describe the resultant wave, by equation and in words, if $\phi = \pi/2$.

## 15–9 Standing Waves; Resonance

**45.** (I) The fundamental frequency of a violin string is 441 Hz when unfingered. What is its fundamental frequency if it is fingered one-third of the way down from the end? (That is, only two-thirds of the string vibrates as a standing wave.)

**46.** (I) If a violin string vibrates at 294 Hz as its fundamental frequency, what are the frequencies of the first four harmonics?

**47.** (I) A particular string resonates in four loops at a frequency of 320 Hz. Name at least three other frequencies at which it will resonate. What is each called?

**48.** (II) In an earthquake, it is noted that a footbridge oscillated up and down in a one-loop (fundamental standing wave) pattern once every 1.3 s (= the period). What other possible resonant periods of motion are there for this bridge? What frequencies do they correspond to?

**49.** (II) If two successive overtones of a vibrating string are 240 Hz and 320 Hz, what is the frequency of the fundamental?

**50.** (II) The speed of waves on a string is 96 m/s. If the frequency of standing waves is 435 Hz, how far apart are two adjacent nodes?

**51.** (II) Show that the frequency of standing waves on a cord of length $\ell$ and linear density $\mu$, which is stretched to a tension $F_T$, is given by

$$f = \frac{n}{2\ell}\sqrt{\frac{F_T}{\mu}}$$

where $n$ is an integer.

**52.** (II) A guitar string is 91 cm long and has a mass of 3.2 g. The vibrating portion of the string from the bridge to the support post is $\ell = 64$ cm and the string is under a tension of 520 N. What are the frequencies of the fundamental and first two overtones?

**53.** (II) One end of a horizontal string is attached to a small-amplitude mechanical 60.0-Hz oscillator. The string's mass per unit length is $3.9 \times 10^{-4}$ kg/m. The string passes over a pulley, a distance $\ell = 1.50$ m away, and weights are hung from this end, Fig. 15–38. What mass $m$ must be hung from this end of the string to produce (*a*) one loop, (*b*) two loops, and (*c*) five loops of a standing wave? Assume the string at the oscillator is a node, which is nearly true.

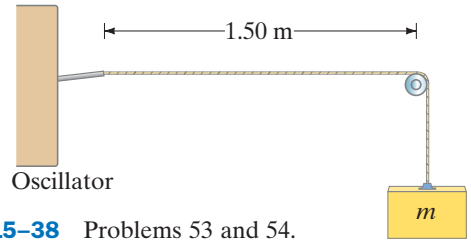

**FIGURE 15–38** Problems 53 and 54.

**54.** (II) In Problem 53, Fig. 15–38, the length of the string may be adjusted by moving the pulley. If the hanging mass $m$ is fixed at 0.070 kg, how many different standing wave patterns may be achieved by varying $\ell$ between 10 cm and 1.5 m?

**55.** (II) The displacement of a standing wave on a string is given by $D = 2.4\sin(0.60x)\cos(42t)$, where $x$ and $D$ are in centimeters and $t$ is in seconds. (*a*) What is the distance (cm) between nodes? (*b*) Give the amplitude, frequency, and speed of each of the component waves. (*c*) Find the speed of a particle of the string at $x = 3.80$ cm when $t = 2.5$ s.

**56.** (II) The displacement of a transverse wave traveling on a string is represented by $D_1 = 4.2\sin(0.84x - 47t + 2.1)$, where $D_1$ and $x$ are in cm and $t$ in s. (*a*) Find an equation that represents a wave which, when traveling in the opposite direction, will produce a standing wave when added to this one. (*b*) What is the equation describing the standing wave?

**57.** (II) A particular violin string plays at a frequency of 294 Hz. If the tension is increased 22%, what will the new frequency be?

**58.** (II) Two traveling waves are described by the functions

$$D_1 = A\sin(kx - \omega t)$$
$$D_2 = A\sin(kx + \omega t),$$

where $A = 0.15$ m, $k = 3.5\ \text{m}^{-1}$, and $\omega = 1.6\ \text{s}^{-1}$. (*a*) Plot these two waves, from $x = 0$ to a point $x$ ($> 0$) that includes one full wavelength. Choose $t = 1.5$ s. (*b*) Plot the sum of the two waves as a function of $x$. Mark the nodes and antinodes in the plot. Are they where we would calculate them to be?

**59.** (II) Plot the two waves given in Problem 58 and their sum, as a function of time from $t = 0$ to $t = T$ (one period). Choose (*a*) $x = 0$ and (*b*) $x = \lambda/4$. Interpret your results.

**60.** (II) A standing wave on a 1.85-m-long horizontal string displays three loops when the string vibrates at 125 Hz. The maximum swing of the string (top to bottom) at the center of each loop is 8.00 cm. (*a*) What is the function describing the standing wave? (*b*) What are the functions describing the two equal-amplitude waves traveling in opposite directions that make up the standing wave?

**61.** (II) On an electric guitar, a "pickup" under each string transforms the string's vibrations directly into an electrical signal. If a pickup is placed 16.25 cm from one of the fixed ends of a 65.00-cm-long string, which of the harmonics from $n = 1$ to $n = 12$ will not be "picked up" by this pickup?

**62.** (II) Two oppositely directed traveling waves given by $D_1 = (5.0\ \text{mm})\cos[(2.0\ \text{m}^{-1})x - (3.0\ \text{rad/s})t]$ and $D_2 = (5.0\ \text{mm})\cos[(2.0\ \text{m}^{-1})x + (3.0\ \text{rad/s})t]$ form a standing wave. Determine the position of nodes along the $x$ axis.

**63.** (II) When you slosh the water back and forth in a tub at just the right frequency, the water alternately rises and falls at each end, remaining relatively calm at the center. Suppose the frequency to produce such a standing wave in a 45-cm-wide tub is 0.85 Hz. What is the speed of the water wave?

## 15–10 Refraction

**64.** (I) Water waves approach an underwater "shelf" where the speed changes from 2.9 m/s to 2.4 m/s. If the incident wave fronts make a 35° angle with the shelf, what will be the angle of refraction?

**65.** (I) An earthquake P wave traveling 8.0 km/s strikes a boundary within the Earth between two kinds of material. If it approaches the boundary at an incident angle of 52° and the angle of refraction is 31°, what is the speed in the second medium?

**66.** (II) For any type of wave that reaches a boundary beyond which its speed is increased, there is a maximum incident angle if there is to be a transmitted refracted wave. This maximum incident angle $\theta_{iM}$ corresponds to an angle of refraction equal to 90°. If $\theta_i > \theta_{iM}$, all the wave is reflected at the boundary and none is refracted, because this would correspond to $\sin\theta_r > 1$ (where $\theta_r$ is the angle of refraction), which is impossible. (*a*) Find a formula for $\theta_{iM}$ using the law of refraction, Eq. 15–19. (*b*) How far from the bank should a trout fisherman stand (Fig. 15–39) so trout won't be frightened by his voice (1.8 m above the ground)? The speed of sound is about 343 m/s in air and 1440 m/s in water. [This phenomenon is referred to as *total internal reflection* in optics.]

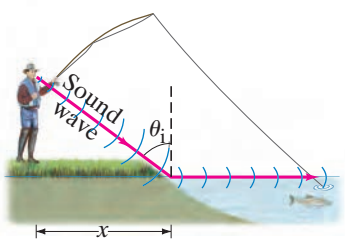

**FIGURE 15–39** Problem 66b.

67. (II) A sound wave is traveling in warm air (15°C) when it hits a layer of cold (−15°C) denser air. If the sound wave hits the cold air interface at an angle of 28°, what is the angle of refraction? The speed of sound as a function of temperature can be approximated by $v = (331 + 0.60\,T)$ m/s, where $T$ is in °C.

68. (II) A longitudinal earthquake wave strikes a boundary between two types of rock at a 41° angle. As the wave crosses the boundary, the specific gravity of the rock changes from 3.6 to 2.8. Assuming that the elastic modulus (Section 15–2) is the same for both types of rock, determine the angle of refraction.

### 15–11 Diffraction

69. (II) A longitudinal wave is traveling upwards in water when it encounters a layer of gasoline floating on the water. The wave is incident on the boundary at an angle of 45 degrees. The bulk modulus of the gasoline is about 65% that of water; the densities of both liquids are given in Table 13-1. Determine the angle of refraction of the wave in the gasoline.

70. (II) What frequencies of sound would easily diffract through an open window 0.85 m wide? (The speed of sound is 344 m/s at 20°C.)

## General Problems

71. A sinusoidal traveling wave has frequency 880 Hz and speed 440 m/s. (*a*) At a given time, find the distance between two positions that correspond to a difference in phase of $\pi/6$ rad. (*b*) At a fixed location, by how much does the phase change during a time interval of $1.0 \times 10^{-4}$ s?

72. A guitar string is supposed to vibrate at 247 Hz, but is measured to actually vibrate at 262 Hz. By what percentage should the tension in the string be changed to get the frequency to the correct value?

73. *Seismic reflection* prospecting is commonly used to map deeply buried formations containing oil. In this technique, a seismic wave generated at the Earth's surface (for example, by an explosion or falling weight) reflects from the subsurface formation and is detected upon its return to ground level. By placing ground-level detectors at a variety of locations relative to the source, and observing the variation in the source-to-detector travel times, the depth of the subsurface formation can be determined. (*a*) Assume a ground-level detector is placed a horizontal distance $x$ away from the seismic-wave source and that a horizontal boundary between subsurface rock and a cavity (hopefully containing oil) exists at depth $D$ (Fig. 15–40a). Determine an expression for the time $t$ taken by the reflected wave to travel from source to detector, assuming the seismic wave propagates at constant speed $v$. (*b*) Suppose several detectors are placed along a line at different distances $x$ from the source as in Fig. 15–40b. Then, when a seismic wave is generated, the different travel times $t$ for each detector are measured. Starting with your result from part (*a*), explain how a graph of $t^2$ vs. $x^2$ can be used to determine $D$.

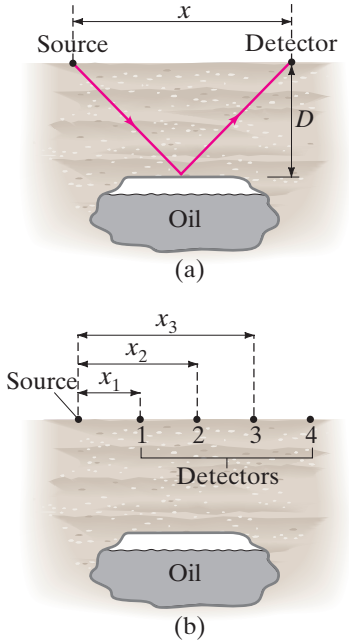

**FIGURE 15–40** Problem 73.

74. A 65-cm guitar string is fixed at both ends. In the frequency range between 1.0 and 2.0 kHz, the string is found to resonate only at frequencies 1.2, 1.5, and 1.8 kHz. What is the speed of traveling waves on this string?

75. A bug on the surface of a pond is observed to move up and down a total vertical distance of 0.10 m, lowest to highest point, as a wave passes. (*a*) What is the amplitude of the wave? (*b*) If the amplitude increases to 0.15 m, by what factor does the bug's maximum kinetic energy change?

76. Destructive interference occurs where two overlapping waves are $\frac{1}{2}$ wavelength or 180° out of phase. Explain why 180° is equivalent to $\frac{1}{2}$ wavelength.

77. An earthquake-produced surface wave can be approximated by a sinusoidal transverse wave. Assuming a frequency of 0.60 Hz (typical of earthquakes, which actually include a mixture of frequencies), what amplitude is needed so that objects begin to leave contact with the ground? [*Hint*: Set the acceleration $a > g$. Why?]

78. When you walk with a cup of coffee (diameter 8 cm) at just the right pace of about one step per second, the coffee sloshes higher and higher in your cup until eventually it starts to spill over the top, Fig 15–41. Estimate the speed of the waves in the coffee.

**FIGURE 15–41** Problem 78.

79. Two solid rods have the same bulk modulus but one is 2.1 times as dense as the other. In which rod will the speed of longitudinal waves be greater, and by what factor?

80. Two waves traveling along a stretched string have the same frequency, but one transports 2.5 times the power of the other. What is the ratio of the amplitudes of the two waves?

**81.** A transverse wave pulse travels to the right along a string with a speed $v = 2.4\,\text{m/s}$. At $t = 0$ the shape of the pulse is given by the function

$$D = \frac{4.0\,\text{m}^3}{x^2 + 2.0\,\text{m}^2},$$

where $D$ and $x$ are in meters. (*a*) Plot $D$ vs. $x$ at $t = 0$ from $x = -10\,\text{m}$ to $x = +10\,\text{m}$. (*b*) Determine a formula for the wave pulse at any time $t$ assuming there are no frictional losses. (*c*) Plot $D(x, t)$ vs. $x$ at $t = 1.00\,\text{s}$. (*d*) Repeat parts (*b*) and (*c*) assuming the pulse is traveling to the left.

**82.** (*a*) Show that if the tension in a stretched string is changed by a small amount $\Delta F_\text{T}$, the frequency of the fundamental is changed by an amount $\Delta f = \frac{1}{2}(\Delta F_\text{T}/F_\text{T})f$. (*b*) By what percent must the tension in a piano string be increased or decreased to raise the frequency from 436 Hz to 448 Hz? (*c*) Does the formula in part (*a*) apply to the overtones as well? Explain.

**83.** A cord of length 1.0 m has two equal-length sections with linear densities of 0.50 kg/m and 1.00 kg/m. The tension in the entire cord is constant. The ends of the cord are oscillated so that a standing wave is set up in the cord with a single node where the two sections meet. What is the ratio of the oscillatory frequencies?

**84.** A wire is composed of aluminum with length $\ell_1 = 0.600\,\text{m}$ and mass per unit length $\mu_1 = 2.70\,\text{g/m}$ joined to a steel section with length $\ell_2 = 0.882\,\text{m}$ and mass per unit length $\mu_2 = 7.80\,\text{g/m}$. This composite wire is fixed at both ends and held at a uniform tension of 135 N. Find the lowest frequency standing wave that can exist on this wire, assuming there is a node at the joint between aluminum and steel. How many nodes (including the two at the ends) does this standing wave possess?

**85.** Two strings on a musical instrument are tuned to play at 392 Hz (G) and 494 Hz (B). (*a*) What are the frequencies of the first two overtones for each string? (*b*) If the two strings have the same length and are under the same tension, what must be the ratio of their masses $(m_\text{G}/m_\text{B})$? (*c*) If the strings, instead, have the same mass per unit length and are under the same tension, what is the ratio of their lengths $(\ell_\text{G}/\ell_\text{B})$? (*d*) If their masses and lengths are the same, what must be the ratio of the tensions in the two strings?

**86.** The ripples in a certain groove 10.8 cm from the center of a 33-rpm vinyl phonograph record have a wavelength of 1.55 mm. What will be the frequency of the sound emitted?

**87.** A 10.0-m-long wire of mass 138 g is stretched under a tension of 255 N. A pulse is generated at one end, and 20.0 ms later a second pulse is generated at the opposite end. Where will the two pulses first meet?

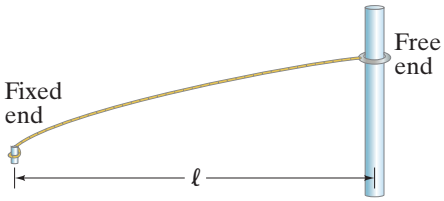
**88.** A uniform cable 2.0-m long hangs vertically under its own weight. (*a*) Determine the speed of waves on the cable as a function the distance $y$ (positive down from the top of the cable, where $y = 0$). (*b*) Plot $v$ vs. $y$.

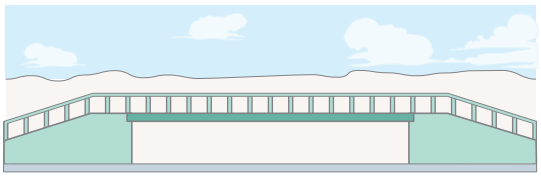
**89.** For a spherical wave traveling uniformly away from a point source, show that the displacement can be represented by

$$D = \left(\frac{A}{r}\right)\sin(kr - \omega t),$$

where $r$ is the radial distance from the source and $A$ is a constant.

**90.** A string can have a "free" end if that end is attached to a ring that can slide without friction on a vertical pole (Fig. 15–42). Determine the wavelengths of the resonant vibrations of such a string with one end fixed and the other free.





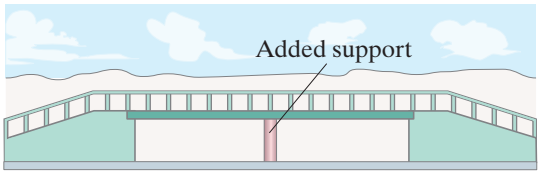


**FIGURE 15–42** Problem 90.

**91.** A highway overpass was observed to resonate as one full loop $(\frac{1}{2}\lambda)$ when a small earthquake shook the ground vertically at 3.0 Hz. The highway department put a support at the center of the overpass, anchoring it to the ground as shown in Fig. 15–43. What resonant frequency would you now expect for the overpass? It is noted that earthquakes rarely do significant shaking above 5 or 6 Hz. Did the modifications do any good? Explain.

Before modification

After modification

**FIGURE 15–43** Problem 91.

**92.** Figure 15–44 shows the wave shape at two instants of time for a sinusoidal wave traveling to the right. What is the mathematical representation of this wave?

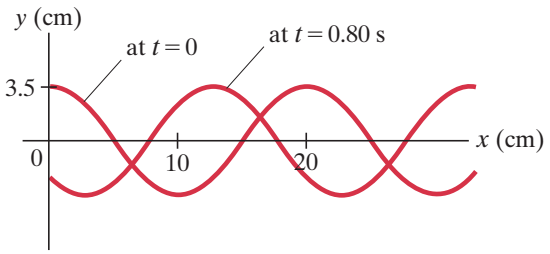

**FIGURE 15–44** Problem 92.

**93.** Estimate the average power of a moving water wave that strikes the chest of an adult standing in the water at the seashore. Assume that the amplitude of the wave is 0.50 m, the wavelength is 2.5 m, and the period is 4.0 s.

**94.** A *tsunami* is a sort of pulse or "wave packet" consisting of several crests and troughs that become dramatically large as they enter shallow water at the shore. Suppose a tsunami of wavelength 215 km and velocity 550 km/h travels across the Pacific Ocean. As it approaches Hawaii, people observe an unusual decrease of sea level in the harbors. Approximately how much time do they have to run to safety? (In the absence of knowledge and warning, people have died during tsunamis, some of them attracted to the shore to see stranded fishes and boats.)

**95.** Two wave pulses are traveling in opposite directions with the same speed of 7.0 cm/s as shown in Fig. 15–45. At $t = 0$, the leading edges of the two pulses are 15 cm apart. Sketch the wave pulses at $t = 1.0\,\text{s}, 2.0\,\text{s}$, and 3.0 s.

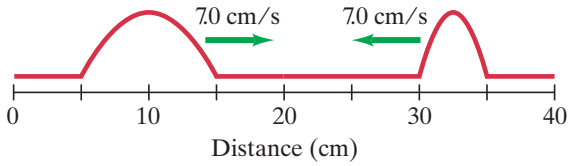

**FIGURE 15–45** Problem 95.

***96. Dimensional analysis.** Waves on the surface of the ocean do not depend significantly on the properties of water such as density or surface tension. The primary "return force" for water piled up in the wave crests is due to the gravitational attraction of the Earth. Thus the speed $v\,(\text{m/s})$ of ocean waves depends on the acceleration due to gravity $g$. It is reasonable to expect that $v$ might also depend on water depth $h$ and the wave's wavelength $\lambda$. Assume the wave speed is given by the functional form $v = Cg^{\alpha}h^{\beta}\lambda^{\gamma}$, where $\alpha, \beta, \gamma$, and $C$ are numbers without dimension. (*a*) In *deep* water, the water deep below the surface does not affect the motion of waves at the surface. Thus $v$ should be independent of depth $h$ (i.e., $\beta = 0$). Using only dimensional analysis (Section 1–7 and Appendix D), determine the formula for the speed of surface ocean waves in deep water. (*b*) In *shallow* water, the speed of surface waves is found experimentally to be independent of the wavelength (i.e., $\gamma = 0$ in our assumed equation above for $v$). Using only dimensional analysis, determine the formula for the speed of waves in shallow water.

## ANSWERS TO EXERCISES

**A:** (*c*).
**B:** (*d*).
**C:** (*c*).
**D:** (*a*).

"If music be the food of physics, play on." [Paraphrase of Shakespeare's *Twelfth Night*, line 1.]

Stringed instruments depend on transverse standing waves on strings to produce their harmonious sounds. The sound of wind instruments originates in longitudinal standing waves of an air column. Trumpets and percussion instruments create more complicated standing waves.

Besides examining sources of sound, we also study the decibel scale of sound level, sound wave interference and beats, the Doppler effect, shock waves and sonic booms, and ultrasound imaging.

16–7 Doppler Effect
*16–8 Shock Waves and the Sonic Boom
*16–9 Applications: Sonar, Ultrasound, and Medical Imaging

## CHAPTER-OPENING QUESTION—Guess now!

A pianist plays the note "middle C." The sound is made by the vibration of the piano string and is propagated outward as a vibration of the air (which can reach your ear). How does the vibration on the string compare to the vibration in the air?

**(a)** The vibration on the string and the vibration in the air have the same wavelength.
**(b)** They have the same frequency.
**(c)** They have the same speed.
**(d)** Neither wavelength, frequency, nor speed are the same in the air as on the string.

Sound is associated with our sense of hearing and, therefore, with the physiology of our ears and the psychology of our brain, which interprets the sensations that reach our ears. The term *sound* also refers to the physical sensation that stimulates our ears: namely, longitudinal pressure waves.

We can distinguish three aspects of any sound. First, there must be a *source* for a sound; as with any mechanical wave, the source of a sound wave is a vibrating object. Second, the energy is transferred from the source in the form of longitudinal sound *waves* in air or other material. And third, the sound is *detected*, usually by an ear or by a microphone. We start by looking at sound waves themselves.

# 16–1 Characteristics of Sound

We saw in Chapter 15, Fig. 15–5, how a vibrating drumhead produces a sound wave in air. Indeed, we usually think of sound waves traveling in the air, because normally it is the vibrations of the air that force our eardrums to vibrate.

But sound waves can also travel in other materials. Two stones struck together under water can be heard by a swimmer beneath the surface, for the vibrations are carried to the ear by the water. When you put your ear flat against the ground, you can hear an approaching train or truck. In this case the ground does not actually touch your eardrum, but the longitudinal wave transmitted by the ground is called a sound wave just the same, since its vibrations cause the outer ear and the air within it to vibrate. Sound cannot travel in the absence of matter. For example, a bell ringing inside an evacuated jar cannot be heard, and sound cannot travel through the empty reaches of outer space.

The **speed of sound** is different in different materials. In air at 0°C and 1 atm, sound travels at a speed of 331 m/s. We saw in Eq. 15–4 $\left(v = \sqrt{B/\rho}\right)$ that the speed depends on the elastic modulus, $B$, and the density, $\rho$, of the material. Thus for helium, whose density is much less than that of air but whose elastic modulus is not greatly different, the speed is about three times as great as in air. In liquids and solids, which are much less compressible and therefore have much greater elastic moduli, the speed is larger still. The speed of sound in various materials is given in Table 16–1. The values depend somewhat on temperature, especially for gases. For example, in air near room temperature, the speed increases approximately 0.60 m/s for each Celsius degree increase in temperature:

$$v \approx (331 + 0.60\,T)\ \text{m/s}, \qquad \text{[speed of sound in air]}$$

where $T$ is the temperature in °C. Unless stated otherwise, we will assume in this Chapter that $T = 20°\text{C}$ precisely, so that $v = [331 + (0.60)(20)]\ \text{m/s} = 343\ \text{m/s}$.

**TABLE 16–1 Speed of Sound in Various Materials**
**(20°C and 1 atm)**

| Material | Speed (m/s) |
|---|---|
| Air | 343 |
| Air (0°C) | 331 |
| Helium | 1005 |
| Hydrogen | 1300 |
| Water | 1440 |
| Sea water | 1560 |
| Iron and steel | ≈ 5000 |
| Glass | ≈ 4500 |
| Aluminum | ≈ 5100 |
| Hardwood | ≈ 4000 |
| Concrete | ≈ 3000 |

**CONCEPTUAL EXAMPLE 16–1** **Distance from a lightning strike.** A rule of thumb that tells how close lightning has struck is "one mile for every five seconds before the thunder is heard." Explain why this works, noting that the speed of light is so high ($3 \times 10^8$ m/s, almost a million times faster than sound) that the time for light to travel to us is negligible compared to the time for the sound.

**PHYSICS APPLIED**
*How far away is the lightning?*

**RESPONSE** The speed of sound in air is about 340 m/s, so to travel 1 km = 1000 m takes about 3 seconds. One mile is about 1.6 kilometers, so the time for the thunder to travel a mile is about $(1.6)(3) \approx 5$ seconds.

Two aspects of any sound are immediately evident to a human listener: "loudness" and "pitch." Each refers to a sensation in the consciousness of the listener. But to each of these subjective sensations there corresponds a physically measurable quantity. **Loudness** is related to the intensity (energy per unit time crossing unit area) in the sound wave, and we shall discuss it in Section 16–3.

The **pitch** of a sound refers to whether it is high, like the sound of a piccolo or violin, or low, like the sound of a bass drum or string bass. The physical quantity that determines pitch is the frequency, as was first noted by Galileo. The lower the frequency, the lower the pitch; the higher the frequency, the higher the pitch.[†] The best human ears can respond to frequencies from about 20 Hz to almost 20,000 Hz. (Recall that 1 Hz is 1 cycle per second.) This frequency range is called the **audible range**. These limits vary somewhat from one individual to another. One general trend is that as people age, they are less able to hear high frequencies, so the high-frequency limit may be 10,000 Hz or less.

[†]Although pitch is determined mainly by frequency, it also depends to a slight extent on loudness. For example, a very loud sound may seem slightly lower in pitch than a quiet sound of the same frequency.

**CAUTION**

*Do not confuse ultrasonic (high frequency) with supersonic (high speed)*

Sound waves whose frequencies are outside the audible range may reach the ear, but we are not generally aware of them. Frequencies above 20,000 Hz are called **ultrasonic**. [Do not confuse with **supersonic**, which is used for objects moving with a speed faster than the speed of sound.] Many animals can hear ultrasonic frequencies; dogs, for example, can hear sounds as high as 50,000 Hz, and bats can detect frequencies as high as 100,000 Hz. Ultrasonic waves have many useful applications in medicine and other fields, which we discuss later in this Chapter.

**PHYSICS APPLIED**

*Autofocusing camera*

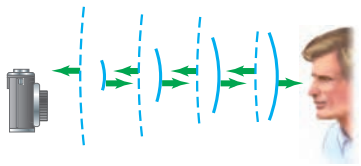

**FIGURE 16–1** Example 16–2. Autofocusing camera that emits an ultrasonic pulse. Solid curved lines represent the wave front of the outgoing wave pulse moving to the right; dashed lines represent the wave front of the pulse reflected off the person's face, returning to the camera. The time between emission and reception by the camera of these waves provides the object distance and allows the camera mechanism to adjust the lens to focus at the proper distance.

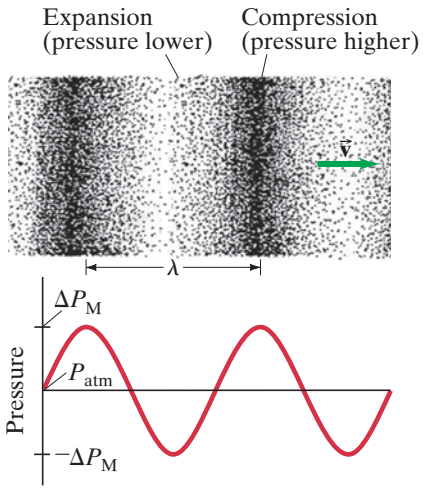
**EXAMPLE 16–2 Autofocusing with sound waves.** Autofocusing cameras can use very high frequency (ultrasonic) sound that is emitted and travels to the object being photographed. A sensor on the camera detects the returning reflected sound, as shown in Fig. 16–1. To get an idea of the time sensitivity of the detector, calculate the travel time of the pulse for an object (*a*) 1.0 m away, and (*b*) 20 m away.

**APPROACH** If we assume the temperature is about 20°C, then the speed of sound is 343 m/s. Using this speed $v$ and the total distance $d$ back and forth in each case, we can obtain the time $(v = d/t)$.

**SOLUTION** (*a*) The pulse travels 1.0 m to the object and 1.0 m back, for a total of 2.0 m. We solve for $t$ in $v = d/t$:

$$t = \frac{d}{v} = \frac{2.0\text{ m}}{343\text{ m/s}} = 0.0058\text{ s} = 5.8\text{ ms}.$$



(*b*) The total distance now is $2 \times 20\text{ m} = 40\text{ m}$, so

$$t = \frac{40\text{ m}}{343\text{ m/s}} = 0.12\text{ s} = 120\text{ ms}.$$

**NOTE** Newer autofocus cameras use infrared light $(v = 3 \times 10^8\text{ m/s})$ instead of ultrasound, and/or a digital sensor array that detects light intensity differences between adjacent receptors as the lens is automatically moved back and forth, choosing the lens position that provides maximum intensity differences (sharpest focus).

Sound waves whose frequencies are below the audible range (that is, less than 20 Hz) are called **infrasonic**. Sources of infrasonic waves include earthquakes, thunder, volcanoes, and waves produced by vibrating heavy machinery. This last source can be particularly troublesome to workers, because infrasonic waves—even though inaudible—can cause damage to the human body. These low-frequency waves act in a resonant fashion, causing motion and irritation of the body's organs.

**FIGURE 16–2** Longitudinal sound wave traveling to the right, and its graphical representation in terms of pressure ($\Delta P$ relative to normal air pressure).

## 16–2 Mathematical Representation of Longitudinal Waves

In Section 15–4, we saw that a one-dimensional sinusoidal wave traveling along the $x$ axis can be represented by the relation (Eq. 15–10c)

$$D = A \sin(kx - \omega t), \qquad \textbf{(16–1)}$$

where $D$ is the displacement of the wave at position $x$ and time $t$, and $A$ is its *amplitude* (maximum value). The wave number $k$ is related to the wavelength $\lambda$ by $k = 2\pi/\lambda$, and $\omega = 2\pi f$ where $f$ is the frequency. For a transverse wave—such as a wave on a string—the displacement $D$ is perpendicular to the direction of wave propagation along the $x$ axis. But for a longitudinal wave the displacement $D$ is *along the direction of wave propagation*. That is, $D$ is parallel to $x$ and represents the displacement of a tiny volume element of the medium from its equilibrium position.

Longitudinal (sound) waves can also be analyzed from the point of view of variations in pressure rather than displacement. Indeed, longitudinal waves are often called **pressure waves**. The pressure variation is usually easier to measure than the displacement (see Example 16–7). As Fig. 16–2 shows, in a wave "compression" (where molecules are closest together), the pressure is higher than normal, whereas in an expansion (or rarefaction) the pressure is less than normal.

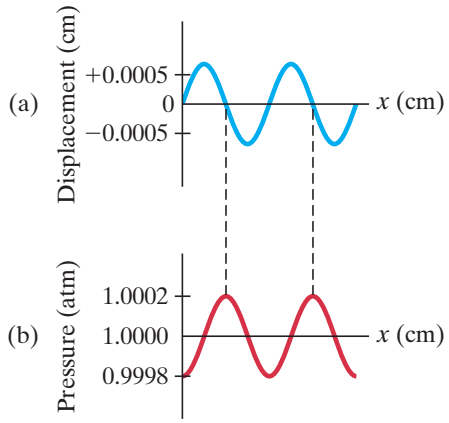


**FIGURE 16–3** Representation of a sound wave in space at a given instant in terms of (a) displacement, and (b) pressure.

Figure 16–3 shows a graphical representation of a sound wave in air in terms of (a) displacement and (b) pressure. Note that the displacement wave is a quarter wavelength, or 90° ($\pi/2$ rad), out of phase with the pressure wave: where the pressure is a maximum or minimum, the displacement from equilibrium is zero; and where the pressure variation is zero, the displacement is a maximum or minimum.

## Pressure Wave Derivation

Let us now derive the mathematical representation of the pressure variation in a traveling longitudinal wave. From the definition of the bulk modulus, $B$ (Eq. 12–7),

$$\Delta P = -B(\Delta V/V),$$

where $\Delta P$ represents the pressure difference from the normal pressure $P_0$ (no wave present) and $\Delta V/V$ is the fractional change in volume of the medium due to the pressure change $\Delta P$. The negative sign reflects the fact that the volume decreases ($\Delta V < 0$) if the pressure is increased. Consider now a layer of fluid, with a fixed number of molecules, through which the longitudinal wave is passing (Fig. 16–4). If this layer has thickness $\Delta x$ and area $S$, then its volume is $V = S\,\Delta x$. As a result of pressure variation in the wave, the volume will change by an amount $\Delta V = S\,\Delta D$, where $\Delta D$ is the change in thickness of this layer as it compresses or expands. (Remember that $D$ represents the displacement of the medium.) Thus we have

$$\Delta P = -B\frac{S\,\Delta D}{S\,\Delta x}.$$

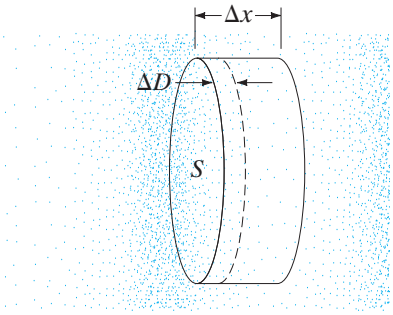
To be precise, we take the limit of $\Delta x \to 0$, so we obtain

$$\Delta P = -B\frac{\partial D}{\partial x}, \qquad \textbf{(16–2)}$$

where we use the partial derivative notation since $D$ is a function of both $x$ and $t$. If the displacement $D$ is sinusoidal as given by Eq. 16–1, then we have from Eq. 16–2 that

$$\Delta P = -(BAk)\cos(kx - \omega t). \qquad \textbf{(16–3)}$$

(Here $A$ is the displacement amplitude, not area which is $S$.) Thus the pressure varies sinusoidally as well, but is out of phase from the displacement by 90° or a quarter wavelength (cosine vs. sine), as in Fig. 16–3. The quantity $BAk$ is called the **pressure variation amplitude**, $\Delta P_{\text{M}}$. It represents the maximum and minimum amounts by which the pressure varies from the normal ambient pressure. We can thus write



$$\Delta P = -\Delta P_{\text{M}}\cos(kx - \omega t), \qquad \textbf{(16–4)}$$

where, using $v = \sqrt{B/\rho}$ (Eq. 15–4), and $k = \omega/v = 2\pi f/v$ (Eq. 15–12), then

$$\begin{aligned}\Delta P_{\text{M}} &= BAk \\ &= \rho v^2 Ak \\ &= 2\pi\rho v A f. \end{aligned} \qquad \textbf{(16–5)}$$

We will use this connection between $\Delta P_{\text{M}}$ and $A$ shortly.

**FIGURE 16–4** Longitudinal wave in a fluid moves to the right. A thin layer of fluid, in a thin imaginary cylinder of area $S$ and thickness $\Delta x$, changes in volume as a result of pressure variation as the wave passes. At the moment shown, the pressure will increase as the wave moves to the right, so the thickness of our layer will decrease, by an amount $\Delta D$.

# 16–3 Intensity of Sound: Decibels

**Loudness** is a sensation in the consciousness of a human being and is related to a physically measurable quantity, the **intensity** of the wave. Intensity is defined as the energy transported by a wave per unit time across a unit area perpendicular to the energy flow. As we saw in Chapter 15, intensity is proportional to the square of the wave amplitude. Intensity has units of power per unit area, or watts/meter$^2$ (W/m$^2$).

**PHYSICS APPLIED**
*Wide range of human hearing*

An average human ear can detect sounds with an intensity as low as $10^{-12}$ W/m$^2$ and as high as 1 W/m$^2$ (and even higher, although above this it is painful). This is an incredibly wide range of intensity, spanning a factor of $10^{12}$ from lowest to highest. Presumably because of this wide range, what we perceive as loudness is not directly proportional to the intensity. To produce a sound that we hear as about twice as loud requires a sound wave that has about 10 times the intensity. This is roughly valid at any sound level for frequencies near the middle of the audible range. For example, a sound wave of intensity $10^{-2}$ W/m$^2$ sounds to an average human being like it is about twice as loud as one with intensity of $10^{-3}$ W/m$^2$, and four times as loud as $10^{-4}$ W/m$^2$.

## Sound Level

Because of this relationship between the subjective sensation of loudness and the physically measurable quantity "intensity," sound intensity levels are usually specified on a logarithmic scale. The unit on this scale is a **bel**, after the inventor Alexander Graham Bell, or much more commonly, the **decibel** (dB), which is $\frac{1}{10}$bel (10 dB = 1 bel).[†] The **sound level**, $\beta$, of any sound is defined in terms of its intensity, $I$, as

$$\beta\,(\text{in dB}) = 10 \log \frac{I}{I_0}, \qquad \textbf{(16–6)}$$

where $I_0$ is the intensity of a chosen reference level, and the logarithm is to the base 10. $I_0$ is usually taken as the minimum intensity audible to a good ear—the "threshold of hearing," which is $I_0 = 1.0 \times 10^{-12}$ W/m$^2$. Thus, for example, the sound level of a sound whose intensity $I = 1.0 \times 10^{-10}$ W/m$^2$ will be

$$\beta = 10 \log\left(\frac{1.0 \times 10^{-10}\ \text{W/m}^2}{1.0 \times 10^{-12}\ \text{W/m}^2}\right) = 10 \log 100 = 20\ \text{dB},$$

since log 100 is equal to 2.0. (Appendix A has a brief review of logarithms.) Notice that the sound level at the threshold of hearing is 0 dB. That is, $\beta = 10 \log 10^{-12}/10^{-12} = 10 \log 1 = 0$ since $\log 1 = 0$. Notice too that an increase in intensity by a factor of 10 corresponds to a sound level increase of 10 dB. An increase in intensity by a factor of 100 corresponds to a sound level increase of 20 dB. Thus a 50-dB sound is 100 times more intense than a 30-dB sound, and so on.

Intensities and sound levels for some common sounds are listed in Table 16–2.

**CAUTION**
*0 dB does not mean zero intensity*

**TABLE 16–2**
**Intensity of Various Sounds**

| Source of the Sound | Sound Level (dB) | Intensity (W/m$^2$) |
|---|---|---|
| Jet plane at 30 m | 140 | 100 |
| Threshold of pain | 120 | 1 |
| Loud rock concert | 120 | 1 |
| Siren at 30 m | 100 | $1 \times 10^{-2}$ |
| Busy street traffic | 80 | $1 \times 10^{-4}$ |
| Noisy restaurant | 70 | $1 \times 10^{-5}$ |
| Talk, at 50 cm | 65 | $3 \times 10^{-6}$ |
| Quiet radio | 40 | $1 \times 10^{-8}$ |
| Whisper | 30 | $1 \times 10^{-9}$ |
| Rustle of leaves | 10 | $1 \times 10^{-11}$ |
| Threshold of hearing | 0 | $1 \times 10^{-12}$ |

**EXAMPLE 16–3** **Sound intensity on the street.** At a busy street corner, the sound level is 75 dB. What is the intensity of sound there?

**APPROACH** We have to solve Eq. 16–6 for intensity $I$, remembering that $I_0 = 1.0 \times 10^{-12}$ W/m$^2$.

**SOLUTION** From Eq. 16–6

$$\log \frac{I}{I_0} = \frac{\beta}{10}.$$

Recalling that $x = \log y$ is the same as $y = 10^x$ (Appendix A–7), then

$$\frac{I}{I_0} = 10^{\beta/10}.$$

With $\beta = 75$, then

$$I = I_0 10^{\beta/10} = (1.0 \times 10^{-12}\ \text{W/m}^2)(10^{7.5}) = 3.2 \times 10^{-5}\ \text{W/m}^2.$$

[†]The dB is dimensionless and so does not have to be included in calculations.

**EXAMPLE 16–4** **Loudspeaker output.** A high-quality loudspeaker is advertised to reproduce, at full volume, frequencies from 30 Hz to 18,000 Hz with uniform sound level $\pm 3$ dB. That is, over this frequency range, the sound level output does not vary by more than 3 dB for a given input level. By what factor does the intensity change for a 3 dB change in output level?

PHYSICS APPLIED
*Loudspeaker response ($\pm 3$ dB)*

**APPROACH** Let us call the desired "correct" output intensity $I_1$ (for a given input) and the corresponding output sound level $\beta_1$. Then the maximum error in output intensity, $I_2$, corresponds to a level $\beta_2 = \beta_1 + 3$ dB. We then use the relation between intensity and sound level, Eq. 16–6.

**SOLUTION** Equation 16–6 gives

$$\beta_2 - \beta_1 = 10 \log \frac{I_2}{I_0} - 10 \log \frac{I_1}{I_0}$$

$$3 \text{ dB} = 10\left(\log \frac{I_2}{I_0} - \log \frac{I_1}{I_0}\right) = 10 \log \frac{I_2}{I_1}$$

because $(\log a - \log b) = \log a/b$, as discussed in Appendix A–7. This last equation gives

$$\log \frac{I_2}{I_1} = 0.30,$$

or

$$\frac{I_2}{I_1} = 10^{0.30} = 2.0.$$

So $\pm 3$ dB corresponds to a doubling or halving of the intensity.

**EXERCISE A** If an increase of 3 dB means "twice as intense," what does an increase of 6 dB mean?

It is worth noting that a sound-level difference of 3 dB (which corresponds to a doubled intensity, as we just saw) corresponds to only a very small change in the subjective sensation of *apparent loudness*. Indeed, the average human can distinguish a difference in sound level of only about 1 or 2 dB.

Normally, the loudness or intensity of a sound decreases as you get farther from the source of the sound. Indoors, this effect is altered because of reflections from the walls. However, if a source is in the open so that sound can radiate out freely in all directions, the intensity decreases as the inverse square of the distance,

$$I \propto \frac{1}{r^2},$$

as we saw in Section 15–3. Over large distances, the intensity decreases faster than $1/r^2$ because some of the energy is transferred into irregular motion of air molecules. This loss happens more for higher frequencies, so any sound of mixed frequencies will be less "bright" at a distance. Far from an outdoor concert, you hear mainly the boom of the drums.

**CONCEPTUAL EXAMPLE 16–5** **Trumpet players.** A trumpeter plays at a sound level of 75 dB. Three equally loud trumpet players join in. What is the new sound level?

**RESPONSE** The intensity of four trumpets is four times the intensity of one trumpet $(= I_1)$ or $4I_1$. The sound level of the four trumpets would be

$$\beta = 10 \log \frac{4I_1}{I_0} = 10 \log 4 + 10 \log \frac{I_1}{I_0}$$

$$= 6.0 \text{ dB} + 75 \text{ dB} = 81 \text{ dB},$$

since $\log 4 = 0.60$ (again Appendix A–7; and $\log ab = \log a + \log b$).

**EXERCISE B** From Table 16–2, we see that *ordinary conversation* corresponds to a sound level of about 65 dB. If two people are talking at once, the sound level would be about (*a*) 65 dB, (*b*) 68 dB, (*c*) 75 dB, (*d*) 130 dB, (*e*) 59 dB.

PHYSICS APPLIED
*Jet plane noise*

**FIGURE 16–5** Example 16–6. Airport worker with sound-intensity-reducing ear covers (headphones).

**EXAMPLE 16–6** **Airplane roar.** The sound level measured 30 m from a jet plane is 140 dB. Estimate the sound level at 300 m. (Ignore reflections from the ground.)

**APPROACH** Given the sound level, we can determine the intensity at 30 m using Eq. 16–6. Because intensity decreases as the square of the distance, ignoring reflections, we can find $I$ at 300 m and again apply Eq. 16–6 to obtain the sound level.

**SOLUTION** The intensity $I$ at 30 m is (Eq. 16–6)

$$140\,\text{dB} = 10\log\left(\frac{I}{10^{-12}\,\text{W/m}^2}\right)$$

or, dividing through by 10,

$$14 = \log\left(\frac{I}{10^{-12}\,\text{W/m}^2}\right).$$

Recall that $y = \log x$ means $10^y = x$ (Appendix A–7). Then

$$10^{14} = \frac{I}{10^{-12}\,\text{W/m}^2},$$

so $I = (10^{14})(10^{-12}\,\text{W/m}^2) = 10^2\,\text{W/m}^2$. At 300 m, 10 times as far, the intensity is assumed to decrease approximately as $1/r^2$, and so will be $(\frac{1}{10})^2 = 1/100$ as much, or $1\,\text{W/m}^2$. Hence, the sound level is

$$\beta = 10\log\left(\frac{1\,\text{W/m}^2}{10^{-12}\,\text{W/m}^2}\right) = 120\,\text{dB}.$$

Even at 300 m, the sound is at the threshold of pain. This is why workers at airports wear ear covers to protect their ears from damage (Fig. 16–5).

**NOTE** Here is a simpler approach that avoids Eq. 16–6. Because the intensity decreases as the square of the distance, at 10 times the distance the intensity decreases by $(\frac{1}{10})^2 = \frac{1}{100}$. We can use the result that 10 dB corresponds to an intensity change by a factor of 10 (see just before Example 16–3). Then an intensity change by a factor of 100 corresponds to a sound-level change of (2)(10 dB) = 20 dB. This confirms our result above: 140 dB − 20 dB = 120 dB.

## Intensity Related to Amplitude

The intensity $I$ of a wave is proportional to the square of the wave amplitude, $A$, as we saw in Section 15–3. We can therefore relate the amplitude quantitatively to the intensity $I$ or level $\beta$, as the following Example shows.

PHYSICS APPLIED
*Incredible sensitivity of the ear*

**EXAMPLE 16–7** **How tiny the displacement is.** (*a*) Calculate the displacement of air molecules for a sound having a frequency of 1000 Hz at the threshold of hearing. (*b*) Determine the maximum pressure variation in such a sound wave.

**APPROACH** In Section 15–3 we found a relation between intensity $I$ and displacement amplitude $A$ of a wave, Eq. 15–7. The amplitude of oscillation of air molecules is what we want to solve for, given the intensity. Assume the temperature is 20°C so the speed of sound is 343 m/s. The pressure variation is found from Eq. 16–5.

**SOLUTION** At the threshold of hearing, $I = 1.0 \times 10^{-12}\,\text{W/m}^2$ (Table 16–2). We solve for the amplitude $A$ in Eq. 15–7:

$$A = \frac{1}{\pi f}\sqrt{\frac{I}{2\rho v}}$$

$$= \frac{1}{(3.14)(1.0\times10^3\,\text{s}^{-1})}\sqrt{\frac{1.0\times10^{-12}\,\text{W/m}^2}{(2)(1.29\,\text{kg/m}^3)(343\,\text{m/s})}} = 1.1\times10^{-11}\,\text{m},$$

where we have taken the density of air to be $1.29\,\text{kg/m}^3$ (Table 13–1).

**NOTE** We see how incredibly sensitive the human ear is: it can detect displacements of air molecules which are less than the diameter of atoms (about $10^{-10}$ m).

(*b*) Now we are dealing with sound as a pressure wave (Section 16–2). From Eq. 16–5,

$$\Delta P_\text{M} = 2\pi\rho v A f$$

$$= 2\pi(1.29\,\text{kg/m}^3)(343\,\text{m/s})(1.1\times10^{-11}\,\text{m})(1.0\times10^3\,\text{s}^{-1}) = 3.1\times10^{-5}\,\text{Pa}$$

or $3.1\times10^{-10}$ atm. Again we see that the human ear is incredibly sensitive.

By combining Eqs. 15–7 and 16–5, we can write the intensity in terms of the pressure amplitude, $\Delta P_M$:

$$I = 2\pi^2 v\rho f^2 A^2 = 2\pi^2 v\rho f^2 \left(\frac{\Delta P_M}{2\pi\rho v f}\right)^2$$

$$I = \frac{(\Delta P_M)^2}{2v\rho}. \qquad \textbf{(16–7)}$$

The intensity in terms of pressure amplitude does not depend on frequency.

### The Ear's Response, and Loudness

The ear is not equally sensitive to all frequencies. To hear the same loudness for sounds of different frequencies requires different intensities. Studies on large numbers of people have produced the curves shown in Fig. 16–6. On this graph, each curve represents sounds that seemed to be equally loud. The number labeling each curve represents the **loudness level** (the units are called *phons*), which is numerically equal to the sound level in dB at 1000 Hz. For example, the curve labeled 40 represents sounds that are heard by an average person to have the same loudness as a 1000-Hz sound with a sound level of 40 dB. From this 40-phon curve, we see that a 100-Hz tone must be at a level of about 62 dB to be perceived as loud as a 1000-Hz tone of only 40 dB.

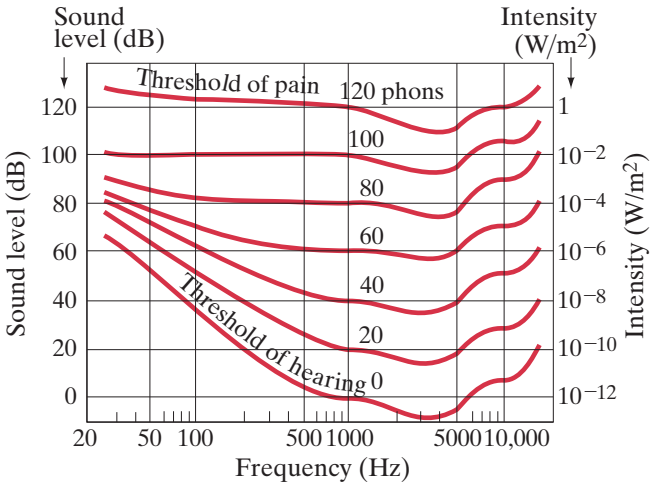


**FIGURE 16–6** Sensitivity of the human ear as a function of frequency (see text). Note that the frequency scale is "logarithmic" in order to cover a wide range of frequencies. We can see that at lower sound levels our ears are less sensitive to high and low frequencies relative to mid-range frequencies (which we hear better).

The lowest curve in Fig. 16–6 (labeled 0) represents the sound level, as a function of frequency, for the *threshold of hearing*, the softest sound that is just audible by a very good ear. Note that the ear is most sensitive to sounds of frequency between 2000 and 4000 Hz, which are common in speech and music. Note too that whereas a 1000-Hz sound is audible at a level of 0 dB, a 100-Hz sound must be nearly 40 dB to be heard. The top curve in Fig. 16–6, labeled 120 phons, represents the *threshold of pain*. Sounds above this level can actually be felt and cause pain.

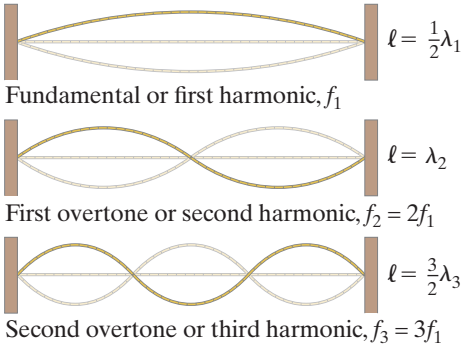
## 16–4 Sources of Sound: Vibrating Strings and Air Columns

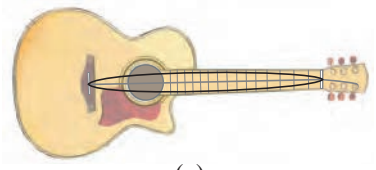
The source of any sound is a vibrating object. Almost any object can vibrate and hence be a source of sound. We now discuss some simple sources of sound, particularly musical instruments. In musical instruments, the source is set into vibration by striking, plucking, bowing, or blowing. Standing waves are produced and the source vibrates at its natural resonant frequencies. The vibrating source is in contact with the air (or other medium) and pushes on it to produce sound waves that travel outward. The frequencies of the waves are the same as those of the source, but the speed and wavelengths can be different. A drum has a stretched membrane that vibrates. Xylophones and marimbas have metal or wood bars that can be set into vibration. Bells, cymbals, and gongs also make use of a vibrating metal. Many instruments make use of vibrating strings, such as the violin, guitar, and piano, or make use of vibrating columns of air, such as the flute, trumpet, and pipe organ. We have already seen that the pitch of a pure sound is determined by the frequency.

**TABLE 16–3 Equally Tempered Chromatic Scale**[†]

| Note (letter) | Note (name) | Frequency (Hz) |
|---|---|---|
| C | do | 262 |
| C♯ or D♭ | | 277 |
| D | re | 294 |
| D♯ or E♭ | | 311 |
| E | mi | 330 |
| F | fa | 349 |
| F♯ or G♭ | | 370 |
| G | sol | 392 |
| G♯ or A♭ | | 415 |
| A | la | 440 |
| A♯ or B♭ | | 466 |
| B | ti | 494 |
| C′ | do | 524 |

[†]Only one octave is included.





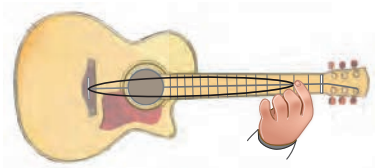


**FIGURE 16–7** Standing waves on a string—only the lowest three frequencies are shown.

**FIGURE 16–8** The wavelength of (a) an unfingered string is longer than that of (b) a fingered string. Hence, the frequency of the fingered string is higher. Only one string is shown on this guitar, and only the simplest standing wave, the fundamental, is shown.

(a)

(b)

Typical frequencies for musical notes on the *equally tempered chromatic scale* are given in Table 16–3 for the octave beginning with middle C. Note that one octave corresponds to a doubling of frequency. For example, middle C has a frequency of 262 Hz whereas C′ (C above middle C) has twice that frequency, 524 Hz. [Middle C is the C or "do" note at the middle of a piano keyboard.][†]

## Stringed Instruments

We saw in Chapter 15, Fig. 15–26b, how standing waves are established on a string, and we show this again here in Fig. 16–7. Such standing waves are the basis for all stringed instruments. The pitch is normally determined by the lowest resonant frequency, the **fundamental**, which corresponds to nodes occurring only at the ends. The string vibrating up and down as a whole corresponds to a half wavelength as shown at the top of Fig. 16–7; so the wavelength of the fundamental on the string is equal to twice the length $\ell$ of the string. Therefore, the fundamental frequency is $f_1 = v/\lambda = v/2\ell$, where $v$ is the velocity of the wave on the string (*not* in the air). The possible frequencies for standing waves on a stretched string are whole-number multiples of the fundamental frequency:

$$f_n = nf_1 = n\frac{v}{2\ell}, \qquad n = 1, 2, 3, \cdots$$

(just as in Eq. 15–17b), where $n = 1$ refers to the fundamental and $n = 2, 3, \cdots$ are the **overtones**. All of the standing waves, $n = 1, 2, 3, \cdots$, are called **harmonics**,[‡] as we saw in Section 15–9.

When a finger is placed on the string of a guitar or violin, the effective length of the vibrating string is shortened. So its fundamental frequency, and pitch, is higher since the wavelength of the fundamental is shorter (Fig. 16–8). You move your fingers to play *different notes* on a string.

The strings on a guitar or violin are all the same length. They sound at a different pitch because the strings have different mass per unit length, $\mu = m/\ell$, which affects the velocity on the string, Eq. 15–2,

$$v = \sqrt{F_T/\mu}. \qquad \text{[stretched string]}$$

Thus the velocity on a heavier string is lower and the frequency will be lower for the same wavelength or string length. The tension $F_T$ also effects the velocity and therefore the frequency. Indeed, adjusting the tension is the means for **tuning** the pitch of each string, to make it precise by turning a knob at the end (6 knobs are visible in Fig. 16–8 but only one string is shown for clarity). In pianos and harps the strings are of different lengths. For the lower notes the strings are not only longer, but heavier as well, and the reason is illustrated in the following Example.

**EXAMPLE 16–8** **Piano strings.** The highest key on a piano corresponds to a frequency about 150 times that of the lowest key. If the string for the highest note is 5.0 cm long, how long would the string for the lowest note have to be if it had the same mass per unit length and was under the same tension?

**APPROACH** Since $v = \sqrt{F_T/\mu}$, the velocity would be the same on each string. So the frequency is inversely proportional to the length $\ell$ of the string ($f = v/\lambda = v/2\ell$).

**SOLUTION** We can write, for the fundamental frequencies of each string, the ratio

$$\frac{\ell_L}{\ell_H} = \frac{f_H}{f_L},$$

where the subscripts L and H refer to the lowest and highest notes, respectively. Thus $\ell_L = \ell_H(f_H/f_L) = (5.0\text{ cm})(150) = 750\text{ cm}$, or 7.5 m. This would be ridiculously long ($\approx 25$ ft) for a piano.

**NOTE** The longer strings of lower frequency are made heavier (higher mass per unit length), so even on grand pianos the strings are less than 3 m long.

**EXERCISE C** How many octaves does the piano of Example 16–8 cover?

[†]Some musicians, bands, or orchestras may use a different middle C. Tuning an orchestra is often done at A, which may be as low as 415 Hz or as high as 445 Hz.

[‡]When overtones are integral multiples of the fundamental, they are harmonics. If the overtones are not integral multiples of the fundamental, as for a vibrating drumhead, they are not harmonics.

**EXAMPLE 16–9** **Frequencies and wavelengths in the violin.** A 0.32-m-long violin string is tuned to play A above middle C at 440 Hz. (*a*) What is the wavelength of the fundamental string vibration, and (*b*) what are the frequency and wavelength of the sound wave produced? (*c*) Why is there a difference?

**APPROACH** The wavelength of the fundamental string vibration equals twice the length of the string (Fig. 16–7). As the string vibrates, it pushes on the air, which is thus forced to oscillate at the same frequency as the string. The speed of sound in air (assumed at 20°C) is 343 m/s, Section 16–1.

**SOLUTION** (*a*) From Fig. 16–7 the wavelength of the fundamental is

$$\lambda = 2\ell = 2(0.32\,\text{m}) = 0.64\,\text{m} = 64\,\text{cm}.$$

This is the wavelength of the standing wave on the string.

(*b*) The sound wave that travels outward in the air (to reach our ears) has the same frequency, 440 Hz. Its wavelength is

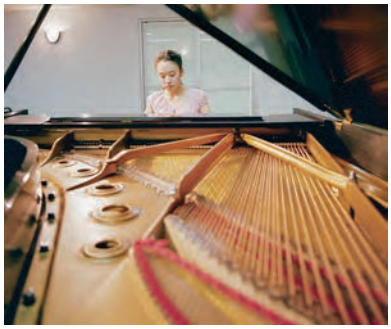
$$\lambda = \frac{v}{f} = \frac{343\,\text{m/s}}{440\,\text{Hz}} = 0.78\,\text{m} = 78\,\text{cm}.$$

(*c*) The wavelength of the sound wave is different from that of the standing wave on the string because the speed of sound in air (343 m/s at 20°C) is different from the speed of the wave on the string $(= f\lambda = 440\,\text{Hz} \times 0.64\,\text{m} = 280\,\text{m/s})$ which depends on the tension in the string and its mass per unit length.

**NOTE** The frequencies on the string and in the air are the same. But the wavelengths are different because the wave speed on the string is different than the speed of sound waves in air (280 m/s vs. 343 m/s at 20°C).

**EXERCISE D** Return to Chapter-Opening Question, page 460, and answer it again now. Try to explain why you may have answered differently the first time.

Stringed instruments would not be very loud if they relied on their vibrating strings to produce the sound waves since the strings are too thin to compress and expand much air. Stringed instruments therefore make use of a kind of mechanical amplifier known as a *sounding board* (piano) or *sounding box* (guitar, violin), which acts to amplify the sound by putting a greater surface area in contact with the air (Fig. 16–9). When the strings are set into vibration, the sounding board or box is set into vibration as well. Since it has much greater area in contact with the air, it can produce a more intense sound wave. On an electric guitar, the sounding box is not so important since the vibrations of the strings are amplified electronically.



## Wind Instruments

Instruments such as woodwinds, the brasses, and the pipe organ produce sound from the vibrations of standing waves in a column of air within a tube (Fig. 16–10). Standing waves can occur in the air of any cavity, including the human throat, but the frequencies present are complicated for any but very simple shapes such as the uniform, narrow tube of a flute or an organ pipe. In some instruments, a vibrating reed or the vibrating lip of the player helps to set up vibrations of the air column. In others, a stream of air is directed against one edge of the opening or mouthpiece, leading to turbulence which sets up the vibrations. Because of the disturbance, whatever its source, the air within the tube vibrates with a variety of frequencies, but only frequencies that correspond to standing waves will persist.

Recall that for a string fixed at both ends, Fig. 16–7, the standing waves have nodes (no movement) at the two ends, and one or more antinodes (large amplitude of vibration) in between. A node separates successive antinodes. The lowest-frequency standing wave, the *fundamental*, corresponds to a single antinode. The higher-frequency standing waves are called **overtones** or **harmonics**, as we saw in Section 15–9. Specifically, the first harmonic is the fundamental, the second harmonic (= first overtone) has twice the frequency of the fundamental, and so on.

**⚠ CAUTION**

*Speed of standing wave on string ≠ speed of sound wave in air*

(a)

(b)

**FIGURE 16–9** (a) Piano, showing sounding board to which strings are attached; (b) sounding box (guitar).

**FIGURE 16–10** Wind instruments: flute (right) and clarinet.

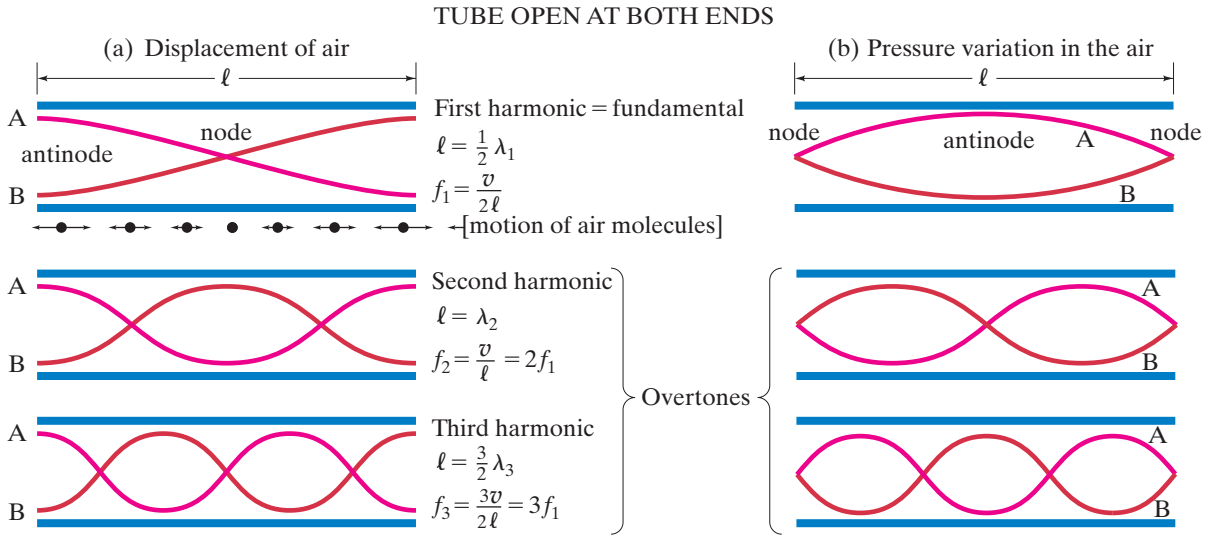


**FIGURE 16–11** Graphs of the three simplest modes of vibration (standing waves) for a uniform tube open at both ends ("open tube"). These simplest modes of vibration are graphed in (a), on the left, in terms of the motion of the air (displacement), and in (b), on the right, in terms of air pressure. Each graph shows the wave form at two times, A and B, a half period apart. The actual motion of molecules for one case, the fundamental, is shown just below the tube at top left.

**PHYSICS APPLIED**
*Wind instruments*

The situation is similar for a column of air in a tube of uniform diameter, but we must remember that it is now air itself that is vibrating. We can describe the waves either in terms of the flow of the air—that is, in terms of the *displacement* of air—or in terms of the *pressure* in the air (see Figs. 16–2 and 16–3). In terms of displacement, the air at the closed end of a tube is a displacement node since the air is not free to move there, whereas near the open end of a tube there will be an antinode because the air can move freely in and out. The air within the tube vibrates in the form of longitudinal standing waves. A few of the possible modes of vibration for a tube open at both ends (called an **open tube**) are shown graphically in Fig. 16–11. Possible vibration modes for a tube that is open at one end but closed at the other (called a **closed tube**) are shown in Fig. 16–12. [A tube closed at *both* ends, having no connection to the outside air, would be useless as an instrument; but see Problem 43.] The graphs in part (a) of each Figure (left-hand sides) represent the displacement amplitude of the vibrating air in the tube. Note that these are graphs, and that the air molecules themselves oscillate *horizontally*, parallel to the tube length, as shown by the small arrows in the top diagram of Fig. 16–11a (on the left). The exact position of the antinode near the open end of a tube depends on the diameter of the tube, but if the diameter is small compared to the length, which is the usual case, the antinode occurs very close to the end as shown.[†] We assume this is the case in the following analysis. (The position of the antinode may also depend slightly on the wavelength and other factors.)

Let us look in detail at the open tube, in Fig. 16–11a, which might be an organ pipe or a flute. An open tube has displacement antinodes at both ends since the air is free to move at open ends. There must be at least one node within an open tube if there is to be a standing wave at all. A single node corresponds to the *fundamental frequency* of the tube. Since the distance between two successive nodes, or between two successive antinodes, is $\frac{1}{2}\lambda$, there is one-half of a wavelength within the length of the tube for the simplest case of the fundamental (top diagram in Fig. 16–11a): $\ell = \frac{1}{2}\lambda$, or $\lambda = 2\ell$. So the fundamental frequency is $f_1 = v/\lambda = v/2\ell$, where $v$ is the velocity of sound in air (the air in the tube). The standing wave with two nodes is the *first overtone* or *second harmonic* and has half the wavelength, $\ell = \lambda$, and twice the frequency of the fundamental. Indeed, in a uniform tube open at both ends, the frequency of each overtone is an integral multiple of the fundamental frequency, as shown in Fig. 16–11a. This is just what is found for a string.

[†]The diameter $D$ of a tube does affect the antinode at the open end of a tube. The end correction can be roughly approximated by adding $D/3$ to $\ell$ to give us an *effective length* for the tube in calculations.

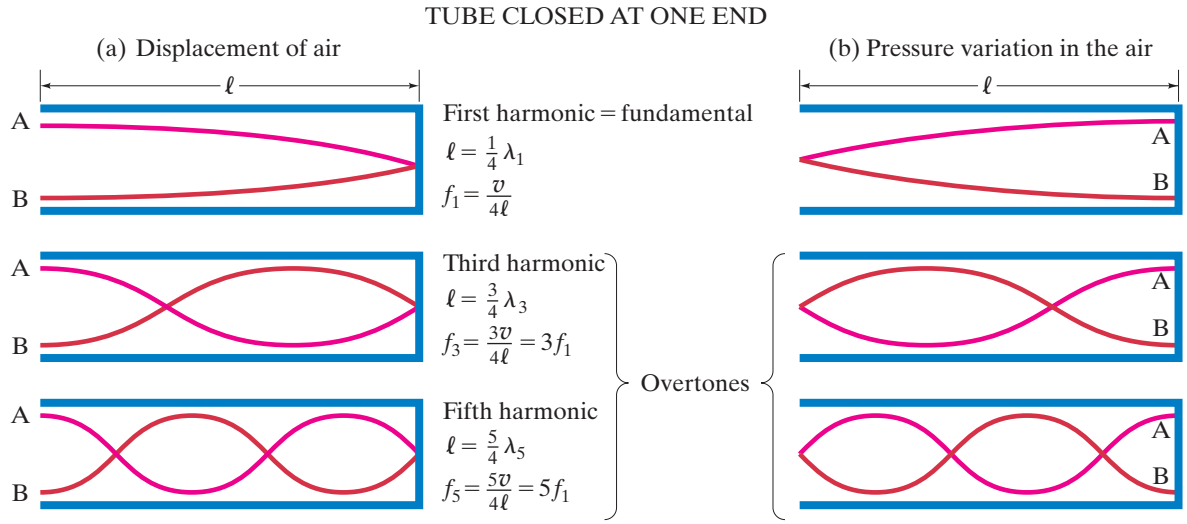

**FIGURE 16–12** Modes of vibration (standing waves) for a tube closed at one end ("closed tube"). See caption for Fig. 16–11.

For a closed tube, shown in Fig. 16–12a, which could be an organ pipe, there is always a displacement node at the closed end (because the air is not free to move) and an antinode at the open end (where the air can move freely). Since the distance between a node and the nearest antinode is $\frac{1}{4}\lambda$, we see that the fundamental in a closed tube corresponds to only one-fourth of a wavelength within the length of the tube: $\ell = \lambda/4$, and $\lambda = 4\ell$. The fundamental frequency is thus $f_1 = v/4\ell$, or half that for an open pipe of the same length. There is another difference, for as we can see from Fig. 16–12a, only the odd harmonics are present in a closed tube: the overtones have frequencies equal to $3, 5, 7, \cdots$ times the fundamental frequency. There is no way for waves with $2, 4, 6, \cdots$ times the fundamental frequency to have a node at one end and an antinode at the other, and thus they cannot exist as standing waves in a closed tube.

Another way to analyze the vibrations in a uniform tube is to consider a description in terms of the *pressure* in the air, shown in part (b) of Figs. 16–11 and 16–12 (right-hand sides). Where the air in a wave is compressed, the pressure is higher, whereas in a wave expansion (or rarefaction), the pressure is less than normal. The open end of a tube is open to the atmosphere. Hence the pressure variation at an open end must be a *node*: the pressure does not alternate, but remains at the outside atmospheric pressure. If a tube has a closed end, the pressure at that closed end can readily alternate to be above or below atmospheric pressure. Hence there is a pressure *antinode* at a closed end of a tube. There can be pressure nodes and antinodes within the tube. Some of the possible vibrational modes in terms of pressure are shown in Fig. 16–11b for an open tube, and in Fig. 16–12b for a closed tube.

**EXAMPLE 16–10** **Organ pipes.** What will be the fundamental frequency and first three overtones for a 26-cm-long organ pipe at 20°C if it is (*a*) open and (*b*) closed?

**APPROACH** All our calculations can be based on Figs. 16–11a and 16–12a.

**SOLUTION** (*a*) For the open pipe, Fig. 16–11a, the fundamental frequency is

$$f_1 = \frac{v}{2\ell} = \frac{343\ \text{m/s}}{2(0.26\ \text{m})} = 660\ \text{Hz}.$$

The speed $v$ is the speed of sound in air (the air vibrating in the pipe). The overtones include all harmonics: 1320 Hz, 1980 Hz, 2640 Hz, and so on.

(*b*) For a closed pipe, Fig. 16–12a, the fundamental frequency is

$$f_1 = \frac{v}{4\ell} = \frac{343\ \text{m/s}}{4(0.26\ \text{m})} = 330\ \text{Hz}.$$

Only odd harmonics are present: the first three overtones are 990 Hz, 1650 Hz, and 2310 Hz.

**NOTE** The closed pipe plays 330 Hz, which, from Table 16–3, is E above middle C, whereas the open pipe of the same length plays 660 Hz, an octave higher.

Pipe organs use both open and closed pipes, with lengths from a few centimeters to 5 m or more. A flute acts as an open tube, for it is open not only where you blow into it, but is open also at the opposite end. The different notes on a flute are obtained by shortening the length of the vibrating air column, by uncovering holes along the tube (so a displacement antinode can occur at the hole). The shorter the length of the vibrating air column, the higher the fundamental frequency. A clarinet, on the other hand, acts as a closed tube (closed at the reed end where you blow), so will sound lower than a flute of similar length.

**EXAMPLE 16–11** **Flute.** A flute is designed to play middle C (262 Hz) as the fundamental frequency when all the holes are covered. Approximately how long should the distance be from the mouthpiece to the far end of the flute? (This is only approximate since the antinode does not occur precisely at the mouthpiece.) Assume the temperature is 20°C.

**APPROACH** When all holes are covered, the length of the vibrating air column is the full length. The speed of sound in air at 20°C is 343 m/s. Because a flute is open at both ends, we use Fig. 16–11: the fundamental frequency $f_1$ is related to the length $\ell$ of the vibrating air column by $f = v/2\ell$.

**SOLUTION** Solving for $\ell$, we find

$$\ell = \frac{v}{2f} = \frac{343\ \text{m/s}}{2(262\ \text{s}^{-1})} = 0.655\ \text{m}.$$

**EXERCISE E** To see why players of wind instruments "warm up" their instruments (so they will be in tune), determine the fundamental frequency of the flute of Example 16–11 when all holes are covered and the temperature is 10°C instead of 20°C.

## *16–5 Quality of Sound, and Noise; Superposition

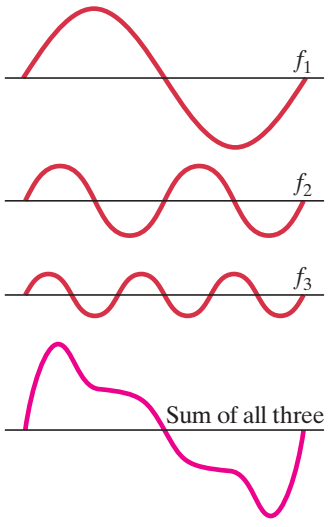

**FIGURE 16–13** In the example shown here, the displacements of the fundamental and first two overtones are added at each point to get the "sum," or composite waveform. Normally many overtones are present.

Whenever we hear a sound, particularly a musical sound, we are aware of its loudness, its pitch, and also of a third aspect called "quality." For example, when a piano and then a flute play a note of the same loudness and pitch (say, middle C), there is a clear difference in the overall sound. We would never mistake a piano for a flute. This is what is meant by the **quality** of a sound. For musical instruments, the terms *timbre* and *tone color* are also used.

Just as loudness and pitch can be related to physically measurable quantities, so too can quality. The quality of a sound depends on the presence of overtones—their number and their relative amplitudes. Generally, when a note is played on a musical instrument, the fundamental as well as overtones are present simultaneously. Figure 16–13 illustrates how the *principle of superposition* (Section 15–6) applies to three wave forms, in this case the fundamental and first two overtones (with particular amplitudes): they add together at each point to give a composite **waveform**. By "waveform" we mean the shape of the wave in space at a given moment. Normally, more than two overtones are present. [Any complex wave can be analyzed into a superposition of sinusoidal waves of appropriate amplitudes, wavelengths, and frequencies—see Section 15–6. Such an analysis is called a *Fourier analysis*.]

The relative amplitudes of the overtones for a given note are different for different musical instruments, which is what gives each instrument its characteristic quality or timbre. A bar graph showing the relative amplitudes of the overtones for a given note produced by an instrument is called a *sound spectrum*. Several typical examples for different musical instruments are shown in Fig. 16–14. The fundamental usually has the greatest amplitude, and its frequency is what is heard as the pitch.

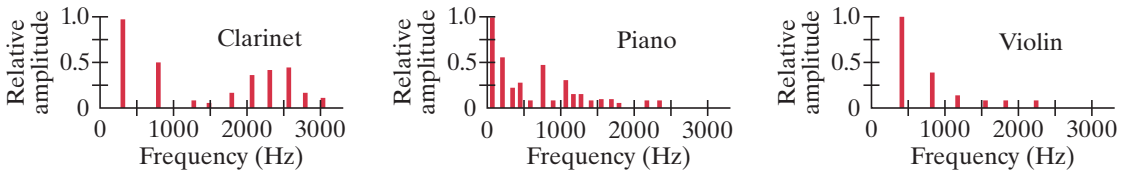

**FIGURE 16–14** Sound spectra for different instruments for a specific note in each case. The spectra will change when the instruments play other notes. The clarinet is a bit complicated: it acts like a closed tube at lower frequencies, having only odd harmonics, but at higher frequencies all harmonics occur as for an open tube.

The manner in which an instrument is played strongly influences the sound quality. Plucking a violin string, for example, makes a very different sound than pulling a bow across it. The sound spectrum at the very start (or end) of a note (as when a hammer strikes a piano string) can be very different from the subsequent sustained tone. This too affects the subjective tone quality of an instrument.

An ordinary sound, like that made by striking two stones together, is a noise that has a certain quality, but a clear pitch is not discernible. Such a noise is a mixture of many frequencies which bear little relation to one another. A sound spectrum made of that noise would not show discrete lines like those of Fig. 16–14. Instead it would show a continuous, or nearly continuous, spectrum of frequencies. Such a sound we call "noise" in comparison with the more harmonious sounds which contain frequencies that are simple multiples of the fundamental.

# 16–6 Interference of Sound Waves; Beats

## Interference in Space

We saw in Section 15–8 that when two waves simultaneously pass through the same region of space, they interfere with one another. Interference also occurs with sound waves.

Consider two large loudspeakers, A and B, a distance $d$ apart as shown in Fig. 16–15. Let us assume the two speakers are emitting sound waves of the same single frequency and that they are in phase: that is, when one speaker is forming a compression, so is the other. (We ignore reflections from walls, floor, etc.) The curved lines in the diagram represent the crests of sound waves from each speaker at one instant in time. We must remember that for a sound wave, a crest is a compression in the air whereas a trough—which falls between two crests—is a rarefaction. A human ear or detector at a point such as C, which is the same distance from each speaker, will experience a loud sound because the interference will be constructive—two crests reach it at one moment, two troughs reach it a moment later. On the other hand, at a point such as D in the diagram, little if any of that single frequency sound will be heard because destructive interference occurs—compressions of one wave meet rarefactions of the other and vice versa (see Figs. 15–23 and 15–24 and the related discussion in Section 15–8).

An analysis where we graphically represent the waveforms of a single frequency is shown in Fig. 16–16. In Fig. 16–16a it can be seen that at point C, constructive interference occurs because both waves simultaneously have crests or simultaneously have troughs when they arrive at C. In Fig. 16–16b we see that, to reach point D, the wave from speaker B must travel a greater distance than the wave from A. Thus the wave from B lags behind that from A. In this diagram, point E is chosen so that the distance ED is equal to AD. Thus we see that if the distance BE is equal to precisely one-half the wavelength of the sound, the two waves will be exactly out of phase when they reach D, and destructive interference occurs.

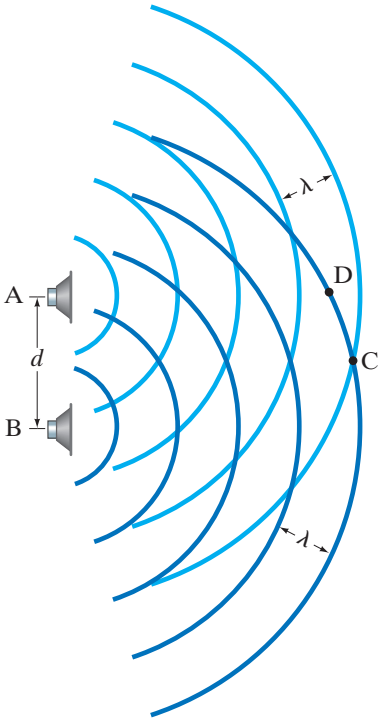

**FIGURE 16–15** Sound waves of a single frequency emitted by two loudspeakers interfere.

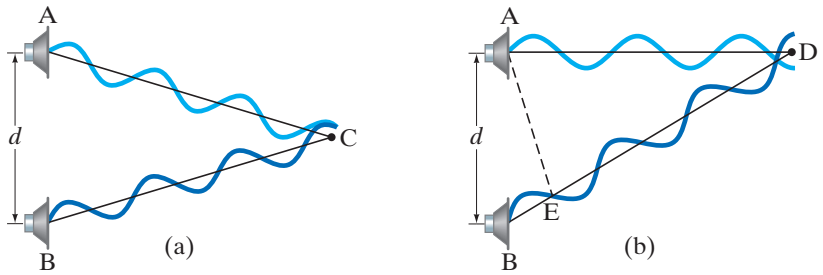

**FIGURE 16–16** Sound waves of a single frequency from loudspeakers A and B (see Fig. 16–15) constructively interfere at C and destructively interfere at D. Shown here are graphical representations, not the actual longitudinal sound waves.

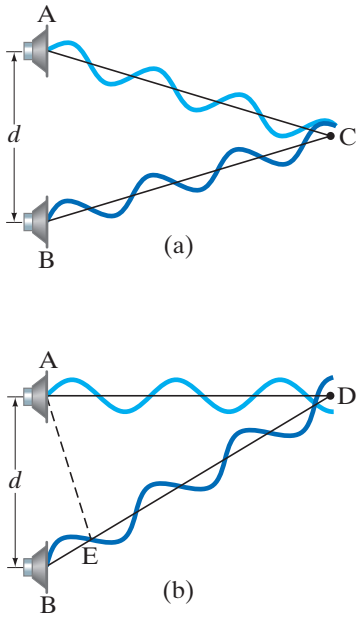

**FIGURE 16–16** (Repeated.) Sound waves of a single frequency from loudspeakers A and B (see Fig. 16–15) constructively interfere at C and destructively interfere at D. Shown here are graphical representations, not the actual longitudinal sound waves.

This then is the criterion for determining at what points destructive interference occurs: destructive interference occurs at any point whose distance from one speaker is one-half wavelength greater than its distance from the other speaker. Notice that if this extra distance (BE in Fig. 16–16b) is equal to a whole wavelength (or 2, 3, $\cdots$ wavelengths), then the two waves will be in phase and *constructive interference* occurs. If the distance BE equals $\frac{1}{2}$, $1\frac{1}{2}$, $2\frac{1}{2}$, $\cdots$ wavelengths, *destructive interference* occurs.

It is important to realize that a person at point D in Fig. 16–15 or 16–16 hears nothing at all (or nearly so), yet sound is coming from both speakers. But if one of the speakers is turned off, the sound from the other speaker will be heard clearly. To confirm this, it would be easier to use two tuning forks at A and B because they emit (very nearly) a single frequency. It is harder to observe with musical instruments because they emit a range of frequencies (overtones, Fig. 16–14). Thus when a loudspeaker emits a whole range of frequencies, only specific wavelengths will destructively interfere completely at a given point. (If you move around near two loudspeakers you might hear a slight change in overall sound quality or timbre.)

**EXAMPLE 16–12** **Loudspeakers' interference.** Two loudspeakers are 1.00 m apart. A person stands 4.00 m from one speaker. How far must this person be from the second speaker to detect destructive interference when the speakers emit an 1150-Hz sound? Assume the temperature is 20°C.

**APPROACH** To sense destructive interference, the person must be one-half wavelength closer to or farther from one speaker than from the other—that is, at a distance = 4.00 m $\pm$ $\lambda/2$. We can determine $\lambda$ because we know $f$ and $v$.

**SOLUTION** The speed of sound at 20°C is 343 m/s, so the wavelength of this sound is (Eq. 15–1)

$$\lambda = \frac{v}{f} = \frac{343\ \text{m/s}}{1150\ \text{Hz}} = 0.30\ \text{m}.$$

For destructive interference to occur, the person must be one-half wavelength farther from one loudspeaker than from the other, or 0.15 m. Thus the person must be 3.85 m or 4.15 m from the second speaker.

**NOTE** If the speakers are less than 0.15 m apart, there will be no location that is 0.15 m farther from one speaker than the other, and there will be no place where destructive interference could occur.

## Beats—Interference in Time

We have been discussing interference of sound waves that takes place in *space*. An interesting and important example of interference that occurs in *time* is the phenomenon known as *beats*: If two sources of sound—say, two tuning forks—are close in frequency but not exactly the same, sound waves from the two sources interfere with each other in an interesting way. The sound level at a given position alternately rises and falls in time, because the two waves are sometimes in phase and sometimes out of phase due to their slightly different frequencies. The regularly spaced intensity changes are called **beats**.

To see how beats arise, consider two equal-amplitude sound waves of frequency $f_A = 50$ Hz and $f_B = 60$ Hz, respectively. In 1.00 s, the first source makes 50 vibrations whereas the second makes 60. We now examine the waves at one point in space equidistant from the two sources. The waveforms for each wave as a function of time, at a fixed position, are shown on the top graph of Fig. 16–17; the red line represents the 50-Hz wave, and the blue line represents the 60-Hz wave. The lower graph in Fig. 16–17 shows the sum of the two waves as a function of time. At time $t = 0$ the two waves are shown to be in phase and interfere constructively. Because the two waves vibrate at different rates, at time $t = 0.05$ s they are completely out of phase and interfere destructively.

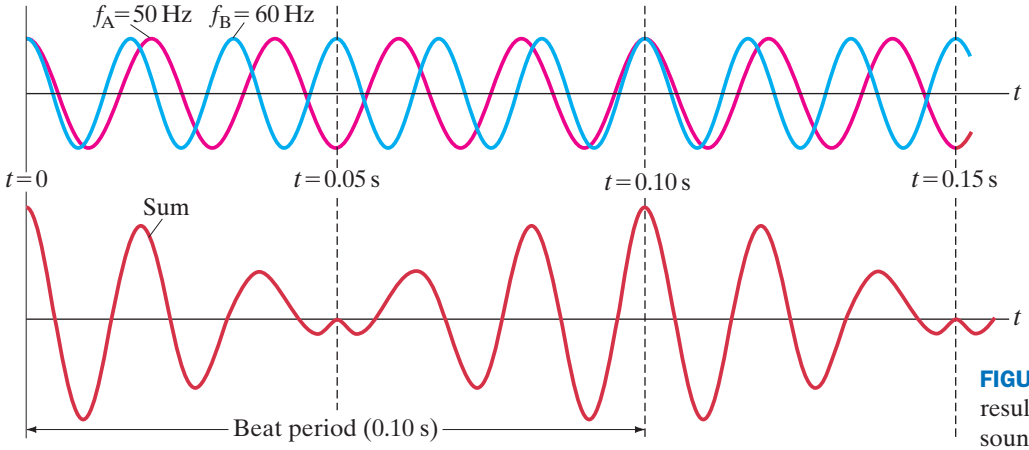

**FIGURE 16–17** Beats occur as a result of the superposition of two sound waves of slightly different frequency.

At $t = 0.10\,\text{s}$, they are again in phase and the resultant amplitude again is large. Thus the resultant amplitude is large every 0.10 s and drops drastically in between. This rising and falling of the intensity[†] is what is heard as beats. In this case the beats are 0.10 s apart. That is, the **beat frequency** is ten per second, or 10 Hz. This result, that the beat frequency equals the difference in frequency of the two waves $(60\,\text{s}^{-1} - 50\,\text{s}^{-1})$, is valid in general, as we now show.

Let the two waves, of frequencies $f_1$ and $f_2$, be represented at a fixed point in space by

$$D_1 = A \sin 2\pi f_1 t$$

and

$$D_2 = A \sin 2\pi f_2 t.$$

The resultant displacement, by the principle of superposition, is

$$D = D_1 + D_2 = A(\sin 2\pi f_1 t + \sin 2\pi f_2 t).$$

Using the trigonometric identity $\sin\theta_1 + \sin\theta_2 = 2\sin\frac{1}{2}(\theta_1 + \theta_2)\cos\frac{1}{2}(\theta_1 - \theta_2)$, we have

$$D = \left[2A\cos 2\pi\left(\frac{f_1 - f_2}{2}\right)t\right]\sin 2\pi\left(\frac{f_1 + f_2}{2}\right)t. \qquad \textbf{(16–8)}$$

We can interpret Eq. 16–8 as follows. The superposition of the two waves results in a wave that vibrates at the average frequency of the two components, $(f_1 + f_2)/2$. This vibration has an amplitude given by the expression in brackets, and this amplitude varies in time, from zero to a maximum of $2A$ (the sum of the separate amplitudes), with a frequency of $(f_1 - f_2)/2$. A beat occurs whenever $\cos 2\pi[(f_1 - f_2)/2]t$ equals $+1$ or $-1$, as we can see in Fig. 16–17; that is, two beats occur per cycle, so the beat frequency is twice $(f_1 - f_2)/2$ which equals $f_1 - f_2$, the difference in frequency of the component waves.

**PHYSICS APPLIED**
*Tuning a piano*

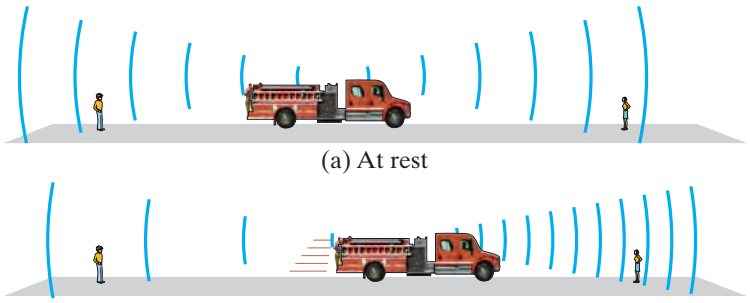
The phenomenon of beats can occur with any kind of wave and is a very sensitive method for comparing frequencies. For example, to tune a piano, a piano tuner begins by listening for beats produced between a standard tuning fork and the frequency of a particular string on the piano, and knows that string is in tune when the beats disappear. The members of an orchestra tune up by listening for beats between a standard tone, usually A above middle C at 440 Hz produced by a piano or an oboe, and an A on their instrument.

Humans hear individual beats if they are only a few per second. For higher beat frequencies, they run together and up to about 20 Hz or so you can still hear an intensity variation like beats (maybe like a buzz). Above 20 Hz you will mainly hear the two original tones, but if the tones are loud enough you may also hear a separate low tone equal to their frequency difference.

[†]Beats will be heard even if the amplitudes are not equal, as long as the difference in amplitude is not great.

**EXAMPLE 16–13** **Beats.** A tuning fork produces a steady 494-Hz tone. When this tuning fork is struck and held near a vibrating guitar string, twenty beats are counted in five seconds. What are the possible frequencies produced by the guitar string?

**APPROACH** For beats to occur, the string must vibrate at a frequency different from 494 Hz by whatever the beat frequency is.



**SOLUTION** The beat frequency is

$$f_{\text{beat}} = 20 \text{ vibrations}/5 \text{ s} = 4 \text{ Hz}.$$

This is the difference of the frequencies of the two waves. Because one wave is known to be 494 Hz, the other must be either 490 Hz or 498 Hz.

## 16–7 Doppler Effect

You may have noticed that you hear the pitch of the siren on a speeding fire truck drop abruptly as it passes you. Or you may have noticed the change in pitch of a blaring horn on a fast-moving car as it passes by you. The pitch of the engine noise of a race car changes as the car passes an observer. When a source of sound is moving toward an observer, the pitch the observer hears is higher than when the source is at rest; and when the source is traveling away from the observer, the pitch is lower. This phenomenon is known as the **Doppler effect**[†] and occurs for all types of waves. Let us now see why it occurs, and calculate the difference between the perceived and source frequencies when there is relative motion between source and observer.

(a) At rest

(b) Fire truck moving

**FIGURE 16–18** (a) Both observers on the sidewalk hear the same frequency from the fire truck at rest. (b) Doppler effect: the observer who sees the fire truck coming towards her hears a higher-frequency sound, and the observer behind the fire truck hears a lower-frequency sound.

Consider the siren of a fire truck at rest, which is emitting sound of a particular frequency in all directions as shown in Fig. 16–18a. The sound waves are moving at the speed of sound in air, $v_{\text{sound}}$, which is independent of the velocity of the source or observer. If our source, the fire truck, is moving, the siren emits sound at the same frequency as it does at rest. But the sound wavefronts it emits forward, in front of it, are closer together than when the fire truck is at rest, as shown in Fig. 16–18b. This is because the fire truck, as it moves, is partly "catching up" to the previously emitted wavefronts, and emits each crest closer to the previous one. Thus an observer on the sidewalk in front of the truck will detect more wave crests passing per second, so the frequency heard is higher. The wavefronts emitted behind the truck, on the other hand, are farther apart than when the truck is at rest because the truck is speeding away from them. Each new wavefront emitted is farther from the preceding one than when the truck is at rest. Hence, fewer wave crests per second pass by an observer behind the moving truck (Fig. 16–18b) and the perceived pitch is lower.

We can calculate the frequency shift by making use of Fig. 16–19. We assume the air (or other medium) is at rest in our reference frame. We consider first the stationary observer off to the right in Fig. 16–18. In Fig. 16–19a, the source of the sound is shown as a red dot, and is at rest. Two successive wave crests are shown, the first on the far right and the second, just emitted, is still near the source.

[†]After J. C. Doppler (1803–1853).

The distance between these crests in Fig. 16–19a is $\lambda$, the emitted wavelength. If the frequency of the source is $f$, then the time between emissions of wave crests is

$$T = \frac{1}{f} = \frac{\lambda}{v_{\text{sound}}}.$$

In Fig. 16–19b, the source is moving with a velocity $v_{\text{source}}$ toward the observer. In the time $T$ (just defined), the first wave crest has moved a distance $d = v_{\text{sound}}\,T = \lambda$, where $v_{\text{sound}}$ is the velocity of the sound wave in air (which is the same whether the source is moving or not). In this same time, the source itself has moved a distance $d_{\text{source}} = v_{\text{source}}\,T$. Then the distance between successive wave crests, which is the wavelength $\lambda'$, that the observer will perceive is

$$\begin{aligned}\lambda' &= d - d_{\text{source}} \\ &= \lambda - v_{\text{source}}\,T \\ &= \lambda - v_{\text{source}}\frac{\lambda}{v_{\text{sound}}} \\ &= \lambda\left(1 - \frac{v_{\text{source}}}{v_{\text{sound}}}\right).\end{aligned}$$

We subtract $\lambda$ from both sides of this equation and find that the shift in wavelength, $\Delta\lambda$, is

$$\Delta\lambda = \lambda' - \lambda = -\lambda\frac{v_{\text{source}}}{v_{\text{sound}}}.$$

So the shift in wavelength is directly proportional to the source speed $v_{\text{source}}$. The frequency $f'$ that will be perceived by our stationary observer on the ground is given by

$$f' = \frac{v_{\text{sound}}}{\lambda'} = \frac{v_{\text{sound}}}{\lambda\left(1 - \frac{v_{\text{source}}}{v_{\text{sound}}}\right)}.$$

Because $v_{\text{sound}}/\lambda = f$, then

$$f' = \frac{f}{\left(1 - \frac{v_{\text{source}}}{v_{\text{sound}}}\right)}. \qquad \left[\begin{array}{l}\text{source moving toward}\\ \text{stationary observer}\end{array}\right] \qquad \textbf{(16–9a)}$$

Because the denominator is less than 1, the observed frequency $f'$ is higher than the source frequency $f$. That is, $f' > f$. For example, if a source emits a sound of frequency 400 Hz when at rest, then when the source moves toward a fixed observer with a speed of 30 m/s, the observer hears a frequency (at 20°C) of

$$f' = \frac{400\text{ Hz}}{1 - \frac{30\text{ m/s}}{343\text{ m/s}}} = 438\text{ Hz}.$$

Now consider a source moving *away* from the stationary observer at a speed $v_{\text{source}}$ (observer on the left in Fig. 16–18). Using the same arguments as above, the wavelength $\lambda'$ perceived by our observer will have the minus sign on $d_{\text{source}}$ (second equation on this page) changed to plus:

$$\begin{aligned}\lambda' &= d + d_{\text{source}} \\ &= \lambda\left(1 + \frac{v_{\text{source}}}{v_{\text{sound}}}\right).\end{aligned}$$

The difference between the observed and emitted wavelengths will be $\Delta\lambda = \lambda' - \lambda = +\lambda\left(v_{\text{source}}/v_{\text{sound}}\right)$. The observed frequency of the wave is $f' = v_{\text{sound}}/\lambda' = (\lambda f)/\lambda'$, which equals

$$f' = \frac{f}{\left(1 + \frac{v_{\text{source}}}{v_{\text{sound}}}\right)}. \qquad \left[\begin{array}{l}\text{source moving away from}\\ \text{stationary observer}\end{array}\right] \qquad \textbf{(16–9b)}$$

If a source emitting at 400 Hz is moving away from a fixed observer at 30 m/s, the observer hears a frequency $f' = (400\text{ Hz})/\left[1 + (30\text{ m/s})/(343\text{ m/s})\right] = 368\text{ Hz}$.

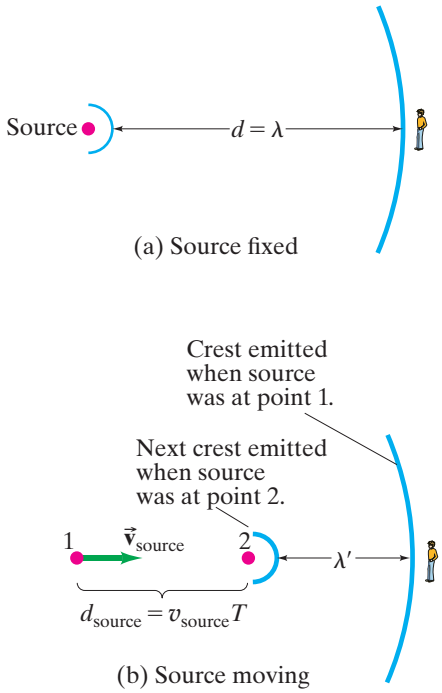


**FIGURE 16–19** Determination of the frequency shift in the Doppler effect (see text). The red dot is the source. The observer is on the far right. (a) Source fixed. (b) Source moving toward observer.

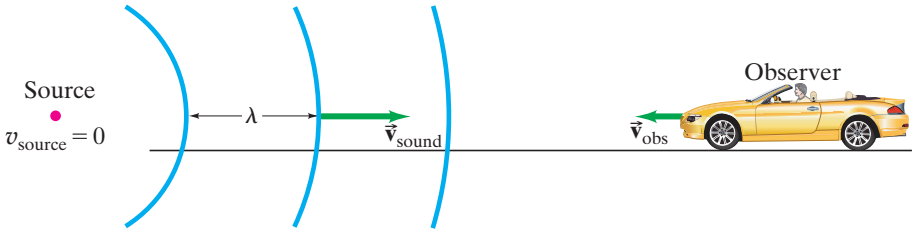

**FIGURE 16–20** Observer moving with speed $v_{obs}$ toward a stationary source detects wave crests passing at speed $v' = v_{sound} + v_{obs}$ where $v_{sound}$ is the speed of the sound waves in air.

The Doppler effect also occurs when the source is at rest and the *observer* is in motion. If the observer is traveling *toward* the source, as in Fig. 16–20, the pitch heard is higher than that of the emitted source frequency. If the observer is traveling *away* from the source, the pitch heard is lower. Quantitatively the change in frequency is different than for the case of a moving source. With a fixed source and a moving observer, the distance between wave crests, the wavelength $\lambda$, is not changed. But the velocity of the crests with respect to the observer *is* changed. If the observer is moving toward the source, Fig. 16–20, the speed $v'$ of the waves relative to the observer is a simple addition of velocities: $v' = v_{sound} + v_{obs}$, where $v_{sound}$ is the velocity of sound in air (we assume the air is still) and $v_{obs}$ is the velocity of the observer. Hence, the frequency $f'$ heard is

$$f' = \frac{v'}{\lambda} = \frac{v_{sound} + v_{obs}}{\lambda}.$$

Because $\lambda = v_{sound}/f$, where $f$ is the frequency of sound emitted by the source, then

$$f' = \frac{(v_{sound} + v_{obs})f}{v_{sound}},$$

or

$$f' = \left(1 + \frac{v_{obs}}{v_{sound}}\right)f. \qquad \begin{bmatrix}\text{observer moving toward}\\ \text{stationary source}\end{bmatrix} \quad \textbf{(16–10a)}$$

If the observer is moving *away* from the source, the relative velocity is $v' = v_{sound} - v_{obs}$, so

$$f' = \left(1 - \frac{v_{obs}}{v_{sound}}\right)f. \qquad \begin{bmatrix}\text{observer moving away}\\ \text{from stationary source}\end{bmatrix} \quad \textbf{(16–10b)}$$

**EXAMPLE 16–14** **A police siren.** The siren of a police car at rest emits at a predominant frequency of 1600 Hz. (*a*) What frequency will you hear if you are at rest and the police car moves at 25.0 m/s toward you? (*b*) What frequency do you hear if you drive 25.0 m/s toward the police car which is at rest?

**APPROACH** The observer is fixed in (*a*), and the source moves, so we use Eqs. 16–9. The frequency you (the observer) hear is the emitted frequency $f$ divided by the factor $\left(1 \pm v_{source}/v_{sound}\right)$ where $v_{source}$ is the speed of the police car. Use the minus sign when the car moves toward you (giving a higher frequency); use the plus sign when the car moves away from you (lower frequency). In (*b*), you move but the source is at rest, so we use Eqs. 16–10.

**SOLUTION** (*a*) The car is moving toward you (at rest), so (Eq. 16–9a)

$$f' = \frac{f}{\left(1 - \frac{v_{source}}{v_{sound}}\right)} = \frac{1600\text{ Hz}}{\left(1 - \frac{25.0\text{ m/s}}{343\text{ m/s}}\right)} = 1726\text{ Hz} \approx 1730\text{ Hz}.$$

(*b*) You are moving toward a stationary source so we use Eq. 16–10a:

$$f' = \left(1 + \frac{v_{obs}}{v_{sound}}\right)f = \left(1 + \frac{25.0\text{ m/s}}{343\text{ m/s}}\right)(1600\text{ Hz}) = 1717\text{ Hz}.$$

**EXERCISE F** (*a*) What frequency would you hear if you were moving at 25.0 m/s away from a stationary police car whose siren emits at 1600 Hz? (*b*) What if you are at rest and the police car moves away from you at a speed of 25.0 m/s?

When a sound wave is reflected from a moving obstacle, the frequency of the reflected wave will be different from that of the incident wave because of the Doppler effect. This is illustrated in the following Example.

**EXAMPLE 16–15** **Two Doppler shifts.** A pure 5000-Hz sound wave is emitted by a stationary source. This sound wave reflects from an object moving 3.50 m/s toward the source (Fig. 16–21). What is the frequency of the wave reflected by the moving object as detected by a detector at rest near the source?

**APPROACH** There are actually two Doppler shifts in this situation. First, the moving object acts like an observer moving toward the source with speed $v_{obs} = 3.50\,\text{m/s}$ (Fig. 16–21a) and so "detects" a sound wave of frequency (Eq. 16–10a) $f' = f\left[1 + (v_{obs}/v_{sound})\right]$. Second, reflection of the wave from the moving object is equivalent to the object reemitting the wave at the same frequency $f'$, and thus acting effectively as a moving source with speed $v_{source} = 3.50\,\text{m/s}$ (Fig. 16–21b). The final frequency detected, $f''$, is given by $f'' = f'/\left[1 - (v_{source}/v_{sound})\right]$, Eq. 16–9a.

**SOLUTION** The frequency $f'$ that is "detected" by the moving object is (Eq. 16–10a):

$$f' = \left(1 + \frac{v_{obs}}{v_{sound}}\right) f = \left(1 + \frac{3.50\,\text{m/s}}{343\,\text{m/s}}\right)(5000\,\text{Hz}) = 5051\,\text{Hz}.$$

The moving object now "emits" (reflects) a sound of frequency (Eq. 16–9a)

$$f'' = \frac{f'}{\left(1 - \dfrac{v_{source}}{v_{sound}}\right)} = \frac{5051\,\text{Hz}}{\left(1 - \dfrac{3.50\,\text{m/s}}{343\,\text{m/s}}\right)} = 5103\,\text{Hz}.$$

Thus the frequency shifts by 103 Hz.

**NOTE** Bats use this technique to be aware of their surroundings. This is also the principle behind Doppler radar as speed-measuring devices for vehicles, baseball pitches, tennis serves, storms such as tornadoes, and other objects.

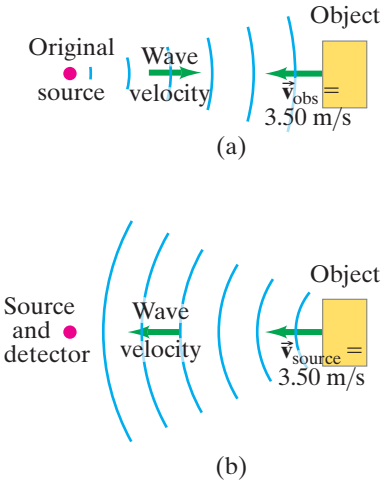

**FIGURE 16–21** Example 16–15.

**PHYSICS APPLIED**
*Bats use Doppler*

The emitted wave and the reflected wave in Example 16–15, when mixed together (say, electronically), interfere with one another and beats are produced. The beat frequency is equal to the difference in the two frequencies, 103 Hz. This Doppler technique is used in a variety of medical applications, usually with ultrasonic waves in the megahertz frequency range. For example, ultrasonic waves reflected from red blood cells can be used to determine the velocity of blood flow. Similarly, the technique can be used to detect the movement of the chest of a young fetus and to monitor its heartbeat.

**PHYSICS APPLIED**
*Doppler blood-flow meter and other medical uses*

For convenience, we can write Eqs. 16–9 and 16–10 as a single equation that covers all cases of both source and observer in motion:

$$f' = f\left(\frac{v_{sound} \pm v_{obs}}{v_{sound} \mp v_{source}}\right). \qquad \left[\begin{array}{l}\text{source and}\\ \text{observer moving}\end{array}\right] \quad \textbf{(16–11)}$$

To get the signs right, recall from your own experience that the frequency is higher when observer and source approach each other, and lower when they move apart. Thus the upper signs in numerator and denominator apply if source and/or observer move toward each other; the lower signs apply if they are moving apart.

**PROBLEM SOLVING**
*Getting the signs right*

**EXERCISE G** How fast would a source have to approach an observer at rest for the observed frequency to be one octave above the produced frequency (frequency doubled)? (*a*) $\frac{1}{2}v_{sound}$, (*b*) $v_{sound}$, (*c*) $2v_{sound}$, (*d*) $4v_{sound}$.

## Doppler Effect for Light

**PHYSICS APPLIED**
*Doppler effect for EM waves, weather forecasting, speed traps*

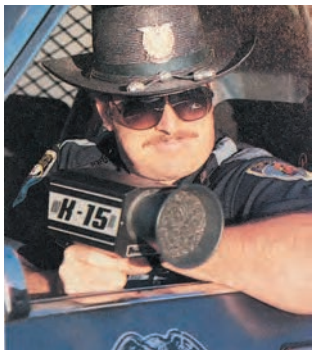

**FIGURE 16–22** Gotcha. Your friendly sheriff checking your speed.

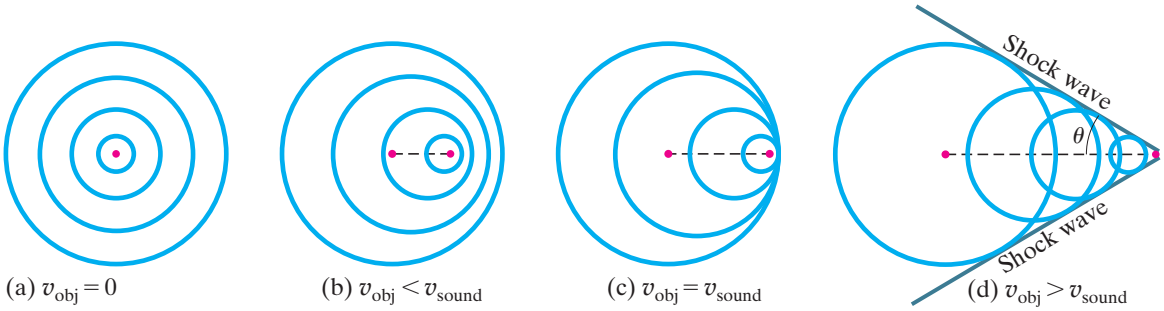
The Doppler effect occurs for waves other than sound. Light and other types of electromagnetic waves (such as for radar) exhibit the Doppler effect: although the formulas for the frequency shift are not identical to Eqs. 16–9 and 16–10, the effect is similar (see Chapter 44). One important application is for *weather forecasting* using radar. The time delay between the emission of a radar pulse and its reception after being reflected off raindrops gives the position of precipitation. Measuring the Doppler shift in frequency (as in Example 16–15) tells how fast the storm is moving and in which direction. *Radar guns* used by police (Fig. 16–22) work similarly, measuring a car's speed by the Doppler shift of electromagnetic waves. So too the speed of tennis balls and baseballs when shown on our TV screens.

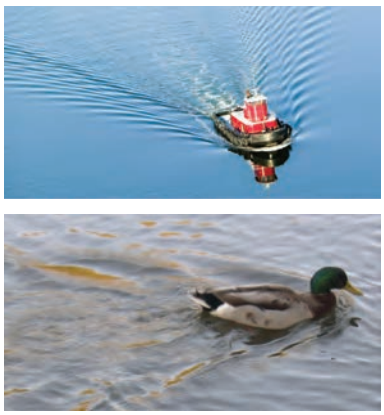
Another important application is to astronomy, where the velocities of galaxies can be estimated from the Doppler shift. It is observed that light from all distant galaxies is shifted toward lower frequencies, indicating that the galaxies are moving away from us. This is called the **redshift** since red has the lowest frequency of visible light. The greater the frequency shift, the greater the velocity of recession. It is also observed that the farther the galaxies are from us, the faster they move away. These observations are the basis for the idea that the universe is expanding, and that the universe had a beginning called the "Big Bang," which would mean that the universe started very small and then expanded enormously over 14 billion years (Chapter 44).

**PHYSICS APPLIED**
*Redshift in cosmology*

# *16–8 Shock Waves and the Sonic Boom

An object such as an airplane traveling faster than the speed of sound is said to have a **supersonic speed**. Such a speed is often given as a **Mach**[†] **number**, which is defined as the ratio of the speed of the object to the speed of sound in the surrounding medium. For example, a plane traveling 600 m/s high in the atmosphere, where the speed of sound is only 300 m/s, has a speed of Mach 2.





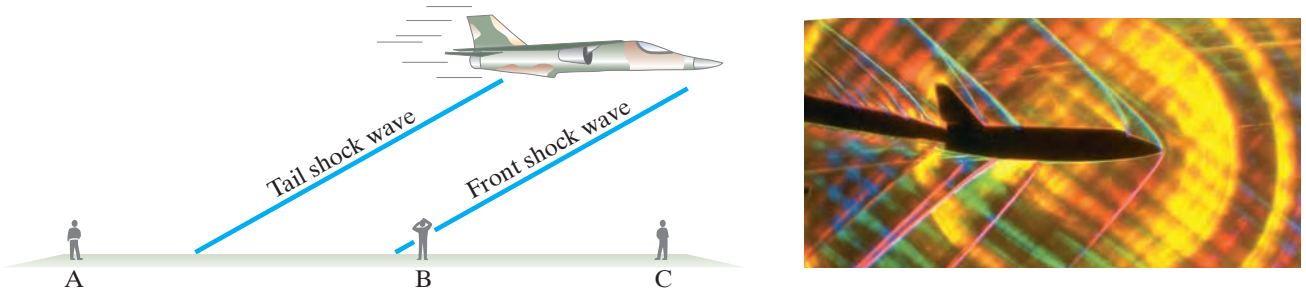


**FIGURE 16–23** Sound waves emitted by an object, the red dot, (a) at rest or (b, c, and d) moving. (b) If the object's velocity is less than the velocity of sound, the Doppler effect occurs (note wavelength changes in front of and behind the moving object, as in Fig. 16–18b). (c) At $v_{obj} = v_{sound}$, the waves pile up in front, forming a "sound barrier." (d) If the object's velocity is greater than the velocity of sound, a shock wave is produced.

**FIGURE 16–24** Bow waves produced by (a) a boat, (b) a duck.

When a source of sound moves at subsonic speeds (less than the speed of sound), the pitch of the sound is altered as we have seen (the Doppler effect); see also Figs. 16–23a and b. But if a source of sound moves faster than the speed of sound, a more dramatic effect known as a **shock wave** occurs. In this case, the source is actually "outrunning" the waves it produces. As shown in Fig. 16–23c, when the source is traveling *at* the speed of sound, the wave fronts it emits in the forward direction "pile up" directly in front of it, forming a *sound barrier* (see next page). When the object moves faster, at a supersonic speed, the wave fronts pile up on one another along the sides, as shown in Fig. 16–23d. The different wave crests overlap one another and form a single very large crest which is the shock wave. Behind this very large crest there is usually a very large trough. A shock wave is essentially the result of constructive interference of a large number of wave fronts. A shock wave in air is analogous to the *bow wave* of a boat (or duck) traveling faster than the speed of the water waves it produces, Fig. 16–24.

[†]After the Austrian physicist Ernst Mach (1838–1916).

(a) (b)

**FIGURE 16–25** (a) The (double) sonic boom has already been heard by person A on the left. The front shock wave is just being heard by person B in the center. And both shock waves will shortly be heard by person C on the right. (b) Special photo of supersonic aircraft showing shock waves produced by different parts of the aircraft in the air.

When an airplane travels at supersonic speeds, greater than the speed of sound in the air, the noise it makes and its disturbance of the air form into a shock wave containing a tremendous amount of sound energy. When the shock wave passes a listener, it is heard as a loud **sonic boom**. A sonic boom lasts only a fraction of a second, but the energy it contains is sometimes sufficient to break windows and cause other damage. Actually, a sonic boom is made up of two or more booms since major shock waves can form at the front and the rear of the aircraft (Fig. 16–25), as well as at the wings and other parts. Bow waves of a boat are also multiple, as can be seen in Fig. 16–24a.

**PHYSICS APPLIED**
*Sonic boom*

When an aircraft accelerates toward the speed of sound, it encounters a barrier of sound waves in front of it (see Fig. 16–23c). To exceed the speed of sound, the aircraft needs extra thrust to pass through this **sound barrier**. This is called "breaking the sound barrier." Once a supersonic speed is attained, this barrier no longer impedes the motion. It is sometimes erroneously thought that a sonic boom is produced only at the moment an aircraft is breaking through the sound barrier. Actually, a shock wave follows the aircraft at all times it is traveling at supersonic speeds. A series of observers on the ground will each hear a loud "boom" as the shock wave passes, Fig. 16–25. The shock wave consists of a cone whose apex is at the aircraft. The angle of this cone, $\theta$ (see Fig. 16–23d), is given by

$$\sin\theta = \frac{v_{\text{sound}}}{v_{\text{obj}}}, \qquad \textbf{(16–12)}$$

where $v_{\text{obj}}$ is the velocity of the object (the aircraft) and $v_{\text{sound}}$ is the velocity of sound in the medium (air for an airplane) where the airplane is moving.

# *16–9 Applications: Sonar, Ultrasound, and Medical Imaging

## *Sonar

The reflection of sound is used in many applications to determine distance. The **sonar**[†] or **pulse-echo** technique is used to locate underwater objects. A transmitter sends out a sound pulse through the water, and a detector receives its reflection, or echo, a short time later. This time interval is carefully measured, and from it the distance to the reflecting object can be determined since the speed of sound in water is known. The depth of the sea and the location of reefs, sunken ships, submarines, or schools of fish can be determined in this way. The interior structure of the Earth is studied in a similar way by detecting reflections of waves traveling through the Earth whose source was a deliberate explosion (called "soundings"). An analysis of waves reflected from various structures and boundaries within the Earth reveals characteristic patterns that are also useful in the exploration for oil and minerals. (*Radar* used at airports to track aircraft involves a similar pulse-echo technique except that it uses electromagnetic (EM) waves, which, like visible light, travel with a speed of $3 \times 10^8$ m/s.)

**PHYSICS APPLIED**
*Sonar: depth finding, Earth soundings*

[†]Sonar stands for "*so*und *na*vigation *r*anging."

Sonar generally makes use of **ultrasonic** frequencies: that is, sound waves whose frequencies are above 20 kHz, beyond the range of human hearing. For sonar, the frequencies are typically in the range 20 kHz to 100 kHz. One reason for using ultrasound waves, other than the fact that they are inaudible, is that for these shorter wavelengths there is less diffraction (Section 15–11) so the beam spreads less, plus smaller objects can be detected.

## *Ultrasound Medical Imaging

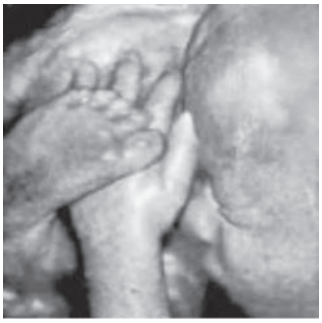

**FIGURE 16–26** Ultrasound image of a human fetus within the uterus.

**PHYSICS APPLIED**
*Ultrasound medical imaging*

The diagnostic use of ultrasound in medicine, in the form of images (sometimes called *sonograms*), is an important and interesting application of physical principles. A **pulse-echo technique** is used, much like sonar, except that the frequencies used are in the range of 1 to 10 MHz $(1\text{ MHz} = 10^6\text{ Hz})$. A high-frequency sound pulse is directed into the body, and its reflections from boundaries or interfaces between organs and other structures and lesions in the body are then detected. *Tumors* and other abnormal growths, or pockets of fluid, can be distinguished; the action of heart valves and the development of a fetus (Fig. 16–26) can be examined; and information about various organs of the body, such as the brain, heart, liver, and kidneys, can be obtained. Although ultrasound does not replace X-rays, for certain kinds of diagnosis it is more helpful. Some kinds of tissue or fluid are not detected in X-ray photographs, but ultrasound waves are reflected from their boundaries. "Real-time" ultrasound images are like a movie of a section of the interior of the body.

The pulse-echo technique for medical imaging works like this. A brief pulse of ultrasound is emitted by a transducer that transforms an electrical pulse into a sound-wave pulse. Part of the pulse is reflected as echoes at each interface in the body, and most of the pulse (usually) continues on, Fig. 16–27a.

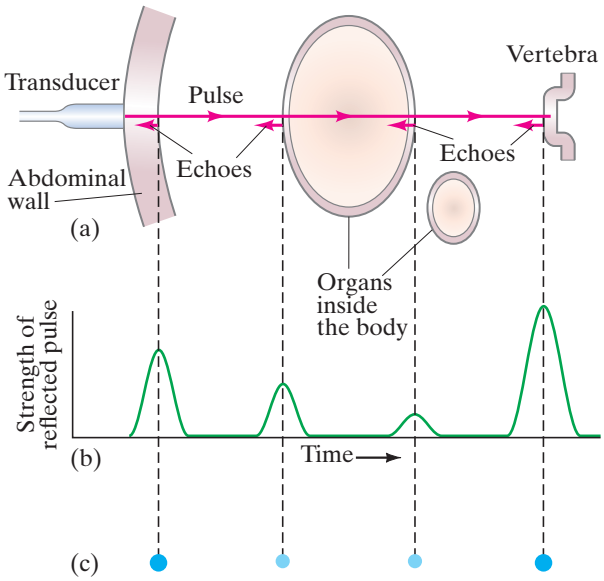

**FIGURE 16–27** (a) Ultrasound pulse passes through the abdomen, reflecting from surfaces in its path. (b) Reflected pulses plotted as a function of time when received by transducer. The vertical dashed lines point out which reflected pulse goes with which surface. (c) "Dot display" for the same echoes: brightness of each dot is related to signal strength.

The detection of reflected pulses by the same transducer can then be displayed on the screen of a display monitor. The time elapsed from when the pulse is emitted to when each reflection (echo) is received is proportional to the distance to the reflecting surface. For example, if the distance from the transducer to the vertebra is 25 cm, the pulse travels a round-trip distance of $2 \times 25\text{ cm} = 0.50\text{ m}$. The speed of sound in human tissue is about 1540 m/s (close to that of sea water), so the time taken is

$$t = \frac{d}{v} = \frac{(0.50\text{ m})}{(1540\text{ m/s})} = 320\,\mu\text{s}.$$

The *strength* of a reflected pulse depends mainly on the difference in density of the two materials on either side of the interface and can be displayed as a pulse or as a dot (Figs. 16–27b and c). Each echo dot (Fig. 16–27c) can be represented as a point whose position is given by the time delay and whose brightness

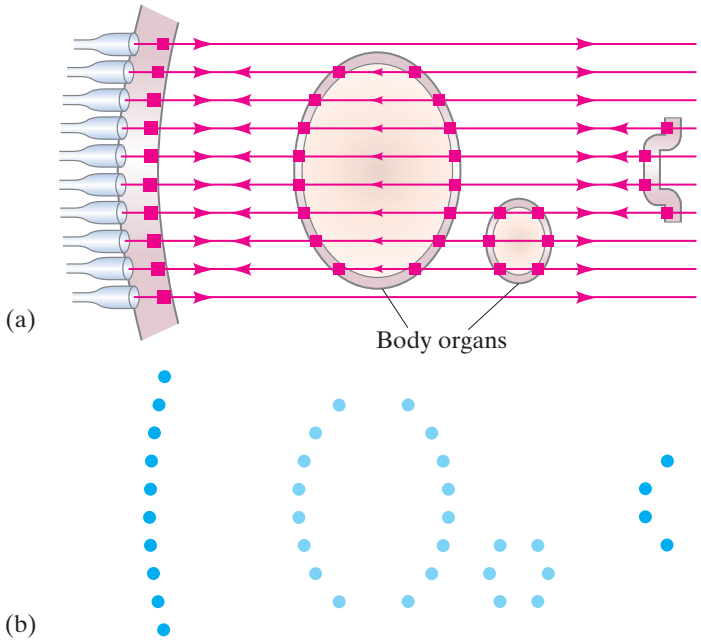

**FIGURE 16–28** (a) Ten traces are made across the abdomen by moving the transducer, or by using an array of transducers. (b) The echoes from interfaces or boundaries (of organs) are plotted as dots to produce the image. More closely spaced traces would give a more detailed image.

depends on the strength of the echo. A two-dimensional image can then be formed out of these dots from a series of scans. The transducer is moved, or an array of transducers is used, each of which sends out a pulse at each position and receives echoes as shown in Fig. 16–28a. Each trace can be plotted, spaced appropriately one below the other, to form an image on a monitor screen as shown in Fig. 16–28b. Only 10 lines are shown in Fig. 16–28, so the image is very low resolution. More lines give a higher resolution image.

This type of ultrasound image shows the shape and position of objects such as internal organs. A **Doppler ultrasound image** uses the Doppler effect to measure movement of tissues (for a heart beating it is called, *Doppler echocardiography*) and the flow speed of fluids such as blood. Example 16–15, and the paragraph below it on page 479, discussed how this is done.

# Summary

Sound travels as a longitudinal wave in air and other materials. In air, the speed of sound increases with temperature. At 20°C, it is about 343 m/s.

The **pitch** of a sound is determined by the frequency; the higher the frequency, the higher the pitch.

The **audible range** of frequencies for humans is at best about 20 Hz to 20,000 Hz (1 Hz = 1 cycle per second).

The **loudness** or **intensity** of a sound is related to the amplitude squared of the wave. Because the human ear can detect sound intensities from $10^{-12}\,\text{W/m}^2$ to over $1\,\text{W/m}^2$, sound levels are specified on a logarithmic scale. The **sound level** $\beta$, specified in decibels, is defined in terms of intensity $I$ as

$$\beta(\text{in dB}) = 10\log\left(\frac{I}{I_0}\right), \qquad \textbf{(16–6)}$$

where the reference intensity $I_0$ is usually taken to be $10^{-12}\,\text{W/m}^2$.

Musical instruments are simple sources of sound in which *standing waves* are produced.

The strings of a stringed instrument may vibrate as a whole with nodes only at the ends; the frequency at which this standing wave occurs is called the **fundamental**. The fundamental frequency corresponds to a wavelength equal to twice the length of the string, $\lambda_1 = 2\ell$. The string can also vibrate at higher frequencies, called **overtones** or **harmonics**, in which there are one or more additional nodes on the string. The frequency of each harmonic is a whole-number multiple of the fundamental.

In wind instruments, standing waves are set up in the column of air within the tube.

The vibrating air in an **open tube** (open at both ends) has displacement antinodes at both ends. The fundamental frequency corresponds to a wavelength equal to twice the tube length: $\lambda_1 = 2\ell$. The harmonics have frequencies that are 1, 2, 3, 4, $\cdots$ times the fundamental frequency, just as for strings.

For a **closed tube** (closed at one end), the fundamental corresponds to a wavelength four times the length of the tube: $\lambda_1 = 4\ell$. Only the odd harmonics are present, equal to 1, 3, 5, 7, $\cdots$ times the fundamental frequency.

Sound waves from different sources can interfere with each other. If two sounds are at slightly different frequencies, **beats** can be heard at a frequency equal to the difference in frequency of the two sources.

The **Doppler effect** refers to the change in the pitch of a sound due to the motion of the source or of the observer. If source and observer are approaching each other, the perceived pitch is higher. If they are moving apart, the perceived pitch is lower.

[*Shock waves and a sonic boom occur when an object moves at a **supersonic** speed—faster than the speed of sound. **Ultrasonic**-frequency (higher than 20 kHz) sound waves are used in many applications, including sonar and medical imaging.]

# Questions

1. What is the evidence that sound travels as a wave?
2. What is the evidence that sound is a form of energy?
3. Children sometimes play with a homemade "telephone" by attaching a string to the bottoms of two paper cups. When the string is stretched and a child speaks into one cup, the sound can be heard at the other cup (Fig. 16–29). Explain clearly how the sound wave travels from one cup to the other.

**FIGURE 16–29** Question 3.

4. When a sound wave passes from air into water, do you expect the frequency or wavelength to change?
5. What evidence can you give that the speed of sound in air does not depend significantly on frequency?
6. The voice of a person who has inhaled helium sounds very high-pitched. Why?
7. Two tuning forks oscillate with the same amplitude, but one has twice the frequency. Which (if either) produces the more intense sound?
8. How will the air temperature in a room affect the pitch of organ pipes?
9. Explain how a tube might be used as a filter to reduce the amplitude of sounds in various frequency ranges. (An example is a car muffler.)
10. Why are the frets on a guitar (Fig. 16–30) spaced closer together as you move up the fingerboard toward the bridge?

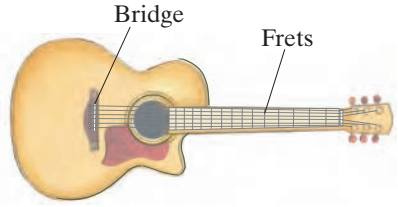

**FIGURE 16–30** Question 10.

11. Why do the strings used for the lowest-frequency notes on a piano normally have wire wrapped around them?
12. A noisy truck approaches you from behind a building. Initially you hear it but cannot see it. When it emerges and you do see it, its sound is suddenly "brighter"—you hear more of the high-frequency noise. Explain. [*Hint*: See Section 15–11 on diffraction.]
13. Traditional methods of protecting the hearing of people who work in areas with very high noise levels have consisted mainly of efforts to block or reduce noise levels. *Noise-cancelling headphones* use a detector which detects the noise, inverts it electronically, then feeds it to the headphones *in addition to* the original loud noise. How could adding *more* noise reduce the sound levels reaching the ears?
14. In Fig. 16–16, if the frequency of the speakers is lowered, would the points D and C (where destructive and constructive interference occur) move farther apart or closer together?
15. Standing waves can be said to be due to "interference in space," whereas beats can be said to be due to "interference in time." Explain.
16. Consider the two waves shown in Fig. 16–31. Each wave can be thought of as a superposition of two sound waves with slightly different frequencies, as in Fig. 16–17. In which of the waves, (a) or (b), are the two component frequencies farther apart? Explain.

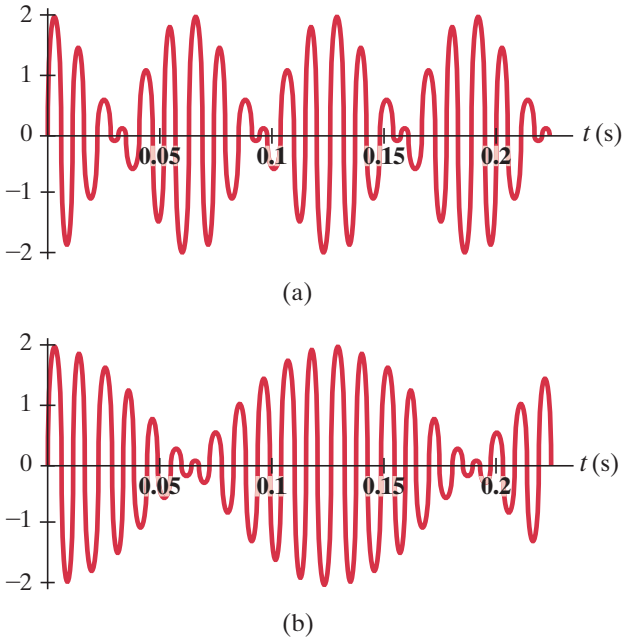

**FIGURE 16–31** Question 16.

17. Is there a Doppler shift if the source and observer move in the same direction, with the same velocity? Explain.
18. If a wind is blowing, will this alter the frequency of the sound heard by a person at rest with respect to the source? Is the wavelength or velocity changed?
19. Figure 16–32 shows various positions of a child on a swing moving toward a person on the ground who is blowing a whistle. At which position, A through E, will the child hear the highest frequency for the sound of the whistle? Explain your reasoning.

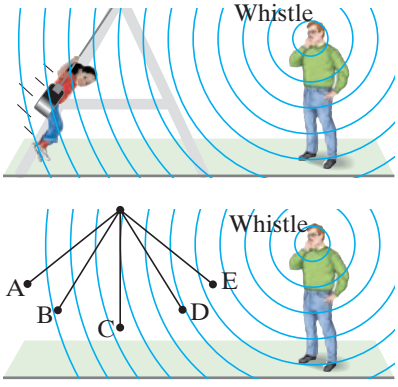

**FIGURE 16–32** Question 19.

# MisConceptual Questions

**1.** Do you expect an echo to return to you more quickly on a hot day or a cold day?
(*a*) Hot day.
(*b*) Cold day.
(*c*) Same on both days.

**2.** Sound waves are
(*a*) transverse waves characterized by the displacement of air molecules.
(*b*) longitudinal waves characterized by the displacement of air molecules.
(*c*) longitudinal waves characterized by pressure differences.
(*d*) Both (*b*) and (*c*).
(*e*) (*a*), (*b*), and (*c*).

**3.** The sound level near a noisy air conditioner is 70 dB. If two such units operate side by side, the sound level near them would be
(*a*) 70 dB.
(*b*) 73 dB.
(*c*) 105 dB.
(*d*) 140 dB.

**4.** To make a given sound seem twice as loud, how should a musician change the intensity of the sound?
(*a*) Double the intensity.
(*b*) Halve the intensity.
(*c*) Quadruple the intensity.
(*d*) Quarter the intensity.
(*e*) Increase the intensity by a factor of 10.

**5.** A musical note that is two octaves higher than a second note
(*a*) has twice the frequency of the second note.
(*b*) has four times the frequency of the second note.
(*c*) has twice the amplitude of the second note.
(*d*) is 3 dB louder than the second note.
(*e*) None of the above.

**6.** In which of the following is the wavelength of the fundamental vibration mode the same as the length of the string or tube?
(*a*) A string.
(*b*) An open tube.
(*c*) A tube closed at one end.
(*d*) All of the above.
(*e*) None of the above.

**7.** When a sound wave passes from air into water, what properties of the wave will change?
(*a*) Frequency.
(*b*) Wavelength.
(*c*) Wave speed.
(*d*) Both frequency and wavelength.
(*e*) Both wave speed and wavelength.

**8.** A guitar string vibrates at a frequency of 330 Hz with wavelength 1.40 m. The frequency and wavelength of this sound in air (20°C) as it reaches our ears are
(*a*) same frequency, same wavelength.
(*b*) higher frequency, same wavelength.
(*c*) lower frequency, same wavelength.
(*d*) same frequency, longer wavelength.
(*e*) same frequency, shorter wavelength.

**9.** A guitar player shortens the length of a guitar's vibrating string by pressing the string straight down onto a fret. The guitar then emits a higher-pitched note, because
(*a*) the string's tension has been increased.
(*b*) the string can vibrate with a much larger amplitude.
(*c*) the string vibrates at a higher frequency.

**10.** An organ pipe with a fundamental frequency $f$ is open at both ends. If one end is closed off, the fundamental frequency will
(*a*) drop by half.
(*b*) not change.
(*c*) double.

**11.** "Hearing the ocean" by holding a sea shell close to your ear (Fig. 16–33) can be done also by using an empty paper towel tube. When you hold such a cardboard tube next to your ear, how would the sound of the "roaring ocean" change if you cover the other end of the tube with your hand?
(*a*) Pitch increases.
(*b*) Pitch decreases.
(*c*) Pitch doesn't change.

**FIGURE 16–33**
MisConceptual Question 11.

**12.** *Middle C* played on a piano sounds different from middle C played on a flute because
(*a*) the two instruments produce a different mix of harmonics.
(*b*) the frequency differs between the two instruments.
(*c*) the fundamental wave amplitudes are different.
(*d*) None of the above.

**13.** You are driving at 75 km/h. Your sister follows in the car behind at 75 km/h. When you honk your horn, your sister hears a frequency
(*a*) higher than the frequency you hear.
(*b*) lower than the frequency you hear.
(*c*) the same as the frequency you hear.
(*d*) You cannot tell without knowing the horn's frequency.

**14.** A guitar string is vibrating at its fundamental frequency $f$. Which of the following is *not* true?
(*a*) Each small section of the guitar string oscillates up and down at a frequency $f$.
(*b*) The wavelength of the standing wave on the guitar string is $\lambda = v/f$, where $v$ is the velocity of the wave on the string.
(*c*) A sound wave created by this vibrating string propagates through the air with frequency $f$.
(*d*) A sound wave created by this vibrating string propagates through the air with wavelength $\lambda = v/f$, where $v$ is the velocity of sound in air.
(*e*) The wavelength of the standing wave on the guitar string is $\lambda = \ell$, where $\ell$ is the length of the string.

# Problems

[Unless stated otherwise, assume $T = 20°C$ and $v_{sound} = 343$ m/s in air.]

## 16–1 Characteristics of Sound

1. (I) A hiker determines the length of a lake by listening for the echo of her shout reflected by a cliff at the far end of the lake. She hears the echo 3 s after shouting. Estimate the length of the lake.
2. (I) (*a*) Calculate the wavelengths in air at 20°C for sounds in the maximum range of human hearing, 20 Hz to 20,000 Hz. (*b*) What is the wavelength of a 22-MHz ultrasonic wave?
3. (II) On a warm summer day (31°C), it takes 4.40 s for an echo to return from a cliff across a lake. On a winter day, it takes 4.80 s. What is the temperature on the winter day?
4. (II) An ocean fishing boat is drifting just above a school of tuna on a foggy day. Without warning, an engine backfire occurs on another boat 1.55 km away (Fig. 16–34). How much time elapses before the backfire is heard (*a*) by the fish, and (*b*) by the fishermen?

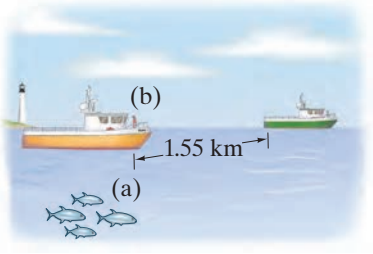

**FIGURE 16–34** Problem 4.

5. (II) Calculate the percent error made over one mile of distance by the "5-second rule" for estimating the distance from a lightning strike if the temperature is (*a*) 30°C, and (*b*) 10°C.
6. (III) A stone is dropped from the top of a cliff. The splash it makes when striking the water below is heard 2.5 s later. How high is the cliff?

## 16–2 Mathematical Representation of Waves

7. (I) The pressure amplitude of a sound wave in air $(\rho = 1.29\ \text{kg/m}^3)$ at 0°C is $3.0 \times 10^{-3}$ Pa. What is the displacement amplitude if the frequency is (*a*) 250 Hz and (*b*) 25 kHz?
8. (I) What must be the pressure amplitude in a sound wave in air (0°C) if the air molecules undergo a maximum displacement equal to the diameter of an oxygen molecule, about $3.0 \times 10^{-10}$ m? Assume a sound-wave frequency of (*a*) 75 Hz and (*b*) 7.5 kHz.
9. (II) Write an expression that describes the pressure variation as a function of $x$ and $t$ for the waves described in Problem 8.
10. (II) The pressure variation in a sound wave is given by

$$\Delta P = 0.0035 \sin(0.38\pi x - 1220\pi t),$$

where $\Delta P$ is in pascals, $x$ in meters, and $t$ in seconds. Determine (*a*) the wavelength, (*b*) the frequency, (*c*) the speed, and (*d*) the displacement amplitude of the wave. Assume the density of the medium to be $\rho = 2.3 \times 10^3\ \text{kg/m}^3$.

## 16–3 Intensity of Sound; Decibels

11. (I) What is the sound level of a sound whose intensity is $3.0 \times 10^{-6}\ \text{W/m}^2$?
12. (I) A 5000-Hz tone must have what sound level to seem as loud as a 100-Hz tone that has a 50-dB sound level? (See Fig. 16–6.)
13. (I) What are the lowest and highest frequencies that an ear can detect when the sound level is 40 dB? (See Fig. 16–6.)
14. (II) (*a*) What is the intensity of a sound at the pain level of 120 dB? (*b*) By what factor is the intensity greater than that of a whisper at 20 dB?
15. (II) Your ears can accommodate a huge range of sound levels. What is the ratio of highest to lowest intensity at (*a*) 100 Hz, (*b*) 5000 Hz? (See Fig. 16–6.)
16. (II) One CD player is said to have a *signal-to-noise ratio* of 86 dB, whereas for a second CD player it is 98 dB. What is the ratio of intensities of the signal and the background noise for each device?
17. (II) A person standing a certain distance from an airplane with four equally noisy jet engines is experiencing a sound level of 140 dB. What sound level would this person experience if the captain shut down all but one engine? [*Hint*: Add intensities, not dBs.]
18. (II) A 45-dB sound wave strikes an eardrum whose area is $5.0 \times 10^{-5}\ \text{m}^2$. (*a*) How much energy is received by the eardrum per second? (*b*) At this rate, how long would it take your eardrum to receive a total energy of 1.0 J?
19. (II) A fireworks shell explodes 100 m above the ground, creating colorful sparks. How much greater is the sound level of the explosion for a person at a point directly below the explosion than for a person a horizontal distance of 200 m away (Fig. 16–35)?

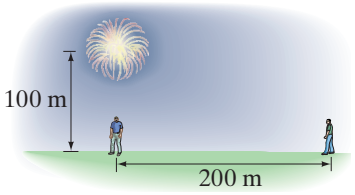

**FIGURE 16–35** Problem 19.

20. (II) At a rock concert, a dB meter registered 130 dB when placed 2.8 m in front of a loudspeaker on stage. (*a*) What was the power output of the speaker, assuming uniform spherical spreading of the sound and neglecting absorption in the air? (*b*) How far away would the sound level be 85 dB?
21. (II) (*a*) Calculate the maximum displacement of air molecules when a 440-Hz sound wave passes whose intensity is at the threshold of pain (120 dB). (*b*) What is the pressure amplitude in this wave?
22. (II) If the amplitude of a sound wave is made 3.5 times greater, (*a*) by what factor will the intensity increase? (*b*) By how many dB will the sound level increase?
23. (II) Two sound waves have equal displacement amplitudes, but one has 3.5 times the frequency of the other. (*a*) Which has the greater pressure amplitude and by what factor is it greater? (*b*) What is the ratio of their intensities?

24. (II) A jet plane emits $5.0 \times 10^5$ J of sound energy per second. (*a*) What is the sound level 25 m away? Now consider that air absorbs sound at a rate of about 7.0 dB/km; calculate what the sound level will be (*b*) 1.00 km and (*c*) 5.00 km away from this jet plane, taking into account air absorption.

25. (II) (*a*) Estimate the power output of sound from a person speaking in normal conversation. Use Table 16–2. Assume the sound spreads roughly uniformly over a sphere centered on the mouth. (*b*) How many people would it take to produce a total sound output of 60 W of ordinary conversation? [*Hint*: Add intensities, not dBs.]

26. (II) What would be the sound level (in dB) of a sound wave in air that corresponds to a displacement amplitude of vibrating air molecules of 0.15 mm at 440 Hz?

27. (II) Expensive amplifier A is rated at 280 W, while the more modest amplifier B is rated at 45 W. (*a*) Estimate the sound level in decibels you would expect at a point 3.5 m from a loudspeaker connected in turn to each amp set to full output. (*b*) What output wattage amp would sound about twice as loud as the 45-W amp?

## 16–4 Sources of Sound: Strings and Air Columns

28. (I) What would you estimate for the length of a bass clarinet, assuming that it is modeled as a closed tube and that the lowest note that it can play is a $D^\flat$ whose frequency is 69 Hz?

29. (I) An organ pipe is 108 cm long. Determine the fundamental and first three audible overtones if the pipe is (*a*) closed at one end, and (*b*) open at both ends.

30. (I) If you were to build a pipe organ with open-tube pipes spanning the range of human hearing (20 Hz to 20 kHz), what would be the range of the lengths of pipes required?

31. (II) Estimate the number of octaves in the human audible range, 20 Hz to 20 kHz.

32. (II) Estimate the frequency of the "sound of the ocean" when you put your ear very near a 15-cm-diameter seashell.

33. (II) A tight guitar string has a frequency of 540 Hz as its third harmonic. What will be its fundamental frequency if it is fingered at a length of only 70% of its original length?

34. (II) How far from the mouthpiece of the flute in Example 16–11 should the hole be that must be uncovered to play F above middle C at 349 Hz?

35. (II) (*a*) Determine the length of an open organ pipe that emits middle C (262 Hz) when the temperature is 18°C. (*b*) What are the wavelength and frequency of the fundamental standing wave in the tube? (*c*) What are $\lambda$ and $f$ in the traveling sound wave produced in the outside air?

36. (II) An unfingered guitar string is 0.68 m long and is tuned to play E above middle C (330 Hz). (*a*) How far from the end of this string must a fret (and your finger, Fig. 16–8) be placed to play A above middle C (440 Hz)? (*b*) What is the wavelength on the string of this 440-Hz wave? (*c*) What are the frequency and wavelength of the sound wave produced in air at 22°C by this fingered string?

37. (II) An organ is in tune at 24°C. By what percent will the frequency be off at 11°C?

38. (II) A particular organ pipe can resonate at 264 Hz, 440 Hz, and 616 Hz, but not at any other frequencies in between. (*a*) Show why this is an open or a closed pipe. (*b*) What is the fundamental frequency of this pipe?

39. (II) A pipe in air at 21.5°C is to be designed to produce two successive harmonics at 308 Hz and 352 Hz. How long must the pipe be, and is it open or closed?

40. (II) A uniform narrow tube 1.50 m long is open at both ends. It resonates at two successive harmonics of frequencies 275 Hz and 330 Hz. What is (*a*) the fundamental frequency, and (*b*) the speed of sound in the gas in the tube?

41. (II) How many overtones are present within the audible range for a 2.18-m-long organ pipe at 20°C (*a*) if it is open, and (*b*) if it is closed?

42. (II) In a *quartz oscillator*, used as a stable "clock" in electronic devices, transverse (shear) standing sound waves are excited across the thickness $d$ of a quartz disk and its frequency $f$ is detected electronically. The parallel faces of the quartz are unsupported and so behave as "free ends" when the standing waves are excited (see Fig. 16–36). If the oscillator is designed to operate with the first overtone, $f_3$, determine the required disk thickness $d$ if $f_3 = 24.0$ MHz. The density and shear modulus of quartz are $\rho = 2650\ \text{kg/m}^3$ and $G = 2.95 \times 10^{10}\ \text{N/m}^2$.

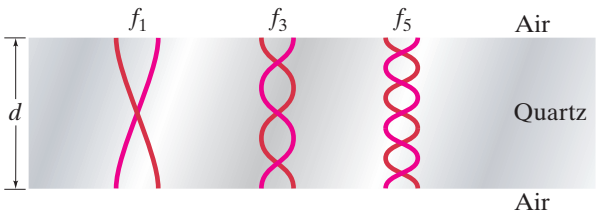

**FIGURE 16–36** Problem 42.

43. (II) Determine the fundamental and first overtone frequencies when you are in a 9.0-m-long hallway with all doors closed. Model the hallway as a *tube closed at both ends*.

44. (II) The human ear canal is approximately 2.5 cm long. It is open to the outside and is closed at the other end by the eardrum. Estimate the frequencies (in the audible range) of the standing waves in the ear canal. What is the relationship of your answer to the information in the graph of Fig. 16–6?

45. (III) When a player's finger presses a guitar string down onto a fret, the length of the vibrating portion of the string is shortened, thereby increasing the string's fundamental frequency (see Fig. 16–37). The string's tension and mass per unit length remain unchanged. If the unfingered length of the string is $\ell = 75.0$ cm, determine the positions $x$ of the first six frets, if each fret raises the pitch of the fundamental by one musical note in comparison to the neighboring fret. On the equally tempered *chromatic scale*, the ratio of frequencies of neighboring notes is $2^{1/12}$.

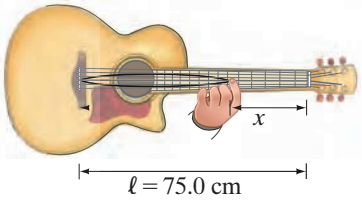

**FIGURE 16–37** Problem 45.

## *16–5 Quality of Sound; Superposition

*46. (II) Approximately what are the intensities of the first two overtones of a violin compared to the fundamental, Fig. 16–14? How many decibels softer than the fundamental are the first and second overtones?

## 16–6 Interference; Beats

47. (I) A piano tuner hears one beat every 2.0 s when trying to adjust two strings, one of which is sounding 340 Hz. How far off in frequency is the other string?

48. (I) A certain *dog whistle* operates at 23.5 kHz, while another (brand X) operates at an unknown frequency. If humans can hear neither whistle when played separately, but a shrill whine of frequency 3000 Hz occurs when they are played simultaneously, estimate the operating frequency of brand X.

49. (I) A guitar string produces 3 beats/s when sounded with a 350-Hz tuning fork and 8 beats/s when sounded with a 355-Hz tuning fork. What is the vibrational frequency of the string? Explain your reasoning.

50. (II) What is the beat frequency if middle C (262 Hz) and C♯ (277 Hz) are played together? What if each is played two octaves lower (each frequency reduced by a factor of 4)?

51. (II) Two violin strings are tuned to the same frequency, 294 Hz. The tension in one string is then decreased by 2.5%. What will be the beat frequency heard when the two strings are played together? [*Hint*: Recall Eq. 15–2.]

52. (II) The two sources of sound in Fig. 16–15 face each other and emit sounds of equal amplitude and equal frequency (305 Hz) but 180° out of phase. For what minimum separation of the two speakers will there be some point at which (*a*) complete constructive interference occurs and (*b*) complete destructive interference occurs? (Assume $T = 20°C$.)

53. (II) How many beats will be heard if two identical flutes, each 0.66 m long, try to play middle C (262 Hz), but one is at 5.0°C and the other at 25°C?

54. (II) Two loudspeakers are placed 3.00 m apart, as shown in Fig. 16–38. They emit 454-Hz sounds, in phase. A microphone is placed 3.20 m distant from a point midway between the two speakers, where an intensity maximum is recorded. (*a*) How far must the microphone be moved to the right to find the first intensity minimum? (*b*) Suppose the speakers are reconnected so that the 454-Hz sounds they emit are exactly out of phase. At what positions are the intensity maximum and minimum now?

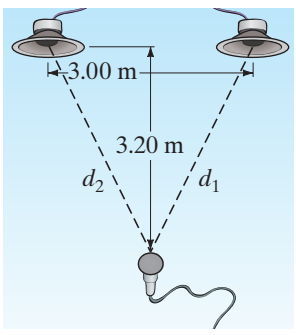

**FIGURE 16–38** Problem 54.

55. (II) Two loudspeakers are 1.60 m apart. A person stands 3.00 m from one speaker and 3.50 m from the other. (*a*) What is the lowest frequency at which destructive interference will occur at this point if the speakers are in phase? (*b*) Calculate two other frequencies that also result in destructive interference at this point (give the next two highest). Let $T = 20°C$.

56. (III) A source emits sound of wavelengths 2.54 m and 2.72 m in air. (*a*) How many beats per second will be heard? (Assume $T = 20°C$.) (*b*) How far apart in space are the regions of maximum intensity?

## 16–7 Doppler Effect

57. (I) The predominant frequency of a certain fire truck's siren is 1650 Hz when at rest. What frequency do you detect if you move with a speed of 25.0 m/s (*a*) toward the fire truck, and (*b*) away from it?

58. (II) A bat at rest sends out ultrasonic sound waves at 50.0 kHz and receives them returned from an object moving directly away from it at 22.0 m/s. What is the received sound frequency?

59. (II) In one of the original Doppler experiments, a tuba was played at a frequency of 75 Hz on a moving flat train car, and a second identical tuba played the same tone while at rest in the railway station. What beat frequency was heard in the station if the train car approached the station at a speed of 14.0 m/s?

60. (II) Two trains emit 508-Hz whistles. One train is stationary. The conductor on the stationary train hears a 4.5-Hz beat frequency when the other train approaches. What is the speed of the moving train?

61. (II) A wave on the ocean surface with wavelength 44 m travels east at a speed of 11 m/s relative to the ocean floor. If, on this stretch of ocean, a ship is moving at 5.0 m/s (relative to the ocean floor), how often does the boat encounter a wave crest, if the boat is traveling (*a*) west, and (*b*) east?

62. (II) (*a*) Compare the shift in frequency if an 1800-Hz source is moving toward you at 18 m/s, versus you moving toward it at 18 m/s. Are the two frequencies exactly the same? Are they close? (*b*) Repeat the calculation for 160 m/s and then again (*c*) for 320 m/s. What can you conclude about the asymmetry of the Doppler formulas? (*d*) Show that at low speeds (relative to the speed of sound), the two formulas—source approaching and detector approaching—yield the same result.

63. (II) A police car sounding a siren with a frequency of 1580 Hz is traveling at 120.0 km/h. (*a*) What frequencies does an observer standing next to the road hear as the car approaches and as it recedes? (*b*) What siren frequencies are heard in a car traveling at 90.0 km/h in the opposite direction before and after passing the police car? (*c*) The police car passes a car traveling in the same direction at 80.0 km/h. What two frequencies are heard in this car?

64. (III) The Doppler effect using ultrasonic waves of frequency $2.25 \times 10^6$ Hz is used to monitor the heartbeat of a fetus. A (maximum) beat frequency of 220 Hz is observed. Assuming that the speed of sound in tissue is 1540 m/s, calculate the maximum velocity of the surface of the beating heart.

**65.** (III) A factory whistle emits sound of frequency 770 Hz. The wind velocity is 15.0 m/s from the north (heading south). What frequency will observers hear who are located, at rest, (*a*) due north, (*b*) due south, (*c*) due east, and (*d*) due west, of the whistle? What frequency is heard by a cyclist heading (*e*) north or (*f*) west, toward the whistle at 12.0 m/s? Assume $T = 20°C$.

## *16–8 Shock Waves; Sonic Boom

***66.** (I) (*a*) How fast is an object moving on land if its speed at 24°C is Mach 0.33? (*b*) A high-flying jet cruising at 3000 km/h displays a Mach number of 3.1 on a screen. What is the speed of sound at that altitude?

***67.** (I) The wake of a speedboat is 12° in a lake where the speed of water waves is 2.2 km/h. What is the speed of the boat? The wake is the full width, $2\theta$ in Fig. 16–24.

***68.** (II) A meteorite traveling 9400 m/s strikes the ocean. Determine the shock wave angle it produces (*a*) in the air just before entering the ocean, and (*b*) in the water just after entering. Assume $T = 20°C$.

***69.** (II) A space probe enters the thin atmosphere of a planet where the speed of sound is only about 55 m/s. (*a*) What is the probe's Mach number if its initial speed is 15,000 km/h? (*b*) What is the angle of the shock wave relative to the direction of motion?

***70.** (II) A supersonic jet traveling at Mach 2.0 at an altitude of 9500 m passes directly over an observer on the ground. Where will the plane be relative to the observer when the latter hears the sonic boom? (See Fig. 16–39.)

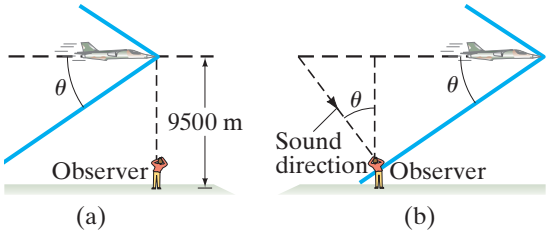

**FIGURE 16–39** Problem 70.

***71.** (II) Show that the angle $\theta$ a sonic boom makes with the path of a supersonic object is given by Eq. 16–12.

***72.** (II) You look directly overhead and see a plane exactly 1.45 km above the ground flying faster than the speed of sound. By the time you hear the sonic boom, the plane has traveled a horizontal distance of 2.0 km. See Fig. 16–40. Determine (*a*) the angle of the shock cone, $\theta$, and (*b*) the speed of the plane and its Mach number. Assume the speed of sound is 330 m/s.

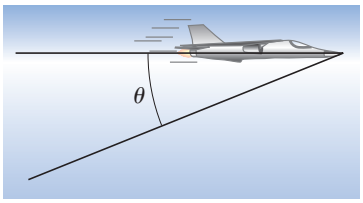

**FIGURE 16–40** Problem 72.

# General Problems

**73.** A *fish finder* uses a sonar device that sends 20,000-Hz sound pulses downward from the bottom of the boat, and then detects echoes. If the maximum depth for which it is designed to work is 85 m, what is the minimum time between pulses (in fresh water)?

**74.** A single mosquito 5.0 m from a person makes a sound close to the threshold of human hearing (0 dB). What will be the sound level of 200 such mosquitoes?

**75.** A **motion sensor** can accurately measure the distance $d$ to an object repeatedly via the sonar technique used in Example 16–2. A short ultrasonic pulse is emitted and reflects from any objects it encounters, creating echo pulses upon their arrival back at the sensor. The sensor measures the time interval $t$ between the emission of the original pulse and the arrival of the first echo. (*a*) The smallest time interval $t$ that can be measured with high precision is 1.0 ms. What is the smallest distance (at 20°C) that can be measured with the motion sensor? (*b*) To measure an object's speed the motion sensor makes 15 distance measurements every second (that is, it emits 15 sound pulses per second at evenly spaced time intervals), the measurement of $t$ must be completed within the time interval between the emissions of successive pulses. What is the largest distance (at 20°C) that can be measured with the motion sensor? (*c*) Assume that during a lab period the room's temperature increases from 20°C to 23°C. What percent error will this introduce into the motion sensor's distance measurements?

**76.** Two loudspeakers face each other at opposite ends of a long corridor. They are connected to the same source which produces a pure tone of 315 Hz. A person walks from one speaker toward the other at a speed of 1.6 m/s. What "beat" frequency does the person hear?

**77.** A stereo amplifier is rated at 225 W output at 1000 Hz. The power output drops by 12 dB at 15 kHz. What is the power output in watts at 15 kHz?

**78.** The sound level 9.75 m from a loudspeaker, placed in the open, is 115 dB. What is the acoustic power output (W) of the speaker, assuming it radiates equally in all directions?

**79.** A science museum has a display called a sewer pipe symphony. It consists of many plastic pipes of various lengths, which are open on both ends. (*a*) If the pipes have lengths of 3.0 m, 2.5 m, 2.0 m, 1.5 m and 1.0 m, what frequencies will be heard by a visitor's ear placed near the ends of the pipes? (*b*) Why does this display work better on a noisy day than on a quiet day?

**80.** Workers around jet aircraft typically wear protective devices over their ears. Assume that the sound level of a jet airplane engine, at a distance of 35 m, is 130 dB, and that the average human ear has an effective radius of 2.0 cm. What would be the power intercepted by an unprotected ear at a distance of 25 m from a jet airplane engine?

**81.** The radius of the hydrogen atom is 0.0529 nm. (*a*) What is the intensity (in dB) of a 100-Hz sound wave whose displacement amplitude is this size? (*b*) Repeat for a 2.0-kHz wave. Is either sound audible? Refer to Fig. 16–6.

**82.** In audio and communications systems, the **gain**, $\beta$, in decibels is defined as

$$\beta = 10 \log\left(\frac{P_{\text{out}}}{P_{\text{in}}}\right),$$

where $P_{\text{in}}$ is the power input to the system and $P_{\text{out}}$ is the power output. (*a*) A particular stereo amplifier puts out 135 W of power for an input of 1.0 mW. What is its gain in dB? (*b*) If a *signal-to-noise* ratio of 93 dB is specified, what is the noise power if the output signal is 10 W?

**83.** At a race track, you can estimate the speed of cars just by listening to the difference in pitch of the engine noise between approaching and receding cars. Suppose the sound of a certain car drops by a full octave (frequency halved) as it goes by on the straightaway. How fast is it going?

**84.** The diameter $D$ of a tube does affect the position of the antinode at the open end of a tube. The end correction can be roughly approximated by adding $D/3$ to $\ell$ to give us an effective length for the tube in calculations. For a closed tube of length 55.0 cm and diameter 3.0 cm, what are the first four harmonics, taking the end correction into consideration?

**85.** A tuning fork is set into vibration above a vertical open tube filled with water (Fig. 16–41). The water level is allowed to drop slowly. As it does so, the air in the tube above the water level is heard to resonate with the tuning fork when the distance from the tube opening to the water level is 0.125 m and again at 0.395 m. What is the frequency of the tuning fork?

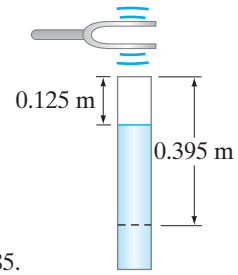

**FIGURE 16–41** Problem 85.

**86.** A person hears the same pure tone in the 500 to 1000-Hz range coming from two sources. The sound is loudest at points equidistant from the two sources. To determine exactly what the frequency is, the person moves about and finds that the sound level is minimal at a point 0.25 m farther from one source than the other. What is the frequency of the sound?

**87.** Each string on a *violin* is tuned to a frequency $1\frac{1}{2}$ times that of its neighbor. The four equal-length strings are to be placed under the same tension; what must be the mass per unit length of each string relative to that of the lowest string?

**88.** A particular whistle produces sound by setting up the fundamental standing wave in an air column 8.40 cm long. The tube is closed at one end. The whistle blower is riding in a car moving away from you at 25 m/s. What frequency do you hear?

**89.** The A string of a violin is 32 cm long between fixed points with a fundamental frequency of 440 Hz and a mass per unit length of $7.2 \times 10^{-4}$ kg/m. (*a*) What are the wave speed and tension in the string? (*b*) What is the length of the tube of a simple wind instrument (say, an organ pipe) closed at one end whose fundamental is also 440 Hz if the speed of sound is 343 m/s in air? (*c*) What is the frequency of the first overtone of each instrument?

**90.** Two loudspeakers are at opposite ends of a railroad car as it moves past a stationary observer at 12.0 m/s, as shown in Fig. 16–42. If the speakers emit identical sound frequencies of 348 Hz, what is the beat frequency heard by the observer when (*a*) he listens from position A, in front of the car, (*b*) he is between the speakers, at B, and (*c*) he hears the speakers after they have passed him, at C?

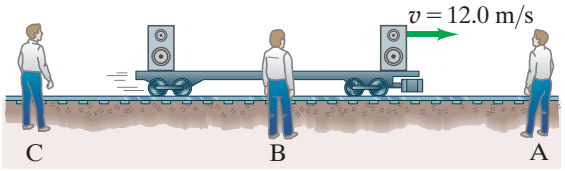

**FIGURE 16–42** Problem 90.

**91.** At a painfully loud concert, a 120-dB sound wave travels away from a loudspeaker at 343 m/s. How much sound wave energy is contained in each 1.0-cm$^3$ volume of air in the region near this loudspeaker?

**92.** Two automobiles are equipped with the same single-frequency horn. When one is at rest and the other is moving toward the first at 6 m/s, the driver at rest hears a beat frequency of about 5 Hz. What is the frequency the horns emit? Assume $T = 20°\text{C}$.

**93.** Two open organ pipes, sounding together, produce a beat frequency of 6.0 Hz. The shorter one is 2.40 m long. How long is the other?

**94.** If the velocity of blood flow in the aorta is normally about 0.32 m/s, what beat frequency would you expect if 4.80-MHz ultrasound waves were directed along the flow and reflected from the red blood cells? Assume that the waves travel with a speed of $1.54 \times 10^3$ m/s.

**95.** A bat emits a series of high-frequency sound pulses as it approaches a moth. The pulses are approximately 65.0 ms apart, and each is about 3.0 ms long. How far away can the moth be detected by the bat so that the echo from one pulse returns before the next pulse is emitted?

**96.** The vibrating portion of an A-string on a particular *violin* measures 32 cm, and its fundamental frequency is precisely 440 Hz. (*a*) How far from the end of the string should the violinist place a finger so that the string plays a note at 588 Hz? (*b*) "Vibrato" in a violin is produced by sliding the finger back and forth along the vibrating string. If the violinist executes "vibrato" by moving the finger 0.5 cm to either side of the position found in part (*a*), what range of frequencies will result?

**97.** A *bugle* is a tube of fixed length that behaves as if it is open at both ends. A bugler, by adjusting his lips correctly and blowing with proper air pressure, can cause a harmonic (usually other than the fundamental) of the air column within the tube to sound loudly. Standard military tunes like *Taps* and *Reveille* require only four musical notes: G4 (392 Hz), C5 (523 Hz), E5 (659 Hz), and G5 (784 Hz). (*a*) For a certain length $\ell$, a bugle will have a sequence of four consecutive harmonics whose frequencies very nearly equal those associated with the notes G4, C5, E5, and G5. Determine this $\ell$. (*b*) Which harmonic is each of the (approximate) notes G4, C5, E5, and G5 for the bugle?

**98.** (*a*) Use the binomial expansion to show that Eqs. 16–9a and 16–10a become essentially the same for small relative velocity between source and observer. (*b*) What percent error would result if Eq. 16–10a were used instead of Eq. 16–9a for a relative velocity of 18.0 m/s?

**99.** The "alpenhorn" (Fig. 16–43) was once used to send signals from one Alpine village to another. Since lower frequency sounds are less susceptible to intensity loss, long horns were used to create deep sounds. When played as a musical instrument, the alpenhorn must be blown in such a way that only one of the overtones is resonating. The most popular alpenhorn is about 3.4 m long, and it is called the F♯ (or G♭) horn. What is the fundamental frequency of this horn, and which overtone is close to F♯? (See Table 16–3.) Model as a tube open at both ends.

**FIGURE 16–43** Problem 99.

**100.** A source of sound waves (wavelength $\lambda$) is a distance $\ell$ from a detector. Sound reaches the detector directly, and also by reflecting off an obstacle, as shown in Fig. 16–44. The obstacle is equidistant from source and detector. When the obstacle is a distance $d$ to the right of the line of sight between source and detector, as shown, the two waves arrive in phase. How much farther to the right must the obstacle be moved if the two waves are to be out of phase by $\frac{1}{2}$ wavelength, so destructive interference occurs? (Assume $\lambda \ll \ell, d$.)

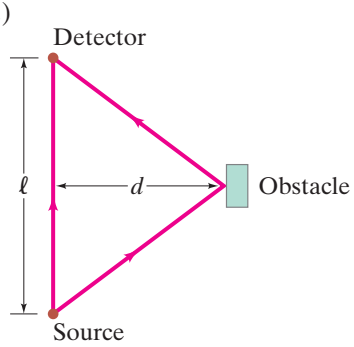

**FIGURE 16–44**
Problem 100.

**101.** A dramatic demonstration, called a "singing rod," involves a long, slender aluminum rod held in the hand near the rod's midpoint. The rod is stroked with the other hand. With a little practice, the rod can be made to "sing," or emit a clear, loud, ringing sound. For an 80-cm-long rod, (*a*) what is the fundamental frequency of the sound? (*b*) What is its wavelength in the rod, and (*c*) what is the traveling wavelength of the sound in air at 20°C?

**102.** A sound-insulating door reduces the sound level by 30 dB. What fraction of the initial sound intensity passes through this door?

**103.** A *Doppler flow meter* is used to measure the speed of blood flow. The transmitter and receiver are placed on the skin, as shown in Fig. 16–45. Typical sound-wave frequencies of about 5.0 MHz are used, which have a reasonable chance of being reflected from red blood cells. By measuring the frequency of the reflected waves, which are Doppler-shifted because the red blood cells are moving, the speed of the blood flow can be deduced. "Normal" blood flow speed is about 0.1 m/s. Suppose that an artery is partly constricted, so that the speed of the blood flow is increased, and the flow meter measures a Doppler shift of 780 Hz. What is the speed of blood flow in the constricted region? The effective angle between the sound waves (both transmitted and reflected) and the direction of blood flow is 45°. Assume the velocity of sound in tissue is 1540 m/s.

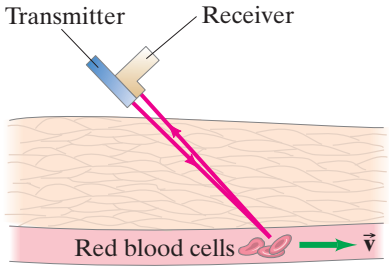

**FIGURE 16–45**
Problem 104.

**104.** Assuming that the maximum displacement of the air molecules in a sound wave is about the same as that of the speaker cone that produces the sound (Fig. 16–46), estimate by how much a loudspeaker cone moves for a fairly loud (105 dB) sound of (*a*) 8.0 kHz, and (*b*) 35 Hz.

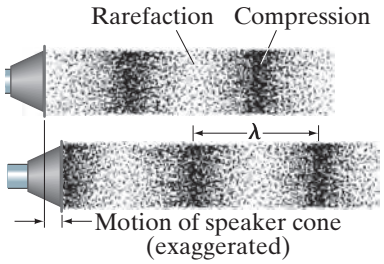

**FIGURE 16–46**
Problem 105.

## ANSWERS TO EXERCISES

**A:** 4 times as intense.
**B:** (*b*).
**C:** 7 octaves, plus; each octave ends a factor of 2 higher in frequency than the previous one: 1 → 2, 4, 8, 16, 32, 64, 128, 256, … . [This is like counting in binary, $2^7 = 128$. See also Section 23–9.]
**D:** (*b*).
**E:** 257 Hz.
**F:** (*a*) 1483 Hz; (*b*) 1491 Hz.
**G:** (*a*).

Heating the air inside a "hot-air" balloon raises the air's temperature, causing it to expand, and forces air out the opening at the bottom. The reduced amount of air inside means its density is lower than the outside air, so there is a net buoyant force upward on the balloon. In this Chapter we study temperature and its effects on matter: thermal expansion and the gas laws.

CHAPTER 17

# Temperature, Thermal Expansion, and the Ideal Gas Law

## CONTENTS

17 – 1 Atomic Theory of Matter
17 – 2 Temperature and Thermometers

17 – 9 Ideal Gas Law in Terms of Molecules: Avogadro's Number
*17–10 Ideal Gas Temperature Scale—a Standard

**CHAPTER-OPENING QUESTION—Guess now!**

A hot-air balloon, open at one end (see photos above), rises when the air inside is heated by a flame. For the following properties, is the air inside the balloon higher, lower, or the same as for the air outside the balloon?

(i) Temperature,
(ii) Pressure,
(iii) Density.

This Chapter is the first of four, 17 through 20, devoted to temperature, kinetic theory, heat, and the thermodynamics of processes of energy transfer as work and heat, including engines (Chapter 20). Much of this Chapter 17 deals with the concept of temperature, how it is measured, and how it affects materials. We also discuss the measured properties of gases such as pressure, volume, and temperature and how they affect each other (the gas laws).

The emphasis in this Chapter is on the concept of temperature. We begin, however, with a brief discussion of the theory that matter is made up of atoms and that these atoms are in continuous random motion. This theory is called *kinetic theory* ("kinetic," you may recall from Chapter 7, is Greek for "moving"), and we discuss it in more detail in Chapter 18.

## 17–1 Atomic Theory of Matter

The idea that matter is made up of atoms dates back to the ancient Greeks. According to the Greek philosopher Democritus, if a pure substance—say, a piece of iron—were cut into smaller and smaller bits, eventually a smallest piece of that substance would be obtained which could not be divided further. This smallest piece was called an **atom**, which in Greek means "indivisible." Today an atom is still the smallest piece of a substance, but we do not consider it indivisible. Rather it is viewed as consisting of a central nucleus (containing protons and neutrons) surrounded by electrons.

Today the atomic theory is universally accepted. The experimental evidence in its favor, however, came mainly in the eighteenth, nineteenth, and twentieth centuries, and much of it was obtained from the analysis of chemical reactions.

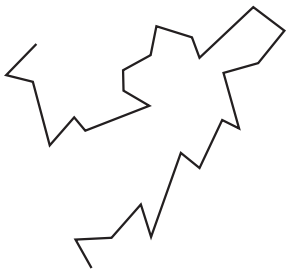
We will often speak of the relative masses of individual atoms and molecules—what we call the **atomic mass** or **molecular mass**, respectively. (The terms *atomic weight* and *molecular weight* are sometimes used.) These masses are based on arbitrarily assigning the most abundant form of carbon atom, $^{12}C$, the atomic mass of exactly 12.0000 **unified atomic mass units** (u). In terms of kilograms,

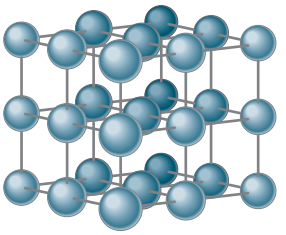
$$1\,\text{u} = 1.6605 \times 10^{-27}\,\text{kg}.$$

The atomic mass of natural hydrogen is 1.0079 u, and the values for other atoms are included in the Periodic Table[†] inside the back cover of this book (and also in Appendix G). The molecular mass of a compound is the sum of atomic masses of the atoms making up the molecules of that compound.

An **element** is a substance, such as neon, gold, iron, or copper, that cannot be broken down into simpler substances by chemical means. **Compounds** are substances made up of elements, and can be broken down into them; examples are carbon dioxide and water. The smallest piece of an element is an **atom**; the smallest piece of a compound is a **molecule**. Molecules are made up of atoms; a molecule of water, for example, is made up of two atoms of hydrogen and one of oxygen; its chemical formula is $H_2O$.

An important piece of evidence for the atomic theory is called **Brownian motion**, named after the biologist Robert Brown, who is credited with its discovery in 1827. While he was observing tiny pollen grains suspended in water under his microscope, Brown noticed that the tiny grains moved about in erratic paths (Fig. 17–1), even though the water appeared to be perfectly still. The atomic theory easily explains Brownian motion if we assume that the atoms of any substance are continually in motion. Then Brown's tiny pollen grains are jostled about by the vigorous barrage of rapidly moving molecules of water.





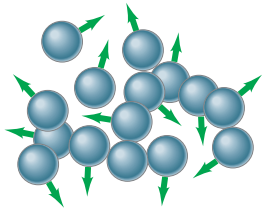


**FIGURE 17–1** Path of a tiny particle (pollen grain, for example) suspended in water. The straight lines connect observed positions of the particle at equal time intervals.

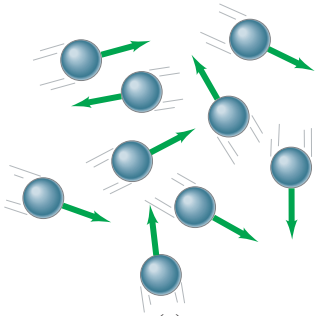

[†]The relative masses of different atoms came from analysis of chemical reactions, and the **law of definite proportions**. It states that when two or more elements combine to form a compound, they always do so in the same proportions by mass. For example, table salt is always formed from 23 parts sodium and 35 parts chlorine; and water from one part hydrogen and eight parts oxygen. A continuous theory of matter could not account for the law of definite proportions but atomic theory does: the proportions of each element that form a compound correspond to the relative masses of the combining atoms. One atom of sodium (Na) combines with one atom of chlorine (Cl) to form one molecule of salt (NaCl), and one atom of sodium has a mass 23/35 times as large as one of chlorine. Hydrogen, the lightest atom, was arbitrarily assigned the relative mass of 1. On this scale, carbon was about 12, oxygen 16, sodium 23, and so on. It was sometimes more complicated. For example, from the various compounds oxygen formed, its relative mass was judged to be 16; but this was inconsistent with the mass ratio in water of oxygen to hydrogen, only 8 to 1. This was explained by assuming two H atoms combine with one O atom to form a water molecule.

(a)

(b)

(c)

**FIGURE 17–2** Atomic arrangements in (a) a crystalline solid, (b) a liquid, and (c) a gas.

In 1905, Albert Einstein examined Brownian motion from a theoretical point of view and was able to calculate from the experimental data the approximate size and mass of atoms and molecules. His calculations showed that the diameter of a typical atom is about $10^{-10}$ m.

At the start of Chapter 13, we distinguished the three common phases (or states) of matter—solid, liquid, gas—based on **macroscopic**, or "large-scale," properties. Now let us see how these three phases of matter differ, using the atomic or **microscopic** point of view. First of all, atoms and molecules must exert attractive forces on each other, because only this explains why a brick or a block of aluminum holds together in one piece. The attractive forces between molecules are of an electrical nature (more on this in later Chapters). When molecules come too close together, the force between them must become repulsive (electric repulsion between their outer electrons). We need this assumption to explain that matter takes up space. Thus molecules maintain a minimum distance from each other. In a solid material, the attractive forces are strong enough that the atoms or molecules move only slightly (oscillate) about relatively fixed positions, often in an array known as a crystal lattice, as shown in Fig. 17–2a. In a liquid, the atoms or molecules are moving more rapidly, or the forces between them are weaker, so that they are sufficiently free to pass around one another, as in Fig. 17–2b. In a gas, the forces are so weak, or the speeds so high, that the molecules do not even stay close together. They move rapidly every which way, Fig. 17–2c, filling any container and occasionally colliding with one another. On average, the speeds are sufficiently high in a gas that when two molecules collide, the force of attraction is not strong enough to keep them close together and they fly off in new directions.

**EXAMPLE 17–1** ESTIMATE **Distance between atoms.** The density of copper is $8.9 \times 10^3\,\text{kg/m}^3$, and each copper atom has a mass of 63 u. Estimate the average distance between the centers of neighboring copper atoms.

**APPROACH** We consider a cube of copper 1 m on a side. From the given density $\rho$ we can calculate the mass $m$ of a cube of volume $V = 1\,\text{m}^3$ $(m = \rho V)$. We divide this mass $m$ by the mass of one atom (63 u) to obtain the number of atoms in $1\,\text{m}^3$. We assume the atoms are in a uniform array, and we let $N$ be the number of atoms in a 1-m length; then $(N)(N)(N) = N^3$ equals the total number of atoms in $1\,\text{m}^3$.

**SOLUTION** The mass of 1 copper atom is $63\,\text{u} = 63 \times 1.66 \times 10^{-27}\,\text{kg} = 1.05 \times 10^{-25}\,\text{kg}$. This means that in a cube of copper 1 m on a side $(\text{volume} = 1\,\text{m}^3)$, there are

$$\frac{8.9 \times 10^3\,\text{kg/m}^3}{1.05 \times 10^{-25}\,\text{kg/atom}} = 8.5 \times 10^{28}\,\text{atoms/m}^3.$$

The volume of a cube of side $\ell$ is $V = \ell^3$, so on one edge of the 1-m-long cube there are $(8.5 \times 10^{28})^{\frac{1}{3}}\,\text{atoms} = 4.4 \times 10^9\,\text{atoms}$. Hence the distance between neighboring atoms is

$$\frac{1\,\text{m}}{4.4 \times 10^9\,\text{atoms}} = 2.3 \times 10^{-10}\,\text{m}.$$

**NOTE** Watch out for units. Even though "atoms" is not a unit, it is helpful to include it to make sure you calculate correctly.

**NOTE** The distance between atoms in a solid is essentially what we mean when we speak of the size or diameter of an atom. So we have calculated the size of a copper atom.

**PROBLEM SOLVING**
*"Size" of an atom*

# 17–2 Temperature and Thermometers

In everyday life, **temperature** is a measure of how hot or cold something is. A hot oven is said to have a high temperature, whereas the ice of a frozen lake is said to have a low temperature.

Many properties of matter change with temperature. For example, most materials expand when their temperature is increased.[†] An iron beam is longer when hot than when cold. Concrete roads and sidewalks expand and contract slightly according to temperature, which is why compressible *spacers* or *expansion joints* (Fig. 17–3) are placed at regular intervals. The electrical resistance of matter changes with temperature (Chapter 25). So too does the color radiated by objects, at least at high temperatures: you may have noticed that the heating element of an electric stove glows with a red color when hot. At higher temperatures, solids such as iron glow orange or even white. The white light from an incandescent lightbulb comes from an extremely hot tungsten wire. The surface temperatures of the Sun and other stars can be measured by the predominant color (more precisely, wavelengths) of light they emit.

Instruments designed to measure temperature are called **thermometers**. There are many kinds of thermometers, but their operation always depends on some property of matter that changes with temperature. Many common thermometers rely on the expansion of a material with an increase in temperature. The first idea for a thermometer, by Galileo, made use of the expansion of a gas. Common thermometers today consist of a hollow glass tube filled with alcohol colored with a red dye, as were the earliest usable thermometers (Fig. 17–4).

Inside a common liquid-in-glass thermometer, the liquid expands more than the glass when the temperature is increased, so the liquid level rises in the tube (Fig. 17–5a). Although metals also expand with temperature, the change in length of a metal rod, say, is generally too small to measure accurately for ordinary changes in temperature. However, a useful thermometer can be made by bonding together two different metals with different rates of expansion (Fig. 17–5b). When the temperature is increased, the different amounts of expansion cause the bimetallic strip to bend. Often the bimetallic strip is in the form of a coil, one end of which is fixed while the other is attached to a pointer, Fig. 17–6. Such thermometers are used as ordinary air thermometers, oven thermometers, automatic off switches in electric coffeepots, and in room thermostats for determining when the heater or air conditioner should go on or off. Very precise thermometers make use of electrical properties (Chapter 25), such as resistance thermometers, thermocouples, and thermistors, often with a digital readout.

[†]Most materials expand when their temperature is raised, but not all. Water, for example, in the range 0°C to 4°C contracts with an increase in temperature (see Section 17–4).

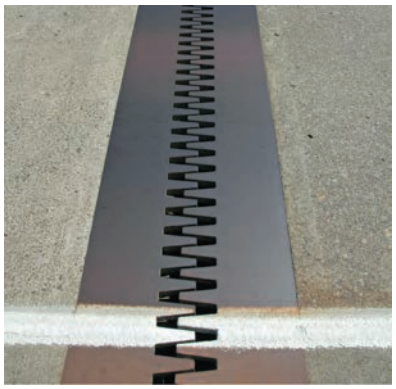

**FIGURE 17–3** Expansion joint on a bridge. Note center white line of highway.

**FIGURE 17–4** Thermometers built by the Accademia del Cimento (1657–1667) in Florence, Italy, are among the earliest known. These sensitive and exquisite instruments contained alcohol, sometimes colored, like many thermometers today.

(b)

**FIGURE 17–7** Celsius and Fahrenheit scales compared.

**PROBLEM SOLVING**

*Convert temperature by remembering* $0°C = 32°F$ *and a change of* $5\,C° = 9\,F°$

## Temperature Scales

In order to measure temperature quantitatively, some sort of numerical scale must be defined. The most common scale today is the **Celsius** or **centigrade** scale. In the United States, the **Fahrenheit** scale is also common. The most important scale in scientific work is the absolute, or Kelvin, scale, and it will be discussed later in this Chapter.

One way to define a temperature scale is to assign arbitrary values to two readily reproducible temperatures. For both the Celsius and Fahrenheit scales these two fixed points are chosen to be the freezing point and the boiling point of water, both taken at standard atmospheric pressure. On the Celsius scale, the freezing point† of water is chosen to be 0°C ("zero degrees Celsius") and the boiling point 100°C. On the Fahrenheit scale, the freezing point is defined as 32°F and the boiling point 212°F. A practical thermometer is calibrated by placing it in carefully prepared environments at each of the two temperatures and marking the position of the liquid or pointer. For a Celsius scale, the distance between the two marks is divided into one hundred equal intervals representing each degree between 0°C and 100°C (hence the name "centigrade scale" meaning "hundred steps"). For the Fahrenheit scale, the two points are labeled 32°F and 212°F and the distance between them is divided into 180 equal intervals. For temperatures below the freezing point of water and above the boiling point of water, the scales may be extended using the same equally spaced intervals. However, thermometers can be used only over a limited temperature range because of their own limitations—for example, an alcohol-in-glass thermometer is rendered useless above temperatures where the alcohol vaporizes. For very low or very high temperatures, specialized thermometers are required, some of which we will mention later.

Every temperature on the Celsius scale corresponds to a particular temperature on the Fahrenheit scale, Fig. 17–7. To convert from one to the other, remember that 0°C corresponds to 32°F and that a range of 100° on the Celsius scale corresponds to a range of 180° on the Fahrenheit scale. Thus, one Fahrenheit degree (1 F°) corresponds to $100/180 = \frac{5}{9}$ of a Celsius degree (1 C°). That is, $1\,F° = \frac{5}{9}\,C°$. (Notice that when we refer to a specific temperature, we say "degrees Celsius," as in 20°C; but when we refer to a *change* in temperature or a temperature interval, we say "Celsius degrees," as in "2 C°.") The conversion between the two temperature scales can be written

$$T(°C) = \tfrac{5}{9}[T(°F) - 32]$$

or

$$T(°F) = \tfrac{9}{5}T(°C) + 32.$$

Rather than memorizing these relations, it is simpler to remember that $0°C = 32°F$ and that a change of $5\,C° =$ a change of $9\,F°$.

**EXAMPLE 17–2** **Taking your temperature.** "Normal" body temperature on average is considered to be 98.6°F. What is this on the Celsius scale?

**APPROACH** We recall that $0°C = 32°F$ and that a change of $5\,C° = 9\,F°$.

**SOLUTION** First we relate the given temperature to the freezing point of water (0°C). That is, 98.6°F is $98.6 - 32.0 = 66.6\,F°$ above the freezing point of water. Since each F° is equal to $\frac{5}{9}$ C°, this corresponds to $66.6 \times \frac{5}{9} = 37.0$ Celsius degrees above the freezing point. The freezing point of water is 0°C, so average normal body temperature is 37.0°C.

†The freezing point of a substance is defined as that temperature at which the solid and liquid phases coexist in equilibrium—that is, without any net liquid changing into the solid or vice versa. Experimentally, this is found to occur at only one definite temperature, for a given pressure. Similarly, the boiling point is defined as that temperature at which the liquid and gas coexist in equilibrium. Since these points vary with pressure, the pressure must be specified (usually it is 1 atm).

**EXERCISE A** Determine the temperature at which both scales give the same numerical reading $(T_C = T_F)$.

Different materials do not expand precisely linearly over a wide temperature range. Consequently, if we calibrate different kinds of thermometers exactly as just described, they may not agree precisely. We calibrate them so they agree at 0°C and at 100°C. But they may not agree precisely at intermediate temperatures; a carefully calibrated alcohol-in-glass thermometer might register 52.0°C, whereas a carefully calibrated thermometer of another type might read 52.6°C.

Because of such discrepancies, some standard kind of thermometer must be chosen so that all temperatures can be precisely defined. The chosen standard for this purpose is the **constant-volume gas thermometer**. As shown in the simplified diagram of Fig. 17–8, this thermometer consists of a hollow rigid bulb filled with a low-pressure gas connected by a thin tube to a mercury manometer (Section 13–6). The volume of the gas is kept constant by raising or lowering the right-hand tube of the manometer so that the mercury in the left-hand tube coincides with the reference mark. An increase in temperature causes a proportional increase in pressure in the bulb, so the right-hand tube must be lifted higher to keep the gas volume constant; the height difference of the mercury in the tube is then a measure of the temperature. This thermometer gives the same results for all gases in the limit of reducing the gas pressure in the bulb toward zero. The resulting scale serves as a basis for the *standard temperature scale* (Section 17–10).

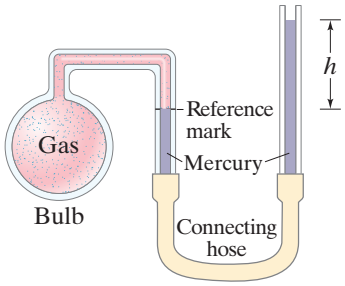

**FIGURE 17–8** Constant-volume gas thermometer.

## 17–3 Thermal Equilibrium and the Zeroth Law of Thermodynamics

We are all familiar with the fact that if two objects at different temperatures are placed in thermal contact (meaning thermal energy can transfer from one to the other), the two objects will eventually reach the same temperature. They are then said to be in **thermal equilibrium**. For example, you leave a fever thermometer in your mouth until it comes into thermal equilibrium with that environment; only then do you read it. Two objects are defined to be in thermal equilibrium if, when placed in thermal contact, no net energy flows from one to the other, and their temperatures don't change. Experiments indicate that

> **if two systems are in thermal equilibrium with a third system, then they are in thermal equilibrium with each other.**

This postulate is called the **zeroth law of thermodynamics**. It has this unusual name because it was not until after the great first and second laws of thermodynamics (Chapters 19 and 20) were worked out that scientists realized that this postulate needed to be stated first.

Temperature is a property of a system that determines whether the system will be in thermal equilibrium with other systems. When two systems are in thermal equilibrium, their temperatures are (by definition) equal, and no net thermal energy will be exchanged between them. This is consistent with our everyday notion of temperature: when a hot object and a cold one are put into contact, they eventually come to the same intermediate temperature. Thus the importance of the zeroth law is that it allows a useful definition of temperature.

## 17–4 Thermal Expansion

Most substances expand when heated and contract when cooled. The amount of expansion or contraction depends on the material. From a microscopic point of view, if the temperature of an object increases, its length increases, which means its molecules are a bit farther apart on average.

## Linear Expansion

Experiments indicate that the change in length $\Delta\ell$ of almost all solids is, to a good approximation, directly proportional to the change in temperature $\Delta T$, as long as $\Delta T$ is not too large. The change in length is also proportional to the original length of the object, $\ell_0$. That is, for the same temperature increase, a 4-m-long iron rod will increase in length twice as much as a 2-m-long iron rod. We can write this proportionality as an equation:

$$\Delta\ell = \alpha\ell_0\Delta T, \qquad \textbf{(17–1a)}$$

where $\alpha$, the proportionality constant, is called the **coefficient of linear expansion** for the particular material and has units of $(\text{C}^\circ)^{-1}$. We write $\ell = \ell_0 + \Delta\ell$ (see Fig. 17–9), and rewrite Eq. 17–1a as

$$\ell = \ell_0(1 + \alpha\Delta T), \qquad \textbf{(17–1b)}$$

where $\ell_0$ is the length initially, at temperature $T_0$, and $\ell$ is the length after heating or cooling to a temperature $T$. If the temperature change $\Delta T = T - T_0$ is negative, then $\Delta\ell = \ell - \ell_0$ is also negative; the length shortens as the temperature decreases.

The values of $\alpha$ for various materials at 20°C are listed in Table 17–1. Actually, $\alpha$ does vary slightly with temperature (which is why thermometers made of different materials do not agree precisely). However, if the temperature range is not too great, the variation can usually be ignored.

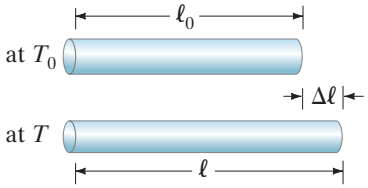

**FIGURE 17–9** A thin rod of length $\ell_0$ at temperature $T_0$ is heated to a new uniform temperature $T$ and acquires length $\ell$, where $\ell = \ell_0 + \Delta\ell$.

**TABLE 17–1 Coefficients of Expansion, near 20°C**

| Material | Coefficient of Linear Expansion, $\alpha\,(\text{C}^\circ)^{-1}$ | Coefficient of Volume Expansion, $\beta\,(\text{C}^\circ)^{-1}$ |
|---|---|---|
| *Solids* | | |
| Aluminum | $25\times10^{-6}$ | $75\times10^{-6}$ |
| Brass | $19\times10^{-6}$ | $56\times10^{-6}$ |
| Copper | $17\times10^{-6}$ | $50\times10^{-6}$ |
| Gold | $14\times10^{-6}$ | $42\times10^{-6}$ |
| Iron or steel | $12\times10^{-6}$ | $35\times10^{-6}$ |
| Lead | $29\times10^{-6}$ | $87\times10^{-6}$ |
| Glass (Pyrex®) | $3\times10^{-6}$ | $9\times10^{-6}$ |
| Glass (ordinary) | $9\times10^{-6}$ | $27\times10^{-6}$ |
| Quartz | $0.6\times10^{-6}$ | $2\times10^{-6}$ |
| Concrete and brick | $\approx 12\times10^{-6}$ | $\approx 36\times10^{-6}$ |
| Marble | $1.4\text{–}3.5\times10^{-6}$ | $4\text{–}10\times10^{-6}$ |
| *Liquids* | | |
| Gasoline | | $950\times10^{-6}$ |
| Mercury | | $180\times10^{-6}$ |
| Ethyl alcohol | | $1100\times10^{-6}$ |
| Glycerin | | $500\times10^{-6}$ |
| Water | | $210\times10^{-6}$ |
| *Gases* | | |
| Air (and most other gases at atmospheric pressure) | | $3400\times10^{-6}$ |

PHYSICS APPLIED
*Expansion in structures*

**EXAMPLE 17–3** **Bridge expansion.** The steel bed of a suspension bridge is 200 m long at 20°C. If the extremes of temperature to which it might be exposed are −30°C to +40°C, how much will it contract and expand?

**APPROACH** We assume the bridge bed will expand and contract linearly with temperature, as given by Eq. 17–1a.

**SOLUTION** From Table 17–1, we find that $\alpha = 12\times10^{-6}(\text{C}^\circ)^{-1}$ for steel. The increase in length when it is at 40°C will be

$$\Delta\ell = \alpha\ell_0\Delta T = (12\times10^{-6}/\text{C}^\circ)(200\,\text{m})(40^\circ\text{C} - 20^\circ\text{C}) = 4.8\times10^{-2}\,\text{m},$$

or 4.8 cm. When the temperature decreases to −30°C, $\Delta T = -50\,\text{C}^\circ$. Then

$$\Delta\ell = (12\times10^{-6}/\text{C}^\circ)(200\,\text{m})(-50\,\text{C}^\circ) = -12.0\times10^{-2}\,\text{m},$$

or a decrease in length of 12 cm. The total range the expansion joints must accommodate is 12 cm + 4.8 cm ≈ 17 cm (Fig. 17–3).

**CONCEPTUAL EXAMPLE 17–4** **Do holes expand or contract?** If you heat a thin, circular ring (Fig. 17–10a) in the oven, does the ring's hole get larger or smaller?

**RESPONSE** You might guess that the metal expands into the hole, making the hole smaller, but it is not so. Imagine the ring is solid, like a coin (Fig. 17–10b). Draw a circle on it with a pen as shown. When the metal expands, the material inside the circle will expand along with the rest of the metal; so the dashed circle expands. Cutting the metal where the circle is shows that the hole in Fig. 17–10a increases in diameter. To see this in another way, consider the row or circle of atoms on the inner surface of the ring. With an increase in temperature, they get farther apart. So the circumference of the inside surface of the ring increases.

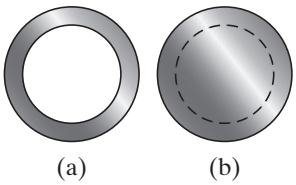

**FIGURE 17–10** Example 17–4.

**EXAMPLE 17–5** **Ring on a rod.** An iron ring is to fit snugly on a cylindrical iron rod (Fig. 17–11). At 20°C, the diameter of the rod is 6.445 cm and the inside diameter of the ring is 6.420 cm. To slip over the rod, the ring must be slightly larger than the rod diameter by about 0.008 cm. To what temperature must the ring be brought if its hole is to be large enough so it will slip over the rod?

**APPROACH** The hole in the ring must be increased from a diameter of 6.420 cm to 6.445 cm + 0.008 cm = 6.453 cm. The ring must be heated since the hole diameter will increase linearly with temperature (Example 17–4).

**SOLUTION** We solve for $\Delta T$ in Eq. 17–1a and find

$$\Delta T = \frac{\Delta \ell}{\alpha \ell_0} = \frac{6.453\ \text{cm} - 6.420\ \text{cm}}{(12 \times 10^{-6}/\text{C}^\circ)(6.420\ \text{cm})} = 430\ \text{C}^\circ.$$

So the ring must be raised at least to $T = (20°\text{C} + 430\ \text{C}^\circ) = 450°\text{C}$.

**NOTE** In doing Problems, do not forget the last step, adding in the initial temperature (20°C here).

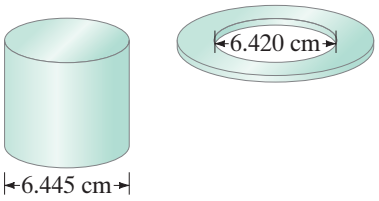

**FIGURE 17–11** Example 17–5.

**CONCEPTUAL EXAMPLE 17–6** **Opening a tight jar lid.** When the lid of a glass jar is tight, holding the lid under hot water for a short time will often make it easier to open (Fig. 17–12). Why?

**RESPONSE** The lid may be struck by the hot water more directly than the glass and so expand sooner. But even if not, metals generally expand more than glass for the same temperature change ($\alpha$ is greater—see Table 17–1).

**PHYSICS APPLIED**
*Opening a tight lid*

**FIGURE 17–12** Example 17–6.

## Volume Expansion

The change in *volume* of a material which undergoes a temperature change is given by a relation similar to Eq. 17–1a, namely,

$$\Delta V = \beta V_0 \Delta T, \qquad \textbf{(17–2)}$$

where $V_0$ is the original volume, $\Delta V$ is the change in volume when the temperature changes by $\Delta T$, and $\beta$ is the **coefficient of volume expansion**. The units of $\beta$ are $(\text{C}^\circ)^{-1}$.

Values of $\beta$ for various materials are given in Table 17–1. Notice that for solids, $\beta$ is normally equal to approximately $3\alpha$. (See Problem 16.) Note also that linear expansion has no meaning for liquids and gases because they do not have fixed shapes.

**EXERCISE B** A long thin bar of aluminum at 0°C is 1.0 m long and has a volume of $1.0000 \times 10^{-3}\ \text{m}^3$. When heated to 100°C, the length of the bar becomes 1.0025 m. What is the approximate volume of the bar at 100°C? (*a*) $1.0000 \times 10^{-3}\ \text{m}^3$; (*b*) $1.0025 \times 10^{-3}\ \text{m}^3$; (*c*) $1.0050 \times 10^{-3}\ \text{m}^3$; (*d*) $1.0075 \times 10^{-3}\ \text{m}^3$; (*e*) $2.5625 \times 10^{-3}\ \text{m}^3$.

Equations 17–1 and 17–2 are accurate only if $\Delta\ell$ (or $\Delta V$) is small compared to $\ell_0$ (or $V_0$). This is of particular concern for liquids and even more so for gases because of the large values of $\beta$. Furthermore, $\beta$ itself varies substantially with temperature for gases. Therefore, a more convenient way of dealing with gases is needed, and will be discussed starting in Section 17–6.

**EXAMPLE 17–7** **Gas tank in the Sun.** The 70-liter (L) steel gas tank of a car is filled to the top with gasoline at 20°C. The car sits in the Sun and the tank reaches a temperature of 40°C (104°F). How much gasoline do you expect to overflow from the tank?

PHYSICS APPLIED
*Gas tank overflow*

**APPROACH** Both the gasoline and the tank expand as the temperature increases, and we assume they do so linearly as described by Eq. 17–2. The volume of overflowing gasoline equals the volume increase of the gasoline minus the increase in volume of the tank.

**SOLUTION** The gasoline expands by

$$\Delta V = \beta V_0 \Delta T = (950 \times 10^{-6}/\text{C}^\circ)(70\,\text{L})(40^\circ\text{C} - 20^\circ\text{C}) = 1.3\,\text{L}.$$

The tank also expands. It is a steel shell that undergoes volume expansion (Table 17–1: $\beta = 35 \times 10^{-6}/\text{C}^\circ \approx 3\alpha$). If you thought of the tank as being solid, the surface layer (the shell) would expand just the same. Thus the tank increases in volume by

$$\Delta V = (35 \times 10^{-6}/\text{C}^\circ)(70\,\text{L})(40^\circ\text{C} - 20^\circ\text{C}) = 0.049\,\text{L},$$

so the tank expansion has little effect. More than a liter of gas could spill out.

## Anomalous Behavior of Water Below 4 °C

Most substances expand more or less uniformly with an increase in temperature, as long as no phase change occurs. Water, however, does not follow the usual pattern. If water at 0°C is heated, it actually *decreases* in volume until it reaches 4°C. Above 4°C water behaves normally and expands in volume as the temperature is increased, Fig. 17–13. Water thus has its greatest density at 4°C. This anomalous behavior of water is of great importance for the survival of aquatic life during cold winters. When the water in a lake (or river) is above 4°C and begins to cool by contact with cold air, the water at the surface sinks because it is denser. It is replaced by warmer water from below. This mixing continues until the temperature of the entire lake reaches 4°C. As the surface water cools further, it remains on the surface because it is less dense than the 4°C water below. Water then freezes first at the surface, and the ice remains on the surface since ice (specific gravity = 0.917) is less dense than water. The water at the bottom remains liquid unless it is so cold that the whole body of water freezes. If water were like most substances, becoming more dense as it cools, the water at the bottom of a lake would be frozen first. Lakes would freeze solid more easily because circulation would bring the warmer water to the surface to be efficiently cooled.

PHYSICS APPLIED
*Life under ice*

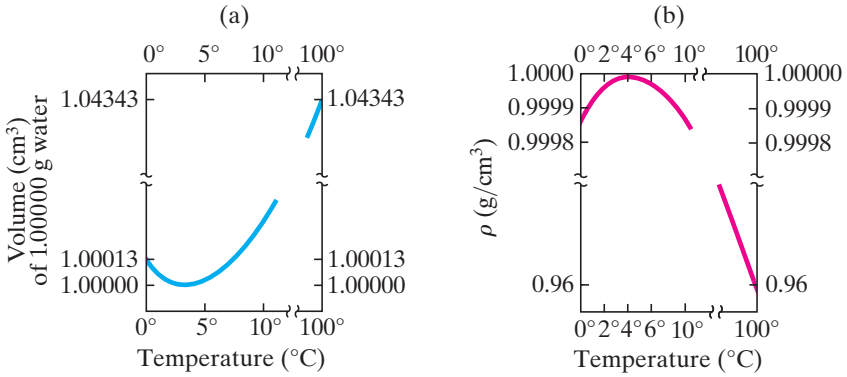

**FIGURE 17–13** Behavior of water as a function of temperature near 4°C. (a) Volume of 1.00000 gram of water, as a function of temperature. (b) Density vs. temperature. [Note the break in each axis.]

The complete freezing of a lake would cause severe damage to its plant and animal life. Because of the unusual behavior of water below 4°C, it is rare for any large and deep body of water to freeze completely, and this is helped by the layer of ice on the surface which acts as an insulator to reduce the flow of heat out of the water into the cold air above. Without this peculiar but wonderful property of water, life on this planet as we know it might not have been possible.

Not only does water expand as it cools from 4°C to 0°C, it expands even more as it freezes to ice. This is why ice cubes float in water and pipes break when water inside them freezes.

## *17–5 Thermal Stresses

In many situations, such as in buildings and roads, the ends of a beam or slab of material are rigidly fixed, which greatly limits expansion or contraction. If the temperature should change, large compressive or tensile stresses, called **thermal stresses**, will occur. The magnitude of such stresses can be calculated using the concept of elastic modulus developed in Chapter 12. To calculate the internal stress in a beam, we can think of this process as occurring in two steps: (1) the beam tries to expand (or contract) by an amount $\Delta\ell$ given by Eq. 17–1; (2) the rigid braces that hold the beam in place exert a force to compress the beam (or expand it), keeping it at its original length. The force $F$ required is given by Eq. 12–4:

$$\Delta\ell = \frac{1}{E}\frac{F}{A}\ell_0,$$

where $E$ is Young's modulus for the material. To calculate the internal stress, $F/A$, we then set $\Delta\ell$ in Eq. 17–1a equal to $\Delta\ell$ in the equation above and find

$$\alpha\ell_0\,\Delta T = \frac{1}{E}\frac{F}{A}\ell_0.$$

Hence, the stress is

$$\frac{F}{A} = \alpha E\,\Delta T.$$

**EXAMPLE 17–8** **Stress in concrete on a hot day.** A highway is to be made of blocks of concrete 10 m long placed end to end with no space between them to allow for expansion. If the blocks were placed at a temperature of 10°C, what compressive stress would occur if the temperature reached 40°C? The contact area between each block is 0.20 $m^2$. Will fracture occur?

PHYSICS APPLIED
*Highway buckling*

**APPROACH** We use the expression for the stress $F/A$ we just derived, and find the value of $E$ from Table 12–1. To see if fracture occurs, we compare this stress to the ultimate strength of concrete in Table 12–2.

**SOLUTION**

$$\frac{F}{A} = \alpha E\,\Delta T = \left(12\times10^{-6}/\text{C}^\circ\right)\left(20\times10^{9}\,\text{N/m}^2\right)\left(30\,\text{C}^\circ\right) = 7.2\times10^{6}\,\text{N/m}^2.$$

This stress is not far from the ultimate strength of concrete under compression (Table 12–2) and exceeds it for tension and shear. If the concrete is not perfectly aligned, part of the force will act in shear, and fracture is likely. This is why soft spacers or expansion joints (Fig. 17–3) are used in concrete sidewalks, highways, and bridges.

**EXERCISE C** How much space would you allow between the 10-m-long concrete blocks in Example 17–8 if you expected a temperature range of 0°F to 110°F?

# 17–6 The Gas Laws and Absolute Temperature

Equation 17–2 for volume expansion is not often useful for describing the expansion of a gas, mainly because gases expand to fill the full volume of whatever container they are in. If the temperature is raised, the pressure in the gas will increase if the container is more or less rigid; if the container is very flexible like a toy balloon, the volume will increase instead. The pressure, temperature, and volume of a gas are intimately related. It is therefore valuable to determine a relation between the volume, the pressure, the temperature, and the quantity of a gas. Such a relation is called an **equation of state**.

We describe the **state** (or condition) of a system, such as a gas in a container, using quantities that are detectable directly by our senses and instruments. Such quantities are called **state variables**. For a gas in a container, they are pressure $P$, volume $V$, temperature $T$, and quantity of the gas which could be mass $m$, or number of "moles" (which are defined in the next Section).

If the state of a system is changed, we will always wait until the pressure and temperature have reached the same values throughout. We thus consider only **equilibrium states** of a system—when the variables that describe it (such as temperature and pressure) are the same throughout the system and are not changing in time. (This is an idealization: real systems cannot be perfectly insulated, so some heat exchange with the environment can occur and the edges of the container will have a slightly different temperature than the center.)

We also consider here gases that are not too dense (the pressure is not too high, on the order of an atmosphere or less), and not cold enough to be close to condensing and becoming a liquid.

Consider a fixed quantity of gas in a flexible container (its volume can change) such as the cylinder shown in Fig. 17–14a, which is fitted with a piston that can move, thereby changing the volume. It is found experimentally that, to a good approximation, *the volume of a gas is inversely proportional to the absolute pressure applied to it when the temperature is kept constant*. That is,

$$V \propto \frac{1}{P}, \qquad \text{[constant } T\text{]}$$

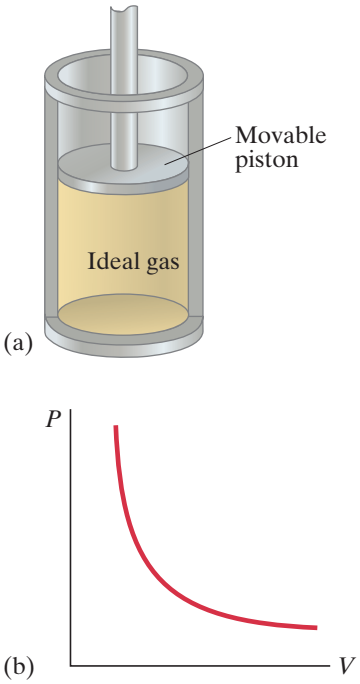
where $P$ is the absolute pressure (*not* "gauge pressure"—see Section 13–4). For example, if the pressure on a fixed amount of gas in a flexible container is doubled, the volume is reduced to half the original volume. This relation is known as **Boyle's law**, after the Englishman Robert Boyle (1627–1691), who first stated it on the basis of his own experiments. A graph of $P$ vs. $V$ for a fixed temperature is shown in Fig. 17–14b. Boyle's law can also be written

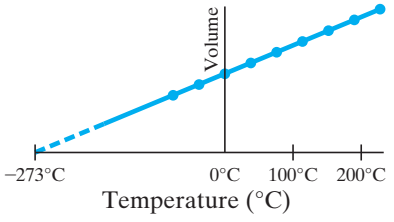
$$PV = \text{constant} \qquad \text{[constant } T\text{]}$$

for a fixed quantity of gas kept at constant temperature. If either the pressure or volume of a fixed amount of gas is allowed to vary, the other variable also changes so that the product $PV$ remains constant.

Temperature also affects the volume of a gas, but a quantitative relationship between $V$ and $T$ was not found until more than a century after Boyle's work. The Frenchman Jacques Charles (1746–1823) found that when the pressure is not too high and is kept constant, the volume of a gas increases with temperature at a nearly linear rate, as shown in Fig. 17–15a. However, all gases liquefy at low temperatures (for example, oxygen liquefies at −183°C), so the graph cannot be extended below the liquefaction point. Nonetheless, the graph is essentially a straight line and if projected to lower temperatures, as shown by the dashed line, it crosses the axis at about −273°C.

Such a graph can be drawn for any gas, and the straight line always projects back to −273°C at zero volume. This seems to imply that if a gas could be cooled to −273°C, it would have zero volume, and at lower temperatures a negative volume, which makes no sense. It could be argued that −273°C is the lowest temperature possible; indeed, many other more recent experiments indicate that this is so. This temperature is called the **absolute zero** of temperature. Its value has been determined to be −273.15°C.





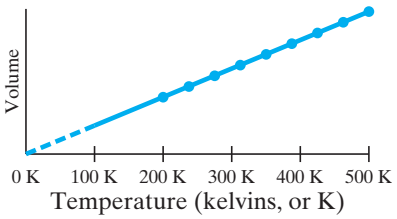


**FIGURE 17–14** (a) An ideal gas in a cylinder fitted with a movable piston. (b) Pressure vs. volume of a fixed amount of gas at a constant temperature, showing the inverse relationship as given by Boyle's law: as the pressure decreases, the volume increases.

**FIGURE 17–15** Volume of a fixed amount of gas as a function of (a) Celsius temperature, and (b) Kelvin temperature, when the pressure is kept constant.

(a)

(b)

Absolute zero forms the basis of a temperature scale known as the **absolute scale** or **Kelvin scale**, and it is used extensively in scientific work. On this scale the temperature is specified as degrees Kelvin or, preferably, simply as *kelvins* (K) without the degree sign. The intervals are the same as for the Celsius scale, but the zero on this scale (0 K) is chosen as absolute zero. Thus the freezing point of water (0°C) is 273.15 K, and the boiling point of water is 373.15 K. Indeed, any temperature on the Celsius scale can be changed to kelvins by adding 273.15 to it:

$$T(\text{K}) = T(^\circ\text{C}) + 273.15.$$

**CAUTION**
*K for kelvins has no degree sign*

Now let us look at Fig. 17–15b, where the graph of the volume of a gas versus absolute temperature is a straight line that passes through the origin. Thus, to a good approximation, *the volume of a fixed quantity of gas is directly proportional to the absolute temperature when the pressure is kept constant*. This is known as **Charles's law**, and is written

$$V \propto T. \qquad [\text{constant } P]$$

A third gas law, known as **Gay-Lussac's law**, after Joseph Gay-Lussac (1778–1850), states that *at constant volume, the absolute pressure of a gas is directly proportional to the absolute temperature*:

$$P \propto T. \qquad [\text{constant } V]$$

The laws of Boyle, Charles, and Gay-Lussac are not really laws in the sense that we use this term today (precise, deep, wide-ranging validity). They are really only approximations that are accurate for real gases only as long as the pressure and density of the gas are not too high, and the gas is not too close to condensing into a liquid (condensation). The term *law* applied to these three relationships has become traditional, however, so we have stuck with that usage.

**PHYSICS APPLIED**
*Throwing a jar into a campfire*

**CONCEPTUAL EXAMPLE 17–9** **Why you should not put a closed glass jar into a campfire.** What could happen if you tossed an empty glass jar, with the lid on tight, into a fire, and why?

**RESPONSE** The inside of the jar is not empty. It is filled with air. As the fire heats the air inside, its temperature rises. The volume of the glass jar changes only slightly due to the heating. According to Gay-Lussac's law the pressure $P$ of the air inside the jar increases, and that pressure can be large enough to cause the jar to explode, throwing glass pieces outward.

## 17–7 The Ideal Gas Law

The gas laws of Boyle, Charles, and Gay-Lussac were obtained by means of an important scientific technique: namely, *considering one quantity and how it is affected by changing only one other variable, keeping all other variables constant*. These laws can now be combined into a single more general relation among all three variables—absolute pressure, volume, and absolute temperature of a fixed amount of gas:

$$PV \propto T.$$

This relation indicates how any of the quantities $P$, $V$, or $T$ will vary when the other two quantities change. This relation reduces to Boyle's, Charles's, or Gay-Lussac's law when either $T$, $P$, or $V$, respectively, is held constant.

Finally, we must incorporate the effect of the amount of gas present. For example, when more air is forced into a balloon, the balloon gets bigger (Fig. 17–16). Indeed, careful experiments show that at constant temperature and pressure, the volume $V$ of an enclosed gas increases in direct proportion to the mass $m$ of gas present. Hence we write

$$PV \propto mT.$$

This proportion can be made into an equation by inserting a constant of proportionality. Experiment shows that this constant has a different value for different gases. However, the constant of proportionality turns out to be the same for all gases if, instead of the mass $m$, we use the number of *moles*, which we now define.

**FIGURE 17–16** Blowing up a balloon means putting more air (more air molecules) into the balloon, which increases its volume. The pressure is nearly constant, at atmospheric pressure, except for the small effect of the balloon's elasticity.

The "mole" is an official SI unit for the amount of any substance. One **mole** (abbreviated mol) has the precise definition of being the number of atoms in exactly 12 grams of carbon-12, whose atomic mass is exactly 12 u (Section 17–1).

An equivalent definition is that 1 mol is that amount of a substance whose mass in grams is numerically equal to the molecular mass of the substance (Section 17–1). For example, the mass of 1 mol of $CO_2$ is $[12 + (2 \times 16)] = 44$ g because carbon has atomic mass 12 and oxygen 16 (see Periodic Table inside the rear cover).

A modern definition of the mole is: an amount of a substance that contains $6.02 \times 10^{23}$ objects (usually atoms, molecules, or ions, etc.). This number is called *Avogadro's number*, as we discuss in Section 17–9.

In general, the number of moles, $n$, in a given sample of a pure substance is equal to the mass of the sample in grams divided by the molecular mass specified as grams per mole:

$$n\,(\text{mole}) = \frac{\text{mass (grams)}}{\text{molecular mass (g/mol)}}.$$

For example, the number of moles in 132 g of $CO_2$ (molecular mass 44 u) is

$$n = \frac{132\text{ g}}{44\text{ g/mol}} = 3.0\text{ mol}.$$

We can now write the proportion above $(PV \propto mT)$ as an equation:

*IDEAL GAS LAW*

$$PV = nRT, \qquad \textbf{(17–3)}$$

where $n$ represents the number of moles and $R$ is the constant of proportionality. $R$ is called the **universal gas constant** because its value is found experimentally to be the same for all gases. The value of $R$, in several sets of units (only the first is the proper SI unit), is

$$\begin{aligned} R &= 8.314\text{ J/(mol}\cdot\text{K)} && \text{[SI units]} \\ &= 0.0821\text{ (L}\cdot\text{atm)/(mol}\cdot\text{K)}^{\dagger} \\ &= 1.99\text{ calories/(mol}\cdot\text{K)}.^{\dagger} \end{aligned}$$

Equation 17–3 is called the **ideal gas law**, or the **equation of state for an ideal gas**. We use the term "ideal" because real gases do not follow Eq. 17–3 precisely, particularly at high pressure (and density) or when the gas is near the condensation point (= boiling point). However, at pressures less than an atmosphere or so, and when $T$ is not close to the condensation point of the gas, Eq. 17–3 is quite accurate and useful for real gases.

**CAUTION**

*Always give T in kelvins and P as absolute (not gauge) pressure*

Always remember, when using the ideal gas law, that temperatures must be given in kelvins (K) and that the pressure $P$ must always be *absolute* pressure, not gauge pressure (Section 13–4).

**EXERCISE D** Return to the Chapter-Opening Question, page 492, and answer it again now. Try to explain why you may have answered differently the first time.

**EXERCISE E** An ideal gas is contained in a steel sphere at 27.0°C and 1.00 atm absolute pressure. If no gas is allowed to escape and the temperature is raised to 127°C, what will be the new pressure? (*a*) 0.21 atm; (*b*) 0.75 atm; (*c*) 1.00 atm; (*d*) 1.33 atm; (*e*) 4.7 atm.

## 17–8 Problem Solving with the Ideal Gas Law

The ideal gas law is an extremely useful tool, and we now consider some Examples. We will often refer to "standard conditions" or **standard temperature and pressure** (abbreviated **STP**), which means:

STP (standard temperature and pressure)

$$T = 273.15\text{ K}\ \ (0°\text{C}) \quad \text{and} \quad P = 1.00\text{ atm} = 1.013 \times 10^5\text{ N/m}^2 = 101.3\text{ kPa}.$$

[†]Sometimes it is useful to use $R$ as given in these non-SI units; calories will be defined in Section 19–1.

**EXAMPLE 17–10** **Volume of one mole at STP.** Determine the volume of 1.00 mol of any gas, assuming it behaves like an ideal gas, at STP.

**APPROACH** We use the ideal gas law, solving for $V$ with $n = 1.00\,\text{mol}$.

**SOLUTION** We solve for $V$ in Eq. 17–3:

$$V = \frac{nRT}{P} = \frac{(1.00\,\text{mol})(8.314\,\text{J/mol}\cdot\text{K})(273.15\,\text{K})}{(1.013\times10^5\,\text{N/m}^2)} = 22.4\times10^{-3}\,\text{m}^3.$$

Since 1 liter (L) is $1000\,\text{cm}^3 = 1.00\times10^{-3}\,\text{m}^3$, 1.00 mol of any (ideal) gas has volume $V = 22.4\,\text{L}$ at STP.

**PROBLEM SOLVING**
*1.00 mol of gas at STP has $V = 22.4$ L*

The value of 22.4 L for the volume of 1 mol of an ideal gas at STP is worth remembering, for it sometimes makes calculation simpler.

**EXERCISE F** What is the volume of 1.00 mol of ideal gas at $546\,\text{K}\ (=2\times273\,\text{K})$ and 1.0 atm absolute pressure? (*a*) 11.2 L; (*b*) 22.4 L; (*c*) 44.8 L; (*d*) 67.2 L; (*e*) 89.6 L.

**EXAMPLE 17–11** **Helium balloon.** A helium party balloon, assumed to be a perfect sphere, has a radius of 18.0 cm. At room temperature (20°C), its internal pressure is 1.05 atm. Find the number of moles of helium in the balloon and the mass of helium needed to inflate the balloon to these values.

**APPROACH** We can use the ideal gas law to find $n$, since we are given $P$ and $T$, and can find $V$ from the given radius.

**SOLUTION** We get the volume $V$ from the formula for a sphere:

$$V = \tfrac{4}{3}\pi r^3 = \tfrac{4}{3}\pi(0.180\,\text{m})^3 = 0.0244\,\text{m}^3.$$

The pressure is given as $1.05\,\text{atm} = 1.064\times10^5\,\text{N/m}^2$. The temperature must be expressed in kelvins, so we change 20°C to $(20+273)\,\text{K} = 293\,\text{K}$. Finally, we use the value $R = 8.314\,\text{J/(mol}\cdot\text{K)}$ because we are using SI units. Thus

$$n = \frac{PV}{RT} = \frac{(1.064\times10^5\,\text{N/m}^2)(0.0244\,\text{m}^3)}{(8.314\,\text{J/mol}\cdot\text{K})(293\,\text{K})} = 1.066\,\text{mol}.$$

The mass of helium (atomic mass = 4.00 g/mol as given in the Periodic Table or Appendix G) can be obtained from

$$\text{mass} = n\times\text{molecular mass} = (1.066\,\text{mol})(4.00\,\text{g/mol}) = 4.26\,\text{g}$$

or $4.26\times10^{-3}\,\text{kg}$.

**EXAMPLE 17–12** **ESTIMATE** **Mass of air in a room.** Estimate the mass of air in a room whose dimensions are $5\,\text{m}\times3\,\text{m}\times2.5\,\text{m}$ high, at STP.

**APPROACH** First we determine the number of moles $n$ using the given volume. Then we can multiply by the mass of one mole to get the total mass.

**SOLUTION** Example 17–10 told us that 1 mol of a gas at 0°C has a volume of $22.4\,\text{L} = 22.4\times10^{-3}\,\text{m}^3$. The room's volume is $5\,\text{m}\times3\,\text{m}\times2.5\,\text{m}$, so

$$n = \frac{(5\,\text{m})(3\,\text{m})(2.5\,\text{m})}{22.4\times10^{-3}\,\text{m}^3/\text{mol}} \approx 1700\,\text{mol}.$$

Air is a mixture of about 20% oxygen $(O_2)$ and 80% nitrogen $(N_2)$. The molecular masses are $2\times16\,\text{u} = 32\,\text{u}$ and $2\times14\,\text{u} = 28\,\text{u}$, respectively, for an average of about 29 u. Thus, 1 mol of air has a mass of about $29\,\text{g} = 0.029\,\text{kg}$, so our room has a mass of air

$$m \approx (1700\,\text{mol})(0.029\,\text{kg/mol}) \approx 50\,\text{kg}.$$

**NOTE** That is roughly 100 lb of air!

**PHYSICS APPLIED**
*The mass of the air in a room is significant*

**EXERCISE G** At 20°C, would there be (*a*) more, (*b*) less, or (*c*) the same mass of air in a room than at 0°C?

Frequently, volume is specified in liters and pressure in atmospheres. Rather than convert these to SI units, we can instead use the value of $R$ given in Section 17–7 as $0.0821\ \text{L}\cdot\text{atm/mol}\cdot\text{K}$.

**PROBLEM SOLVING**
*Using the ideal gas law as a ratio*

In many situations it is not necessary to use the value of $R$ at all. For example, many problems involve a change in the pressure, temperature, and volume of a fixed amount of gas. In this case, $PV/T = nR = \text{constant}$, since $n$ and $R$ remain constant. If we now let $P_1$, $V_1$, and $T_1$ represent the appropriate variables initially, and $P_2$, $V_2$, $T_2$ represent the variables after the change is made, then we can write

$$\frac{P_1 V_1}{T_1} = \frac{P_2 V_2}{T_2}. \qquad \text{[fixed } n\text{]}$$

If we know any five of the quantities in this equation, we can solve for the sixth. Or, if one of the three variables is constant ($V_1 = V_2$, or $P_1 = P_2$, or $T_1 = T_2$) then we can use this equation to solve for one unknown when given the other three quantities.

**PHYSICS APPLIED**
*Pressure in a hot tire*

**FIGURE 17–17** Example 17–13.

**EXAMPLE 17–13 Check tires cold.** An automobile tire is filled to a gauge pressure of 210 kPa (= 30 psi) at 10°C (Fig. 17–17). After a drive of 100 km, the temperature within the tire rises to 40°C due to friction with the road. What is the pressure within the tire now?

**APPROACH** We do not know the number of moles of gas, or the volume of the tire, but we assume they are constant. We use the ratio form of the ideal gas law.

**SOLUTION** Since $V_1 = V_2$, then

$$\frac{P_1}{T_1} = \frac{P_2}{T_2}.$$

This is, incidentally, a statement of Gay-Lussac's law. Since the pressure given is the gauge pressure (Section 13–4), we must add atmospheric pressure (= 101 kPa) to get the absolute pressure $P_1 = (210\ \text{kPa} + 101\ \text{kPa}) = 311\ \text{kPa}$. We convert temperatures to kelvins by adding 273 and solve for $P_2$:

$$P_2 = P_1\left(\frac{T_2}{T_1}\right) = (3.11\times 10^5\ \text{Pa})\left(\frac{313\ \text{K}}{283\ \text{K}}\right) = 344\ \text{kPa}.$$

Subtracting atmospheric pressure, we find the resulting gauge pressure to be 243 kPa, which is a 16% increase (= 35 psi).

**NOTE** This Example shows why car manuals emphasize checking tire pressure when the tires are cold.

## 17–9 Ideal Gas Law in Terms of Molecules: Avogadro's Number

The fact that the gas constant $R$ in the ideal gas law has the same value for all gases demonstrates a remarkable simplicity in nature. It was first recognized, although in a slightly different form, by the Italian scientist Amedeo Avogadro (1776–1856). Avogadro proposed that *equal volumes of gas at the same pressure and temperature contain equal numbers of molecules*. This relationship is called **Avogadro's hypothesis** or **Avogadro's Principle**.

This is consistent with $R$ being the same for all gases because, from the ideal gas law (Eq. 17–3) $PV/T = nR$, then $n$ is the same for all gases if and only if $R$ is the same for all gases. Thus Avogadro's hypothesis is equivalent to $R$ being the same for all gases.

The number of molecules in one mole of any pure substance is known as **Avogadro's number**, $N_A$. Although Avogadro conceived the notion, he was not

able to actually determine the value of $N_A$. Indeed, precise measurements were not done until the twentieth century.

A number of methods have been devised to measure $N_A$, and the accepted value today is

$$N_A = 6.02 \times 10^{23}. \qquad \text{[molecules/mole]}$$

*Avogadro's number*

Since the total number of molecules, $N$, in a gas is equal to $N_A$ times the number of moles $(N = nN_A)$, the ideal gas law, Eq. 17–3, can be written in terms of the number of molecules present:

$$PV = nRT = \frac{N}{N_A} RT,$$

or

$$PV = NkT, \qquad \textbf{(17–4)}$$

*IDEAL GAS LAW (in terms of molecules)*

where $k = R/N_A$ is called the **Boltzmann constant** and has the value

$$k = \frac{R}{N_A} = \frac{8.314\,\text{J/mol}\cdot\text{K}}{6.02 \times 10^{23}/\text{mol}} = 1.38 \times 10^{-23}\,\text{J/K}.$$

**EXAMPLE 17–14** **Hydrogen atom mass.** Use Avogadro's number to determine the mass of a hydrogen atom.

**APPROACH** The mass of one atom equals the mass of 1 mol divided by the number of atoms in 1 mol, $N_A$.

**SOLUTION** One mole of hydrogen atoms (atomic mass = 1.008 u, Section 17–1 or Appendix G) has a mass of $1.008 \times 10^{-3}$ kg and contains $6.02 \times 10^{23}$ atoms. Thus one atom has a mass

$$m = \frac{1.008 \times 10^{-3}\,\text{kg}}{6.02 \times 10^{23}} = 1.67 \times 10^{-27}\,\text{kg}.$$

**NOTE** Historically, the reverse was done: a precise value of $N_A$ was obtained from a precise measurement of the mass of the hydrogen atom.

**EXAMPLE 17–15** **ESTIMATE** **How many molecules in one breath?** Estimate how many molecules you breathe in with a 1.0-L breath of air.

**PHYSICS APPLIED** *Molecules in a breath*

**APPROACH** We determine what fraction of a mole 1.0 L is by using the result of Example 17–10 that 1 mole has a volume of 22.4 L at STP, and then multiply that by $N_A$ to get the number of molecules in this number of moles.

**SOLUTION** One mole corresponds to 22.4 L at STP, so 1.0 L of air is $(1.0\,\text{L})/(22.4\,\text{L/mol}) = 0.045$ mol. Then 1.0 L of air contains

$$(0.045\,\text{mol})\,(6.02 \times 10^{23}\,\text{molecules/mol}) \approx 3 \times 10^{22}\,\text{molecules}.$$

## *17–10 Ideal Gas Temperature Scale—a Standard

It is important to have a very precisely defined temperature scale so that measurements of temperature made at different laboratories around the world can be accurately compared. Called the **ideal gas temperature scale**, it is based on the property of an ideal gas that the pressure is directly proportional to the absolute temperature (Gay-Lussac's law). A real gas approaches this ideal at very low density. To set up a scale we need two fixed points. One fixed point will be $P = 0$ at $T = 0$ K.

The second fixed point is chosen to be the **triple point** of water, which is that point where water in the solid, liquid, and gas states can coexist in equilibrium. This occurs only at a unique temperature and pressure, and can be reproduced at different laboratories with great precision.[†] The pressure on the water at its triple point can only be 4.58 torr, and its temperature can only be 0.01°C. In fact, the triple point is now *defined* to have a temperature of exactly 273.16 K (= 273.15 K + 0.01 K).

The absolute or Kelvin temperature $T$ of a substance is determined by putting that substance in good thermal contact with a constant-volume gas thermometer (page 497, Fig. 17–8). The temperature $T$ is then defined as

$$T = (273.16\,\text{K}) \lim_{P_{tp} \to 0} \left( \frac{P}{P_{tp}} \right). \qquad \text{[constant volume]} \quad \textbf{(17–5)}$$

In this relation, $P_{tp}$ is the pressure of the gas in the rigid bulb of the constant-volume gas thermometer when it is placed in water at its triple point, and $P$ is the pressure in that same thermometer when it is instead in contact with the substance where $T$ is being determined. (Do not confuse the pressure of 4.58 torr in water at its triple point, with $P_{tp}$ which is the pressure in the bulb of the thermometer (Fig. 17–8) when that bulb is immersed in water at its triple point. Both $P$ and $P_{tp}$ refer to the pressure inside the thermometer bulb.) Note that if we let $P = P_{tp}$ in Eq. 17–5, then $T = 273.16$ K, as it must.

The pressure inside the bulb ($P$ and $P_{tp}$ at the two different temperatures) can be reduced by allowing some gas to escape, and that is just what we must do to take the limit in Eq. 17–5. The reason we use the limit process is because we get different results for the temperature depending on the type and amount of gas in the bulb of the thermometer (see Fig. 17–18). But whatever real gas we use, when making a series of measurements in which the amount of gas in the thermometer bulb is reduced to smaller and smaller amounts (so that both $P$ and $P_{tp}$ become smaller and smaller), it is found experimentally that an extrapolation of such data to $P_{tp} = 0$ always gives the *same value* for the temperature (Fig. 17–18). That is, all gases approach an ideal gas in this limit, as suggested at the end of Section 17–2. One of the great advantages of this **ideal gas temperature scale** is that the value for $T$ does not depend on the kind of gas used. Helium has the lowest condensation point of all gases and at very low pressures it liquefies at about 1 K; so temperatures below this cannot be defined on this scale.

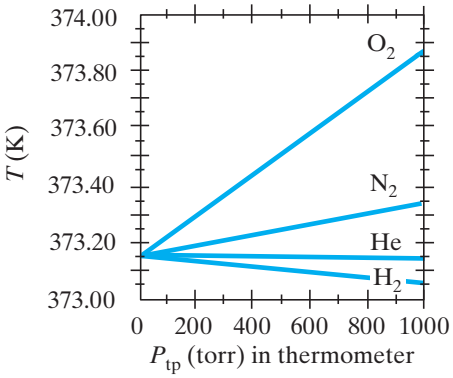

**FIGURE 17–18** Temperature readings of a constant-volume gas thermometer immersed in boiling water at 1.00 atm are graphed, for different gases, as a function of the gas pressure in the thermometer at the triple point $(P_{tp})$. Note that as the amount of gas in the thermometer is reduced, so that $P_{tp} \to 0$, all gases give the same reading, 373.15 K. For pressure less than 0.10 atm (76 torr), the variation shown is less than 0.07 K.

[†]Liquid water and steam can coexist (the boiling point) at a range of temperatures depending on the pressure. Water boils at a lower temperature when the pressure is less, such as high in the mountains. The triple point represents a more precisely reproducible fixed point than does either the freezing point or boiling point of water at, say, 1 atm. See Section 18–3 for further discussion.

# Summary

The atomic theory of matter postulates that all matter is made up of tiny entities called **atoms**, which are typically $10^{-10}$ m in diameter.

**Atomic** and **molecular masses** are specified on a scale where the most common form of carbon $(^{12}C)$ is arbitrarily given the value 12.0000 u (atomic mass units), exactly.

The distinction between solids, liquids, and gases can be attributed to the strength of the attractive forces between the atoms or molecules and to their average speed.

**Temperature** is a measure of how hot or cold something is. **Thermometers** are used to measure temperature on the **Celsius** (°C), **Fahrenheit** (°F), and **Kelvin** (K) scales. Two standard points on each scale are the freezing point of water (0°C, 32°F, 273.15 K) and the boiling point of water (100°C, 212°F, 373.15 K). A one-kelvin change in temperature equals a change of one Celsius degree or $\frac{9}{5}$ Fahrenheit degrees. Kelvins are related to °C by

$$T(\text{K}) = T(^\circ\text{C}) + 273.15.$$

When two objects at different temperatures are placed in contact, they eventually reach the same temperature and are then said to be in **thermal equilibrium**.

The change in length, $\Delta\ell$, of a solid, when its temperature changes by an amount $\Delta T$, is directly proportional to the temperature change and to its original length $\ell_0$. That is,

$$\Delta\ell = \alpha\ell_0\Delta T, \qquad \textbf{(17–1a)}$$

where $\alpha$ is the *coefficient of linear expansion*.

The change in volume of most solids, liquids, and gases is proportional to the temperature change and to the original volume $V_0$:

$$\Delta V = \beta V_0\Delta T. \qquad \textbf{(17–2)}$$

The *coefficient of volume expansion*, $\beta$, is approximately equal to $3\alpha$ for uniform solids.

Water is unusual because, unlike most materials whose volume increases with temperature, water's volume actually *decreases* as the temperature increases from 0°C to 4°C.

The **ideal gas law**, or **equation of state for an ideal gas**, relates the absolute pressure $P$, volume $V$, and temperature $T$ (in kelvins) of $n$ moles of gas by the equation

$$PV = nRT, \qquad \textbf{(17–3)}$$

where $R = 8.314\ \text{J/mol}\cdot\text{K}$ for all gases. Real gases obey the ideal gas law quite accurately if they are not at too high a pressure or near their liquefaction point.

One **mole** is that amount of a substance whose mass in grams is numerically equal to the atomic or molecular mass of that substance.

**Avogadro's number**, $N_A = 6.02\times10^{23}$, is the number of atoms or molecules in 1 mol of any pure substance.

The ideal gas law can be written in terms of the number of molecules $N$ in the gas as

$$PV = NkT, \qquad \textbf{(17–4)}$$

where $k = R/N_A = 1.38\times10^{-23}\ \text{J/K}$ is **Boltzmann's constant**.

# Questions

1. Which has more atoms: 1 kg of lead or 1 kg of copper? (See the Periodic Table or Appendix G.) Explain why.
2. Name several properties of materials that could be used to make a thermometer.
3. Which is larger, 1 C° or 1 F°? Explain why.
4. If system A is in thermal equilibrium with system B, but B is not in thermal equilibrium with system C, what can you say about the temperatures of A, B, and C?
5. Suppose system C is not in thermal equilibrium with system A nor in thermal equilibrium with system B. Does this imply that A and B are not in thermal equilibrium? What can you infer regarding the temperatures of A, B, and C?
6. In the relation $\Delta\ell = \alpha\ell_0\Delta T$, should $\ell_0$ be the initial length, the final length, or does it matter?
7. A flat bimetallic strip consists of a strip of aluminum riveted to a strip of iron. When heated, the strip will bend. Which metal will be on the outside of the curve? Why?
8. Long steam pipes that are fixed at the ends often have a section in the shape of a U. Why?
9. Figure 17–19 shows a diagram of a simple bimetallic **thermostat** used to control a furnace (or other heating or cooling system). The electric switch (attached to the bimetallic strip) is a glass vessel containing liquid mercury that conducts electricity when it touches both contact wires. Explain how this device controls the furnace and how it can be set at different temperatures.

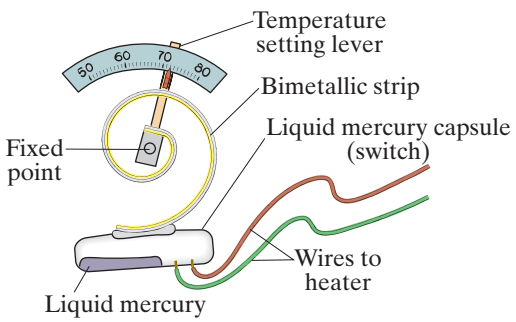

**FIGURE 17–19** A thermostat (Question 9).

10. A lead cylinder floats in mercury at 0°C. Will the lead float higher or lower if the temperature is raised? Explain.
11. A glass container may break if one part of it is heated or cooled more rapidly than adjacent parts. Explain.
12. Explain why it is advisable to add water to an overheated automobile engine only slowly, and only with the engine running.
13. The units for the coefficients of linear expansion $\alpha$ are $(\text{C}^\circ)^{-1}$, and there is no mention of a length unit such as meters. Would the expansion coefficient change if we used feet or millimeters instead of meters? Explain.
14. When a cold alcohol-in-glass thermometer is first placed in a hot tub of water, the alcohol initially descends a bit and then rises. Explain.
15. The principal virtue of **Pyrex glass** is that its coefficient of linear expansion is much smaller than that for ordinary glass (Table 17–1). Explain why this gives rise to the higher heat resistance of Pyrex.
16. Will a clock using a pendulum supported on a long thin brass rod that is accurate at 20°C run fast or slow on a hot day (30°C)? Explain.
17. Freezing a can of soda will cause its bottom and top to bulge so badly the can will not stand up. What has happened?
18. Why might you expect an alcohol-in-glass thermometer to be more precise than a mercury-in-glass thermometer?
19. Will the buoyant force on an aluminum sphere submerged in water increase, decrease, or remain the same, if the temperature is increased from 20°C to 40°C? Explain.
20. If an atom is measured to have a mass of $6.7\times10^{-27}$ kg, what atom do you think it is?

*21. From a practical point of view, does it really matter what gas is used in a constant-volume gas thermometer? If so, explain. [*Hint*: See Fig. 17–18.]

# MisConceptual Questions

**1.** Rod A has twice the diameter of rod B, but both are made of iron and have the same initial length. Both rods are now subjected to the same change in temperature (but remain solid). How would the change in the rods' lengths compare?
(*a*) Rod A changes in length more than rod B.
(*b*) Rod B changes in length more than rod A.
(*c*) The same.
(*d*) Need to know whether the rods were cooled or heated.

**2.** Rod A is twice as long as rod B, but both are made of iron and have the same diameter. Both rods are now subjected to the same increase in temperature (but remain a solid). How would the change in the rods' lengths compare?
(*a*) Rod A increases in length more than rod B.
(*b*) Rod B increases in length more than rod A.
(*c*) The same.
(*d*) Not enough information.

**3.** The linear expansion of a rod depends on which of the following?
(*a*) The length of the rod.
(*b*) The change in temperature of the rod.
(*c*) The type of material.
(*d*) All of the above.
(*e*) Both (*b*) and (*c*).

**4.** A steel plate has a hole in it with a diameter of exactly 1.0 cm when the plate is at a temperature of 20°C. A steel ring has an inner diameter of exactly 1.0 cm at 20°C. Both the plate and the ring are heated to 100°C. Which statement is true?
(*a*) The hole in the plate gets smaller, and the opening in the ring gets larger.
(*b*) The opening in the ring gets larger, but we need the relative size of the plate and the hole to know what happens to the hole.
(*c*) The hole in the plate and the opening in the ring get larger.
(*d*) The hole in the plate and the opening in the ring get smaller.
(*e*) The hole in the plate gets larger, and the opening in the ring gets smaller.

**5.** A steel *tape measure* is marked such that it gives accurate length measurements at room temperature. If the tape measure is used outside on a very hot day, how will its length measurements be affected?
(*a*) Measured lengths will still be accurate.
(*b*) Measured lengths will be smaller than the real lengths.
(*c*) Measured lengths will be larger than the real lengths.

**6.** One mole of an ideal gas in a sealed rigid container is initially at a temperature of 100°C. The temperature is then increased to 200°C. The pressure in the gas
(*a*) remains constant.
(*b*) increases by about 25%.
(*c*) doubles.
(*d*) triples.
(*e*) is halved.

**7.** When an ideal gas is warmed from 20°C to 40°C, the gas's temperature $T$ that appears in the ideal gas law increases by a factor
(*a*) of 2.
(*b*) of 1.07.
(*c*) that depends on the temperature scale you use.

**8.** When using the ideal gas law, which of the following rules must be obeyed?
(*a*) Always use temperature in kelvins and absolute pressure.
(*b*) Always use volume in $m^3$ and temperature in kelvins.
(*c*) Always use gauge pressure and temperature in degrees Celsius.
(*d*) Always use gauge pressure and temperature in kelvins.
(*e*) Always use volume in $m^3$ and gauge pressure.

**9.** The temperature of an ideal gas increases. Which of the following is true?
(*a*) The pressure must decrease.
(*b*) The pressure must increase.
(*c*) The pressure must increase while the volume decreases.
(*d*) The volume must increase while the pressure decreases.
(*e*) The pressure, the volume, or both, may increase.

**10.** When you blow up a balloon, which of the following increases significantly?
(*a*) The temperature inside the balloon.
(*b*) The pressure inside the balloon.
(*c*) The number of air molecules inside the balloon.
(*d*) The volume of the balloon.

**11.** You carry an airtight bag of potato chips onto an airplane. After the plane has ascended to cruising altitude, you notice that the unopened bag has puffed up. The most plausible explanation is that the volume of a gas (such as air) increases when
(*a*) temperature increases, if pressure is approximately constant.
(*b*) pressure decreases, if temperature is approximately constant.
(*c*) pressure increases, if temperature is approximately constant.
(*d*) temperature decreases, if pressure is approximately constant.

**12.** Two identical car tires are at the same temperature but contain different amounts of air. A pressure gauge indicates 1.0 atm for tire A and 2.0 atm for tire B. If the volume of the two tires is the same, how are the amounts of air in the two tires related?
(*a*) A contains twice as much air as B.
(*b*) B contains twice as much air as A.
(*c*) B contains more air than A, but not twice as much.
(*d*) B contains more than twice as much air as A.
(*e*) A contains more than B, but not twice as much.

# Problems

## 17–1 Atomic Theory

1. (II) How many atoms are there in a 3.4-g copper coin?
2. (II) How does the number of atoms in a 31.5-g gold ring compare to the number in a silver ring of the same mass?

## 17–2 Temperature and Thermometers

3. (I) (*a*) "Room temperature" is often taken to be 68°F. What is this on the Celsius scale? (*b*) The temperature of the filament in a lightbulb is about 1900°C. What is this on the Fahrenheit scale?
4. (I) Among the highest and lowest natural air temperatures ever recorded are 136°F in the Libyan desert and −129°F in Antarctica. What are these temperatures on the Celsius scale?
5. (I) A thermometer tells you that you have a fever of 38.5°C. What is this in Fahrenheit?
6. (I) (*a*) 22° below zero on the Celsius scale is what Fahrenheit temperature? (*b*) 22° below zero on the Fahrenheit scale is what Celsius temperature?
7. (II) In an alcohol-in-glass thermometer, the alcohol column has length 12.61 cm at 0.0°C and length 22.79 cm at 100.0°C. What is the temperature if the column has length (*a*) 18.50 cm, and (*b*) 14.40 cm?

## 17–4 Thermal Expansion

8. (I) A concrete highway is built of slabs 14 m long at 15°C. How wide should the expansion cracks between the slabs be (at 15°C) to prevent buckling if the range of temperature is −30°C to +50°C?
9. (I) The Eiffel Tower (Fig. 17–20) is built of wrought iron approximately 300 m tall. Estimate how much its height changes between January (average temperature of 2°C) and July (average temperature of 25°C). Ignore the angles of the iron beams and treat the tower as a vertical beam.

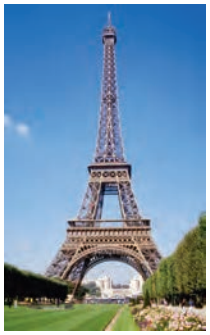

**FIGURE 17–20** Problem 9. The Eiffel Tower in Paris.

10. (I) Super Invar™, an alloy of iron and nickel, is a strong material with a very low coefficient of thermal expansion $(0.20 \times 10^{-6}/\text{C}^\circ)$. A 1.8-m-long tabletop made of this alloy is used for sensitive laser measurements where extremely high tolerances are required. How much will this alloy table expand along its length if the temperature increases 7.5 C°? Compare to tabletops made of steel.
11. (II) The density of water at 4°C is $1.00 \times 10^3\ \text{kg/m}^3$. What is water's density at 94°C? Assume a constant coefficient of volume expansion.
12. (II) To what temperature would you have to heat a brass rod for it to be 1.5% longer than it is at 22°C?
13. (II) To make a secure fit, *rivets* that are larger than the rivet hole are often used and the rivet is cooled (usually in dry ice) before it is placed in the hole. A steel rivet 1.872 cm in diameter is to be placed in a hole 1.870 cm in diameter in a metal at 24°C. To what temperature must the rivet be cooled if it is to fit in the hole?
14. (II) At a given latitude, ocean water in the so-called *mixed layer* (from the surface to a depth of about 50 m) is at approximately the same temperature due to the mixing action of waves. Assume that because of *global warming*, the temperature of the mixed layer is everywhere increased by 0.5°C, while the temperature of the deeper portions of the ocean remains unchanged. Estimate the resulting rise in sea level. The ocean covers about 70% of the Earth's surface.
15. (II) An aluminum sphere is 8.75 cm in diameter. What will be its % change in volume if it is heated from 30°C to 140°C?
16. (II) A uniform rectangular plate of length $\ell$ and width $w$ has a coefficient of linear expansion $\alpha$. (*a*) Show that, if we neglect very small quantities, the change in area of the plate due to a temperature change $\Delta T$ is $\Delta A = 2\alpha\ell w\,\Delta T$. See Fig. 17–21. (*b*) The plate has thickness $t$. Show that the coefficient of volume expansion is $\beta \approx 3\alpha$.

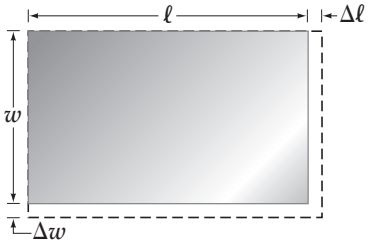

**FIGURE 17–21** Problem 16(a). A rectangular plate is heated.

17. (II) A glass is filled to the brim with 450.0 mL of water, all at 100.0°C. If the temperature of glass and water is decreased to 20.0°C, how much water could be added to the glass?
18. (II) A certain car has 14.0 L of liquid coolant circulating at a temperature of 93°C through the engine's cooling system. Assume that, in this normal condition, the coolant completely fills the 3.5-L volume of the aluminum radiator and the 10.5-L internal cavities within the aluminum engine. When a car overheats, the radiator, engine, and coolant expand and a small reservoir connected to the radiator catches any resultant coolant overflow. Estimate how much coolant overflows to the reservoir if the system goes from 93°C to 105°C. Model the radiator and engine as hollow shells of aluminum. The coefficient of volume expansion for coolant is $\beta = 410 \times 10^{-6}/\text{C}^\circ$.
19. (II) It is observed that 55.50 mL of water at 20°C completely fills a container to the brim. When the container and the water are heated to 60°C, 0.35 g of water is lost. (*a*) What is the coefficient of volume expansion of the container? (*b*) What is the most likely material of the container? Density of water at 60°C is 0.98324 g/mL.
20. (II) A brass plug is to be placed in a ring made of iron. At 15°C, the diameter of the plug is 8.756 cm and that of the inside of the ring is 8.742 cm. They must both be brought to what common temperature in order to fit?
21. (II) If a fluid is contained in a long narrow vessel so it can expand in essentially one direction only, show that the effective coefficient of linear expansion $\alpha$ is approximately equal to the coefficient of volume expansion $\beta$.
22. (II) (*a*) Show that the change in the density $\rho$ of a substance, when the temperature changes by $\Delta T$, is given by $\Delta\rho = -\beta\rho\,\Delta T$. (*b*) What is the fractional change in density of a lead sphere whose temperature decreases from 35°C to −55°C?

23. (II) Wine bottles are never completely filled: a small volume of air is left in the glass bottle's cylindrically shaped neck (inner diameter $d = 18.5\,\text{mm}$) to allow for wine's fairly large coefficient of thermal expansion. The distance $H$ between the surface of the liquid contents and the bottom of the cork is called the "headspace height" (Fig. 17–22), and is typically $H = 1.5\,\text{cm}$ for a 750-mL bottle filled at 20°C. Due to its alcoholic content, wine's coefficient of volume expansion is about double that of water; in comparison, the thermal expansion of glass can be neglected. Estimate $H$ if the bottle is kept (*a*) at 10°C, (*b*) at 30°C.

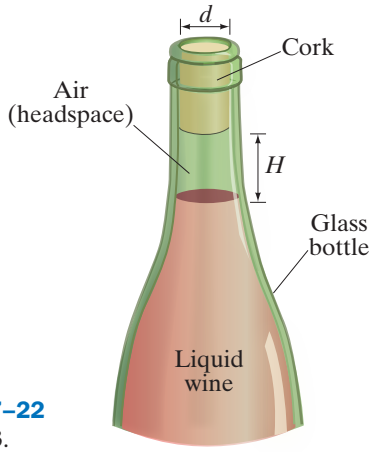

**FIGURE 17–22**
Problem 23.

24. (III) (*a*) Determine a formula for the change in surface area of a uniform solid sphere of radius $r$ if its coefficient of linear expansion is $\alpha$ (assumed constant) and its temperature is changed by $\Delta T$. (*b*) What is the increase in area of a solid iron sphere of radius 60.0 cm if its temperature is raised from 15°C to 225°C?

25. (III) The pendulum in a grandfather clock is made of brass and keeps perfect time at 17°C. How much time is gained or lost in a year if the clock is kept at 26°C? (Assume the frequency dependence on length for a simple pendulum applies; see Chapter 14.)

26. (III) Water's coefficient of volume expansion in the temperature range from 0°C to about 20°C is given approximately by $\beta = a + bT + cT^2$, with $a = -6.43 \times 10^{-5}(\text{C}^\circ)^{-1}$, $b = 1.70 \times 10^{-5}(\text{C}^\circ)^{-2}$, and $c = -2.02 \times 10^{-7}(\text{C}^\circ)^{-3}$. Using the formula for density from Problem 22, show that water has its greatest density at approximately 4.0°C.

## *17–5 Thermal Stresses

*27. (II) An aluminum bar has the desired length when at 12°C. How much stress is required to keep it at this length if the temperature increases to 38°C? [See Table 12–1.]

*28. (II) (*a*) A horizontal steel I-beam of cross-sectional area $0.041\,\text{m}^2$ is rigidly connected to two fixed vertical supports. If the beam was installed when the temperature was 25°C, what stress is developed in the beam when the temperature drops to −25°C? (*b*) Is the ultimate strength of the steel exceeded? (*c*) What stress is developed if the beam is concrete and has a cross-sectional area of $0.15\,\text{m}^2$? Will it fracture?

*29. (III) A barrel of diameter 134.122 cm at 20°C is to be enclosed by an iron band. The circular band has an inside diameter of 134.110 cm at 20°C. It is 9.4 cm wide and 0.65 cm thick. (*a*) To what temperature must the band be heated so that it will fit over the barrel? (*b*) What will be the tension in the band when it cools to 20°C?

## 17–6 Gas Laws; Absolute Temperature

30. (I) What are the following temperatures on the Kelvin scale: (*a*) 58°C, (*b*) 86°F, (*c*) −55°C, (*d*) 5100°C?

31. (I) Absolute zero is what temperature on the Fahrenheit scale?

32. (II) A weather forecast states that tomorrow's temperature will be twice what it is today. Today's temperature is 10°C. Using the forecast, compute tomorrow's temperature on the Celsius, Fahrenheit, and Kelvin scales. Which value is most believable?

33. (II) Typical temperatures in the interior of the Earth and Sun are about 4000°C and $15 \times 10^6$ °C, respectively. (*a*) What are these temperatures in kelvins? (*b*) What percent error is made in each case if a person forgets to change °C to K?

## 17–7 and 17–8 Ideal Gas Law

34. (I) In an internal combustion engine, air at atmospheric pressure and a temperature of about 20°C is compressed in the cylinder by a piston to $\frac{1}{9}$ of its original volume (compression ratio = 9.0). Estimate the temperature of the compressed air, assuming the pressure reaches 40 atm.

35. (I) If $3.50\,\text{m}^3$ of a gas initially at STP is placed under a pressure of 2.80 atm, the temperature of the gas rises to 38.0°C. What is the volume?

36. (II) If 12.50 mol of helium gas is at 10.0°C and a gauge pressure of 0.350 atm, calculate (*a*) the volume of the helium gas under these conditions, and (*b*) the temperature if the gas is compressed to precisely half the volume at a gauge pressure of 1.00 atm.

37. (II) Calculate the density of nitrogen at STP using the ideal gas law.

38. (II) A storage tank contains 21.6 kg of nitrogen $(N_2)$ at an absolute pressure of 3.45 atm. What will the pressure be if the nitrogen is replaced by an equal mass of $CO_2$ at the same temperature?

39. (II) A storage tank at STP contains 26.5 kg of nitrogen $(N_2)$. (*a*) What is the volume of the tank? (*b*) What is the pressure if an additional 32.2 kg of nitrogen is added without changing the temperature?

40. (II) A *scuba* tank is filled with air to a gauge pressure of 202 atm when the air temperature is 29°C. A diver then jumps into the ocean and, after a short time on the ocean surface, checks the tank's pressure and finds that it is only 191 atm. Assuming the diver has inhaled a negligible amount of air from the tank, what is the temperature of the ocean water?

41. (II) What is the pressure inside a 41.0-L container holding 105.0 kg of argon gas at 21.6°C?

42. (II) A tank contains 30.0 kg of $O_2$ gas at a gauge pressure of 8.20 atm. If the oxygen is replaced by helium at the same temperature, how many kilograms of the latter will be needed to produce a gauge pressure of 8.00 atm?

43. (II) A sealed metal container contains a gas at 30.0°C and absolute pressure 1.00 atm. To what temperature must the gas be heated for the pressure to double to 2.00 atm? (Ignore expansion of the container.)

44. (II) A tire is filled with air at 15°C to a gauge pressure of 230 kPa. If the tire reaches a temperature of 38°C, what fraction of the original air must be removed if the original pressure of 230 kPa is to be maintained?

45. (II) If 59.2 L of oxygen at 18.0°C and an absolute pressure of 2.45 atm are compressed to 38.8 L and at the same time the temperature is raised to 56.0°C, what will the new pressure be?

46. (II) A helium-filled balloon escapes a child's hand at sea level and 20.0°C. When it reaches an altitude of 3600 m, where the temperature is 5.0°C and the pressure only 0.64 atm, how will its volume compare to that at sea level?

47. (II) A sealed metal container can withstand a pressure difference of 0.50 atm. The container initially is filled with an ideal gas at 18°C and 1.0 atm. To what temperature can you cool the container before it collapses? (Ignore any changes in the container's volume due to thermal expansion.)

48. (II) A helium balloon rises because of a buoyant force. By what percentage does the buoyant force on a helium balloon change if the temperature of the helium is increased from 15°C to 25°C while the temperature of the surrounding air is unchanged? Assume that the pressure of the helium remains constant.

49. (II) The atmospheric pressure on the surface of Mars has an average value of about 600 Pa. (*a*) What is the volume of 1.0 mole of the *Martian atmosphere* where the average temperature is about −50°C? (*b*) What is the density of the Martian atmosphere under these conditions, which is about 96% carbon dioxide? (*c*) What fraction is this density as compared to the Earth's atmospheric density of 1.29 kg/m$^3$, at 0°C and 1 atm pressure?

50. (II) You buy an "airtight" *potato chip bag* packaged at sea level, and take the chips on an airplane flight. When you take the potato chip bag out of your "carry-on" bag, you notice it has noticeably "puffed up." Airplane cabins are typically pressurized at 0.75 atm, and assuming the temperature inside an airplane is about the same as inside a potato chip processing plant, by what percentage has the bag "puffed up" in comparison to when it was packaged?

51. (II) A typical *scuba tank*, when fully charged, contains 12 L of air at 204 atm. Assume an "empty" tank contains air at 34 atm gauge pressure, and is connected to an air compressor at sea level. The air compressor intakes air from the atmosphere, compresses it to high pressure, and then inputs this high-pressure air into the scuba tank. If the (average) flow rate of air from the atmosphere into the intake port of the air compressor is 290 L/min, how long will it take to fully charge the scuba tank? Assume the tank remains at the same temperature as the surrounding air during the filling process.

52. (II) Compare the value for the density of water vapor at exactly 100°C and 1 atm (Table 13–1) with the value predicted from the ideal gas law. Why would you expect a difference?

53. (II) A sealed test tube traps 28.0 cm$^3$ of air at a pressure of 1.00 atm and temperature of 18°C. The test tube's stopper has a diameter of 1.50 cm and will "pop off" the test tube if a net upward force of 10.0 N is applied to it. To what temperature would you have to heat the trapped air in order to "pop off" the stopper? Assume the air surrounding the test tube is always at a pressure of 1.00 atm.

54. (III) A sealed container containing 3.5 mol of gas is squeezed, changing its volume from 0.020 m$^3$ to 0.018 m$^3$. During this process, the temperature decreases by 9.0 K while the pressure increases by 450 Pa. What were the original pressure and temperature of the gas in the container?

55. (III) An air bubble at the bottom of a lake 32.0 m deep has a volume of 1.00 cm$^3$. If the temperature at the bottom is 5.5°C and at the top 18.5°C, what is the radius of the bubble just before it reaches the surface?

### 17–9 Ideal Gas Law in Terms of Molecules: Avogadro's Number

56. (I) Calculate the number of molecules/m$^3$ in an ideal gas at STP.

57. (II) How many moles of water are there in 1.00 L at STP? How many molecules?

58. (II) Estimate the number of (*a*) moles and (*b*) molecules of water in all the Earth's oceans. Assume water covers 75% of the Earth to an average depth of 3 km.

59. (II) What is the pressure in a region of outer space where there is 1 molecule/cm$^3$ and the temperature is 3 K?

60. (II) Is a gas mostly empty space? Check by assuming that a typical width of a gas molecule in air is about $\ell_0 = 0.3$ nm so one gas molecule occupies an approximate volume equal to $\ell_0^3$. Assume STP.

61. (II) The lowest pressure attainable using the best available vacuum techniques is about $10^{-12}$ N/m$^2$. At such a pressure, how many molecules are there per cm$^3$ at 0°C?

### *17–10 Ideal Gas Temperature Scale

*62. (II) In a constant-volume gas thermometer, what is the limiting ratio of the pressure at the boiling point of water at 1 atm to that at the triple point? (Keep five significant figures.)

*63. (II) At the boiling point of sulfur (444.6°C) the pressure in a constant-volume gas thermometer is 187 torr. Estimate (*a*) the pressure at the triple point of water, (*b*) the temperature when the pressure in the thermometer is 128 torr.

*64. (II) Use Fig. 17–18 to determine the inaccuracy of a constant-volume gas thermometer using oxygen if it reads a pressure $P = 268$ torr at the boiling point of water at 1 atm. Express answer (*a*) in kelvins and (*b*) as a percentage.

*65. (III) A constant-volume gas thermometer is being used to determine the temperature of the melting point of a substance. The pressure in the thermometer at this temperature is 218 torr; at the triple point of water, the pressure is 286 torr. Some gas is now released from the thermometer bulb so that the pressure at the triple point of water becomes 163 torr. At the temperature of the melting substance, the pressure is 128 torr. Estimate, as accurately as possible, the melting-point temperature of the substance.

## General Problems

66. A Pyrex measuring cup was calibrated at normal room temperature. How much error will be made in a recipe calling for 375 mL of cool water, if the water and the cup are hot, at 95°C, instead of at room temperature? Neglect the glass expansion.

67. A precise steel *tape measure* has been calibrated at 14°C. At 37°C, (*a*) will it read high or low, and (*b*) what will be the percentage error?

68. A cubic box of volume $8.25 \times 10^{-2}$ m$^3$ is filled with air at atmospheric pressure at 15°C. The box is closed and heated to 165°C. What is the net force on each side of the box?

69. The gauge pressure in a helium gas cylinder is initially 28 atm. After many balloons have been blown up, the gauge pressure has decreased to 5 atm. What fraction of the original gas remains in the cylinder?

**70.** If a rod of original length $\ell_1$ has its temperature changed from $T_1$ to $T_2$, determine a formula for its new length $\ell_2$ in terms of $T_1, T_2$, and $\alpha$. Assume (*a*) $\alpha =$ constant, (*b*) $\alpha = \alpha(T)$ is some function of temperature, and (*c*) $\alpha = \alpha_0 + bT$ where $\alpha_0$ and $b$ are constants.

**71.** If a *scuba diver* fills his lungs to full capacity of 4.8 L when 9.0 m below the surface of sea water, to what volume would his lungs expand if he quickly rose to the surface? Is this advisable?

**72.** (*a*) Use the ideal gas law to show that, for an ideal gas at constant pressure, the coefficient of volume expansion is equal to $\beta = 1/T$, where $T$ is the kelvin temperature. Compare to Table 17–1 for gases at $T = 293$ K. (*b*) Show that the bulk modulus (Section 12–5) for an ideal gas held at constant temperature is $B = P$, where $P$ is the pressure.

**73.** A house has a volume of 1200 $m^3$. (*a*) What is the total mass of air inside the house at 15°C? (*b*) If the temperature in the house drops to −12°C, what mass of air enters or leaves the house?

**74.** Estimate the number of air molecules in a room of length 6.0 m, width 3.0 m, and height 2.5 m. Assume the temperature is 22°C. How many moles does that correspond to?

**75.** Estimate how many *molecules of air* are in each 2.0-L *breath* you inhale that were also in the last breath Galileo took. Assume the atmosphere is about 10 km high and of constant density. What other assumptions did you make?

**76.** Assume that in an alternate universe, the laws of physics are very different from ours and that "ideal" gases behave as follows: (i) At constant temperature, pressure is inversely proportional to the square of the volume. (ii) At constant pressure, the volume varies directly with the $\frac{2}{3}$ power of the temperature. (iii) At 273.15 K and 1.00 atm pressure, 1.00 mole of an ideal gas is found to occupy 22.4 L. Obtain the form of the ideal gas law in this alternate universe, including the value of the gas constant $R$.

**77.** An iron cube floats in a bowl of liquid mercury at 0°C. (*a*) If the temperature is raised to 25°C, will the cube float higher or lower in the mercury? (*b*) By what percent will the fraction of volume submerged change? [*Hint*: See Chapter 13.]

**78.** (*a*) The tube of a mercury thermometer has an inside diameter of 0.140 mm. The bulb has a volume of 0.285 $cm^3$. How far will the thread of mercury move when the temperature changes from 10.5°C to 33.0°C? Take into account expansion of the Pyrex glass. (*b*) Determine a formula for the change in length of the mercury column in terms of relevant variables. Ignore tube volume compared to bulb volume.

**79.** Many cars warn the driver when the *tire pressure* is low. Suppose a warning light comes on when the pressure drops by 20% from the specified gauge pressure of 2.4 atm. Neglecting volume change and assuming constant temperature, find the fraction of air that has leaked out of the tire.

**80.** From the known value of atmospheric pressure at the surface of the Earth, estimate the total number of air molecules in the Earth's atmosphere.

**81.** What is the average distance between nitrogen molecules at STP?

**82.** Estimate the percent difference in the density of iron at STP, and when it is a solid deep in the Earth where the temperature is 2000°C and under 5000 atm of pressure. Assume the bulk modulus $(90 \times 10^9\ \text{N/m}^2)$ and the coefficient of volume expansion do not vary with temperature and are the same as at STP.

**83.** A standard *cylinder of oxygen* used in a hospital has gauge pressure = 2000 psi (13,800 kPa) and volume = 14 L $(0.014\ \text{m}^3)$ at $T = 295$ K. How long will the cylinder last if the flow rate, measured at atmospheric pressure, is constant at 2.0 L/min?

**84.** A helium balloon, assumed to be a perfect sphere, has a radius of 26.0 cm. At room temperature (20°C), its internal pressure is 1.08 atm. Determine the number of moles of helium in the balloon, and the mass of helium needed to inflate the balloon to these values.

**85.** The density of gasoline at 0°C is $0.68 \times 10^3\ \text{kg/m}^3$. (*a*) What is the density on a hot day, when the temperature is 33°C? (*b*) What is the percent change in density?

**86.** A brass lid screws tightly onto a glass jar at 15°C. To help open the jar, it can be placed into a bath of hot water. After this treatment, the temperatures of the lid and the jar are both 55°C. The inside diameter of the lid is 7.0 cm. Find the size of the gap (difference in radius) that develops by this procedure.

**87.** The first real length standard, adopted more than 200 years ago, was a platinum bar with two very fine marks separated by what was defined to be exactly one meter. If this standard bar was to be accurate to within $\pm 1.0\ \mu$m, how carefully would the trustees have needed to control the temperature? The coefficient of linear expansion is $9 \times 10^{-6}/\text{C}°$.

**88.** A helium balloon has volume $V_0$ and temperature $T_0$ at sea level where the pressure is $P_0$ and the air density is $\rho_0$. The balloon is allowed to float up in the air to altitude $y$ where the temperature is $T_1$. (*a*) Show that the volume occupied by the balloon is then $V = V_0(T_1/T_0)e^{+cy}$ where $c = \rho_0 g/P_0 = 1.25 \times 10^{-4}\ \text{m}^{-1}$. (*b*) Show that the buoyant force does not depend on altitude $y$. Assume that the skin of the balloon maintains the helium pressure at a constant factor of 1.05 times greater than the outside pressure. [*Hint*: Assume that the pressure change with altitude is $P = P_0 e^{-cy}$, Eq. 13–6c in Chapter 13.]

**89.** If a steel band were to fit snugly around the Earth's equator at 25°C, but then was heated to 55°C, how high above the Earth would the band be (assume equal everywhere)?

**90.** A 28.4-kg solid aluminum cylindrical wheel of radius 0.41 m is rotating about its axle in frictionless bearings with angular velocity $\omega = 32.8$ rad/s. If its temperature is then raised from 15.0°C to 95.0°C, what is the fractional change in $\omega$?

**91.** A copper wire sags 54.0 cm between two utility poles 30.0 m apart when the temperature is −15°C. Estimate the amount of sag when the temperature is +35°C. [*Hint*: An estimate can be made by assuming the shape of the wire is approximately an arc of a circle; hard equations can sometimes be solved by guessing values.]

**92.** A temperature controller, designed to work in a steam environment, involves a bimetallic strip constructed of brass and steel, connected at their ends by rivets. Each of the metals is 1.6 mm thick. At 20°C, the strip is 10.0 cm long and straight. Find the radius of curvature $r$ of the assembly at 100°C. See Fig. 17–23.

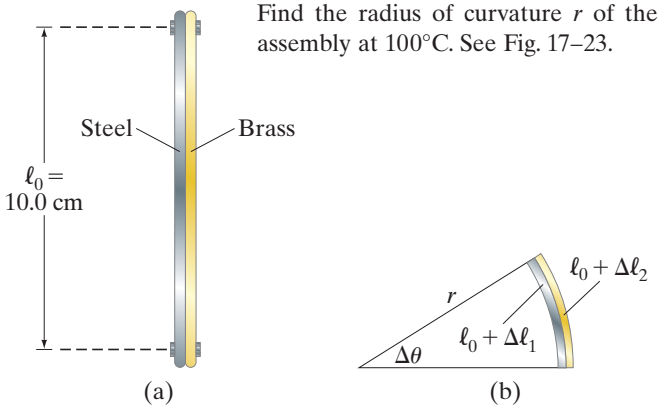

**FIGURE 17–23** Problem 92.

**93.** You have a vial of an unknown liquid which might be octane (gasoline), water, glycerin, or ethyl alcohol. You are trying to determine its identity by studying how its volume changes with temperature changes. You fill a Pyrex graduated cylinder to 100.00 mL with the liquid when the liquid and the cylinder are at 0.000°C. You raise the temperature in five-degree increments, allowing the graduated cylinder and liquid to come to equilibrium at each temperature. You read the volumes listed below off the graduated cylinder at each temperature. Take into account the expansion of the Pyrex glass cylinder. Graph the data and determine the slope of the line to find the effective (combined) coefficient of volume expansion $\beta$. Then determine $\beta$ for the liquid and which liquid is in the vial.

| Temperature (°C) | Volume Reading (apparent mL) |
|---|---|
| 0.000 | 100.00 |
| 5.000 | 100.24 |
| 10.000 | 100.50 |
| 15.000 | 100.72 |
| 20.000 | 100.96 |
| 25.000 | 101.26 |
| 30.000 | 101.48 |
| 35.000 | 101.71 |
| 40.000 | 101.97 |
| 45.000 | 102.20 |
| 50.000 | 102.46 |

**94.** A *scuba tank* when fully charged has an absolute pressure of 185 atm at 18°C. The volume of the tank is 11.3 L. (*a*) What would the volume of the air be at 1.00 atm and at the same temperature? (*b*) Before entering the water, a person consumes 2.0 L of air in each breath, and breathes 12 times a minute. At this rate, 2.0 L at 1 atm per breathe, how long would the tank last? (*c*) At a depth of 23.0 m in sea water at a temperature of 10°C, how long would the same tank last assuming the breathing rate does not change?

**95.** This Chapter gives two ways to calculate the thermal expansion of a gas at a constant pressure of 1.0 atm. Use both methods to calculate the volume change of 750 L of an ideal gas as it goes from −100°C to 0°C and from 0°C to 100°C. Why are the answers different?

**96.** A *hot-air balloon* achieves its buoyant lift by heating the air inside the balloon, which makes it less dense than the air outside. Suppose the volume of a balloon is 1800 $m^3$ and the required lift is 3300 N (rough estimate of the weight of the equipment and passenger). Calculate the temperature of the air inside the balloon which will produce the required lift. Assume the outside air is an ideal gas at 0°C. What factors limit the maximum altitude attainable by this method for a given load? [*Hint*: See Chapter 13, Example 13–5.]

**97.** **Why snorkels are not 4 feet long.** Snorkelers breathe through short tubular "snorkels" while swimming under water very near the surface (Fig. 17–24). One end of the snorkel is in the snorkeler's mouth and the other end protrudes just above the water's surface. Unfortunately, snorkels cannot support breathing to any great depth: it is said that a typical snorkeler below a water depth of only about 30 cm cannot draw a breath through a snorkel. Based on this observation, what is the approximate change in a typical person's lung pressure (in atm) when drawing a breath? (Note that your diaphragm muscles, which expand your lungs, must work also against the extra water pressure.)

**FIGURE 17–24** Problem 97.

## ANSWERS TO EXERCISES

**A:** −40°C = −40°F.
**B:** (*d*).
**C:** $7\frac{1}{2}$ mm [$\Delta T = 110(5/9)$].
**D:** (i) Higher, (ii) same, (iii) lower.
**E:** (*d*).
**F:** (*c*).
**G:** (*b*) Less.

In this winter scene in Yosemite National Park, we recognize the three states of matter for water: as a liquid (the river), as a solid (snow and ice), and as a gas (steam). In this Chapter we examine the microscopic theory of matter as atoms or molecules that are always in motion, which we call kinetic theory. The temperature of a gas is directly related to the average translational kinetic energy of its molecules. We will consider ideal gases, but will also look at real gases and how they change phase, including evaporation, vapor pressure, and humidity. We also discover how the temperature of boiling water decreases with altitude.

CHAPTER 18

# Kinetic Theory of Gases

## CONTENTS

18–1 The Ideal Gas Law and the Molecular Interpretation of Temperature
18–2 Distribution of Molecular Speeds
18–3 Real Gases and Changes of Phase
18–4 Vapor Pressure and Humidity
18–5 Temperature Decrease of Boiling Water with Altitude
18–6 Van der Waals Equation of State
18–7 Mean Free Path
18–8 Diffusion

**CHAPTER-OPENING QUESTION—Guess now!**

The typical speed of an air molecule at room temperature (20°C) is

**(a)** nearly at rest (<10 km/h).
**(b)** on the order of 10 km/h.
**(c)** on the order of 100 km/h.
**(d)** on the order of 1000 km/h.
**(e)** nearly the speed of light.

The analysis of matter in terms of atoms in continuous random motion (see Fig. 17–2) is called **kinetic theory**. We now investigate the properties of a gas from the point of view of kinetic theory, which is based on the laws of classical mechanics. But to apply Newton's laws to each one of the vast number of molecules in a gas ($>10^{25}/m^3$ at STP) is far beyond the capability of any present computer. Instead we take a statistical approach and determine averages of certain quantities, and connect these averages to macroscopic variables. We will demand that our microscopic description correspond to the macroscopic properties of gases; otherwise our theory would be of little value. Most importantly, we will arrive at an important relation between the average kinetic energy of molecules in a gas and the absolute temperature.

## 18–1 The Ideal Gas Law and the Molecular Interpretation of Temperature

We make the following assumptions about the molecules in a gas. These assumptions reflect a simple view of a gas, but nonetheless the results they predict correspond well to the essential features of real gases that are at low pressure and far from the liquefaction point. Under these conditions real gases follow the ideal gas law quite closely, and indeed the gas we now describe is referred to as an **ideal gas**.

The assumptions representing the basic postulates of the kinetic theory for an ideal gas are

1. There are a large number of molecules, $N$, each of mass $m$, moving in random directions with a variety of speeds. This assumption agrees with our observation that a gas fills its container and, in the case of air on Earth, is kept from escaping only by the force of gravity.
2. The molecules are, on average, far apart from one another. That is, their average separation is much greater than the diameter of each molecule.
3. The molecules are assumed to obey the laws of classical mechanics, and are assumed to interact with one another only when they collide. Although molecules exert weak attractive forces on each other between collisions, the potential energy associated with these forces is small compared to the kinetic energy.
4. Collisions with another molecule or the wall of the vessel are assumed to be perfectly elastic, like the collisions of perfectly elastic billiard balls (Chapter 9). We assume the collisions are of very short duration compared to the time between collisions. Then we can ignore the potential energy associated with collisions in comparison to the kinetic energy between collisions.

We can see how this kinetic view of a gas can explain Boyle's law (Section 17–6). The pressure exerted on a wall of a container of gas is due to the constant bombardment of molecules. If the volume is reduced by (say) half, the molecules are closer together and twice as many will be striking a given area of the wall per second. Hence we expect the pressure to be twice as great, in agreement with Boyle's law.

Now let us calculate quantitatively the pressure a gas exerts on its container in terms of microscopic quantities. We imagine that the molecules are inside a rectangular container (at rest) whose ends have area $A$ and whose length is $\ell$, as shown in Fig. 18–1a. The pressure exerted by the gas on the walls of its container is, according to our model, due to the collisions of the molecules with the walls. Let us focus our attention on the wall, of area $A$, at the left end of the container and examine what happens when one molecule strikes this wall, as shown in Fig. 18–1b. This molecule exerts a force on the wall, and according to Newton's third law the wall exerts an equal and opposite force back on the molecule. The magnitude of this force on the molecule, according to Newton's second law, is equal to the molecule's rate of change of momentum, $F = dp/dt$ (Eq. 9–2). Assuming the collision is elastic, only the $x$ component of the molecule's momentum changes, and it changes from $-mv_x$ (it is moving in the negative $x$ direction) to $+mv_x$. Thus the change in the molecule's momentum, $\Delta(mv)$, which is the final momentum minus the initial momentum, is

$$\Delta(mv) = mv_x - (-mv_x) = 2mv_x$$

for one collision. This molecule will make many collisions with the wall, each separated by a time $\Delta t$, which is the time it takes the molecule to travel across the container and back again, a distance ($x$ component) equal to $2\ell$. Thus $2\ell = v_x\,\Delta t$, or

$$\Delta t = \frac{2\ell}{v_x}.$$

The time $\Delta t$ between collisions of one molecule with the wall is very small, so the number of collisions per second is very large. Thus the average force due to one molecule—averaged over many collisions—will be equal to the momentum change during one collision with the wall divided by the time between collisions (Newton's second law):

$$F = \frac{\Delta(mv)}{\Delta t} = \frac{2mv_x}{2\ell/v_x} = \frac{mv_x^2}{\ell}. \qquad \text{[due to one molecule]}$$

During its passage back and forth across the container, the molecule may collide with the tops and sides of the container, but this does not alter its $x$ component of momentum and thus does not alter our result. It may also collide with other molecules, which may change its $v_x$. However, any loss (or gain) of momentum is exchanged with the other molecule in the collision, and because we will eventually sum over all the molecules, this effect will be included. So our result above is not altered.

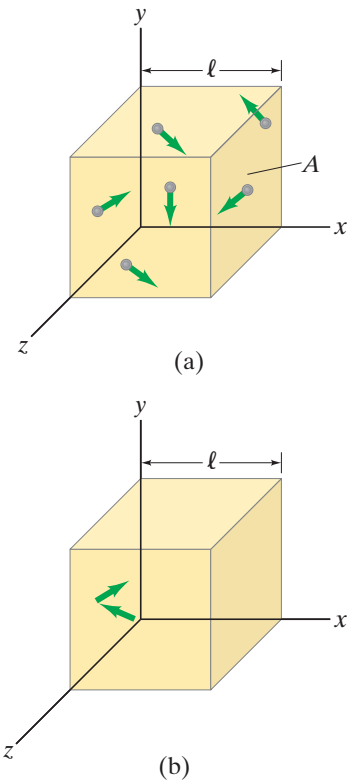

**FIGURE 18–1** (a) Molecules of a gas moving about in a rectangular container. (b) Arrows indicate the momentum of one molecule as it rebounds from the end wall.

The actual force due to one molecule is intermittent, but because a huge number of molecules are striking the wall per second, the force is, on average, nearly constant. To calculate the force due to *all* the molecules in the container, we have to add the contributions of each. If all $N$ molecules have the same mass $m$, the net force on the wall is

$$F = \frac{m}{\ell}(v_{x1}^2 + v_{x2}^2 + \cdots + v_{xN}^2),$$

where $v_{x1}$ means $v_x$ for molecule number 1 (we arbitrarily assign each molecule a number) and the sum extends over the total number of molecules $N$ in the container. The average value of the square of the $x$ component of velocity is

$$\overline{v_x^2} = \frac{v_{x1}^2 + v_{x2}^2 + \cdots + v_{xN}^2}{N}, \qquad \textbf{(18–1)}$$

**CAUTION**
*Overbar ($\bar{}$) means average*

where the overbar ($\bar{}$) means "average." Thus we can write the force as

$$F = \frac{m}{\ell} N\overline{v_x^2}. \qquad \textbf{(i)}$$

We know that the square of any vector is equal to the sum of the squares of its components (theorem of Pythagoras). That is, $v^2 = v_x^2 + v_y^2 + v_z^2$ for any velocity $v$. Taking averages, we obtain

$$\overline{v^2} = \overline{v_x^2} + \overline{v_y^2} + \overline{v_z^2}. \qquad \textbf{(ii)}$$

Since the velocities of the molecules in our gas are assumed to be random, there is no preference to one direction or another. Hence

$$\overline{v_x^2} = \overline{v_y^2} = \overline{v_z^2}. \qquad \textbf{(iii)}$$

Combining Eqs. (iii) and (ii) we get:

$$\overline{v^2} = 3\overline{v_x^2}. \qquad \textbf{(iv)}$$

We substitute Eq. (iv) into Eq. (i) for the net force $F$, and find

$$F = \frac{m}{\ell} N \frac{\overline{v^2}}{3}.$$

The pressure on the wall is then

$$P = \frac{F}{A} = \frac{1}{3}\frac{Nm\overline{v^2}}{A\ell}$$

or

$$P = \frac{1}{3}\frac{Nm\overline{v^2}}{V}, \qquad \left[\begin{array}{c}\text{pressure in an}\\ \text{ideal gas}\end{array}\right] \qquad \textbf{(18–2)}$$

where $V = \ell A$ is the volume of the container. This is the result we were seeking, the pressure exerted by a gas on its container expressed in terms of molecular properties.

Equation 18–2 can be rewritten in a clearer form by multiplying both sides by $V$ and rearranging the right-hand side:

$$PV = \tfrac{2}{3}N(\tfrac{1}{2}m\overline{v^2}). \qquad \textbf{(18–3)}$$

The quantity $\frac{1}{2}m\overline{v^2}$ is the average translational kinetic energy $\overline{K}$ of the molecules in the gas. If we compare Eq. 18–3 with Eq. 17–4, the ideal gas law $PV = NkT$, we see that the two agree if (recall $k$ = Boltzmann constant = $1.38 \times 10^{-23}$ J/K; Section 17–9)

*TEMPERATURE RELATED TO AVERAGE KINETIC ENERGY OF MOLECULES*

$$\tfrac{2}{3}(\tfrac{1}{2}m\overline{v^2}) = kT,$$

or

$$\overline{K} = \tfrac{1}{2}m\overline{v^2} = \tfrac{3}{2}kT. \qquad \text{[ideal gas]} \quad \textbf{(18–4)}$$

This equation tells us that

> **the average translational kinetic energy of molecules in random motion in an ideal gas is directly proportional to the absolute temperature of the gas.**

The higher the temperature, according to kinetic theory, the faster the molecules are moving on average. This relation is a fundamental one in physics: it relates

an everyday macroscopic quantity ($T$) to theoretical microscopic quantities. Because of this relationship (Eq. 18–4), the random motion of molecules in a gas is sometimes referred to as **thermal motion**.

**EXAMPLE 18–1 Molecular kinetic energy.** What is the average translational kinetic energy of molecules in an ideal gas at 37°C?

**APPROACH** We use the absolute temperature in Eq. 18–4.

**SOLUTION** We change 37°C to 310 K and insert into Eq. 18–4:

$$\overline{K} = \tfrac{3}{2}kT = \tfrac{3}{2}(1.38\times10^{-23}\,\text{J/K})(310\,\text{K}) = 6.42\times10^{-21}\,\text{J}.$$

**NOTE** A mole of molecules would have a total translational kinetic energy equal to $(6.42\times10^{-21}\,\text{J})(6.02\times10^{23}) = 3860\,\text{J}$, which equals the kinetic energy of a 1-kg stone traveling almost 90 m/s.

**EXERCISE A** If molecules of hydrogen gas and oxygen gas were placed in the same balloon at room temperature, how would the average kinetic energies of the molecules compare? (*a*) They would be the same. (*b*) The hydrogen molecules would have greater kinetic energy. (*c*) The oxygen molecules would have greater kinetic energy. (*d*) Need more information.

**PHYSICS APPLIED**
*Molecules in human cells*

Equation 18–4 holds not only for gases, but also applies reasonably accurately to liquids and solids. Thus the result of Example 18–1 would apply to molecules within living cells at body temperature (37°C).

We can use Eq. 18–4 to calculate how fast molecules are moving on the average. Notice that the average in Eqs. 18–1 through 18–4 is over the *square* of the speed. The square root of $\overline{v^2}$ is called the **root-mean-square** speed, $v_{\text{rms}}$ (since we are taking the square *root* of the *mean* of the *square* of the speed):

$$v_{\text{rms}} = \sqrt{\overline{v^2}} = \sqrt{\frac{3kT}{m}}. \qquad \textbf{(18–5)}$$

**EXAMPLE 18–2 Speeds of air molecules.** What is the rms speed of air molecules ($O_2$ and $N_2$) at room temperature (20°C)?

**APPROACH** To obtain $v_{\text{rms}}$, we need the masses of $O_2$ and $N_2$ molecules and then apply Eq. 18–5 to oxygen and nitrogen separately, since they have different masses.

**SOLUTION** The masses of one molecule of $O_2$ (molecular mass = 32 u) and $N_2$ (molecular mass = 28 u) are (where $1\,\text{u} = 1.66\times10^{-27}\,\text{kg}$)

$$m(O_2) = (32)(1.66\times10^{-27}\,\text{kg}) = 5.3\times10^{-26}\,\text{kg},$$

$$m(N_2) = (28)(1.66\times10^{-27}\,\text{kg}) = 4.6\times10^{-26}\,\text{kg}.$$

Thus, for oxygen

$$v_{\text{rms}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{(3)(1.38\times10^{-23}\,\text{J/K})(293\,\text{K})}{(5.3\times10^{-26}\,\text{kg})}} = 480\,\text{m/s},$$

and for nitrogen the result is $v_{\text{rms}} = 510\,\text{m/s}$.

**NOTE** These speeds are more than 1700 km/h or 1000 mi/h, and are greater than the speed of sound $\approx 340$ m/s at 20°C (Chapter 16).

**NOTE** The speed $v_{\text{rms}}$ is a magnitude only. The *velocity of molecules averages to zero*. Why? The velocity has direction, and as many molecules move to the right as to the left, as many up as down, as many inward as outward.

**EXERCISE B** What is the rms speed of $O_2$ molecules in your lungs (37°C)?

**EXERCISE C** Now you can return to the Chapter-Opening Question, page 516, and answer it correctly. Try to explain why you may have answered differently the first time.

**EXERCISE D** If you double the volume of a gas while keeping the pressure and number of moles constant, the average (rms) speed of the molecules (*a*) doubles, (*b*) quadruples, (*c*) increases by $\sqrt{2}$, (*d*) is half, (*e*) is $\frac{1}{4}$.

**CONCEPTUAL EXAMPLE 18–3** **Less helium in the tank.** A tank of helium is used to fill balloons. As each balloon is filled, the number of helium atoms remaining in the tank decreases. How does this affect the rms speed of molecules remaining in the tank?

**RESPONSE** The rms speed is given by Eq. 18–5: $v_{\text{rms}} = \sqrt{3kT/m}$. So only the temperature matters, not pressure $P$ or number of moles $n$. If the tank remains at a constant (ambient) temperature, then the rms speed remains constant even though the pressure of helium in the tank decreases.

In a collection of molecules, the **average speed**, $\bar{v}$, is the average of the magnitudes of the speeds themselves; $\bar{v}$ is generally not equal to $v_{\text{rms}}$. To see the difference between the average speed and the rms speed, consider the following Example.

**EXAMPLE 18–4** **Average speed and rms speed.** Eight particles have the following speeds, given in m/s: 1.0, 6.0, 4.0, 2.0, 6.0, 3.0, 2.0, 5.0. Calculate (*a*) the average speed and (*b*) the rms speed.

**APPROACH** In (*a*) we sum the speeds and divide by $N = 8$. In (*b*) we square each speed, sum the squares, divide by $N = 8$, and take the square root.

**SOLUTION** (*a*) The average speed is

$$\bar{v} = \frac{1.0 + 6.0 + 4.0 + 2.0 + 6.0 + 3.0 + 2.0 + 5.0}{8} = 3.6\,\text{m/s}.$$

(*b*) The rms speed is (Eq. 18–1):

$$v_{\text{rms}} = \sqrt{\frac{(1.0)^2 + (6.0)^2 + (4.0)^2 + (2.0)^2 + (6.0)^2 + (3.0)^2 + (2.0)^2 + (5.0)^2}{8}}\,\text{m/s}$$
$$= 4.0\,\text{m/s}.$$

We see in this Example that $\bar{v}$ and $v_{\text{rms}}$ are not necessarily equal. In fact, for an ideal gas they differ by about 8%. We will see in the next Section how to calculate $\bar{v}$ for an ideal gas. We already have the tool to calculate $v_{\text{rms}}$ (Eq. 18–5).

### Kinetic Energy Near Absolute Zero

Equation 18–4, $\overline{K} = \frac{3}{2}kT$, implies that as the temperature approaches absolute zero, the kinetic energy of molecules approaches zero. Modern quantum theory, however, tells us this is not quite so. Instead, as absolute zero is approached, the kinetic energy approaches a very small nonzero minimum value. Even though all real gases become liquid or solid near 0 K, molecular motion does not cease, even at absolute zero.

## 18–2 Distribution of Molecular Speeds

### The Maxwell Distribution

The molecules in a gas are assumed to be in random motion, which means that many molecules have speeds less than the rms speed and others have greater speeds. In 1859, James Clerk Maxwell (1831–1879) worked out a formula for the

most probable distribution of speeds in a gas containing $N$ molecules. We will not give a derivation here but merely quote his result:

$$f(v) = 4\pi N\left(\frac{m}{2\pi kT}\right)^{\frac{3}{2}} v^2 e^{-\frac{1}{2}\frac{mv^2}{kT}} \qquad \textbf{(18–6)}$$

where $f(v)$ is called the **Maxwell distribution of speeds**, and is plotted in Fig. 18–2. The quantity $f(v)\,dv$ represents the *number of molecules* that have speed between $v$ and $v + dv$. Notice that $f(v)$ does not give the number of molecules with speed $v$; $f(v)$ must be multiplied by $dv$ to give the number of molecules (the number of molecules depends on the "width" or "range" of velocities included, $dv$). In the formula for $f(v)$, $m$ is the mass of a single molecule, $T$ is the absolute temperature, and $k$ is the Boltzmann constant. Since $N$ is the total number of molecules in the gas, when we sum over all the molecules in the gas we must get $N$; thus we must have

$$\int_0^\infty f(v)\,dv = N.$$

(Problem 23 is an exercise to show that this is true.)

Experiments to determine the distribution of molecular speeds in real gases, starting in the 1920s, confirmed with considerable accuracy the Maxwell distribution (for gases at not too high a pressure) and the direct proportion between average kinetic energy and absolute temperature, Eq. 18–4.

The Maxwell distribution for a pure gas depends only on its absolute temperature. Figure 18–3 shows the Maxwell distribution for two different temperatures. Just as $v_{\text{rms}}$ increases with temperature, so the whole distribution curve shifts to the right at higher temperatures.

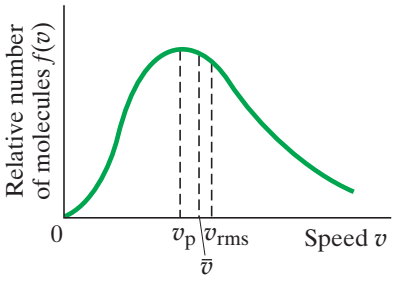

**FIGURE 18–2** Distribution of speeds of molecules in an ideal gas. Note that $\bar{v}$ and $v_{\text{rms}}$ are not at the peak of the curve. This is because the curve is not symmetrical. It is skewed to the right (where the curve can go on and on farther out). The speed at the peak of the curve is the "most probable speed," $v_p$.

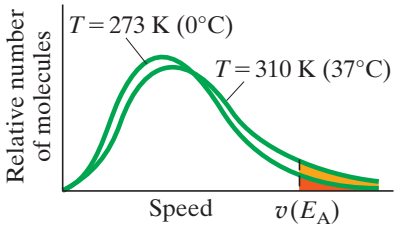

**FIGURE 18–3** Distribution of molecular speeds for two different temperatures.

Figure 18–3 illustrates how kinetic theory can explain why many chemical reactions, including those in biological cells, take place more rapidly as the temperature increases. Most chemical reactions occur in a liquid solution, and the molecules have a speed distribution close to the Maxwell distribution. Two molecules may chemically react only if their kinetic energy is high enough so that when they collide, they partially penetrate into each other. The minimum energy required for a particular chemical reaction is called the *activation energy*, $E_A$. The molecular speed corresponding to a kinetic energy of $E_A$ for a particular reaction is indicated in Fig. 18–3. The relative number of molecules with energy greater than this value is given by the area under the curve to the right of $v(E_A)$, shown in Fig. 18–3 by the two different shadings. We see that the number of molecules that have kinetic energies above $E_A$ increases greatly for a small increase in temperature. The rate of a chemical reaction is proportional to the number of molecules with energy greater than $E_A$, and thus we see why reaction rates increase rapidly with increased temperature.

**PHYSICS APPLIED**
*How chemical reactions depend on temperature*

## Calculations Using the Maxwell Distribution

Let us see how the Maxwell distribution can be used to obtain some interesting results.

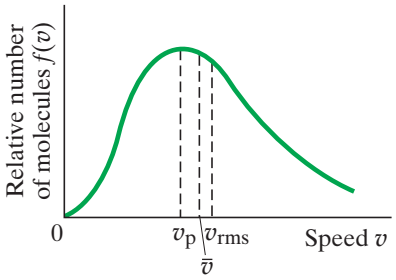

**FIGURE 18–2** (Repeated.) Distribution of speeds of molecules in an ideal gas. Note that $\bar{v}$ and $v_{rms}$ are not at the peak of the curve. This is because the curve is not symmetrical. It is skewed to the right (where the curve can go on and on farther out). The speed at the peak of the curve is the "most probable speed," $v_p$.

**EXAMPLE 18–5** **Determining $\bar{v}$ and $v_p$.** Derive formulas for (*a*) the average speed, $\bar{v}$, and (*b*) the most probable speed, $v_p$, of molecules in an ideal gas at temperature $T$.

**APPROACH** (*a*) The average value of a quantity is found by multiplying each possible value of the quantity (here, speed) by the number of molecules having that value, then summing them and dividing by $N$ (the total number). For (*b*), we want to find where the curve of Fig. 18–2 has a maximum, with zero slope; so we set $df/dv = 0$.

**SOLUTION** (*a*) To find the average speed of molecules, $\bar{v}$, we sum (integrate) over the product of $v$ and the number $f(v)\,dv$ that have speed $v$ using Eq. 18–6:

$$\bar{v} = \frac{\int_0^\infty v f(v)\,dv}{N} = 4\pi\left(\frac{m}{2\pi kT}\right)^{\frac{3}{2}}\int_0^\infty v^3 e^{-\frac{1}{2}\frac{mv^2}{kT}}\,dv.$$

We can integrate by parts or look up the definite integral in a Table (Appendix B–5), and obtain

$$\bar{v} = 4\pi\left(\frac{m}{2\pi kT}\right)^{\frac{3}{2}}\left(\frac{2k^2T^2}{m^2}\right) = \sqrt{\frac{8}{\pi}\frac{kT}{m}} \approx 1.60\sqrt{\frac{kT}{m}}.$$

(*b*) The **most probable speed**, $v_p$, occurs more than any other speed, where $f(v)$ has its maximum value. The slope there is zero: the derivative of Eq. 18–6 gives

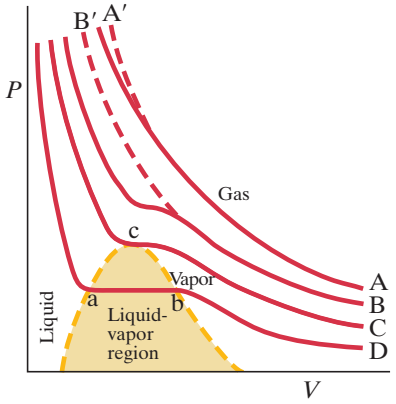
$$\frac{df(v)}{dv} = 4\pi N\left(\frac{m}{2\pi kT}\right)^{\frac{3}{2}}\left(2ve^{-\frac{mv^2}{2kT}} - \frac{2mv^3}{2kT}e^{-\frac{mv^2}{2kT}}\right) = 0.$$

Solving for $v$, we find

$$v_p = \sqrt{\frac{2kT}{m}} \approx 1.41\sqrt{\frac{kT}{m}}.$$

In summary,

$$v_p = \sqrt{2\frac{kT}{m}} \approx 1.41\sqrt{\frac{kT}{m}} \quad \text{[most probable speed]} \quad \textbf{(18–7a)}$$



$$\bar{v} = \sqrt{\frac{8}{\pi}\frac{kT}{m}} \approx 1.60\sqrt{\frac{kT}{m}} \quad \text{[average speed]} \quad \textbf{(18–7b)}$$

and, repeating Eq. 18–5 for completeness,

$$v_{rms} = \sqrt{3\frac{kT}{m}} \approx 1.73\sqrt{\frac{kT}{m}}. \quad \text{[rms speed]} \quad \textbf{(18–5)}$$

All three are indicated in Fig. 18–2. The speeds of molecules in a gas vary from zero to many times the rms speed, but as Figs. 18–2 and 18–3 show, most molecules have speeds that are not far from the average. Less than 1% of the molecules exceed four times $v_{rms}$.

**FIGURE 18–4** *PV* diagram for a real substance. Curves A, B, C, and D represent the same substance at different temperatures ($T_A > T_B > T_C > T_D$).

## 18–3 Real Gases and Changes of Phase

The ideal gas law $PV = NkT$ is an accurate description of the behavior of a real gas as long as the pressure is not too high and as long as the temperature is far from the liquefaction point. But what happens when these two criteria are not satisfied? First we discuss real gas behavior, and then we examine how kinetic theory can help us understand this behavior.

Let us look at a graph of pressure plotted against volume for a given amount of gas. On such a ***PV* diagram**, Fig. 18–4, each point represents the pressure and volume of an equilibrium state of the given substance. The four curves (labeled A, B, C, and D) show how the pressure varies, as the volume is changed at constant temperature, for four different values of constant temperature. The red dashed curve A′ represents the behavior of a gas as predicted by the ideal gas law; that is, $PV$ = constant. The solid curve A represents the behavior of a *real* gas at the same temperature. Notice that at high pressure, the volume of a real gas is less than that predicted by the ideal gas law. The curves B and C in Fig. 18–4 represent the (real) gas at successively lower temperatures, and we see that the behavior deviates

even more from the curves predicted by the ideal gas law (for example, B′), and the difference is greater the closer the gas is to liquefying.

To explain this behavior, note that at higher pressure we expect the molecules to be closer together. And at lower temperatures, the potential energy associated with attractive forces between the molecules (which we ignored before) is no longer negligible compared to their kinetic energy. These attractive forces (of an electrical nature) tend to pull the molecules closer together so the volume of a real gas (solid curves in Fig. 18–4) is less than expected from the ideal gas law (dashed curves A′ and B′ in Fig. 18–4). At still lower temperatures, these forces cause **liquefaction** as the substance becomes a liquid (also called **condensation**), and the molecules become very close together. Section 18–6 discusses in more detail the effect of these attractive molecular forces, as well as the effect of the volume which the molecules themselves occupy.

Curve D represents the situation when liquefaction occurs. At low pressure on curve D (on the lower right in Fig. 18–4), the substance is a gas and occupies a large volume. As the pressure is increased, the volume decreases until point b is reached. From point b to point a, the volume of the substance decreases with no change in pressure, even though we try gently to compress it: the substance is gradually changing from the gas to the liquid phase. At point a, all of the substance has changed to liquid. Further increase in pressure reduces the volume only slightly—liquids are nearly incompressible—so on the left curve D is very steep as seen in Fig. 18–4. The shaded area under the gold dashed line represents the region where the gas and liquid phases exist together in equilibrium.

Curve C in Fig. 18–4 represents the behavior of the substance at its **critical temperature**; the point c (the one point where curve C is horizontal) is called the **critical point**. At temperatures less than the critical temperature, a gas will change to the liquid phase if sufficient pressure is applied. Above the critical temperature (and this is the definition of the term), no amount of pressure can cause a gas to change phase and become a liquid. (Thus curves A and B represent the substance at temperatures where it can only be a gas.) The critical temperatures for various gases are given in Table 18–1. Scientists tried for many years to liquefy oxygen without success, which led to the idea that there must be a critical point. Oxygen can be liquefied only if first cooled below its critical temperature of −118°C.

Often a distinction is made between the terms "gas" and "vapor": a substance below its critical temperature in the gaseous state is called a **vapor**; above the critical temperature, it is called a **gas**.

The behavior of a substance can be diagrammed not only on a *PV* diagram but also on a *PT* diagram. A ***PT* diagram**, often called a **phase diagram**, is particularly convenient for comparing the different phases of a substance. Figure 18–5 is the phase diagram for water. The curve labeled $\ell$-$v$ represents those points where the liquid and vapor phases are in equilibrium—it is thus a graph of the boiling point versus pressure. Note that the curve correctly shows that at a pressure of 1 atm the boiling point is 100°C, and that the boiling point is lowered for a decreased pressure. The curve $s$-$\ell$ represents points where solid and liquid exist in equilibrium and thus is a graph of the freezing point versus pressure. At 1 atm, the freezing point of water is 0°C, as shown. Notice also in Fig. 18–5 that at a pressure of 1 atm, the substance is in the liquid phase if the temperature is between 0°C and 100°C, but is in the solid or vapor phase if the temperature is below 0°C or above 100°C. The curve labeled $s$-$v$ is the *sublimation point* versus pressure curve. **Sublimation** refers to the process whereby at low pressures a solid changes directly into the vapor phase without passing through the liquid phase. For water, sublimation occurs if the pressure of the water vapor is less than 0.006 atm. Carbon dioxide, which in the solid phase is called dry ice, sublimates even at atmospheric pressure (Fig. 18–6).

The intersection of the three curves (in Fig. 18–5) is the **triple point**. For water this occurs at $T = 273.16\ \text{K}$ $(= 0.01°\text{C})$ and $P = 6.03 \times 10^{-3}$ atm. It is only at the triple point that the three phases can exist together in equilibrium. Because the triple point corresponds to a unique value of temperature and pressure, it is precisely reproducible and is often used as a point of reference. For example, the standard of temperature is usually specified as exactly 273.16 K at the triple point of water, rather than 273.15 K at the freezing point of water at 1 atm.

**⚠ CAUTION**

*Gases above a certain "critical temperature" cannot be liquefied*

**TABLE 18–1 Critical Temperatures and Pressures**

| Substance | Critical Temperature °C | Critical Temperature K | Critical Pressure (atm) |
|---|---|---|---|
| Water | 374 | 647 | 218 |
| $CO_2$ | 31 | 304 | 72.8 |
| Oxygen | −118 | 155 | 50 |
| Nitrogen | −147 | 126 | 33.5 |
| Hydrogen | −239.9 | 33.3 | 12.8 |
| Helium | −267.9 | 5.3 | 2.3 |

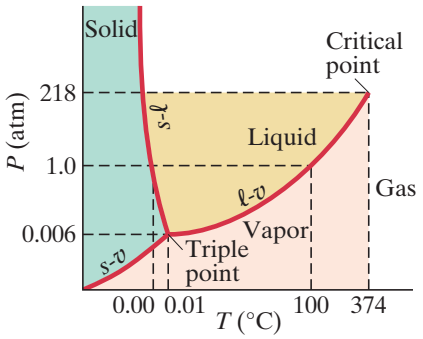


**FIGURE 18–5** Phase diagram for water (note that the scales are not linear).

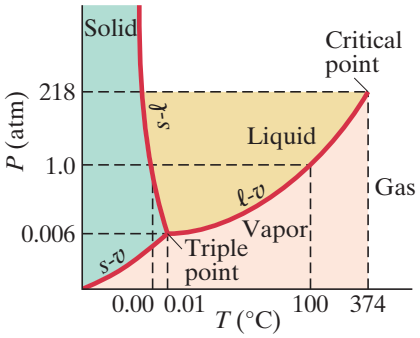

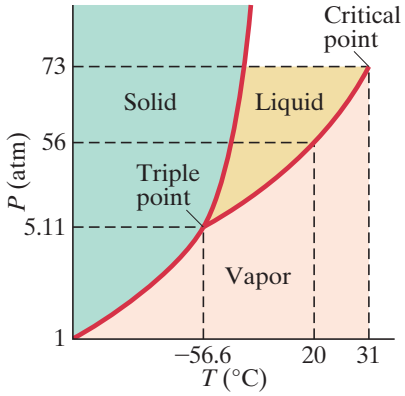

**FIGURE 18–5** (Repeated.) Phase diagram for water (note that the scales are not linear).

**FIGURE 18–6** Phase diagram for carbon dioxide.

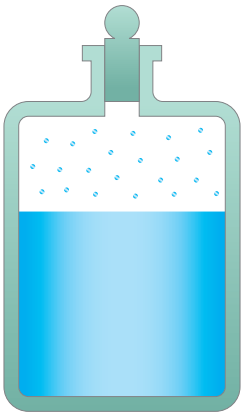
The solid-liquid ($s$-$\ell$) curve for water (Fig. 18–5) slopes upward to the left. This is true only of substances that *expand* upon freezing: at a higher temperature the pressure needs to be lower to allow that expansion. Most substances contract upon freezing and the $s$-$\ell$ curve slopes upward to the right, as shown for carbon dioxide ($CO_2$) in Fig. 18–6.

At temperatures above the critical temperature (374° for water), a substance is in the gas state. However, at temperatures below the critical temperature but at high pressure above the critical pressure (218 atm for water), the substance has some properties like a gas and some like a liquid. The lower the temperature, the more liquid-like it is, but there is no phase transition: this is the area directly above the tan-colored area labeled "liquid" in Figs. 18–5 and 18–6.

The phase transitions we have been discussing are the common ones. Some substances, however, can exist in several forms in the solid phase. A transition from one phase to another occurs at a particular temperature and pressure, just like ordinary phase changes. For example, ice has been observed in at least eight forms at very high pressure. Ordinary helium has two distinct liquid phases, called helium I and II. They exist only at temperatures within a few degrees of absolute zero. Helium II exhibits very unusual properties referred to as **superfluidity**. It has essentially zero viscosity and exhibits strange properties such as climbing up the sides of an open container. Also interesting are **liquid crystals** (used for computer and TV screens, Section 34–8) which can be considered to be in a phase between liquid and solid.

# 18–4 Vapor Pressure and Humidity

## Evaporation



If a glass of water is left out overnight, by morning the water level drops. We say the water evaporated, meaning some of the water has changed to the vapor or gas phase.

This process of **evaporation** can be explained on the basis of kinetic theory. The molecules in a liquid move past one another with a variety of speeds that follow, approximately, the Maxwell distribution. There are strong attractive (electric) forces between these molecules, which keeps them close together in the liquid phase. A molecule near the surface of the liquid may, because of its speed, leave the liquid momentarily. But just as a rock thrown into the air returns to the Earth due to gravity, so the attractive electric forces due to the other molecules can pull the vagabond molecule back to the liquid surface—that is, if its velocity is not too large. A molecule with a high enough velocity, however, will escape the liquid entirely, like a rocket escaping the Earth, and become part of the gas phase. Only those molecules that have kinetic energy above a particular value can escape to the gas phase. We have already seen that kinetic theory predicts that the relative number of molecules with kinetic energy above a particular value (such as $E_A$ in Fig. 18–3) increases with temperature. This is in accord with the well-known observation that the evaporation rate is greater at higher temperatures.

**PHYSICS APPLIED**
*Evaporation cools*

Because it is the fastest molecules that escape from the surface, the average speed of those remaining is less. When the average speed is less, the absolute temperature is less. Thus kinetic theory predicts that *evaporation is a cooling process*. You may have noticed this effect when you stepped out of a warm shower and felt cold as the water on your body began to evaporate; or after working up a sweat on a hot day, even a slight breeze makes you feel cool through evaporation. Try wetting your finger and then blow on it.

**FIGURE 18–7** Vapor appears above a liquid in a closed container.

## Vapor Pressure

Air normally contains water vapor (water in the gas phase), and it comes mainly from evaporation. To look at this process in a little more detail, consider a closed container that is partially filled with water (or another liquid) and from which the air has been removed (Fig. 18–7). The fastest moving molecules quickly evaporate into the empty space above the liquid's surface. As they move about, some of these molecules strike the liquid surface and again become part of the liquid phase: this is called **condensation**. The number of molecules in the vapor increases until the number of molecules returning to the liquid equals the number leaving in the same time interval. Equilibrium then exists, and the space above the liquid surface is said to be *saturated*.

The pressure of the vapor when it is saturated is called the **saturated vapor pressure**.

The saturated vapor pressure of any substance depends on the temperature, and not on the volume of the container. At higher temperatures, more molecules have sufficient kinetic energy to break from the liquid surface into the vapor phase. Hence equilibrium will be reached at a higher saturated vapor pressure. The saturated vapor pressure of water at various temperatures is given in Table 18–2. Notice that even solids—for example, ice—have a measurable vapor pressure.

In everyday situations, evaporation from a liquid takes place into the air above it rather than into a vacuum. This does not materially alter the discussion above relating to Fig. 18–7. Equilibrium will still be reached when there are sufficient molecules in the gas phase that the number reentering the liquid equals the number leaving. The concentration of particular molecules (such as water) in the gas phase is not affected by the presence of air, although collisions with air molecules may lengthen the time needed to reach equilibrium. Thus equilibrium occurs at the same value of the saturated vapor pressure as if air were not there.

If the container is large or is not closed, all the liquid may evaporate before saturation is reached. And if the container is not sealed—as, for example, a room in your house—it is not likely that the air will become saturated with water vapor (unless it is raining outside).

**TABLE 18–2 Saturated Vapor Pressure of Water**

| Temperature (°C) | Vapor Pressure† | |
|---|---|---|
| | atm | Pa (= N/m$^2$) |
| −50 | $3.9 \times 10^{-5}$ | 4.0 |
| −10 | $2.6 \times 10^{-3}$ | $2.60 \times 10^2$ |
| 0 | $6.1 \times 10^{-3}$ | $6.11 \times 10^2$ |
| 5 | $8.6 \times 10^{-3}$ | $8.72 \times 10^2$ |
| 10 | 0.012 | $1.23 \times 10^3$ |
| 15 | 0.017 | $1.71 \times 10^3$ |
| 20 | 0.023 | $2.33 \times 10^3$ |
| 25 | 0.031 | $3.17 \times 10^3$ |
| 30 | 0.042 | $4.24 \times 10^3$ |
| 40 | 0.073 | $7.37 \times 10^3$ |
| 50 | 0.12 | $1.23 \times 10^4$ |
| 60 | 0.20 | $1.99 \times 10^4$ |
| 70 | 0.31 | $3.12 \times 10^4$ |
| 80 | 0.47 | $4.73 \times 10^4$ |
| 90 | 0.70 | $7.01 \times 10^4$ |
| 100 | 1.00 | $1.01 \times 10^5$ |
| 120 | 2.00 | $1.99 \times 10^5$ |
| 150 | 4.70 | $4.76 \times 10^5$ |

†Other units (see Table 13–2) are 1 bar = $10^5$ Pa, 1 mbar = 100 Pa, 1 torr = 1 mm-Hg = 133 Pa.

## Boiling

The saturated vapor pressure of a liquid increases with temperature. When the temperature is raised to the point where the saturated vapor pressure at that temperature equals the external pressure, **boiling** occurs (Fig. 18–8). As the boiling point is approached, tiny bubbles tend to form in the liquid, which indicate a change from the liquid to the gas phase. However, if the vapor pressure inside the bubbles is less than the external pressure, the bubbles immediately are crushed. As the temperature is increased, the vapor pressure inside a bubble eventually becomes equal to or exceeds the external pressure. The bubble will then not collapse but can rise to the surface. Boiling has then begun. *A liquid boils when its saturated vapor pressure equals the external pressure*. This occurs for water at a pressure of 1 atm (760 torr) at 100°C, as confirmed in Table 18–2.

**FIGURE 18–8** Boiling: bubbles of water vapor float upward from the bottom (where the temperature is highest).

## Partial Pressure and Humidity

When we refer to the weather as being dry or humid, we are referring to the water vapor content of the air. In a gas such as air, which is a mixture of several types of gases, the total pressure is the sum of the *partial pressures* of each gas present.† By **partial pressure**, we mean the pressure each gas would exert if it alone were present. The partial pressure of water in the air can be as low as zero and can vary up to a maximum equal to the saturated vapor pressure of water at the given temperature. Thus, at 20°C, the partial pressure of water cannot exceed 0.023 atm (see Table 18–2). The **relative humidity** is defined as the ratio of the partial pressure of water vapor to the saturated vapor pressure at a given temperature. It is usually expressed as a percentage:

$$\text{Relative humidity} = \frac{\text{partial pressure of } H_2O}{\text{saturated vapor pressure of } H_2O} \times 100\%.$$

Thus, when the humidity is close to 100%, the air holds nearly all the water vapor it can.

**EXAMPLE 18–6** **Relative humidity.** On a particular hot day, the temperature is 30°C and the partial pressure of water vapor in the air is 0.030 atm. What is the relative humidity?

**APPROACH** From Table 18–2, we see that the saturated vapor pressure of water at 30°C is 0.042 atm.

**SOLUTION** The relative humidity is thus

$$\frac{0.030 \text{ atm}}{0.042 \text{ atm}} \times 100\% = 71\%.$$

†For example, 78% (by volume) of air molecules are nitrogen and 21% oxygen, with much smaller amounts of water vapor, argon, carbon dioxide, and other gases. At an air pressure of 1 atm, oxygen exerts a partial pressure of 0.21 atm and nitrogen 0.78 atm.

**PHYSICS APPLIED**
*Humidity and comfort*

Humans are sensitive to humidity. A relative humidity of 40–50% is generally optimum for both health and comfort. High humidity, particularly on a hot day, reduces the evaporation of moisture from the skin, which is one of the body's vital mechanisms for regulating body temperature. Very low humidity, on the other hand, can dry the skin and mucous membranes.

**PHYSICS APPLIED**
*Weather*

Air is saturated with water vapor when the partial pressure of water in the air is equal to the saturated vapor pressure at that temperature. If the partial pressure of water exceeds the saturated vapor pressure, the air is said to be **supersaturated**. This situation can occur when a temperature decrease occurs. For example, suppose the temperature is 30°C and the partial pressure of water is 0.030 atm, which represents a humidity of 71% as we saw in Example 18–6. Suppose now that the temperature falls to, say, 20°C, as might happen at nightfall. From Table 18–2 we see that the saturated vapor pressure of water at 20°C is 0.023 atm. Hence the relative humidity would be greater than 100%, and the supersaturated air cannot hold this much water vapor. The excess water may condense and appear as dew, clouds, or as fog or rain (Fig. 18–9).

When air containing a given amount of water is cooled, a temperature is reached where the partial pressure of water equals the saturated vapor pressure. This is called the **dew point**. Measurement of the dew point is the most accurate means of determining the relative humidity. One method uses a polished metal surface while in contact with air, which is gradually cooled down. The temperature at which moisture begins to appear on the surface is the dew point, and the partial pressure of water can then be obtained from saturated vapor pressure Tables, such as Table 18–2. If, for example, on a given day the temperature is 20°C and the dew point is 5°C, then the partial pressure of water in the 20°C air is $8.6 \times 10^{-3}$ atm (5°C in Table 18–2), whereas the saturated vapor pressure of the 20°C air is 0.023 atm; hence the relative humidity is $8.6 \times 10^{-3}/0.023 = 37\%$.

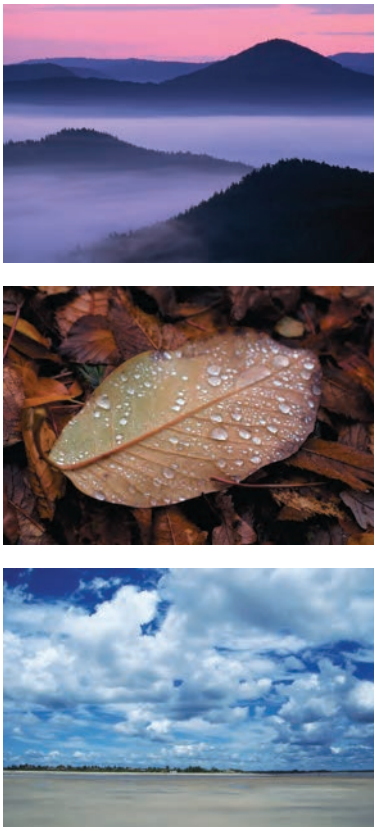


**FIGURE 18–9** (a) Fog or mist settling in a valley where the temperature has dropped below the dew point. (b) Dew drops on a leaf. (c) Clouds form on a sunny day at the beach due to air, nearly saturated with water vapor, rising to an altitude where the cooler temperature is at the dew point.

**EXERCISE E** As the air warms up in the afternoon, how would the relative humidity change if there were no further evaporation? It would (*a*) increase, (*b*) decrease, (*c*) stay the same.

**CONCEPTUAL EXAMPLE 18–7** **Dryness in winter.** Why does the air inside heated buildings seem very dry on a cold winter day?

**RESPONSE** Suppose the relative humidity outside on a −10°C day is 50%. Table 18–2 tells us the partial pressure of water in the air is about $1.3 \times 10^{-3}$ atm. If this air is brought indoors and heated to +20°C, the relative humidity is $(1.3 \times 10^{-3}\ \text{atm})/(0.023\ \text{atm}) = 5.7\%$. Even if the outside air is fully saturated (partial pressure $2.6 \times 10^{-3}$ atm at −10°C), the inside relative humidity would still be low at 11%.

## 18–5 Temperature Decrease of Boiling Water with Altitude

**PHYSICS APPLIED**
*Food cooks slower at altitude*

Backpackers, mountain climbers, campers, and others who travel or live at high altitudes are aware that cooking food by boiling takes longer at high elevations than at sea level (or won't cook at all†). Why? Because the temperature of the boiling water is lower.

We can estimate the temperature of boiling water at various altitudes by using Table 18–2 and Eq. 13–6c which gives the pressure $P$ of the atmosphere (on average) as a function of altitude $y$ above sea level:

$$P = P_0 e^{-(\rho_0 g/P_0)y} = P_0 e^{-(1.25 \times 10^{-4}\,\text{m}^{-1})y}.$$

$P_0$ is $1.00\ \text{atm} = 1.013 \times 10^5\ \text{N/m}^2$, atmospheric pressure at sea level, and in Section 13–3 (see page 370) we calculated $\rho_0 g/P_0 = 1.25 \times 10^{-4}\ \text{m}^{-1}$.

So let's do some calculations of atmospheric pressure at different altitudes.

**(1)** At sea level, water boils at 100°C = 212°F.

†For example, spaghetti usually cooks fine at 8,000 ft, but thick rigatoni may never quite become tender.

**(2)** At an altitude of $y = 1200\,\text{m} \approx 4{,}000\,\text{ft}$,

$$P = (1.00\,\text{atm})e^{-(1.25\times10^{-4}\,\text{m}^{-1})(1200\,\text{m})} = (1.00\,\text{atm})e^{-0.15} = 0.86\,\text{atm}.$$

Now we look at Table 18–2 and interpolate between 90°C (0.70 atm) and 100°C (1.00 atm) and write $[(0.86 - 0.70)/(1.00 - 0.70)] \times 10\,\text{C}^\circ = 5.3\,\text{C}^\circ$, so $T \approx 95°\text{C} = 203°\text{F}$ is the boiling point of water at 1200 m above sea level.

**(3)** At $y = 2400\,\text{m}$ (twice as high), about 8,000 ft elevation, $P = (1.00\,\text{atm})\,e^{-0.30} = 0.74\,\text{atm}$, so $T$ is 91°C = 196°F, and you will notice a difference in cooking times.

**(4)** At the summit of Mt. Whitney, highest point in the lower 48 states at 4420 m = 14,500 ft, we have $(1.00\,\text{atm})e^{-(1.25\times10^{-4}\,\text{m}^{-1})(4420\,\text{m})} = 0.58\,\text{atm}$. Air pressure is reduced to almost half what it is at sea level. In Table 18–2 we interpolate between 80°C (0.47 atm) and 90°C (0.70 atm) and find $T = 85°\text{C} = 185°\text{F}$.

**(5)** The highest point on Earth is the summit of Mt. Everest, 8850 m = 29,040 ft above sea level. $P = (1.00\,\text{atm})e^{-(1.25\times10^{-4}\,\text{m}^{-1})(8850\,\text{m})} = 0.33\,\text{atm}$. Only $\frac{1}{3}$ as much air as at sea level—really hard to breathe. In Table 18–2, this corresponds to a temperature of about 71°C = 160°F.

**(6)** The lowest dry land on Earth is at the Dead Sea, 410 m below sea level, and $y = -410\,\text{m}$. Then $P = (1.00\,\text{atm})e^{+(1.25\times10^{-4}\,\text{m}^{-1})(410\,\text{m})} = 1.05\,\text{atm}$. Harder to interpolate: going up toward 120°C, this is a 5% change so $T \approx 101°\text{C}$.

Our interpolations are approximations because we assume linearity, which may not be true. See Table 18–3 for a summary of these results.

Pressure cookers reduce cooking time because they build up pressure as high as 2 atm, allowing higher cooking (boiling) temperature.

**TABLE 18–3 Boiling of Water**

| Altitude | Boiling Temperature of Water |
|---|---|
| 0 m | 100°C = 212°F |
| 1200 m = 4,000 ft | 95°C = 203°F |
| 2400 m = 8,000 ft | 91°C = 196°F |
| Mt. Whitney | 85°C = 185°F |
| Mt. Everest | 71°C = 160°F |
| Dead Sea | 101°C = 214°F |

## 18–6 Van der Waals Equation of State

In Section 18–3, we discussed how real gases deviate from ideal gas behavior, particularly at high densities or when near condensing to a liquid. We would like to understand these deviations using a microscopic (molecular) point of view. J. D. van der Waals (1837–1923) analyzed this problem and in 1873 arrived at an equation of state which fits real gases more accurately than the ideal gas law. His analysis is based on kinetic theory but takes into account: (1) the finite size of molecules (we previously neglected the actual volume of the molecules themselves, compared to the total volume of the container, and this assumption becomes poorer as the density increases and molecules become closer together); (2) the range of the forces between molecules may be greater than the size of the molecules (we previously assumed that molecular forces act only during collisions, when the molecules are "in contact"). Let us now look at this analysis and derive the van der Waals equation of state.

Assume the molecules in a gas are spherical with radius $r$. If we assume these molecules behave like hard spheres, then two molecules collide and bounce off one another if the distance between their centers (Fig. 18–10) gets as small as $2r$. Thus the actual volume in which the molecules can move about is somewhat less than the volume $V$ of the container holding the gas. The amount of "unavailable volume" depends on the number of molecules and on their size. Let $b$ represent the "unavailable volume per mole" of gas. Then in the ideal gas law we replace $V$ by $(V - nb)$, where $n$ is the number of moles, and we obtain

$$P(V - nb) = nRT.$$

If we divide through by $n$, we have

$$P\left(\frac{V}{n} - b\right) = RT. \qquad \textbf{(18–8)}$$

This relation (sometimes called the **Clausius equation of state**) predicts that for a given temperature $T$ and volume $V$, the pressure $P$ will be greater than for an ideal gas. This makes sense since the reduced "available" volume means the number of collisions with the walls is increased.

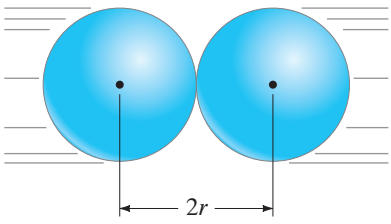

**FIGURE 18–10** Molecules, of radius $r$, colliding.

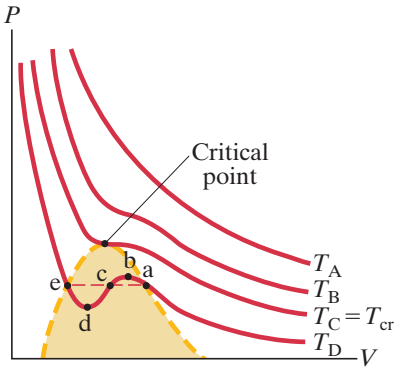

**FIGURE 18–11** *PV* diagram for a van der Waals gas, shown for four different temperatures. For $T_A$, $T_B$, and $T_C$ ($T_C$ is chosen equal to the critical temperature), the curves fit experimental data quite well for most real gases. The curve labeled $T_D$, a temperature below the critical point, passes through the liquid–vapor region. The maximum (point b) and minimum (point d) would seem to be artifacts, since we usually see constant pressure, as indicated by the horizontal dashed line (and Fig. 18–4). However, for very pure supersaturated vapors or supercooled liquids, the sections ab and ed, respectively, have been observed. (The section bd would be unstable and has not been observed.)

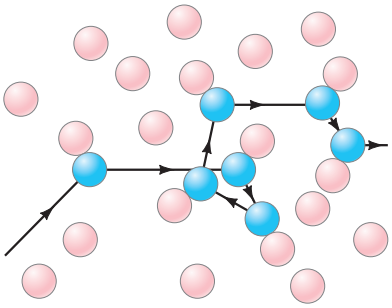
Next we consider the effects of attractive forces between molecules, which are responsible for holding molecules in the liquid and solid states at lower temperatures. These forces are electrical in nature and although they act even when molecules are not touching, we assume their range is small—that is, they act mainly between nearest neighbors. Molecules at the edge of the gas, headed toward a wall of the container, are slowed down by a net force pulling them back into the gas. Thus these molecules will exert less force and less pressure on the wall than if there were no attractive forces. The reduction in pressure will be proportional to the density of molecules in the layer of gas at the surface, and also to the density in the next layer, which exerts the inward force.[†] Therefore we expect the pressure to be reduced by a factor proportional to the density squared $(n/V)^2$, here written as moles per volume. We solve for the pressure $P$ in Eq. 18–8, and reduce this by an amount $a(n/V)^2$ where $a$ is a proportionality constant. Thus we have

$$P = \frac{RT}{(V/n) - b} - \frac{a}{(V/n)^2}$$

or

$$\left(P + \frac{a}{(V/n)^2}\right)\left(\frac{V}{n} - b\right) = RT, \qquad \textbf{(18–9)}$$



which is the **van der Waals equation of state**.

The constants $a$ and $b$ in the van der Waals equation are different for different gases and are determined by fitting to experimental data for each gas. For $CO_2$ gas, the best fit is obtained for $a = 0.36\,\text{N}\cdot\text{m}^4/\text{mol}^2$ and $b = 4.3 \times 10^{-5}\,\text{m}^3/\text{mol}$. Figure 18–11 shows a typical *PV* diagram for Eq. 18–9 (a "van der Waals gas") for four different temperatures, with detailed caption, and it should be compared to Fig. 18–4 for real gases.

Neither the van der Waals equation of state nor the many other equations of state that have been proposed are accurate for all gases under all conditions. Yet Eq. 18–9 is a very useful relation. And because it is quite accurate for many situations, its derivation gives us further insight into the nature of gases at the microscopic level. Note that at low densities, $a/(V/n)^2 \ll P$ and $b \ll V/n$, so that the van der Waals equation reduces to the equation of state for an ideal gas, $PV = nRT$.

## 18–7 Mean Free Path

**FIGURE 18–12** Zigzag path of a molecule colliding with other molecules.

If gas molecules were truly point particles, they would have zero cross-section and never collide with one another. If you opened a perfume bottle, you would be able to smell it almost instantaneously across the room, since molecules travel hundreds of meters per second as we saw in Example 18–2. In reality, it takes time before you detect an odor and, according to kinetic theory, this must be due to collisions between molecules of nonzero size.

If we were to follow the path of a particular molecule, we would expect to see it follow a zigzag path as shown in Fig. 18–12. Between each collision the molecule would move in a straight-line path. (Not quite true if we take account of the small intermolecular forces that act between collisions.) An important parameter for a given situation is the **mean free path**, which is defined as the average distance a molecule travels between collisions. We would expect that the greater the gas density, and the larger the molecules, the shorter the mean free path would be. We now determine the nature of this relationship for an ideal gas.

Suppose our gas is made up of molecules which are hard spheres of radius $r$. A collision will occur whenever the centers of two molecules come within a distance $2r$ of one another. Let us follow a molecule as it traces a straight-line path.

[†]This is similar to the gravitational force in which the force on mass $m_1$ due to mass $m_2$ is proportional to the product of their masses (Newton's law of universal gravitation, Chapter 6).

In Fig. 18–13, the dashed line represents the path of our particle if it makes no collisions. Also shown is a cylinder of radius $2r$. If the center of another molecule lies within this cylinder, a collision will occur. (Of course, when a collision occurs the particle's path would change direction, as would our imagined cylinder, but our result won't be altered by unbending a zigzag cylinder into a straight one for purposes of calculation.) Assume our molecule is an average one, moving at the mean speed $\bar{v}$ in the gas. For the moment, let us assume that the other molecules are not moving, and that the concentration of molecules (number per unit volume) is $N/V$. Then the number of molecules whose centers lie within the cylinder of Fig. 18–13 is $N/V$ times the volume of this cylinder, and this also represents the number of collisions that will occur. In a time $\Delta t$, our molecule travels a distance $\bar{v}\,\Delta t$, so the length of the cylinder is $\bar{v}\,\Delta t$ and its volume is $\pi(2r)^2\,\bar{v}\,\Delta t$. Hence the number of collisions that occur in a time $\Delta t$ is $(N/V)\pi(2r)^2\,\bar{v}\,\Delta t$. We define the **mean free path**, $\ell_M$, as the average distance between collisions. This distance is equal to the distance traveled $(\bar{v}\,\Delta t)$ in a time $\Delta t$ divided by the number of collisions made in time $\Delta t$:

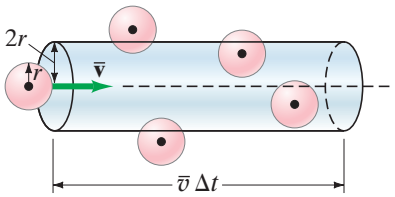


**FIGURE 18–13** Molecule at left moves to the right with speed $\bar{v}$. It collides with any molecule whose center is within the cylinder of radius $2r$.

$$\ell_M = \frac{\bar{v}\,\Delta t}{(N/V)\pi(2r)^2\,\bar{v}\,\Delta t} = \frac{1}{4\pi r^2(N/V)}. \qquad \textbf{(18–10a)}$$

Thus we see that $\ell_M$ is inversely proportional to the cross-sectional area $(=\pi r^2)$ of the molecules and to their concentration (number/volume), $N/V$. However, Eq. 18–10a is not fully correct since we assumed the other molecules are all at rest. In fact, they are moving, and the number of collisions in a time $\Delta t$ must depend on the *relative* speed of the colliding molecules, rather than on $\bar{v}$. Hence the number of collisions in time $\Delta t$ is $(N/V)\pi(2r)^2 v_{rel}\,\Delta t$ (rather than $(N/V)\pi(2r)^2\,\bar{v}\,\Delta t$), where $v_{rel}$ is the average relative speed of colliding molecules. A careful calculation shows that for a Maxwellian distribution of speeds $v_{rel} = \sqrt{2}\bar{v}$. Hence the mean free path is

$$\ell_M = \frac{1}{4\pi\sqrt{2}r^2(N/V)}. \qquad \textbf{(18–10b)}$$

*Mean free path*

**EXAMPLE 18–8** ESTIMATE **Mean free path of air molecules at STP.** Estimate the mean free path of air molecules at STP, standard temperature and pressure (0°C, 1 atm). The diameter of $O_2$ and $N_2$ molecules is about $3 \times 10^{-10}$ m.

**APPROACH** We saw in Example 17–10 that 1 mol of an ideal gas occupies a volume of $22.4 \times 10^{-3}\ m^3$ at STP. We can thus determine $N/V$ and apply Eq. 18–10b.

**SOLUTION**

$$\frac{N}{V} = \frac{6.02 \times 10^{23}\ \text{molecules}}{22.4 \times 10^{-3}\ m^3} = 2.69 \times 10^{25}\ \text{molecules/m}^3.$$

Then

$$\ell_M = \frac{1}{4\pi\sqrt{2}\,(1.5 \times 10^{-10}\ m)^2(2.7 \times 10^{25}\ m^{-3})} \approx 9 \times 10^{-8}\ m.$$

**NOTE** This is about 300 times the diameter of an air molecule.

At very low densities, such as in an evacuated vessel, the concept of mean free path loses meaning since collisions with the container walls may occur more frequently than collisions with other molecules. For example, in a cubical box that is (say) 20 cm on a side containing air at $\approx 10^{-10}$ atm, the mean free path would be about 900 m, which means many more collisions are made with the walls than with other molecules. (Note, nonetheless, that the box contains over $10^{12}$ molecules.) If the concept of mean free path included also collision with the walls, it would be closer to 0.2 m than to the 900 m calculated from Eq. 18–10b.

# 18–8 Diffusion

If you carefully place a few drops of food coloring in a glass of water as in Fig. 18–14, you will find that the color spreads throughout the water. The process may take some time in a still liquid (you do not shake the glass), but eventually the color will become uniform. This mixing, known as **diffusion**, is explained by kinetic theory as due to the random movement of the molecules. Diffusion occurs in gases too. Common examples include perfume or smoke (or the odor of something cooking on a stove) diffusing in air, although convection (moving air currents) often plays a greater role in spreading odors than does diffusion. Diffusion depends on concentration, by which we mean the number of molecules or moles per unit volume. In general, *the diffusing substance moves from a region where its concentration is high to a region where its concentration is low.*

(a) (b) (c)

**FIGURE 18–14** A few drops of food coloring (a) dropped into water, (b) spreads slowly throughout the water, eventually (c) becoming uniform.

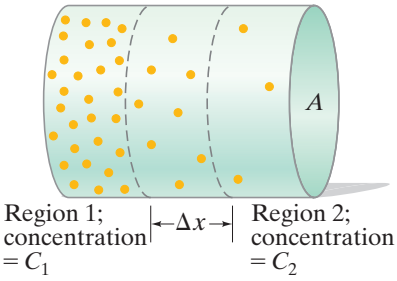

**FIGURE 18–15** Diffusion occurs from a region of high concentration to one of lower concentration (only one type of molecule is shown).

Diffusion can be readily understood on the basis of kinetic theory and the random motion of molecules. Consider a tube of cross-sectional area $A$ containing molecules in a higher concentration on the left than on the right, Fig. 18–15. We assume the molecules are in random motion. Yet there will be a net flow of molecules to the right. To see why, let us consider the small section of tube of length $\Delta x$ as shown. Molecules from both regions 1 and 2 cross into this central section as a result of their random motion. The more molecules there are in a region, the more will strike a given area or cross a boundary. Since there is a greater concentration of molecules in region 1 than in region 2, more molecules cross into the central section from region 1 than from region 2. There is, then, a net flow of molecules from left to right, from high concentration toward low concentration. The net flow becomes zero only when the concentrations become equal.

We might expect that the greater the difference in concentration, the greater the flow rate. Indeed, the rate of diffusion, $J$ (number of molecules or moles or kg per second), is directly proportional to the difference in concentration per unit distance, $(C_1 - C_2)/\Delta x$ (which is called the **concentration gradient**), and to the cross-sectional area $A$ (see Fig. 18–15):

$$J = DA\frac{C_1 - C_2}{\Delta x},$$

or, in terms of derivatives,

$$J = DA\frac{dC}{dx}. \qquad \textbf{(18–11)}$$

$D$ is a constant of proportionality called the **diffusion constant**. Equation 18–11 is known as the **diffusion equation**, or **Fick's law**. If the concentrations are given in $\text{mol/m}^3$, then $J$ is the number of moles passing through a given area $A$ per second. If the concentrations are given in $\text{kg/m}^3$, then $J$ is the mass movement per second (kg/s). The length $\Delta x$ is given in meters, and area $A$ in $\text{m}^2$. The values of $D$ for a variety of substances diffusing in a particular medium are given in Table 18–4.

**TABLE 18–4 Diffusion Constants, $D$ (20°C, 1 atm)**

| Diffusing Molecules | Medium | $D$ ($\text{m}^2$/s) |
|---|---|---|
| $H_2$ | Air | $6.3 \times 10^{-5}$ |
| $O_2$ | Air | $1.8 \times 10^{-5}$ |
| $O_2$ | Water | $100 \times 10^{-11}$ |
| Blood hemoglobin | Water | $6.9 \times 10^{-11}$ |
| Glycine (an amino acid) | Water | $95 \times 10^{-11}$ |
| DNA (mass $6 \times 10^6$ u) | Water | $0.13 \times 10^{-11}$ |

## *Applications of Diffusion

**EXAMPLE 18–9** **ESTIMATE** **Diffusion of ammonia in air.** To get an idea of the time required for diffusion, estimate how long it might take for ammonia ($NH_3$) to be detected 10 cm from a bottle after it is opened, assuming only diffusion is occurring.

**APPROACH** This will be an order-of-magnitude calculation. The rate of diffusion $J$ can be set equal to the number of molecules $N$ diffusing across area $A$ in a time $t$: $J = N/t$. Then the time $t = N/J$, where $J$ is given by Eq. 18–11. We will have to make some assumptions and rough approximations about concentrations to use Eq. 18–11.

PHYSICS APPLIED
*Diffusion time*

**SOLUTION** Using Eq. 18–11, we find

$$t = \frac{N}{J} = \frac{N}{DA}\frac{\Delta x}{\Delta C}.$$

The average concentration (in molecules/$m^3$), midway between bottle and nose, can be approximated by $\overline{C} \approx N/V$, where $V$ is the volume over which the molecules move and is roughly on the order of $V \approx A\,\Delta x$, where $\Delta x$ is 10 cm = 0.10 m. We substitute $N = \overline{C}V = \overline{C}A\,\Delta x$ into the above equation:

$$t \approx \frac{(\overline{C}A\,\Delta x)\,\Delta x}{DA\,\Delta C} = \frac{\overline{C}}{\Delta C}\frac{(\Delta x)^2}{D}.$$

The concentration of ammonia is high near the bottle ($C$) and low near the detecting nose ($\approx 0$), so $\overline{C} \approx C/2 \approx \Delta C/2$, or $(\overline{C}/\Delta C) \approx \frac{1}{2}$. Since $NH_3$ molecules have a size somewhere between $H_2$ and $O_2$, from Table 18–4 we can estimate $D \approx 4 \times 10^{-5}\,m^2/s$. Then

$$t \approx \tfrac{1}{2}\frac{(0.10\,m)^2}{(4 \times 10^{-5}\,m^2/s)} \approx 100\,s,$$

or about a minute or two.

**NOTE** This result seems rather long from experience, suggesting that air currents (convection) are more important than diffusion for transmitting odors.

**CONCEPTUAL EXAMPLE 18–10** **Colored rings on a paper towel.** A child colors a small spot on a wet paper towel with a brown marking pen. Later, she discovers that instead of a brown spot, there are concentric colored rings around the marked spot. What happened?

**RESPONSE** The ink in a brown marker is composed of several different inks that mix to make brown. These inks each diffuse at different rates ($D$ is different for each) through the wet paper towel. After a period of time the inks have diffused far enough that the differences in distances traveled is sufficient to see the separation of the different colors. Biochemists and chemists use a similar technique, called **chromatography**, to separate large molecules or small cell components based on their diffusion rates through a medium.

PHYSICS APPLIED
*Chromatography*

Diffusion is extremely important for living organisms. For example, molecules produced in certain chemical reactions within cells diffuse to other areas where they take part in other reactions.

PHYSICS APPLIED
*Diffusion in living organisms*

Gas diffusion is important too. Plants require carbon dioxide for photosynthesis. The $CO_2$ diffuses into leaves from the outside air through tiny openings (stomata). As $CO_2$ is utilized by the cells, its concentration drops below that in the air outside, and more diffuses inward. Water vapor and oxygen produced by the cells diffuse outward into the air.

Animals also exchange oxygen and $CO_2$ with the environment. Oxygen required for energy-producing reactions in animals must diffuse into cells. $CO_2$ is produced as an end product of many metabolic reactions and must diffuse out of cells.

But diffusion is slow over longer distances, so only the smallest organisms in the animal world could survive without having developed complex respiratory and circulatory systems. In humans, oxygen is taken into the lungs, where it diffuses short distances across lung tissue and into the blood. The blood (not diffusion) circulates the oxygen to cells throughout the body. The blood also carries $CO_2$ produced by the cells back to the lungs, where it diffuses outward.

# Summary

According to the **kinetic theory** of gases, which is based on the idea that a gas is made up of molecules that are moving rapidly and randomly, the average translational kinetic energy of the molecules is proportional to the Kelvin temperature $T$:

$$\overline{K} = \tfrac{1}{2}m\overline{v^2} = \tfrac{3}{2}kT \qquad \textbf{(18–4)}$$

where $k$ is Boltzmann's constant.

At any moment, there exists a wide distribution of molecular speeds within a gas. The **Maxwell distribution of speeds** is derived from simple kinetic theory assumptions, and is in good accord with experiment for gases at not too high a pressure.

The behavior of real gases at high pressure, and/or when near their liquefaction point, deviates from the ideal gas law due to the finite size of molecules and to the attractive forces between molecules.

Below the **critical temperature**, a gas can change to a liquid if sufficient pressure is applied; but if the temperature is higher than the critical temperature, no amount of pressure will cause a liquid surface to form.

The **triple point** of a substance is that unique temperature and pressure at which all three phases—solid, liquid, and gas—can coexist in equilibrium. Because of its precise reproducibility, the triple point of water is often taken as a standard reference point.

**Evaporation** of a liquid is the result of the fastest moving molecules escaping from the surface. Because the average molecular velocity is less after the fastest molecules escape, the temperature decreases when evaporation takes place.

**Saturated vapor pressure** refers to the pressure of the vapor above a liquid when the two phases are in equilibrium. The vapor pressure of a substance (such as water) depends strongly on temperature and is equal to atmospheric pressure at the boiling point.

**Relative humidity** of air at a given place is the ratio of the partial pressure of water vapor in the air to the saturated vapor pressure at that temperature; it is usually expressed as a percentage.

The **van der Waals equation of state** takes into account the finite volume of molecules, and the attractive forces between molecules, to better approximate the behavior of real gases.

The **mean free path** is the average distance a molecule moves between collisions with other molecules.

**Diffusion** is the process whereby molecules of a substance move (on average) from one area to another because of a difference in that substance's concentration.

# Questions

1. Why doesn't the size of different molecules enter into the ideal gas law?
2. When a gas is rapidly compressed (say, by pushing down a piston as in Fig. 17–14a), its temperature increases. When a gas expands against a piston, it cools. Explain these changes in temperature using the kinetic theory, in particular noting what happens to the momentum of molecules when they strike the moving piston.
3. In Section 18–1 we assumed the gas molecules made perfectly elastic collisions with the walls of the container. This assumption is not necessary as long as the walls are at the same temperature as the gas. Why?
4. Explain in words how Charles's law follows from kinetic theory and the relation between average kinetic energy and the absolute temperature.
5. Explain in words how Gay-Lussac's law follows from kinetic theory.
6. As you go higher in the Earth's atmosphere, the ratio of $N_2$ molecules to $O_2$ molecules increases. Why?
7. Can you determine the temperature of a vacuum?
8. Explain why the peak of the curve for 310 K in Fig. 18–3 is not as high as for 273 K. (Assume the total number of molecules is the same for both.)
9. Is temperature a macroscopic or microscopic variable?
10. Escape velocity from the Earth refers to the minimum speed an object must have to leave the Earth and never return. (*a*) The escape velocity from the Moon is about one-fifth what it is from the Earth due to the Moon's smaller mass. Explain why the Moon has practically no atmosphere. (*b*) If hydrogen was once in the Earth's atmosphere, why would it have probably escaped?
11. If a container of gas is at rest, the average velocity of molecules must be zero. Yet the average speed is not zero. Explain.
12. If the pressure in a gas is doubled while its volume is held constant, by what factor do (*a*) $v_{\text{rms}}$ and (*b*) $\bar{v}$ change?
13. What everyday observation would tell you that not all molecules in a material have the same speed?
14. Alcohol evaporates more quickly than water at room temperature. What can you infer about the molecular properties of one relative to the other?
15. Explain why a hot humid day is far more uncomfortable than a hot dry day at the same temperature.
16. Is it possible to boil water at room temperature (20°C) without heating it? Explain.

17. What exactly does it mean when we say that oxygen boils at −183°C?
18. A length of thin wire is placed over a block of ice (or an ice cube) at 0°C. The wire hangs down both sides of the ice, and weights are hung from the ends of the wire. It is found that the wire cuts its way through the ice cube, but leaves solid ice above it. This process is called *regelation*. Explain how this happens by inferring how the freezing point of water depends on pressure.
19. Consider two days when the air temperature is the same but the humidity is different. Which is more dense, the dry air or the humid air at the same $T$? Explain.
20. (*a*) Why does food cook faster in a pressure cooker? (*b*) Why does pasta or rice need to boil longer at high altitudes? (*c*) Is it harder to boil water at high altitudes?
21. How do a gas and a vapor differ?
22. (*a*) At suitable temperatures and pressures, can ice be melted by applying pressure? (*b*) At suitable temperatures and pressures, can carbon dioxide be melted by applying pressure?
23. Why does dry ice not last long at room temperature?
24. Under what conditions can liquid $CO_2$ exist? Be specific. Can it exist as a liquid at normal room temperature?
25. Why does exhaled air appear as a little white cloud in the winter (Fig. 18–16)?

**FIGURE 18–16**
Question 25.

26. Discuss why sound waves can travel in a gas only if their wavelength is somewhat larger than the mean free path.
27. Name several ways to reduce the mean free path in a gas.

# MisConceptual Questions

1. An ideal gas is in a sealed rigid container. The average kinetic energy of the gas molecules depends mainly on
   (*a*) the size of the container.
   (*b*) the number of molecules in the container.
   (*c*) the temperature of the gas.
   (*d*) the mass of the molecules.
2. Two ideal gases, A and B, are at the same temperature. If the molecular mass of the molecules in gas A is twice that of the molecules in gas B, the molecules' root-mean-square speed is
   (*a*) the same in both gases.
   (*b*) twice as great in A.
   (*c*) $\sqrt{2}$ times greater in A.
   (*d*) twice as great in B.
   (*e*) $\sqrt{2}$ times greater in B.
3. In a mixture of the gases oxygen and helium in equilibrium, which statement is valid?
   (*a*) The helium atoms will be moving faster than the oxygen molecules, on average.
   (*b*) They will be moving at the same average speed.
   (*c*) The oxygen molecules will be moving faster than the helium atoms, on average.
   (*d*) The kinetic energy of helium atoms will exceed that of oxygen molecules.
   (*e*) None of the above.
4. Which of the following is *not* true about an ideal gas?
   (*a*) The average kinetic energy of the gas molecules increases as the temperature increases.
   (*b*) The volume of an ideal gas increases with temperature if the pressure is held constant.
   (*c*) The pressure of an ideal gas increases with temperature if the volume is held constant.
   (*d*) All gas molecules have the same speed at a particular temperature.
   (*e*) The molecules are assumed to be far apart compared to their size.
5. By what factor must the absolute temperature change to double $v_{\text{rms}}$?
   (*a*) $\sqrt{2}$. (*b*) 2. (*c*) $2\sqrt{2}$. (*d*) 4. (*e*) 16.
6. The rms speed of the molecules of an ideal gas
   (*a*) is the same as the most probable speed of the molecules.
   (*b*) is always equal to $\sqrt{2}$ times the maximum molecular speed.
   (*c*) will increase as the temperature of a gas increases.
   (*d*) All of the above.
7. A sample of an ideal gas is slowly compressed to one-half its original volume with no change in temperature. What happens to the average speed of the molecules in the sample?
   (*a*) It doubles.
   (*b*) It does not change.
   (*c*) It halves.
   (*d*) It quadruples.
   (*e*) None of the above.
8. The air in this room is composed of mostly nitrogen and oxygen. Select all of the true statements below.
   (*a*) The nitrogen and oxygen molecules have the same rms speed.
   (*b*) The rms speed of the oxygen molecules is larger.
   (*c*) The rms speed of the nitrogen molecules is larger.
   (*d*) The average kinetic energies are the same.
   (*e*) The average kinetic energy of oxygen is larger.
   (*f*) The average kinetic energy of nitrogen is larger.
9. About how fast are molecules of nitrogen in air at room temperature moving? As fast as a
   (*a*) tortoise.
   (*b*) sprinter.
   (*c*) car at the highway speed limit.
   (*d*) passenger jet plane.
   (*e*) satellite in orbit around the Earth.
10. An ice cube could go directly from the solid phase to the gas phase (a process called sublimation)
    (*a*) never.
    (*b*) if the temperature and pressure are low enough.
    (*c*) if the temperature and pressure are high enough.
    (*d*) always.

# Problems

## 18–1 Molecular Interpretation of Temperature

**1.** (I) Calculate the rms speed of helium atoms near the surface of the Sun at a temperature of about 6000 K.

**2.** (I) By what factor will the rms speed of gas molecules increase if the temperature is increased from 0°C to 160°C?

**3.** (I) Twelve molecules have the following speeds, given in arbitrary units: 6.0, 2.0, 4.0, 6.0, 0.0, 4.0, 1.0, 8.0, 5.0, 3.0, 7.0, and 8.0. Calculate (*a*) the mean speed, and (*b*) the rms speed.

**4.** (I) What speed would a 1.5-g paper clip have if it had the same kinetic energy as a molecule at 22°C?

**5.** (II) A gas is at 30°C. To what temperature must it be raised to triple the rms speed of its molecules?

**6.** (II) (*a*) What is the average translational kinetic energy of a nitrogen molecule at STP? (*b*) What is the total translational kinetic energy of 1.0 mol of $N_2$ molecules at 25°C?

**7.** (II) A 1.0-mol sample of helium gas has a temperature of 18°C. (*a*) What is the total kinetic energy of all the gas atoms in the sample? (*b*) How fast would a 65-kg person have to run to have the same kinetic energy?

**8.** (II) At what temperature do the atoms of helium gas have the same rms speed as molecules of water vapor at 20.0°C?

**9.** (II) If the pressure in a gas is tripled while its volume is held constant, by what factor does $v_{\text{rms}}$ change?

**10.** (II) Show that the rms speed of molecules in a gas is given by $v_{\text{rms}} = \sqrt{3P/\rho}$, where $P$ is the pressure in the gas, and $\rho$ is the gas density.

**11.** (II) Show that for a mixture of two gases at the same temperature, the ratio of their rms speeds is equal to the inverse ratio of the square roots of their molecular masses, $v_1/v_2 = \sqrt{M_2/M_1}$.

**12.** (II) What is the rms speed of nitrogen molecules contained in a 7.2-$m^3$ volume at 2.9 atm if the total amount of nitrogen is 2100 mol?

**13.** (II) (*a*) For an ideal gas at temperature $T$ show that

$$\frac{dv_{\text{rms}}}{dT} = \frac{1}{2}\frac{v_{\text{rms}}}{T},$$

and using the approximation $\Delta v_{\text{rms}} \approx \frac{dv_{\text{rms}}}{dT}\Delta T$, show that

$$\frac{\Delta v_{\text{rms}}}{v_{\text{rms}}} \approx \frac{1}{2}\frac{\Delta T}{T}.$$

(*b*) If the average air temperature changes from −5°C in winter to 25°C in summer, estimate the percent change in the rms speed of air molecules between these seasons.

**14.** (II) What is the average distance between oxygen molecules at STP?

**15.** (II) The rms speed of molecules in a gas at 20.0°C is to be increased by 5.0%. To what temperature must it be raised?

**16.** (II) Can pockets of vacuum persist in an ideal gas? Assume that a room is filled with air at 20°C and that somehow a small spherical region of radius 1 cm within the room becomes devoid of air molecules. Estimate how long it will take for air to refill this region of vacuum. Assume the atomic mass of air is 29 u.

**17.** (II) Calculate (*a*) the rms speed of an oxygen molecule at 0°C and (*b*) determine how many times per second it would move back and forth across a 6.0-m-long room on average, assuming it made very few collisions with other molecules.

**18.** (II) A friend calculates the room temperature rms speed of $CO_2$ molecules to be about $1.7 \times 10^{-11}$ m/s. Looking back at Example 18–2, you conclude that there must be something wrong. What was the mistake and what is the correct rms speed?

**19.** (III) Estimate how many air molecules rebound from a wall in a typical room per second, assuming an ideal gas of $N$ molecules contained in a cubic room with sides of length $\ell$ at temperature $T$ and pressure $P$. (*a*) Show that the frequency $f$ with which gas molecules strike a wall is

$$f = \frac{\bar{v}_x}{2}\frac{P}{kT}\ell^2$$

where $\bar{v}_x$ is the average $x$ component of the molecule's velocity. (*b*) Show that the equation can then be written as

$$f \approx \frac{P\ell^2}{\sqrt{4mkT}}$$

where $m$ is the mass of a gas molecule. (*c*) Determine $f$ for a cubic air-filled room at sea level, at a temperature 20°C, with sides of length $\ell = 3$ m.

## 18–2 Distribution of Molecular Speeds

**20.** (II) A group of 25 particles have the following speeds: two have speed 10 m/s, seven have 15 m/s, four have 20 m/s, three have 25 m/s, six have 30 m/s, one has 35 m/s, and two have 40 m/s. Determine (*a*) the average speed, (*b*) the rms speed, and (*c*) the most probable speed.

**21.** (II) If you changed the type of molecules in a gas so that their mass is tripled, is it possible to change the temperature to keep the velocity distribution from changing? If so, what do you need to do to the temperature?

**22.** (II) A gas consisting of 14,500 molecules, each of mass $2.00 \times 10^{-26}$ kg, has the following distribution of speeds, which crudely mimics the Maxwell distribution:

| Number of Molecules | Speed (m/s) |
|---|---|
| 1500 | 220 |
| 3900 | 440 |
| 4600 | 660 |
| 2900 | 880 |
| 1200 | 1100 |
| 400 | 1320 |

(*a*) Determine $v_{\text{rms}}$ for this distribution of speeds. (*b*) Given your value for $v_{\text{rms}}$, what (effective) temperature would you assign to this gas? (*c*) Determine the mean speed $\bar{v}$ of this distribution and use this value to assign an (effective) temperature to the gas. Is the temperature you find here consistent with the one you determined in part (*b*)? If not, what is the difference between these two temperatures?

23. (III) Starting from the Maxwell distribution of speeds, Eq. 18–6, show (*a*)

$$\int_0^\infty f(v)\,dv = N,$$

which is the total number of molecules, and (*b*)

$$\overline{v^2} = v_{\text{rms}}^2 = \int_0^\infty v^2 f(v)\,dv/N = 3kT/m,$$

so $\frac{1}{2}m\overline{v^2} = \frac{3}{2}kT$ (Eq. 18–4).

## 18–3 Real Gases; Phase Changes

24. (I) $CO_2$ exists in what phase when the pressure is 35 atm and the temperature is 35°C (Fig. 18–6)?

25. (I) (*a*) At atmospheric pressure, in what phases can $CO_2$ exist? (*b*) For what range of pressures and temperatures can $CO_2$ be a liquid? Refer to Fig. 18–6.

26. (I) Water is in which phase when the pressure is 0.01 atm and the temperature is (*a*) 90°C, (*b*) −20°C?

27. (II) You have a sample of water and are able to control temperature and pressure arbitrarily. (*a*) Using Fig. 18–5, describe the phase changes you would see if you started at a temperature of 85°C, a pressure of 180 atm, and decreased the pressure to 0.004 atm while keeping the temperature fixed. (*b*) Repeat part (*a*) with the temperature at 0.0°C. Assume that you held the system at the starting conditions long enough for the system to stabilize before making further changes.

## 18–4 Vapor Pressure and Humidity

28. (I) What is the partial pressure of water on a day when the temperature is 25°C and the relative humidity is 75%?

29. (I) What is the partial pressure of water vapor at 30°C if the humidity is 35%?

30. (I) What is the air pressure at a place where water boils at 80°C?

31. (II) If the air pressure at a particular place in the mountains is 0.80 atm, estimate the temperature at which water boils.

32. (II) What is the dew point if the humidity is 55% on a day when the temperature is 25°C?

33. (II) A **pressure cooker** is a sealed pot designed to cook food with the steam produced by boiling water somewhat above 100°C. The pressure cooker in Fig. 18–17 uses a weight of mass *m* to allow steam to escape at a certain pressure through a small hole (diameter *d*) in the cooker's lid. If $d = 3.0$ mm, what should *m* be in order to cook food at 120°C? Assume that atmospheric pressure outside the cooker is $1.01 \times 10^5$ Pa.

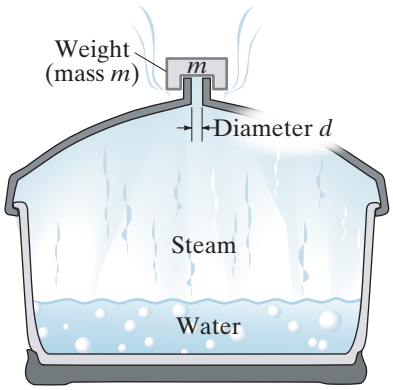

**FIGURE 18–17**
Problem 33.

34. (II) What is the mass of water vapor in a closed room 5.0 m × 6.0 m × 2.4 m when the temperature is 22°C and the relative humidity is 45%?

35. (II) What is the approximate pressure inside a pressure cooker if the water is boiling at a temperature of 130°C? Assume no air escaped during the heating process, which started at 18°C.

36. (II) If the humidity in a sealed room of volume 420 $m^3$ at 25°C is 65%, what mass of water can still evaporate from an open pan?

37. (III) When using a mercury barometer (Section 13–6), the vapor pressure of mercury is usually assumed to be zero. At room temperature mercury's vapor pressure is about 0.0015 mm-Hg. At sea level, the height *h* of mercury in a barometer is about 760 mm. (*a*) If the vapor pressure of mercury is neglected, is the true atmospheric pressure greater or less than the value read from the barometer? (*b*) What is the percent error? (*c*) What is the percent error if you use a water barometer and ignore water's saturated vapor pressure at STP?

38. (III) Air that is at its dew point of 5°C is drawn into a building where it is heated to 22°C. What will be the relative humidity at this temperature? Assume constant pressure of 1.0 atm. Take into account the expansion of the air.

## 18–5 Temperature of Boiling Water

39. (II) (*a*) At what temperature does water boil at 10,000 ft (3000 m) of elevation? (*b*) At what elevation would water boil at 80°C?

40. (II) (*a*) Estimate at what temperature the water boils in Denver, Colorado—called "the mile high city." (*b*) If water boils at 89°C, at what elevation are you?

## 18–6 Van der Waals Equation of State

41. (II) In the van der Waals equation of state, the constant *b* represents the amount of "unavailable volume" (per mole) occupied by the molecules themselves. Thus *V* is replaced by $(V - nb)$, where *n* is the number of moles. For oxygen, *b* is about $3.2 \times 10^{-5}$ $m^3$/mol. Estimate the diameter of an oxygen molecule.

42. (II) For oxygen gas, the van der Waals equation of state achieves its best fit for $a = 0.14\ \text{N}\cdot\text{m}^4/\text{mol}^2$ and $b = 3.2 \times 10^{-5}\ \text{m}^3/\text{mol}$. Determine the pressure in 1.0 mol of the gas at 0°C if its volume is 0.70 L, calculated using (*a*) the van der Waals equation, (*b*) the ideal gas law.

43. (III) A 0.5-mol sample of $O_2$ gas is in a large cylinder with a movable piston on one end so it can be compressed (as in Fig. 17–14a). The initial volume is large enough that there is not a significant difference between the pressure given by the ideal gas law and that given by the van der Waals equation. As the gas is slowly compressed at constant temperature (use 300 K), at what volume does the van der Waals equation give a pressure that is 5% different than the ideal gas law pressure? Let $a = 0.14\ \text{N}\cdot\text{m}^4/\text{mol}^2$ and $b = 3.2 \times 10^{-5}\ \text{m}^3/\text{mol}$.

44. (III) How well does the ideal gas law describe the pressurized air in a scuba tank? (*a*) To fill a typical scuba tank, an air compressor intakes about 2300 L of air at 1.0 atm and compresses this gas into the tank's 12-L internal volume. If the filling process occurs at 20°C, show that a tank holds about 96 mol of air. (*b*) Assume the tank has 96 mol of air at 20°C. Use the ideal gas law to predict the air's pressure within the tank. (*c*) Use the van der Waals equation of state to predict the air's pressure within the tank. For air, the van der Waals constants are $a = 0.1373\ \text{N}\cdot\text{m}^4/\text{mol}^2$ and $b = 3.72 \times 10^{-5}\ \text{m}^3/\text{mol}$. (*d*) Assuming the van der Waals pressure is the true pressure inside the full tank, show that the ideal gas law predicts a pressure that is in error by only about 3%.

### 18–7 Mean Free Path

**45.** (II) Below a certain threshold pressure, the air molecules (0.3-nm diameter) within a research vacuum chamber are in the "collision-free regime," meaning that a particular air molecule is as likely to cross the container and collide with the opposite wall as it is to collide with another air molecule. Estimate the threshold pressure for a vacuum chamber of side 1.0 m at 20°C.

**46.** (II) At about what pressure would the mean free path of air molecules be (*a*) 0.30 m and (*b*) equal to the diameter of air molecules, $\approx 3 \times 10^{-10}$ m? Assume $T = 20°C$.

**47.** (II) (*a*) The mean free path of $CO_2$ molecules at STP is about $5.6 \times 10^{-8}$ m. Estimate the diameter of a $CO_2$ molecule. (*b*) Do the same for He gas for which $\ell_M \approx 25 \times 10^{-8}$ m at STP.

**48.** (II) A very small amount of hydrogen gas is released into the air. If the air is at 1.0 atm and 15°C, estimate the mean free path for an $H_2$ molecule. What assumptions did you make?

**49.** (II) We saw in Example 18–8 that the mean free path $\ell_M$ of air molecules at STP is about $9 \times 10^{-8}$ m. Estimate the collision frequency $f$, the number of collisions per unit time.

**50.** (II) A cubic box 1.40 m on a side is placed under one of the best possible vacuums, so the pressure of air inside is $10^{-13}$ atm. Estimate how many collisions molecules make with each other for each collision with a wall (0°C).

**51.** (III) Estimate the maximum allowable pressure in an electronic tube if 98% of all electrons leaving the hot negative electrode must hit the positive electrode 3.5 cm away without first striking an air molecule. Assume electrons are point particles (zero diameter).

**52.** (III) Sound waves in a gas can only propagate if the gas molecules collide with each other on the time scale of the sound wave's period. Thus the highest possible frequency $f_{max}$ for a sound wave in a gas is approximately equal to $1/t_{coll}$, the inverse of the average collision time between molecules. Assume a gas, composed of molecules with mass $m$ and radius $r$, is at pressure $P$ and temperature $T$. (*a*) Show that the *highest sound frequency* in the gas is

$$f_{max} \approx 16Pr^2\sqrt{\frac{\pi}{mkT}}.$$

(*b*) Determine $f_{max}$ for 20°C air at sea level. How many times larger is $f_{max}$ than the highest frequency in the human audio range (20 kHz)?

### 18–8 Diffusion

***53.** (I) Approximately how long would it take for the ammonia of Example 18–9 to be detected 1.0 m from the bottle after it is opened? What does this suggest about the relative importance of diffusion and convection for carrying odors?

***54.** (II) Estimate the time needed for a glycine molecule (see Table 18–3) to diffuse a distance of 25 $\mu$m in water at 20°C if its concentration varies over that distance from 1.00 mol/m$^3$ to 0.50 mol/m$^3$. Compare this "speed" to its rms (thermal) speed. The molecular mass of glycine is about 75 u.

***55.** (II) *Oxygen diffuses* from the surface of *insects* to the interior through tiny tubes called tracheae. An average trachea is about 2 mm long and has cross-sectional area of $2 \times 10^{-9}$ m$^2$. Assume the concentration of oxygen inside is half what it is outside in the atmosphere. (*a*) Show that the concentration of oxygen in the air (assume 21% is oxygen) at 20°C is about 8.7 mol/m$^3$. (*b*) Calculate the diffusion rate $J$. (*c*) Estimate the average time for a molecule to diffuse through a trachea. Assume the diffusion constant is $1 \times 10^{-5}$ m$^2$/s.

## General Problems

**56.** A sample of ideal gas must contain at least $N = 10^6$ molecules in order for the Maxwell distribution to be a valid description of the gas, and to assign it a meaningful temperature. For an ideal gas at STP, what is the smallest length scale $\ell$ (volume $V = \ell^3$) for which a valid temperature can be assigned?

**57.** In outer space the density of matter is about one atom per cm$^3$, mainly hydrogen atoms, and the temperature is about 2.7 K. Calculate the rms speed of these hydrogen atoms, and the pressure (in atmospheres).

**58.** Calculate approximately the total translational kinetic energy of all the molecules in an *E. coli* bacterium of mass $2.0 \times 10^{-15}$ kg at 37°C. Assume 70% of the cell, by weight, is water, and the other molecules have an average molecular mass on the order of $10^5$ u.

**59.** (*a*) Estimate the rms speed of an amino acid, whose molecular mass is 89 u, in a living cell at 37°C. (*b*) What would be the rms speed of a protein of molecular mass 85,000 u at 37°C?

**60.** A 0.40-kg trash-can lid is suspended against gravity by tennis balls thrown vertically upward at it. How many tennis balls per second must rebound from the lid elastically, assuming they have a mass of 0.060 kg and are thrown at 15 m/s?

**61.** The escape speed from the Earth is $1.12 \times 10^4$ m/s (Section 8–7). So a gas molecule traveling away from Earth near the outer boundary of the Earth's atmosphere would, at this speed, be able to escape from the Earth's gravitational field and be lost to the atmosphere. At what temperature is the rms speed of (*a*) oxygen molecules, and (*b*) helium atoms equal to $1.12 \times 10^4$ m/s? (*c*) Can you explain why our atmosphere contains oxygen but not helium?

**62.** Assuming a typical nitrogen or oxygen molecule is about 0.3 nm in diameter, what percent of the room you are sitting in is taken up by the volume of the molecules themselves?

**63.** A *scuba* tank has a volume of 3100 cm$^3$. For very deep dives, the tank is filled with 50% (by volume) pure oxygen and 50% pure helium. (*a*) How many molecules are there of each type in the tank if at 20°C the gauge pressure reads 14 atm? (*b*) What is the ratio of the average kinetic energies of the two types of molecule? (*c*) What is the ratio of the rms speeds of the two types of molecule?

**64.** A *sauna* has 7.8 m$^3$ of air volume, and the temperature is 85°C. The air is perfectly dry. How much water (in kg) should be evaporated if we want to increase the relative humidity from 0% to 10%? (See Table 18–2.)

**65.** (*a*) The second postulate of kinetic theory is that molecules in a gas are, on average, far apart from one another. That is, their average separation is much greater than the diameter of each molecule. Is this assumption reasonable? To check, calculate the average distance between molecules of a gas at STP, and compare it to the diameter of a typical gas molecule, about 0.3 nm. (*b*) If the molecules had the diameter of ping-pong balls, say 4 cm, how far away would the next ping-pong ball be on average? (*c*) Repeat part *a*, but now assume the gas has been compressed so that the pressure is now 3 atm but still at 273 K. (*d*) Estimate what % of the total volume of gas is taken up by molecules themselves in parts *a* and *c*. [Note that the volume of the molecules themselves can become a significant part of the total volume at lower temperatures and higher pressures. Hence the actual volume the molecules have to bounce around in is less than the total volume. This contributes to the effect shown in Fig. 18–4 at high pressures where real gases (solid red lines) deviate from ideal gas behavior (dashed lines A′ and B′).]

**66.** Two isotopes of uranium, $^{235}U$ and $^{238}U$ (the superscripts refer to their atomic masses), can be separated by a gas diffusion process by combining them with fluorine to make the gaseous compound $UF_6$. Calculate the ratio of the rms speeds of these molecules for the two isotopes, at constant $T$. Use Appendix G for masses.

**67.** Consider a container of oxygen gas at a temperature of 23°C that is 1.50 m tall. Compare the gravitational potential energy of a molecule at the top of the container (assuming the potential energy is zero at the bottom) with the average kinetic energy of the molecules. Is it reasonable to neglect the potential energy?

**68.** In humid climates, people constantly *dehumidify* their cellars to prevent rot and mildew. If the cellar in a house (kept at 20°C) has 105 $m^2$ of floor space and a ceiling height of 2.4 m, what is the mass of water that must be removed from it in order to drop the humidity from 95% to a more reasonable 45%?

**69.** A space vehicle returning from the Moon enters the Earth's atmosphere at a speed of about 42,000 km/h. Molecules (assume nitrogen) striking the nose of the vehicle with this speed correspond to what temperature? (Because of this high temperature, the nose of a space vehicle must be made of special materials; indeed, part of it does vaporize, and this is seen as a bright blaze upon reentry.)

**70.** Calculate the total water vapor pressure in the air on the following two days: (*a*) a hot summer day, with the temperature 30°C and the relative humidity at 75%; (*b*) a cold winter day, with the temperature 5°C and the relative humidity at 75%.

**71.** At room temperature, it takes approximately $2.45 \times 10^3$ J to evaporate 1.00 g of water. Estimate the average speed of evaporating molecules. What multiple of $v_{rms}$ (at 20°C) for water molecules is this? (Assume Eq. 18–4 holds.)

**72.** If the humidity is 65% at 30.0°C, what is the dew point? Use linear interpolation to find the temperature of the dew point to the nearest degree.

**73.** A sample of cesium vapor is in an oven at 400°C. The volume of the oven is 75 $cm^3$, the vapor pressure of Cs at 400°C is 17 mm-Hg, and the diameter of cesium atoms in the vapor is 0.33 nm. (*a*) Calculate the mean speed of cesium atoms in the vapor. (*b*) Determine the number of collisions a single Cs atom undergoes with other cesium atoms per second. (*c*) Determine the total number of collisions per second between all of the cesium atoms in the vapor. Note that a collision involves two Cs atoms and assume the ideal gas law holds.

**74.** Using the ideal gas law, find an expression for the mean free path $\ell_M$ that involves pressure and temperature instead of $(N/V)$. Use this expression to find the mean free path for nitrogen molecules at a pressure of 7.5 atm and 300 K.

**75.** The density of atoms, mostly hydrogen, in interstellar space is about one per cubic centimeter. Estimate the mean free path of the hydrogen atoms, assuming an atomic diameter of $1.0 \times 10^{-10}$ m.

**76.** At 300 K, an 8.50-mol sample of carbon dioxide occupies a volume of 0.220 $m^3$. Calculate the gas pressure, first by the ideal gas law, and then by using the van der Waals equation of state. (The values for $a$ and $b$ are given in Section 18–6.) In this range of pressure and volume, the van der Waals equation is very accurate. What percent error did you make in assuming ideal-gas-law behavior?

**77.** (*a*) From the van der Waals equation of state, show that the critical temperature and pressure are given by

$$T_{cr} = \frac{8a}{27bR}, \qquad P_{cr} = \frac{a}{27b^2}.$$

[*Hint*: Use the fact that the $P$ versus $V$ curve has an inflection point at the critical point so that the first and second derivatives are zero.] (*b*) Determine $a$ and $b$ for $CO_2$ from the measured values of $T_{cr} = 304$ K and $P_{cr} = 72.8$ atm.

**78.** For oxygen gas the van der Waals constants are $a = 0.14\ N \cdot m^4/mol^2$ and $b = 3.2 \times 10^{-5}\ m^3/mol$. Using these values, graph six curves of pressure vs. volume between $V = 2 \times 10^{-5}\ m^3$ and $2.0 \times 10^{-4}\ m^3$, for 1 mol of oxygen gas at temperatures of 80 K, 100 K, 120 K, 130 K, 150 K, and 170 K. From the graphs determine approximately the critical temperature for oxygen.

## ANSWERS TO EXERCISES

**A:** (*a*).
**B:** Almost 500 m/s.
**C:** (*d*).
**D:** (*c*).
**E:** (*b*).

When it is cold, warm clothes act as insulators to reduce heat loss from the body to the environment by conduction and convection. Heat radiation from a campfire can warm you and your clothes. The fire can also transfer energy directly by heat convection and conduction to what you are cooking. Heat, like work, represents a transfer of energy. Heat is defined as a transfer of energy due to a difference of temperature. Work is a transfer of energy by mechanical means, not due to a temperature difference. The first law of thermodynamics links the two in a general statement of energy conservation: the heat $Q$ added to a system minus the net work $W$ done by the system equals the change in internal energy $\Delta E_{\text{int}}$ of the system: $\Delta E_{\text{int}} = Q - W$. Internal energy $E_{\text{int}}$ is the sum total of all the energy of the molecules of the system.

19–10 Heat Transfer: Conduction, Convection, Radiation

**CHAPTER-OPENING QUESTION—Guess now!**

A 5-kg cube of warm iron (60°C) is put in thermal contact with a 10-kg cube of cold iron (15°C). Which statement is valid:

**(a)** Heat flows spontaneously from the warm cube to the cold cube until both cubes have the same heat content.
**(b)** Heat flows spontaneously from the warm cube to the cold cube until both cubes have the same temperature.
**(c)** Heat can flow spontaneously from the warm cube to the cold cube, but can also flow spontaneously from the cold cube to the warm cube.
**(d)** Heat flows from the larger cube to the smaller one because the larger one has more internal energy.

When a pot of cold water is placed on a hot burner of a stove, the temperature of the water increases. We say that heat "flows" from the hot burner to the cold water. When two objects at different temperatures are put in contact, heat spontaneously flows from the hotter one to the colder one. The spontaneous flow of heat is in the direction tending to equalize the temperature. If the two objects are kept in contact long enough for their temperatures to become equal, the objects are said to be in thermal equilibrium, and there is no further heat flow between them. For example, when a fever thermometer is first placed in your mouth, heat flows from your mouth to the thermometer.

When the thermometer reaches the same temperature as the inside of your mouth, the thermometer and your mouth are then in equilibrium, and no more heat flows.

Heat and temperature are often confused. They are very different concepts and we will make the clear distinction between them. We start this Chapter by defining and using the concept of heat. We also begin our discussion of *thermodynamics*, which is the name we give to the study of processes in which energy is transferred as heat and as work.

## 19–1 Heat as Energy Transfer

We use the term "heat" in everyday life as if we knew what we meant. But the term is often used inconsistently, so it is important for us to define heat clearly, and to clarify the phenomena and concepts related to heat.

We commonly speak of the flow of heat—heat flows from a stove burner to a pot of soup, from the Sun to the Earth, from a person's mouth into a fever thermometer. Heat flows spontaneously from an object at higher temperature to one at lower temperature. Indeed, an eighteenth-century model of heat pictured heat flow as movement of a fluid substance called *caloric*. However, the caloric fluid could never be detected. In the nineteenth century, it was found that the various phenomena associated with heat could be described consistently using a new model that views heat as akin to work, as we will discuss in a moment. First we note that a common unit for heat, still in use today, is named after caloric. It is called the **calorie** (cal) and is defined as *the amount of heat necessary to raise the temperature of 1 gram of water by 1 Celsius degree*. [To be precise, the particular temperature range from 14.5°C to 15.5°C is specified because the heat required is very slightly different at different temperatures. The difference is less than 1% over the range 0 to 100°C, and we will ignore it for most purposes.] More often used than the calorie is the **kilocalorie** (kcal), which is 1000 calories. Thus *1 kcal is the heat needed to raise the temperature of 1 kg of water by 1 C°*. Often a kilocalorie is called a **Calorie** (with a capital C), and this Calorie (or the kJ) is used to specify the energy value of food. In the British system of units, heat is measured in British thermal units (Btu). One Btu is defined as the heat needed to raise the temperature of 1 lb of water by 1 F°. It can be shown (Problem 4) that 1 Btu = 0.252 kcal = 1056 J. [Gas companies may use the **therm**, which is $10^5$ Btu.]

**CAUTION**
*Heat is not a fluid*

The idea that heat is related to energy transfer was pursued by a number of scientists in the 1800s, particularly by an English brewer, James Prescott Joule (1818–1889). Joule and others performed a number of experiments that were crucial for establishing our present-day view that heat, like work, represents a transfer of energy. One of Joule's experiments is shown (simplified) in Fig. 19–1. The falling weight causes the paddle wheel to turn. The friction between the water and the paddle wheel causes the temperature of the water to rise slightly (barely measurable, in fact, by Joule). The same temperature rise could also be obtained by heating the water on a hot stove. In this and many other experiments (some involving electrical energy), Joule determined that a given amount of work done was always equivalent to a particular amount of heat input.

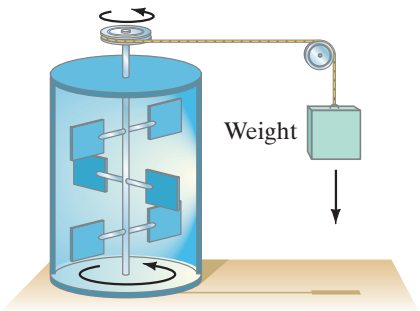

**FIGURE 19–1** Joule's experiment on the mechanical equivalent of heat. [The work is transformed into internal energy (Section 19–2).]

Quantitatively, 4.186 joules (J) of work was found to be equivalent to 1 calorie (cal) of heat. This is known as the **mechanical equivalent of heat**:

$$4.186\,\text{J} = 1\,\text{cal};$$
$$4.186\,\text{kJ} = 1\,\text{kcal}.$$

**CAUTION**
*Heat is energy transferred because of a $\Delta T$*

As a result of these and other experiments, scientists came to interpret heat not as a substance, and not exactly as a form of energy. Rather, heat refers to a *transfer of energy*: when heat flows from a hot object to a cooler one, it is energy that is being transferred from the hot to the cold object. Thus, **heat** is *energy transferred from one object to another because of a difference in temperature*. In SI units, the unit for heat, as for any form of energy, is the joule. Nonetheless, calories and kcal are still sometimes used. Today the calorie is *defined* in terms of the joule (via the mechanical equivalent of heat, above), rather than in terms of the properties of water, as given previously. The latter is still handy to remember: 1 cal raises 1 g of water by 1 C°, or 1 kcal raises 1 kg of water by 1 C°.

**PHYSICS APPLIED**
*Working off Calories*

**EXAMPLE 19–1** **ESTIMATE** **Working off the extra Calories.** Suppose you throw caution to the wind and eat 500 Calories of ice cream and cake. To compensate, you want to do an equivalent amount of work climbing stairs or a mountain. How much total height must you climb?

**APPROACH** The work $W$ you need to do in climbing stairs equals the change in gravitational potential energy: $W = mgh$, where $h$ is the vertical height climbed. For this estimate, approximate your mass as $m \approx 60\,\text{kg}$.

**SOLUTION** 500 food Calories are 500 kcal, which in joules is

$$(500\,\text{kcal})\left(4.186 \times 10^3\,\text{J/kcal}\right) = 2.1 \times 10^6\,\text{J}.$$

The work done to climb a vertical height $h$ is $W = mgh$. We solve for $h$:

$$h = \frac{W}{mg} = \frac{2.1 \times 10^6\,\text{J}}{(60\,\text{kg})\left(9.80\,\text{m/s}^2\right)} = 3600\,\text{m}.$$

This is a huge elevation change (over 11,000 ft).

**NOTE** The human body does not transform food energy with 100% efficiency—it is more like 20% efficient. As we shall discuss in the next Chapter, some energy is always "wasted," so you would actually have to climb only about $(0.2)(3600\,\text{m}) \approx 700\,\text{m}$, which is more reasonable (about 2300 ft of elevation gain).

# 19–2 Internal Energy

The sum total of all the energy of all the molecules in an object is called its **internal energy**. (Sometimes **thermal energy** is used to mean the same thing.) We introduce the concept of internal energy now since it will help clarify ideas about heat.

## Distinguishing Temperature, Heat, and Internal Energy

**CAUTION**
*Distinguish heat from internal energy and from temperature*

Using the kinetic theory, we can make a clear distinction between temperature, heat, and internal energy. Temperature (in kelvins) is a measure of the average kinetic energy of individual molecules (Eq. 18–4). Internal energy refers to the *total* energy of all the molecules within the object. (Thus two equal-mass hot ingots of iron may have the same temperature, but two of them have twice as much internal energy as one does.) Heat, finally, refers to a *transfer* of energy from one object to another because of a difference in temperature.

**CAUTION**
*Direction of heat flow depends on temperature (not on amount of internal energy)*

Notice that the direction of heat flow between two objects depends on their temperatures, not on how much internal energy each has. Thus, if 50 g of water at 30°C is placed in contact (or mixed) with 200 g of water at 25°C, heat flows *from* the water at 30°C *to* the water at 25°C even though the internal energy of the 25°C water is much greater because there is so much more of it.

### Internal Energy of an Ideal Gas

Let us calculate the internal energy of $n$ moles of an ideal monatomic (one atom per molecule) gas. The internal energy, $E_{\text{int}}$, is the sum of the translational kinetic energies of all the atoms.[†] This sum is equal to the average kinetic energy per molecule times the total number of molecules, $N$:

$$E_{\text{int}} = N\left(\tfrac{1}{2}m\overline{v^2}\right).$$

Using Eq. 18–4, $\overline{K} = \frac{1}{2}m\overline{v^2} = \frac{3}{2}kT$, we can write this as

$$E_{\text{int}} = \tfrac{3}{2}NkT \qquad \textbf{(19–1a)}$$

or (recall Section 17–9)

$$E_{\text{int}} = \tfrac{3}{2}nRT, \qquad \left[\begin{array}{c}\text{internal energy of}\\ \text{ideal monatomic gas}\end{array}\right] \qquad \textbf{(19–1b)}$$

where $n$ is the number of moles. Thus, the internal energy of an ideal gas depends only on the Kelvin temperature and the number of moles (or molecules) of gas.

If the gas molecules contain more than one atom, then the rotational and vibrational energy of the molecules (Fig. 19–2) must also be taken into account. The internal energy will then be greater at a given temperature than for a monatomic gas, but it will still be a function only of temperature for an ideal gas.

The internal energy of real gases also depends mainly on temperature, but where real gases deviate from ideal gas behavior, their internal energy depends also somewhat on pressure and volume (due to atomic potential energy).

The internal energy of liquids and solids is quite complicated, for it includes electrical potential energy associated with the forces (or "chemical" bonds) between atoms and molecules.

**EXERCISE A** Return to the Chapter-Opening Question, page 538, and answer it again now. Try to explain why you may have answered differently the first time.

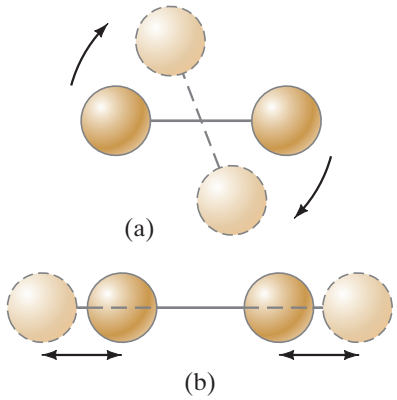

**FIGURE 19–2** Besides translational kinetic energy, molecules can have (a) rotational kinetic energy, and (b) vibrational energy (both kinetic and potential).

# 19–3 Specific Heat

If heat flows into an object, the object's temperature rises (assuming no phase change). But how much does the temperature rise? That depends. As early as the eighteenth century, experimenters had recognized that the amount of heat $Q$ required to change the temperature of a given material is proportional to the mass $m$ of the material present and to the temperature change $\Delta T$. This remarkable simplicity in nature can be expressed in the equation

$$Q = mc\,\Delta T, \qquad \textbf{(19–2)}$$

where $c$ is a quantity characteristic of the material called its **specific heat**. Because $c = Q/(m\,\Delta T)$, specific heat is specified in units[‡] of $\text{J/kg}\cdot\text{C}^\circ$ (the proper SI unit) or $\text{kcal/kg}\cdot\text{C}^\circ$. For water at 15°C and a constant pressure of 1 atm, $c = 4.186\times10^3\,\text{J/kg}\cdot\text{C}^\circ$ or $1.00\,\text{kcal/kg}\cdot\text{C}^\circ$, since, by definition of the cal and the joule, it takes 1 kcal of heat to raise the temperature of 1 kg of water by 1 C°. Table 19–1 gives the values of specific heat for other substances at 20°C. The values of $c$ depend to some extent on temperature (as well as slightly on pressure), but for temperature changes that are not too great, $c$ can often be considered constant.[§] [Gases are complicated and are treated in Section 19–8.] Values for $c$ are the same using kelvins: $1\,\text{J/kg}\cdot\text{C}^\circ = 1\,\text{J/kg}\cdot\text{K}$.

**TABLE 19–1 Specific Heats**
**(at 1 atm constant pressure and 20°C unless otherwise stated)**

| Substance | Specific Heat, $c$ | |
|---|---|---|
| | $\frac{\text{J}}{\text{kg}\cdot\text{C}^\circ}$ | $\frac{\text{kcal}}{\text{kg}\cdot\text{C}^\circ}$ (= cal/g·C°) |
| Aluminum | 900 | 0.22 |
| Alcohol (ethyl) | 2400 | 0.58 |
| Copper | 390 | 0.093 |
| Glass | 840 | 0.20 |
| Iron or steel | 450 | 0.11 |
| Lead | 130 | 0.031 |
| Marble | 860 | 0.21 |
| Mercury | 140 | 0.033 |
| Silver | 230 | 0.056 |
| Wood | 1700 | 0.4 |
| Water | | |
| Ice (−5°C) | 2100 | 0.50 |
| Liquid (15°C) | 4186 | 1.00 |
| Steam (110°C) | 2010 | 0.48 |
| Human body (average) | 3470 | 0.83 |
| Protein | 1700 | 0.4 |

[†]The symbol $U$ is used in some books for internal energy. The use of $E_{\text{int}}$ avoids confusion with $U$ which stands for potential energy (Chapter 8).

[‡]Note that $\text{J/kg}\cdot\text{C}^\circ$ means $\dfrac{\text{J}}{\text{kg}\cdot\text{C}^\circ}$ and *not* $(\text{J/kg})\cdot\text{C}^\circ = \text{J}\cdot\text{C}^\circ/\text{kg}$ (otherwise we would have written it that way).

[§]To take into account the dependence of $c$ on $T$, we can write Eq. 19–2 in differential form: $dQ = mc(T)\,dT$, where $c(T)$ means $c$ is a function of temperature $T$. Then the heat $Q$ required to change the temperature from $T_1$ to $T_2$ is

$$Q = \int_{T_1}^{T_2} mc(T)\,dT.$$

**EXAMPLE 19–2** **How heat transferred depends on specific heat.** (*a*) How much heat input is needed to raise the temperature of an empty 20-kg vat made of iron from 10°C to 90°C? (*b*) What if the vat is filled with 20 kg of water?

**APPROACH** We apply Eq. 19–2 to the different materials involved.

**SOLUTION** (*a*) Our system is the iron vat alone. From Table 19–1, the specific heat of iron is 450 J/kg · C°. The change in temperature is (90°C − 10°C) = 80 C°. Thus,

$$Q_{\text{vat}} = mc\,\Delta T = (20\,\text{kg})(450\,\text{J/kg}\cdot\text{C}^\circ)(80\,\text{C}^\circ) = 7.2\times10^5\,\text{J} = 720\,\text{kJ}.$$

(*b*) Our system is the vat plus the water. The water alone would require

$$Q_{\text{w}} = mc\,\Delta T = (20\,\text{kg})(4186\,\text{J/kg}\cdot\text{C}^\circ)(80\,\text{C}^\circ) = 6.7\times10^6\,\text{J} = 6700\,\text{kJ},$$

or almost 10 times what an equal mass of iron requires. The total, for the vat plus the water, is 720 kJ + 6700 kJ = 7400 kJ.

**NOTE** In (*b*), the iron vat and the water underwent the same temperature change, $\Delta T = 80\,\text{C}^\circ$, but their specific heats are different.

**PHYSICS APPLIED**
*Practical effects of water's high specific heat*

If the iron vat in part (*a*) of Example 19–2 had been *cooled* from 90°C to 10°C, 720 kJ of heat would have flowed *out* of the iron. In other words, Eq. 19–2 is valid for heat flow either in or out, with a corresponding increase or decrease in temperature. We saw in part (*b*) that water requires almost 10 times as much heat as an equal mass of iron to make the same temperature change. Water has one of the highest specific heats of all substances, which makes it an ideal substance for hot-water space-heating systems and other uses that require a minimal drop in temperature for a given amount of heat transfer. It is the water content, too, that causes the apples rather than the crust in hot apple pie to burn our tongues through heat transfer.

**CONCEPTUAL EXAMPLE 19–3** **A very hot frying pan.** You accidentally make a bad mistake by letting an empty iron frying pan get very hot on the stove (200°C or even more). What happens when you dunk it into a few inches of cool water in the bottom of the sink? Will the final temperature be midway between the initial temperatures of the water and pan? Will the water start boiling? Assume the mass of water is roughly the same as the mass of the frying pan.

**RESPONSE** Experience may tell you that the water warms up—perhaps by as much as 10 or 20 degrees. The water doesn't come close to boiling. The water's temperature increase is a lot less than the frying pan's temperature decrease. Why? Because the mass of water is roughly equal to that of the pan, and iron has a specific heat nearly 10 times smaller than that of water (Table 19–1). As heat leaves the frying pan and enters the water, the iron pan's temperature change will be about 10 times greater than that of the water. If, instead, you let a few drops of water fall onto the hot pan, that very small mass of water will sizzle and boil away (the pan's mass may be hundreds of times larger than that of the water drops).

## 19–4 Calorimetry—Solving Problems

**CAUTION**
*Types of SYSTEM*

In discussing heat and thermodynamics, we often consider a particular **system**, which is any object or set of objects we choose to consider. Everything else in the universe is its "environment" (or the "surroundings"). There are several categories of systems. A **closed system** is one for which no mass enters or leaves (but energy may be exchanged with the environment). In an **open system**, mass may enter or leave (as may energy). Many (idealized) systems we study in physics are closed systems. But many systems, including plants and animals, are open systems since they exchange materials (food, oxygen, waste products) with the environment. A closed system is said to be **isolated** if no energy in any form (as well as no mass) passes across its boundaries; otherwise it is not isolated.

A perfectly isolated system is an ideal, but we often try to set up a system that can be closely approximated as an isolated system (preferably one we can deal with fairly easily). When different parts of an isolated system are at different temperatures, heat will flow (energy is transferred) from the part at higher temperature to the part at lower temperature—that is, within the system—until **thermal equilibrium** is reached, meaning the entire system is at the same temperature. For an isolated system, no energy is transferred into or out of it. So we can apply *conservation of energy* to such an isolated system. A simple intuitive way to set up a conservation of energy equation is to write that the heat lost by one part of the system is equal to the heat gained by the other part:

$$\text{heat lost} = \text{heat gained} \qquad \text{[isolated system]}$$

or

$$\text{energy } \textit{out} \text{ of one part} = \text{energy } \textit{into} \text{ another part.} \qquad \text{[isolated system]}$$

**EXAMPLE 19–4** **The cup cools the tea.** If 200 $\text{cm}^3$ of tea at 95°C is poured into a 150-g glass cup initially at 25°C (Fig. 19–3), what will be the common final temperature $T$ of the tea and cup when equilibrium is reached, assuming no heat flows to the surroundings?

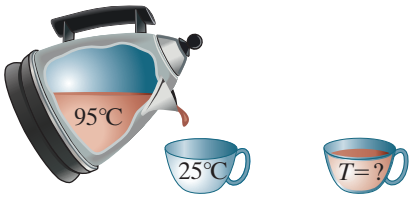

**FIGURE 19–3** Example 19–4.

**APPROACH** We apply conservation of energy to our system of tea plus cup, which we are assuming is isolated: all of the heat that leaves the tea flows into the cup. We can use the specific heat equation, Eq. 19–2, to determine how the heat flow is related to the temperature changes.

**SOLUTION** Because tea is mainly water, we can take its specific heat as 4186 $\text{J/kg} \cdot \text{C}^\circ$ (Table 19–1), and its mass $m$ is its density times its volume $(V = 200\ \text{cm}^3 = 200 \times 10^{-6}\ \text{m}^3)$: $m = \rho V = (1.0 \times 10^3\ \text{kg/m}^3)(200 \times 10^{-6}\ \text{m}^3) = 0.20\ \text{kg}$. We use Eq. 19–2, apply conservation of energy, and let $T$ be the as yet unknown final temperature:

$$\begin{aligned} \text{heat lost by tea} &= \text{heat gained by cup} \\ m_{\text{tea}} c_{\text{tea}} (95^\circ\text{C} - T) &= m_{\text{cup}} c_{\text{cup}} (T - 25^\circ\text{C}). \end{aligned}$$

Putting in numbers and using Table 19–1 ($c_{\text{cup}} = 840\ \text{J/kg} \cdot \text{C}^\circ$ for glass), we solve for $T$, and find

$$\begin{aligned} (0.20\ \text{kg})(4186\ \text{J/kg} \cdot \text{C}^\circ)(95^\circ\text{C} - T) &= (0.15\ \text{kg})(840\ \text{J/kg} \cdot \text{C}^\circ)(T - 25^\circ\text{C}) \\ 79{,}500\ \text{J} - (837\ \text{J/C}^\circ)T &= (126\ \text{J/C}^\circ)T - 3150\ \text{J} \\ T &= 86^\circ\text{C}. \end{aligned}$$

The tea drops in temperature by 9 $\text{C}^\circ$ by coming into equilibrium with the cup.

**NOTE** The cup increases in temperature by $86^\circ\text{C} - 25^\circ\text{C} = 61\ \text{C}^\circ$. Its much greater change in temperature (compared with that of the tea water) is mainly due to its much smaller specific heat compared to that of water.

**NOTE** In this calculation, the $\Delta T$ (of Eq. 19–2, $Q = mc\,\Delta T$) is a positive quantity on both sides of our conservation of energy equation. On the left is "heat lost" and $\Delta T$ is the initial minus the final temperature $(95^\circ\text{C} - T)$, whereas on the right is "heat gained" and $\Delta T$ is the final minus the initial temperature.

**CAUTION**
*When using heat lost = heat gained, $\Delta T$ is positive on both sides*

Another way to set up the energy conservation equation for heat transfer within an isolated system, which is perhaps more general, is to write that the sum of all internal heat transfers within the system adds up to zero:

$$\Sigma Q = 0. \qquad \text{[isolated system]} \quad \textbf{(19–3)}$$

Each $Q$ represents the heat entering or leaving one part of the system. Each term is written as $Q = mc(T_{\text{f}} - T_{\text{i}})$, and $\Delta T = T_{\text{f}} - T_{\text{i}}$ is always the final minus the initial temperature. $\Delta T$ can be either positive or negative, depending on whether heat flows into or out of that part. Let us redo Example 19–4 using $\Sigma Q = 0$.

**PROBLEM SOLVING**
*Alternate approach: $\Sigma Q = 0$*

**EXAMPLE 19–4′ Alternate Solution, $\Sigma Q = 0$, for "cup cools tea."**

**APPROACH** We use Eq. 19–3, $\Sigma Q = 0$.

**SOLUTION** We redo Example 19–4, using $m_{\text{cup}} = 0.15\,\text{kg}$, $m_{\text{tea}} = 0.20\,\text{kg}$, $c_{\text{cup}} = 840\,\text{J/kg}\cdot\text{C}^\circ$ and $c_{\text{tea}} = 4186\,\text{J/kg}\cdot\text{C}^\circ$. For each term in Eq. 19–3, $\Delta T = T_{\text{f}} - T_{\text{i}}$. If $T_{\text{f}} < T_{\text{i}}$, then $\Delta T < 0$. Equation 19–3, $\Sigma Q = 0$, becomes

$$m_{\text{cup}}\, c_{\text{cup}}(T - 25°\text{C}) + m_{\text{tea}}\, c_{\text{tea}}(T - 95°\text{C}) = 0.$$

The second term is negative because $T$ will be less than 95°C. Solving the algebra gives the same result, $T = 86°\text{C}$.

You are free to use either approach. They are entirely equivalent, algebraically. For example, if you move the first term in the displayed equation of the alternate Example 19–4′ over to the other side of the equals sign, you obtain the "heat lost = heat gained" equation in the first version of Example 19–4.

The exchange of energy, as exemplified in Example 19–4, is the basis for a technique known as **calorimetry**, which is the quantitative measurement of heat exchange. To make such measurements, a **calorimeter** is used; a simple water calorimeter is shown in Fig. 19–4. It is very important that the calorimeter be well insulated so that almost no heat is exchanged with the surroundings. One important use of the calorimeter is in the determination of specific heats of substances. In the technique known as the "method of mixtures," a sample of a substance is heated to a high temperature, which is accurately measured, and then quickly placed in the cool water of the calorimeter. The heat lost by the sample will be gained by the water and the calorimeter cup. By measuring the final temperature of the mixture, the specific heat can be calculated, as illustrated in the following Example.

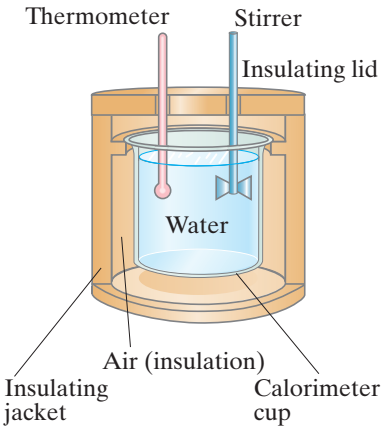

**FIGURE 19–4** Simple water calorimeter. In Example 19–5, we assume the temperature of the insulating jacket doesn't change significantly because of the insulating air space between it and the calorimeter cup.

**EXAMPLE 19–5 Unknown specific heat determined by calorimetry.** An engineer wishes to determine the specific heat of a new metal alloy. A 0.150-kg sample of the alloy is heated to 540°C. It is then quickly placed in 0.400 kg of water at 10.0°C, which is contained in a 0.200-kg aluminum calorimeter cup. The final temperature of the system is 30.5°C. Calculate the specific heat of the alloy.

**APPROACH** We apply conservation of energy to our system, which we take to be the alloy sample, the water, and the calorimeter cup. We assume this system is isolated, and apply Eq. 19–3, $\Sigma Q = 0$.

**SOLUTION** Each term is of the form $Q = mc(T_{\text{f}} - T_{\text{i}})$. Thus $\Sigma Q = 0$ gives

$$m_{\text{a}}\, c_{\text{a}}\, \Delta T_{\text{a}} + m_{\text{w}}\, c_{\text{w}}\, \Delta T_{\text{w}} + m_{\text{cal}}\, c_{\text{cal}}\, \Delta T_{\text{cal}} = 0$$

where the subscripts a, w, and cal refer to the alloy, water, and calorimeter, respectively, and each $\Delta T$ is the final temperature (30.5°C) minus the initial temperature for each object. When we put in values and use Table 19–1 ($c_{\text{cal}} = 900\,\text{J/kg}\cdot\text{C}^\circ$ for aluminum), this equation becomes

$$(0.150\,\text{kg})(c_{\text{a}})(30.5°\text{C} - 540°\text{C}) + (0.400\,\text{kg})(4186\,\text{J/kg}\cdot\text{C}^\circ)(30.5°\text{C} - 10.0°\text{C}) + (0.200\,\text{kg})(900\,\text{J/kg}\cdot\text{C}^\circ)(30.5°\text{C} - 10.0°\text{C}) = 0,$$

or

$$-(76.4\,\text{kg}\cdot\text{C}^\circ)c_{\text{a}} + 34{,}300\,\text{J} + 3690\,\text{J} = 0.$$

Solving for $c_{\text{a}}$ we obtain:

$$c_{\text{a}} = 497\,\text{J/kg}\cdot\text{C}^\circ \approx 500\,\text{J/kg}\cdot\text{C}^\circ.$$

**NOTE** We rounded off because we have ignored any heat transferred to the thermometer and the stirrer (which is used to quicken the heat transfer process and thus reduce heat loss to the outside). To take them into account we would have to add (small) additional terms to the equation.

In all Examples and Problems of this sort, be sure to include *all* objects that gain or lose heat (within reason). For simplicity, we have ignored very small masses, such as the thermometer and the stirrer, which will affect the energy balance only very slightly.

**PROBLEM SOLVING**
*Be sure to consider all possible sources of energy transfer*

### Bomb Calorimeter

A **bomb calorimeter** is used to measure the thermal energy released when a substance burns (including foods) to determine their Calorie content. A carefully weighed sample of the substance, with an excess amount of oxygen, is placed in a sealed container (the "bomb"). The bomb is placed in the water of the calorimeter and a fine wire passing into the bomb is then heated to ignite the mixture. The Calorie content of foods determined in this way can be unreliable because our human bodies may not metabolize all the available energy. Careful measurements and calculations need to take this into account.

**PHYSICS APPLIED**
*Measuring Calorie content*

## 19–5 Latent Heat

When a material changes phase from solid to liquid, or from liquid to gas (see also Section 18–3), a certain amount of energy is involved in this **change of phase**. For example, let us trace what happens when a 1.0-kg block of ice at $-40°C$ is heated at a slow steady rate until all the ice has changed to water, then the (liquid) water is heated to 100°C and changed to steam, and heated further above 100°C, all at 1 atm pressure. As shown in the graph of Fig. 19–5, as the ice is heated starting at $-40°C$, its temperature rises at a rate of about 2 C°/kcal of heat added (since for ice, $c \approx 0.50\,\text{kcal/kg}\cdot\text{C}°$). However, when 0°C is reached, the temperature stops increasing even though heat is still being added. The ice gradually changes to water in the liquid state, with no change in temperature. After about 40 kcal has been added at 0°C, half the ice remains and half has changed to water. After about 80 kcal, or 330 kJ, has been added, all the ice has changed to water, still at 0°C. Continued addition of heat causes the water's temperature to again increase, now at a rate of 1 C°/kcal ($c_{\text{water}} = 1.00\,\text{kcal/kg}\cdot\text{C}°$). When 100°C is reached, the temperature again remains constant as the heat added changes the liquid water to vapor (steam). About 540 kcal (2260 kJ) is required to change the 1.0 kg of water completely to steam, after which the graph rises again, indicating that the temperature of the steam rises as heat is added.

The heat required to change 1.0 kg of a substance from the solid to the liquid state is called the **heat of fusion**; it is denoted by $L_F$. The heat of fusion of water is 79.7 kcal/kg or, in proper SI units, 333 kJ/kg $(= 3.33 \times 10^5\,\text{J/kg})$. The heat required to change a substance from the liquid to the vapor phase is called the **heat of vaporization**, $L_V$. For water it is 539 kcal/kg or 2260 kJ/kg. Other substances follow graphs similar to Fig. 19–5, although the melting-point and boiling-point temperatures are different, as are the specific heats and heats of fusion and vaporization.

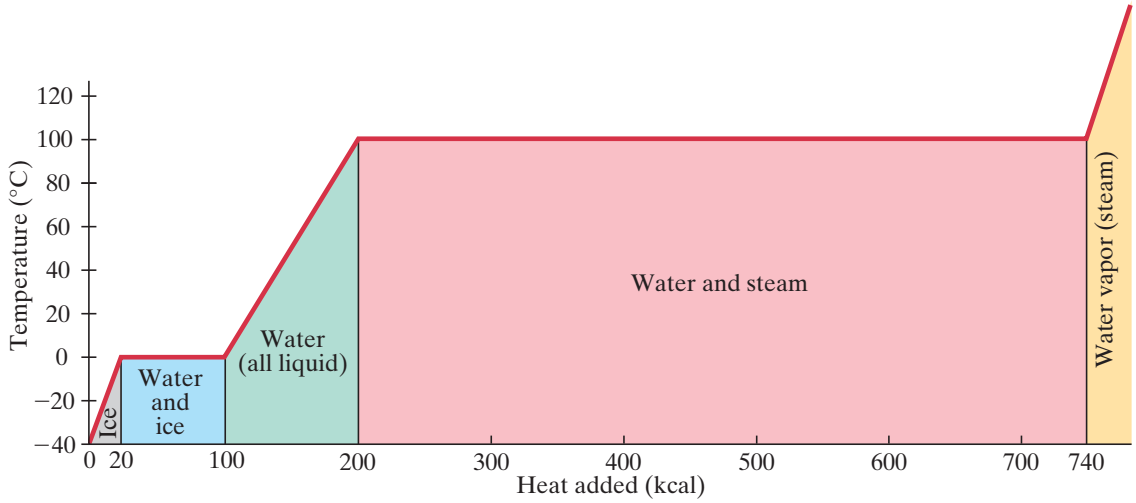

**FIGURE 19–5** Temperature as a function of the heat added to bring 1.0 kg of ice at −40°C to steam above 100°C.

**TABLE 19–2 Latent Heats (at 1 atm)**

| Substance | Melting Point (°C) | Heat of Fusion kJ/kg | Heat of Fusion kcal/kg† | Boiling Point (°C) | Heat of Vaporization kJ/kg | Heat of Vaporization kcal/kg† |
|---|---|---|---|---|---|---|
| Oxygen | −218.8 | 14 | 3.3 | −183 | 210 | 51 |
| Nitrogen | −210.0 | 26 | 6.1 | −195.8 | 200 | 48 |
| Ethyl alcohol | −114 | 104 | 25 | 78 | 850 | 204 |
| Ammonia | −77.8 | 332 | 80 | −33.4 | 1369 | 330 |
| Water | 0 | 333 | 79.7 | 100 | 2260 | 539 |
| Lead | 327 | 25 | 5.9 | 1750 | 870 | 208 |
| Silver | 961 | 88 | 21 | 2193 | 2300 | 558 |
| Iron | 1538 | 289 | 69.1 | 3023 | 6340 | 1520 |
| Tungsten | 3410 | 184 | 44 | 5900 | 4800 | 1150 |

†Numerical values in kcal/kg are the same in cal/g.

Values for the heats of fusion and vaporization, which are also called the **latent heats**, are given in Table 19–2 for a number of substances.

The heats of vaporization and fusion also refer to the amount of heat *released* by a substance when it changes from a gas to a liquid, or from a liquid to a solid. Thus, steam releases 2260 kJ/kg when it changes to water, and water releases 333 kJ/kg when it becomes ice. [In these cases of heat release, $Q < 0$ when using the $\Sigma Q = 0$ approach, Eq. 19–3.]

The heat involved in a change of phase depends not only on the latent heat but also on the total mass of the substance. That is,

$$Q = mL, \tag{19–4}$$

where $L$ is the latent heat of the particular process and substance, $m$ is the mass of the substance, and $Q$ is the heat added or released during the phase change. For example, when 5.00 kg of water freezes at 0°C, $(5.00\,\text{kg})(3.33 \times 10^5\,\text{J/kg}) = 1.67 \times 10^6\,\text{J}$ of energy is released.

**EXERCISE B** A pot of water is boiling on a gas stove, and then you turn up the heat. What happens? (*a*) The temperature of the water starts increasing. (*b*) There is no change in the rate of water loss by evaporation. (*c*) The rate of water loss by evaporation increases. (*d*) There is an appreciable increase in both the rate of boiling and the temperature of the water. (*e*) None of these.

Calorimetry sometimes involves a change of state, as the following Examples show. Indeed, latent heats are often measured using calorimetry.

**EXAMPLE 19–6 Making ice.** How much energy does a freezer have to remove from 1.5 kg of water at 20°C to make ice at −12°C?

**APPROACH** We need to calculate the total energy removed by adding the heat outflow (1) to reduce the water temperature from 20°C to 0°C, (2) to change the liquid water to solid ice at 0°C, and (3) to lower the ice temperature from 0°C to −12°C.

**SOLUTION** The heat $Q$ that needs to be removed from the 1.5 kg of water is

$$\begin{aligned} Q &= mc_w(20°\text{C} - 0°\text{C}) + mL_F + mc_{ice}[0° - (-12°\text{C})] \\ &= (1.5\,\text{kg})(4186\,\text{J/kg}\cdot\text{C}°)(20\,\text{C}°) + (1.5\,\text{kg})(3.33 \times 10^5\,\text{J/kg}) \\ &\quad + (1.5\,\text{kg})(2100\,\text{J/kg}\cdot\text{C}°)(12\,\text{C}°) \\ &= 6.6 \times 10^5\,\text{J} = 660\,\text{kJ}. \end{aligned}$$

**EXERCISE C** Which process in Example 19–6 required the greatest heat loss?

**EXAMPLE 19–7** **ESTIMATE** **Will all the ice melt?** At a party, a 0.50-kg chunk of ice at $-10°C$ is placed in 3.0 kg of "iced" tea at 20°C. At what temperature and in what phase will the final mixture be? The tea can be considered as water. Ignore any heat flow to the surroundings, including the container.

**PROBLEM SOLVING**
*First determine (or estimate) the final state*

**APPROACH** Before we can write down an equation applying conservation of energy, we must first check to see if the final state will be all ice, a mixture of ice and water at 0°C, or all water. To bring the 3.0 kg of water at 20°C down to 0°C would require an energy release of

$$m_w c_w (20°C - 0°C) = (3.0\,\text{kg})(4186\,\text{J/kg}\cdot\text{C}°)(20\,\text{C}°) = 250{,}000\,\text{J}.$$

On the other hand, to raise the ice from $-10°C$ to 0°C would require

$$m_{ice} c_{ice}[0°C - (-10°C)] = (0.50\,\text{kg})(2100\,\text{J/kg}\cdot\text{C}°)(10\,\text{C}°) = 10{,}500\,\text{J},$$

and to change the ice to water at 0°C would require

$$m_{ice} L_F = (0.50\,\text{kg})(333\,\text{kJ/kg}) = 167{,}000\,\text{J}.$$

The sum of the last two quantities is $10.5\,\text{kJ} + 167\,\text{kJ} = 177\,\text{kJ}$. This is not enough energy to bring the 3.0 kg of water at 20°C down to 0°C, so we see that the mixture must end up all water, somewhere between 0°C and 20°C.

**PROBLEM SOLVING**
*Then determine the final temperature*

**SOLUTION** To determine the final temperature $T$, we apply conservation of energy. We present both of the techniques discussed in Section 19–4.

*Method 1*: "$\Sigma Q = 0$" gives

$$\begin{pmatrix}\text{heat to raise}\\ \text{0.50 kg of ice}\\ \text{from } -10°C\\ \text{to } 0°C\end{pmatrix} + \begin{pmatrix}\text{heat to change}\\ \text{0.50 kg}\\ \text{of ice}\\ \text{to water}\end{pmatrix} + \begin{pmatrix}\text{heat to raise}\\ \text{0.50 kg of water}\\ \text{from } 0°C\\ \text{to } T\end{pmatrix} + \begin{pmatrix}\text{heat lost by}\\ \text{3.0 kg of}\\ \text{water cooling}\\ \text{from } 20°C \text{ to } T\end{pmatrix} = 0.$$

Using some of the results from the "Approach" above, we obtain

$$10{,}500\,\text{J} + 167{,}000\,\text{J} + (0.50\,\text{kg})(4186\,\text{J/kg}\cdot\text{C}°)(T - 0°C) + (3.0\,\text{kg})(4186\,\text{J/kg}\cdot\text{C}°)(T - 20°C) = 0.$$

Solving for $T$ we obtain

$$T = 5.0°C.$$

*Method 2*: "heat gained = heat lost" produces a word equation like the one above (the last plus sign becomes an equals sign and we lose the "$= 0$"). That is,

$$10{,}500\,\text{J} + 167{,}000\,\text{J} + (0.50\,\text{kg})(4186\,\text{J/kg}\cdot\text{C}°)(T - 0°C) = (3.0\,\text{kg})(4186\,\text{J/kg}\cdot\text{C}°)(20°C - T).$$

The term on the right is heat lost by 3.0 kg of water cooling from 20°C to $T$; here $\Delta T = T_i - T_f = 20°C - T$ for this approach. Algebraically, this equation is identical to the one above in the first method.

**EXERCISE D** How much more ice at $-10°C$ would be needed in Example 19–7 to bring the tea down to 0°C, while just melting all the ice?

PROBLEM SOLVING

## Calorimetry

1. Be sure you have sufficient information to apply energy conservation. Define what your system is, and ask yourself: **is the system isolated** (or nearly so, enough to get a good estimate)? Do we know or can we calculate all significant sources of energy transfer?
2. Apply **conservation of energy**. Either write
   $$\text{heat gained} = \text{heat lost},$$
   or use
   $$\Sigma Q = 0.$$
3. If **no phase changes** occur, each term in the energy conservation equation will have the form
   $$Q = mc\,\Delta T.$$
4. If **phase changes** do or might occur, there may be terms in the energy conservation equation of the form $Q = mL$, where $L$ is the latent heat. But *before* applying energy conservation, determine (or estimate) in which phase the final state will be, as we did in Example 19–7 by calculating the different contributing values for heat $Q$.
5. Note that when the system reaches thermal **equilibrium**, the final **temperature** of each substance will have the *same* value. There is only one $T_f$.
6. **Solve** your energy equation for the unknown.

**EXAMPLE 19–8 Determining a latent heat.** The specific heat of liquid mercury is $140\,\text{J/kg}\cdot\text{C}^\circ$. When 1.0 kg of solid mercury at its melting point of $-39^\circ\text{C}$ is placed in a 0.50-kg aluminum calorimeter filled with 1.2 kg of water at 20.0°C, all the mercury melts and the final temperature of the combination is found to be 16.5°C. What is the heat of fusion of mercury in J/kg?

**APPROACH** We follow the Problem Solving Strategy we just read, previous page.

**SOLUTION**

1. **Is the system isolated**? The mercury is placed in a calorimeter, which we assume is well insulated. Our isolated system is the calorimeter, the water, and the mercury.
2. **Conservation of energy**. The heat gained by the mercury = the heat lost by the water and calorimeter.
3. and **4. Phase changes**. There is a phase change (of mercury), plus we use specific heat equations. The heat gained by the mercury (Hg) includes a term representing the melting of the Hg,

$$Q(\text{melt solid Hg}) = m_{\text{Hg}} L_{\text{Hg}},$$

plus a term representing the heating of the liquid Hg from $-39^\circ\text{C}$ to $+16.5^\circ\text{C}$:

$$\begin{aligned} Q(\text{heat liquid Hg}) &= m_{\text{Hg}} c_{\text{Hg}}[16.5^\circ\text{C} - (-39^\circ\text{C})] \\ &= (1.0\,\text{kg})(140\,\text{J/kg}\cdot\text{C}^\circ)(55.5\,\text{C}^\circ) = 7770\,\text{J}. \end{aligned}$$

All of this heat gained by the mercury is obtained from the water and calorimeter (aluminum, $c_{\text{cal}} = 900\,\text{J/kg}\cdot\text{C}^\circ$), which cool down:

$$\begin{aligned} Q_{\text{cal}} + Q_{\text{w}} &= m_{\text{cal}} c_{\text{cal}}(20.0^\circ\text{C} - 16.5^\circ\text{C}) + m_{\text{w}} c_{\text{w}}(20.0^\circ\text{C} - 16.5^\circ\text{C}) \\ &= (0.50\,\text{kg})(900\,\text{J/kg}\cdot\text{C}^\circ)(3.5\,\text{C}^\circ) + (1.2\,\text{kg})(4186\,\text{J/kg}\cdot\text{C}^\circ)(3.5\,\text{C}^\circ) \\ &= 19{,}200\,\text{J}. \end{aligned}$$

5. **Energy equation**. The conservation of energy tells us the heat lost by the water and calorimeter cup must equal the heat gained by the mercury:

$$Q_{\text{cal}} + Q_{\text{w}} = Q(\text{melt solid Hg}) + Q(\text{heat liquid Hg})$$

or

$$19{,}200\,\text{J} = m_{\text{Hg}} L_{\text{Hg}} + 7770\,\text{J}.$$

6. **Equilibrium temperature**. It is given as 16.5°C, and we already used it.
7. **Solve**. The only unknown in our energy equation (point 5) is $L_{\text{Hg}}$, the latent heat of fusion (or melting) of mercury. We solve for it, putting in $m_{\text{Hg}} = 1.0\,\text{kg}$:

$$L_{\text{Hg}} = \frac{19{,}200\,\text{J} - 7770\,\text{J}}{1.0\,\text{kg}} = 11{,}400\,\text{J/kg} \approx 11\,\text{kJ/kg},$$

where we rounded off to 2 significant figures.

## Evaporation

The latent heat to change a liquid to a gas is needed not only at the boiling point. Water can change from the liquid to the gas phase even at room temperature. This process is called **evaporation** (see also Section 18–4). The value of the heat of vaporization of water increases slightly with a decrease in temperature: at 20°C, for example, it is 2450 kJ/kg (585 kcal/kg) compared to 2260 kJ/kg (= 539 kcal/kg) at 100°C. When water evaporates, the remaining liquid cools, because the energy required (the latent heat of vaporization) comes from the water itself; so its internal energy, and therefore its temperature, must drop.[†]

**PHYSICS APPLIED**
*Evaporation cools*

[†]Also from kinetic theory, evaporation is a cooling process because it is the fastest-moving molecules that escape from the surface (Section 18–4). Hence the average speed of the remaining molecules is less, so by Eq. 18–4 the temperature is less.

Evaporation of water from the skin is one of the most important ways the body uses to control its temperature. When the temperature of the blood rises slightly above normal, the hypothalamus region of the brain detects this temperature increase and sends a signal to the sweat glands to increase their production. The energy (latent heat) required to vaporize this water comes from the body, so the body cools.

**PHYSICS APPLIED**
*Body temperature and evaporation*

### Kinetic Theory of Latent Heats

We can make use of kinetic theory to see why energy is needed to melt or vaporize a substance. At the melting point, the latent heat of fusion does not act to increase the average kinetic energy (and the temperature) of the molecules in the solid, but instead is used to overcome the potential energy associated with the forces between the molecules. That is, work must be done against these attractive forces to break the molecules loose from their relatively fixed positions in the solid so they can freely roll over one another in the liquid phase. Similarly, energy is required for molecules held close together in the liquid phase to escape into the gaseous phase where they are far apart. The vaporization process is a more energetic reorganization of the molecules than is melting (the average distance between the molecules is greatly increased), and hence the heat of vaporization is generally much greater than the heat of fusion for a given substance.

## 19–6 The First Law of Thermodynamics

Thermodynamics is the study of processes in which energy is transferred as heat and work. In this Chapter we have discussed internal energy and heat, and now we bring in work.

In Chapter 8 we saw that work is done when energy is transferred from one object to another by mechanical means. In Section 19–1 we saw that heat is a transfer of energy from one object to a second one at a lower temperature. Thus, heat is much like work. To distinguish them, *heat* is defined as a *transfer of energy due to a difference in temperature*, whereas work is a transfer of energy that is not due to a temperature difference.

In Section 19–2, we defined the internal energy of a system as the sum total of all the energy of the molecules within the system. Then the internal energy of a system should increase if work is done on the system, or if heat is added to it. Similarly the internal energy should decrease if heat flows out of the system or if work is done by the system on something in the surroundings.

Thus it is reasonable to extend conservation of energy and propose an important law: the change in internal energy of a closed system, $\Delta E_{\text{int}}$, will be equal to the energy added to the system by heating minus the work done by the system on the surroundings. In equation form we write

$$\Delta E_{\text{int}} = Q - W \qquad \textbf{(19–5)}$$

*FIRST LAW OF THERMODYNAMICS*

where $Q$ is the net heat *added* to the system and $W$ is the net work done *by* the system.[†] We must be careful and consistent in following the **sign conventions** for $Q$ and $W$: Because $W$ in Eq. 19–5 is the work done *by* the system, then if work is done *on* the system, $W$ will be negative and $E_{\text{int}}$ will increase. Similarly, $Q$ is positive for heat added to the system, so if heat leaves the system, $Q$ is negative.

**CAUTION**
*Sign Conventions*
*Heat added is +*
*Heat lost is −*
*Work* on *system is −*
*Work* by *system is +*

Equation 19–5 is known as the **first law of thermodynamics**. It is one of the great laws of physics, and its validity rests on experiments (such as Joule's) to which no exceptions have been seen. Since $Q$ and $W$ represent energy transferred into or out of the system, the internal energy changes accordingly. Thus, the first law of thermodynamics is a general statement of the **law of conservation of energy**.

Note that the conservation of energy law was not formulated until the 1800s, because it depended on the interpretation of heat as a transfer of energy.

[†]This convention relates historically to steam engines: the interest was in the heat *input* and the work *output*, both regarded as positive. *CAUTION*: You may see the first law of thermodynamics written in other books as $\Delta E_{\text{int}} = Q + W$, in which case $W$ refers to the work done *on* the system.

Equation 19–5, $\Delta E_{\text{int}} = Q - W$, applies to a closed system. It also applies to an open system (page 542) if we take into account the change in internal energy due to the increase or decrease in the amount of matter. For an isolated system (page 542), no work is done and no heat enters or leaves the system, so $W = Q = 0$, and hence $\Delta E_{\text{int}} = 0$.

**CAUTION**

*$P$, $V$, $T$, $E_{int}$, $m$, $n$ are state variables. $W$ and $Q$ are not: a system does not* have *an amount of heat or work*

A given system at any moment is in a particular state and can be said to have a certain amount of internal energy, $E_{\text{int}}$. But a system does not "have" a certain amount of heat or work. Rather, when work is done on a system (such as compressing a gas), or when heat is added or removed from a system, the state of the system *changes*. Thus, work and heat are involved in *thermodynamic processes* that can change the system from one state to another; they are not characteristic of the state itself. Quantities which describe the state of a system, such as internal energy $E_{\text{int}}$, pressure $P$, volume $V$, temperature $T$, and mass $m$ or number of moles $n$, are referred to as **state variables**. $Q$ and $W$ are *not* state variables.

Because $E_{\text{int}}$ is a *state variable*, which depends only on the state of the system and not on how the system arrived in that state, we can write

$$\Delta E_{\text{int}} = E_{\text{int},2} - E_{\text{int},1} = Q - W$$

where $E_{\text{int},1}$ and $E_{\text{int},2}$ represent the internal energy of the system in states 1 and 2, and $Q$ and $W$ are the heat added to the system and work done by the system in going from state 1 to state 2.

It is sometimes useful to write the first law of thermodynamics in differential form:

$$dE_{\text{int}} = đQ - đW.$$

Here, $dE_{\text{int}}$ represents an infinitesimal change in internal energy when an infinitesimal amount of heat $đQ$ is added to the system, and the system does an infinitesimal amount of work $đW$ The horizontal bars on the $đ$ (for differential) are a reminder that $Q$ and $W$ can *not* be written as general mathematical functions of state variables such as $P$, $V$, $T$, $n$, because $Q$ and $W$ are *not* properties of the system. That is, $đQ$ and $đW$ mean only infinitesimal amounts of heat and work. Sometimes we don't bother to write the bars. (Internal energy $E_{\text{int}}$ *is* a property of the system and *is* a function of state variables.)

**EXAMPLE 19–9** **Using the first law.** 2500 J of heat is added to a system, and 1800 J of work is done on the system. What is the change in internal energy of the system?

**APPROACH** We apply the first law of thermodynamics, Eq. 19–5, to our system.

**SOLUTION** The heat added to the system is $Q = 2500\,\text{J}$. The work $W$ done *by* the system is $-1800\,\text{J}$. Why the minus sign? Because 1800 J done *on* the system (as given) equals $-1800\,\text{J}$ done *by* the system, and it is the latter we need for the sign conventions we used in Eq. 19–5. Hence

$$\Delta E_{\text{int}} = 2500\,\text{J} - (-1800\,\text{J}) = 2500\,\text{J} + 1800\,\text{J} = 4300\,\text{J}.$$

**NOTE** We did this calculation in detail to emphasize the importance of keeping careful track of signs. Both the heat and the work are inputs to the system, so we expect $\Delta E_{\text{int}}$ to be increased by both.

**EXERCISE E** What would be the internal energy change in Example 19–9 if 2500 J of heat is added to the system and 1800 J of work is done *by* the system (i.e., as output)?

## The First Law of Thermodynamics Extended

To write the first law of thermodynamics in a more complete form, consider a system that is moving so it has kinetic energy $K$, and suppose there is also potential energy $U$. Then the first law of thermodynamics would have to include these terms and would be written as

$$\Delta K + \Delta U + \Delta E_{\text{int}} = Q - W. \qquad \textbf{(19–6)}$$

This is a full summary of energy conservation.

**EXAMPLE 19–10** **Kinetic energy transformed to thermal energy.** A 3.0-g bullet traveling at a speed of 400 m/s enters a tree and exits the other side with a speed of 200 m/s. Where did the bullet's lost kinetic energy go, and how much energy was transferred?

**APPROACH** Take the bullet and tree as our system. No potential energy is involved. No work is done on (or by) the system by outside forces, nor is any heat added because no energy was transferred to or from the system due to a temperature difference. Thus the kinetic energy gets transformed into internal energy of the bullet and tree. This answers the first question.

**PROBLEM SOLVING**
*Always define your system*

**SOLUTION** In the first law of thermodynamics as written in Eq. 19–6, we are given $Q = W = \Delta U = 0$, so we have

$$\Delta K + \Delta E_{\text{int}} = 0$$

or, using subscripts i and f for initial and final velocities

$$\Delta E_{\text{int}} = -\Delta K = -(K_{\text{f}} - K_{\text{i}}) = \tfrac{1}{2}m(v_{\text{i}}^2 - v_{\text{f}}^2)$$
$$= \tfrac{1}{2}(3.0 \times 10^{-3}\,\text{kg})\left[(400\,\text{m/s})^2 - (200\,\text{m/s})^2\right] = 180\,\text{J}.$$

**NOTE** The internal energy of the bullet and tree both increase, as both experience a rise in temperature. If we had chosen the bullet alone as our system, work would be done on it and heat transfer would occur.

# 19–7 Thermodynamic Processes and the First Law

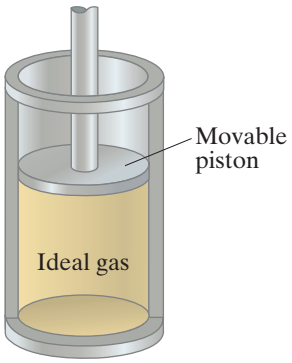
Let us analyze some thermodynamic processes in light of the first law of thermodynamics.

## Isothermal Processes ($\Delta T = 0$)

To begin, we choose a very simple system: a fixed mass of a monatomic ideal gas enclosed in a container fitted with a movable piston as shown in Fig. 19–6.

First we consider an idealized process, such as adding heat or doing work, that is carried out at constant temperature. Such a process is called an **isothermal** process (from the Greek meaning "same temperature"). If the system is an ideal gas, then $PV = nRT$ (Eq. 17–3), so for a fixed amount of gas kept at constant temperature, $PV =$ constant. Thus a graph of pressure $P$ vs. volume $V$, a ***PV* diagram**, would follow a curve like AB in Fig. 19–7 for an isothermal process. Each point on the curve, such as point A, represents the state of the system at a given moment—that is, its pressure $P$ and volume $V$. At a lower temperature, another isothermal process would be represented by a curve like A′B′ in Fig. 19–7 (the product $PV = nRT =$ constant is less when $T$ is less). The curves shown in Fig. 19–7 are referred to as *isotherms*. We assume the gas at any instant is in contact with a **heat reservoir** (a body whose mass is so large that, ideally, its temperature does not change significantly when heat is exchanged with our system). We also assume that a process of compression (volume decrease) or expansion (volume increase) is done **quasistatically** (= almost statically), meaning very slowly, so that the process can be considered a *series of equilibrium states* all at the same constant temperature. Thus a $PV$ diagram is an idealized approximation to a real process. We cannot plot $P$ vs. $V$ for a real process precisely, because a real process is not quasistatic, which would take forever. (For each change in $P$ or $V$, the pressure $P$ at any instant will not be the same at all points within the gas.)

If the gas is initially in a state represented by point A in Fig. 19–7, and an amount of heat $Q$ is added to the system, the pressure and volume will change and the state of the system will be represented by another point, B, on the diagram.



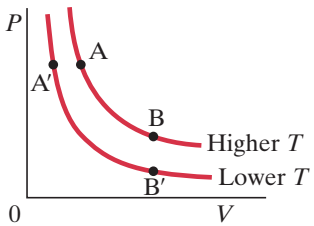


**FIGURE 19–6** An ideal gas in a cylinder fitted with a movable piston.

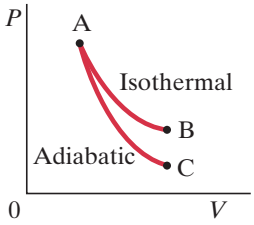
**FIGURE 19–7** *PV* diagram for ideal gas undergoing isothermal quasistatic processes at two different temperatures.

If the temperature is to remain constant, the gas will expand and do an amount of work $W$ on the environment (it exerts a force on the piston in Fig. 19–6 and moves it through a distance). The temperature and mass are kept constant so, from Eq. 19–1, the internal energy does not change: $\Delta E_{\text{int}} = \frac{3}{2}nR\,\Delta T = 0$. Hence, by the first law of thermodynamics, Eq. 19–5, $\Delta E_{\text{int}} = Q - W = 0$, so $W = Q$: the work done by the gas in an isothermal process equals the heat added to the gas.

## Adiabatic Processes ($Q = 0$)

An **adiabatic** process is one in which no heat is allowed to flow into or out of the system: $Q = 0$. This situation can occur if the system is extremely well insulated, or the process happens so quickly that heat—which flows slowly—has no time to flow in or out. The very rapid expansion of gases in an internal combustion engine is one example of a process that is very nearly adiabatic. Such a rapid expansion could not be graphed on a $PV$ diagram because the system would be tumultuous and turbulent, without a fixed pressure $P$ throughout the gas at any moment, and thus not a sequence of (quasistatic) equilibrium states needed for such a plot. If an ideal gas undergoes an adiabatic expansion very slowly, it can be represented by a curve like that labeled AC in Fig. 19–8. Since $Q = 0$, we have from Eq. 19–5 that $\Delta E_{\text{int}} = -W$. When a gas expands, it does work and $W$ is positive, so the internal energy decreases; hence the temperature decreases as well (because $\Delta E_{\text{int}} = \frac{3}{2}nR\,\Delta T$). This is seen in Fig. 19–8 where the product $PV\ (= nRT)$ is less at point C than at point B. (Compare to curve AB for an isothermal process, in which $\Delta E_{\text{int}} = 0$ and $\Delta T = 0$.) In the reverse operation, an adiabatic compression (going from C to A, for example), work is done *on* the gas, and hence the internal energy increases and the temperature rises.



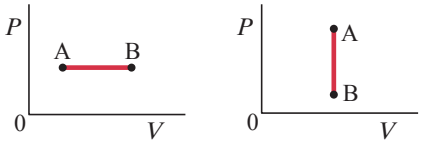


**FIGURE 19–8** $PV$ diagram for adiabatic (AC) and isothermal (AB) processes on an ideal gas.

In a diesel engine, the fuel–air mixture is rapidly compressed adiabatically by a factor of 15 or more; the temperature rise is so great that the mixture ignites spontaneously, without spark plugs.

## Isobaric and Isovolumetric Processes

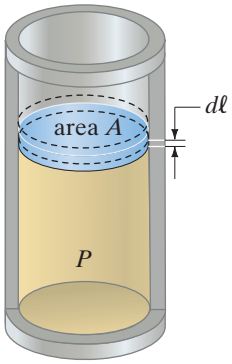
Isothermal and adiabatic processes are just two possible processes that can occur. Two other simple thermodynamic processes are illustrated on the $PV$ diagrams of Fig. 19–9: (a) an **isobaric** process is one in which the pressure is kept constant, so the process is represented by a straight horizontal line on the $PV$ diagram (Fig. 19–9a); (b) an **isovolumetric** (or *isochoric*) process is one in which the volume does not change (Fig. 19–9b). In these, and in all other processes, the first law of thermodynamics holds.

**FIGURE 19–9** (a) Isobaric ("same pressure") process. (b) Isovolumetric ("same volume") process.

(a) Isobaric (b) Isovolumetric

## Work Done in Volume Changes

We often want to calculate the work done in a process. Suppose we have a gas confined to a cylindrical container fitted with a movable piston (Fig. 19–10). We must always be careful to define exactly what our system is. In this case we choose our system to be the gas; so the container's walls and the piston are parts of the environment. Now let us calculate the work done by the gas when it expands quasistatically, so that $P$ and $T$ are defined for the system at all instants. The gas expands against the piston, whose area is $A$. The gas exerts a force $F = PA$ on the piston, where $P$ is the pressure in the gas. The work done by the gas to move the piston an infinitesimal displacement $d\vec{\boldsymbol{\ell}}$ is



$$dW = \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}} = PA\,d\ell = P\,dV \qquad \textbf{(19–7)}$$

since the infinitesimal increase in volume is $dV = A\,d\ell$. If the gas was *compressed* so that $d\vec{\boldsymbol{\ell}}$ pointed into the gas, the volume would decrease and $dV < 0$. The work done by the gas in this case would then be negative, which is equivalent to saying that positive work was done *on* the gas, not by it. For a finite change in volume from $V_{\text{A}}$ to $V_{\text{B}}$, the work $W$ done by the gas will be

$$W = \int dW = \int_{V_{\text{A}}}^{V_{\text{B}}} P\,dV. \qquad \textbf{(19–8)}$$

Equations 19–7 and 19–8 are valid for the work done in any volume change—by a gas, a liquid, or a solid—as long as it is done quasistatically.

**FIGURE 19–10** The work done by a gas when its volume increases by $dV = A\,d\ell$ is $dW = P\,dV$.

In order to integrate Eq. 19–8, we need to know how the pressure varies during the process, and this depends on the type of process. Let us first consider a quasistatic isothermal expansion of an ideal gas. This idealized process is represented by the curve between points A and B on the $PV$ diagram of Fig. 19–11. The work done by the gas in this process, according to Eq. 19–8, is just the area between the $PV$ curve and the $V$ axis, and is shown shaded in Fig. 19–11. We can do the integral in Eq. 19–8 for an ideal gas by using the ideal gas law, $P = nRT/V$. The work done at constant $T$ is

$$W = \int_{V_A}^{V_B} P\,dV = nRT\int_{V_A}^{V_B}\frac{dV}{V} = nRT\ln\frac{V_B}{V_A}. \quad \left[\begin{array}{c}\text{isothermal process;}\\ \text{ideal gas}\end{array}\right] \quad \textbf{(19–9)}$$

Let us next consider a different way of taking an ideal gas between the same states A and B. This time, let us lower the pressure in the gas from $P_A$ to $P_B$, as indicated by the line AD in Fig. 19–12. (In this *isovolumetric* process, heat must be allowed to flow out of the gas so its temperature drops.) Then let the gas expand from $V_A$ to $V_B$ at constant pressure $(= P_B)$, which is indicated by the line DB in Fig. 19–12. (In this *isobaric* process, heat is added to the gas to raise its temperature.) No work is done in the isovolumetric process AD, since $dV = 0$:

$$W = 0. \qquad \text{[isovolumetric process]}$$

In the isobaric process DB the pressure remains constant, so

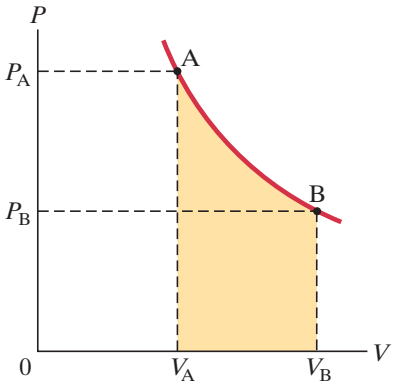
$$W = \int_{V_A}^{V_B} P\,dV = P_B(V_B - V_A) = P\,\Delta V. \quad \text{[isobaric process]} \quad \textbf{(19–10a)}$$

The work done is again represented on the $PV$ diagram by the area between the curve (ADB) and the $V$ axis, as indicated by the shading in Fig. 19–12. Using the ideal gas law, we can also write

$$W = P_B(V_B - V_A) = nRT_B\left(1 - \frac{V_A}{V_B}\right). \quad \left[\begin{array}{c}\text{isobaric process;}\\ \text{ideal gas}\end{array}\right] \quad \textbf{(19–10b)}$$

As can be seen from the shaded areas in Figs. 19–11 and 19–12, or by putting in numbers in Eqs. 19–9 and 19–10 (try it for $V_B = 2V_A$), the work done in these two processes is different. This is a general result. *The work done in taking a system from one state to another depends not only on the initial and final states but also on the type of process* (*or "path"*).

This result reemphasizes the fact that work cannot be considered a property of a system. The same is true of heat. The heat input required to change the gas from state A to state B depends on the process; for the isothermal process of Fig. 19–11, the heat input turns out to be greater than for the process ADB of Fig. 19–12. In general, *the amount of heat added or removed in taking a system from one state to another depends not only on the initial and final states but also on the path or process*.



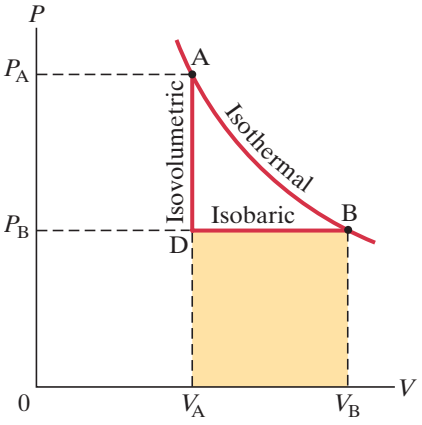


**FIGURE 19–11** Work done by an ideal gas in an isothermal process equals the area under the $PV$ curve. Shaded area equals the work done by the gas when it expands from $V_A$ to $V_B$.

**FIGURE 19–12** Process ADB consists of an isovolumetric (AD) and an isobaric (DB) process.

**CONCEPTUAL EXAMPLE 19–11** **Work in isothermal and adiabatic processes.** In Fig. 19–8 we saw the $PV$ diagrams for a gas expanding in two ways, isothermally and adiabatically. The initial volume $V_A$ was the same in each case, and the final volumes were the same $(V_B = V_C)$. In which process was more work done by the gas?

**RESPONSE** Our system is the gas. More work was done by the gas in the isothermal process, which we can see in two simple ways by looking at Fig. 19–8. First, the "average" pressure was higher during the isothermal process AB, so $W = \bar{P}\,\Delta V$ was greater ($\Delta V$ is the same for both processes). Second, we can look at the area under each curve: the area under curve AB in Fig. 19–11, which represents the work done in an isothermal process, is greater (because curve AB is higher) than the area under AC in Fig. 19–8.

**EXERCISE F** Is the work done by the gas in process ADB of Fig. 19–12 greater than, less than, or equal to the work done in the isothermal process AB?

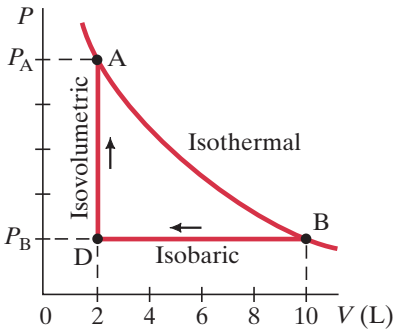

**FIGURE 19–13** Example 19–12.

**EXAMPLE 19–12 First law in isobaric and isovolumetric processes.** An ideal gas is slowly compressed at a constant pressure of 2.0 atm from 10.0 L to 2.0 L. This process is represented in Fig. 19–13 as the path B to D. (In this process, some heat flows out of the gas and the temperature drops.) Heat is then added to the gas, holding the volume constant, and the pressure and temperature are allowed to rise (line DA) until the temperature reaches its original value $(T_A = T_B)$. Calculate (*a*) the total work done by the gas in the process BDA, and (*b*) the total heat flow into the gas.

**APPROACH** (*a*) Work is done only in the compression process BD. In process DA, the volume is constant so $\Delta V = 0$ and no work is done. (*b*) We use the first law of thermodynamics, Eq. 19–5.

**SOLUTION** (*a*) During the compression BD, the pressure is $2.0\,\text{atm} = 2(1.01 \times 10^5\,\text{N/m}^2)$ and the work done is $(\text{since } 1\,\text{L} = 10^3\,\text{cm}^3 = 10^{-3}\,\text{m}^3)$

$$W = P\,\Delta V = (2.02 \times 10^5\,\text{N/m}^2)(2.0 \times 10^{-3}\,\text{m}^3 - 10.0 \times 10^{-3}\,\text{m}^3)$$
$$= -1.6 \times 10^3\,\text{J}.$$

The total work done *by* the gas is $-1.6 \times 10^3\,\text{J}$, where the minus sign means that $+1.6 \times 10^3\,\text{J}$ of work is done *on* the gas.

(*b*) The temperature at the beginning and at the end of process BDA is the same, so even though the internal energy changes along the path BDA, it is the same at the end (A) as at the start (B): $\Delta E_{\text{int}} = 0$. From the first law of thermodynamics we have

$$0 = \Delta E_{\text{int}} = Q - W$$

so

$$Q = W = -1.6 \times 10^3\,\text{J}.$$

Because $Q$ is negative, 1600 J of heat flows out of the gas for the whole process, BDA.

**EXERCISE G** In Example 19–12, if the heat lost from the gas in the process BD is $8.4 \times 10^3\,\text{J}$, what is the change in internal energy of the gas during process BD?

**EXAMPLE 19–13 Work done in an engine.** In an engine, 0.25 mol of an ideal monatomic gas in a cylinder expands rapidly and adiabatically against the piston. In the process, the temperature of the gas drops from 1150 K to 400 K. How much work does the gas do?

**APPROACH** We take the gas as our system (the piston is part of the surroundings). The pressure is not constant, and its varying value is not given. Instead, we can use the first law of thermodynamics to find $W$ because $Q = 0$ (the process is adiabatic), and we can determine $\Delta E_{\text{int}}$ (from $\Delta T$).

**SOLUTION** We determine $\Delta E_{\text{int}}$ from Eq. 19–1 for the internal energy of an ideal monatomic gas, using subscripts f and i for final and initial states:

$$\Delta E_{\text{int}} = E_{\text{int,f}} - E_{\text{int,i}} = \tfrac{3}{2}nR(T_f - T_i)$$
$$= \tfrac{3}{2}(0.25\,\text{mol})(8.314\,\text{J/mol}\cdot\text{K})(400\,\text{K} - 1150\,\text{K})$$
$$= -2300\,\text{J}.$$

Then, from the first law of thermodynamics, Eq. 19–5,

$$W = Q - \Delta E_{\text{int}} = 0 - (-2300\,\text{J}) = 2300\,\text{J}.$$

Table 19–3 (next page) shows a brief summary of a few processes we have discussed.

**TABLE 19–3 Simple Thermodynamic Processes and the First Law**

| Process | What is constant: | The first law, $\Delta E_{\text{int}} = Q - W$, predicts |
|---|---|---|
| Isothermal | $T$ = constant | $\Delta T = 0$ makes $\Delta E_{\text{int}} = 0$, so $Q = W$ |
| Isobaric | $P$ = constant | $Q = \Delta E_{\text{int}} + W = \Delta E_{\text{int}} + P\,\Delta V$ |
| Isovolumetric | $V$ = constant | $\Delta V = 0$ makes $W = 0$, so $Q = \Delta E_{\text{int}}$ |
| Adiabatic | $Q = 0$ | $\Delta E_{\text{int}} = -W$ |

**EXAMPLE 19–14** **$\Delta E_{\text{int}}$ for boiling water to steam.** Determine the change in internal energy of 1.00 liter of water (mass 1.00 kg) at 100°C when it is fully boiled from liquid to gas, which results in 1671 liters of steam at 100°C. Assume the process is done at atmospheric pressure.

**APPROACH** Our system is the water. The heat required here does not result in a temperature change; rather, a change in phase occurs. We can determine the heat $Q$ required using the latent heat of water, as in Section 19–5. Work too will be done because the volume changes. The first law of thermodynamics will then give us $\Delta E_{\text{int}}$.

**SOLUTION** The latent heat of vaporization of water (Table 19–2) is $L_V = 22.6 \times 10^5\,\text{J/kg}$. So the heat input required for this process is (Eq. 19–4)

$$Q = mL = (1.00\,\text{kg})(22.6 \times 10^5\,\text{J/kg}) = 22.6 \times 10^5\,\text{J}.$$

The work done by the water ($P$ = constant = 1 atm) is (Eq. 19–10a)

$$W = P\,\Delta V = (1.01 \times 10^5\,\text{N/m}^2)[(1671 \times 10^{-3}\,\text{m}^3) - (1 \times 10^{-3}\,\text{m}^3)]$$
$$= 1.69 \times 10^5\,\text{J},$$

where we used $1\,\text{atm} = 1.01 \times 10^5\,\text{N/m}^2$ and $1\,\text{L} = 10^3\,\text{cm}^3 = 10^{-3}\,\text{m}^3$. Then

$$\Delta E_{\text{int}} = Q - W = (22.6 \times 10^5\,\text{J}) - (1.7 \times 10^5\,\text{J}) = 20.9 \times 10^5\,\text{J}.$$

**NOTE** Most of the heat added goes to increasing the internal energy of the water (increasing molecular energy to overcome the attraction that held the molecules close together in the liquid state). Only a small part ($< 10\%$) goes into doing work.

**NOTE** Equation 19–1, $E_{\text{int}} = \frac{3}{2}nRT$, would tell us that $\Delta E_{\text{int}} = 0$ here because $\Delta T = 0$. Yet we determined that $\Delta E_{\text{int}} \approx 21 \times 10^5\,\text{J}$. What is wrong? Equation 19–1 applies only to an ideal monatomic gas, not to liquid water.

## Free Expansion

One type of adiabatic process is a **free expansion** in which a gas is allowed to expand in volume adiabatically without doing any work. The apparatus to accomplish a free expansion is shown in Fig. 19–14. It consists of two well-insulated compartments (to ensure no heat flow in or out) connected by a valve or stopcock. One compartment is filled with gas, the other is empty. When the valve is opened, the gas expands to fill both containers. No heat flows in or out ($Q = 0$), and no work is done because the gas does not move any other object. Thus $Q = W = 0$ and by the first law of thermodynamics, $\Delta E_{\text{int}} = 0$. *The internal energy of a gas does not change in a free expansion*. For an ideal gas, $\Delta T = 0$ also, since $E_{\text{int}}$ depends only on $T$ (Section 19–2). Experimentally, the free expansion has been used to determine if the internal energy of *real gases* depends only on $T$. The experiments are very difficult to do accurately, but it has been found that the temperature of a real gas drops very slightly in a free expansion. Thus the internal energy of real gases does depend, a little, on pressure or volume as well as on temperature.

A free expansion can not be plotted on a $PV$ diagram, because the process is rapid, not quasistatic. The intermediate states are not equilibrium states, and hence the pressure (and even the volume at some instants) is not clearly defined.

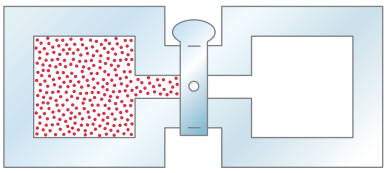

**FIGURE 19–14** Free expansion.

# 19–8 Molar Specific Heats for Gases, and the Equipartition of Energy

In Section 19–3 we discussed the concept of specific heat and applied it to solids and liquids. The values of the specific heat for gases depend much more on how the thermodynamic process is carried out. Two important processes are those in which either the volume or the pressure is kept constant. Although for solids and liquids it matters little, Table 19–4 shows that for gases the specific heats at constant volume $(c_V)$ and at constant pressure $(c_P)$ are quite different.

**TABLE 19–4 Specific Heats of Gases at 15°C**

| Gas | Specific heats (kcal/kg · K) | | Molar specific heats (cal/mol · K) | | $C_P - C_V$ (cal/mol · K) | $\gamma = \frac{C_P}{C_V}$ |
|---|---|---|---|---|---|---|
| | $c_V$ | $c_P$ | $C_V$ | $C_P$ | | |
| Monatomic | | | | | | |
| He | 0.75 | 1.15 | 2.98 | 4.97 | 1.99 | 1.67 |
| Ne | 0.148 | 0.246 | 2.98 | 4.97 | 1.99 | 1.67 |
| Diatomic | | | | | | |
| $N_2$ | 0.177 | 0.248 | 4.96 | 6.95 | 1.99 | 1.40 |
| $O_2$ | 0.155 | 0.218 | 5.03 | 7.03 | 2.00 | 1.40 |
| Triatomic | | | | | | |
| $CO_2$ | 0.153 | 0.199 | 6.80 | 8.83 | 2.03 | 1.30 |
| $H_2O$ (100°C) | 0.350 | 0.482 | 6.20 | 8.20 | 2.00 | 1.32 |
| Polyatomic | | | | | | |
| $C_2H_6$ | 0.343 | 0.412 | 10.30 | 12.35 | 2.05 | 1.20 |

## Molar Specific Heats for Gases

The difference in specific heats for gases is nicely explained in terms of the first law of thermodynamics and kinetic theory. For gases, we usually use **molar specific heats**, $C_V$ and $C_P$, which are defined as the heat required to raise 1 mol of the gas by 1 C° at constant volume and at constant pressure, respectively. We use moles $n$ in place of $m$ in Eq. 19–2: the heat $Q$ needed to raise the temperature of $n$ moles of gas by $\Delta T$ is

$$Q = nC_V \Delta T \qquad \text{[volume constant]} \qquad \textbf{(19–11a)}$$

$$Q = nC_P \Delta T. \qquad \text{[pressure constant]} \qquad \textbf{(19–11b)}$$

We can see from the definition of molar specific heat (or by comparing Eqs. 19–2 and 19–11) that

$$C_V = Mc_V$$
$$C_P = Mc_P,$$

where $M$ is the molecular mass of the gas $(M = m/n$ in grams/mol$)$.[†] The values for molar specific heats are included in Table 19–4. These values are nearly the same for different gases that have the same number of atoms per molecule.

Now we use kinetic theory and imagine that an ideal gas is slowly heated via two different processes—first at constant volume, and then at constant pressure. In both processes, we let the temperature increase by the same amount, $\Delta T$. In the constant-volume process, no work is done since $\Delta V = 0$. Thus, according to the first law of thermodynamics, the heat added (which we denote by $Q_V$) all goes into increasing the internal energy of the gas:

$$Q_V = \Delta E_{int}.$$

In the constant-pressure process, work *is* done. Hence the heat added, $Q_P$, must not only increase the internal energy but also is used to do the work $W = P\,\Delta V$.

[†]For example, $M = 4$ g/mol for He, and $M = 32$ g/mol for $O_2$ (see Periodic Table inside rear cover).

Thus, more heat will be needed in the process at constant pressure than in the process at constant volume. For the process at constant pressure, the first law of thermodynamics gives

$$Q_P = \Delta E_{int} + P\,\Delta V.$$

Since $\Delta E_{int}$ is the same in the two processes (we chose $\Delta T$ to be the same), we can combine the two preceding equations:

$$Q_P - Q_V = P\,\Delta V.$$

From the ideal gas law, $V = nRT/P$, so for a process at constant pressure $\Delta V = nR\,\Delta T/P$. Putting this into the last equation and using Eqs. 19–11, we find

$$nC_P\,\Delta T - nC_V\,\Delta T = P\left(\frac{nR\,\Delta T}{P}\right)$$

or, after cancellations,

$$C_P - C_V = R. \qquad \textbf{(19–12)}$$

The gas constant $R = 8.314\,\text{J/mol}\cdot\text{K} = 1.99\,\text{cal/mol}\cdot\text{K}$, so our prediction is that $C_P$ will be larger than $C_V$ by about $1.99\,\text{cal/mol}\cdot\text{K}$. Indeed, this is very close to what is obtained experimentally, as shown in the next to last column of Table 19–4.

Now we calculate the value of the molar specific heat of a monatomic gas using kinetic theory. In a process carried out at constant volume, no work is done; so the first law of thermodynamics tells us that

$$\Delta E_{int} = Q_V.$$

For an ideal monatomic gas, the internal energy $E_{int}$ is the total kinetic energy of all the $N$ molecules,

$$E_{int} = N\left(\tfrac{1}{2}m\overline{v^2}\right) = \tfrac{3}{2}nRT$$

as we saw in Section 19–2. Then, using Eq. 19–11a, we can write $\Delta E_{int} = Q$ as

$$\Delta E_{int} = \tfrac{3}{2}nR\,\Delta T = nC_V\,\Delta T \qquad \textbf{(19–13)}$$

or

$$C_V = \tfrac{3}{2}R. \qquad \textbf{(19–14)}$$

Since $R = 8.314\,\text{J/mol}\cdot\text{K} = 1.99\,\text{cal/mol}\cdot\text{K}$, kinetic theory predicts that $C_V = 2.98\,\text{cal/mol}\cdot\text{K}$ for an ideal monatomic gas. This is very close to the experimental values for monatomic gases such as helium and neon (Table 19–4). From Eq. 19–12, $C_P$ is predicted to be $R + C_V = (1.99 + 2.98)\,\text{cal/mol}\cdot\text{K} = 4.97\,\text{cal/mol}\cdot\text{K}$, also in agreement with experiment (Table 19–4). So we are quite happy with kinetic theory's predictions.

## Equipartition of Energy

The measured molar specific heats for more complex gases (Table 19–4), such as diatomic (two atoms) and triatomic (three atoms) gases, increase with the increased number of atoms per molecule. We can explain this by assuming that the internal energy includes not only translational kinetic energy but other forms of energy as well. For example, in a diatomic gas (Fig. 19–15), the two atoms can rotate about two different axes (but rotation about a third axis passing through the two atoms would give rise to very little energy since the moment of inertia is so small). The molecules can have rotational as well as translational kinetic energy. It is useful to introduce the idea of **degrees of freedom**, by which we mean the number of independent ways molecules can possess energy. For example, a monatomic gas has three degrees of freedom, because an atom can have velocity along the $x$, $y$, and $z$ axes. These are considered to be three independent motions because a change in any one of the components would not affect the others.

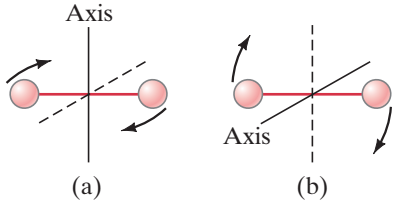

**FIGURE 19–15** A diatomic molecule can rotate about two different axes.

A diatomic molecule has the same three degrees of freedom associated with translational kinetic energy plus two more degrees of freedom associated with rotational kinetic energy (Fig. 19–15), for a total of five degrees of freedom.

Table 19–4 indicates that the $C_V$ for diatomic gases is about $\frac{5}{3}$ times as great as for a monatomic gas—that is, in the same ratio as their degrees of freedom. This result led nineteenth-century physicists to the **principle of equipartition of energy**. This principle states that energy is shared equally among the active degrees of freedom, and each active degree of freedom of a molecule has on average an energy equal to $\frac{1}{2}kT$. Thus, the average energy for a molecule of a monatomic gas, with its 3 degrees of freedom, would be $\frac{3}{2}kT$ (which we already knew) and for a diatomic gas, with its 5 degrees of freedom, $\frac{5}{2}kT$. Hence the internal energy of a diatomic gas would be $E_{\text{int}} = N\left(\frac{5}{2}kT\right) = \frac{5}{2}nRT$, where $N$ is the number of molecules and $n$ is the number of moles. Using the same argument we did for monatomic gases, we see that for diatomic gases the molar specific heat at constant volume would be $C_V = \frac{5}{2}R = 4.97\ \text{cal/mol} \cdot \text{K}$, close to measured values (Table 19–4). More complex molecules have even more degrees of freedom and thus greater molar specific heats.

However, measurements show that for diatomic gases at very low temperatures, $C_V$ has a value of only $\frac{3}{2}R$, as if it had only three degrees of freedom. And at very high temperatures, $C_V$ was about $\frac{7}{2}R$, as if there were seven degrees of freedom. The explanation is that at low temperatures, nearly all molecules have only translational kinetic energy. That is, no energy goes into rotational energy and only three degrees of freedom are "active." At very high temperatures, all five degrees of freedom are active plus two additional ones. We can interpret the two new degrees of freedom as being associated with the two atoms vibrating, as if they were connected by a spring (Fig. 19–16). One degree of freedom comes from the kinetic energy of the vibrational motion, and the second comes from the potential energy of vibrational motion $\left(\frac{1}{2}kx^2\right)$. At room temperature, these two degrees of freedom are apparently not active. See Fig. 19–17.

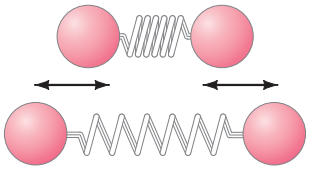

**FIGURE 19–16** A diatomic molecule can vibrate, as if the two atoms were connected by a spring. Of course they are not connected by a spring; rather they exert forces on each other that are electrical in nature, but of a form that resembles a spring force.

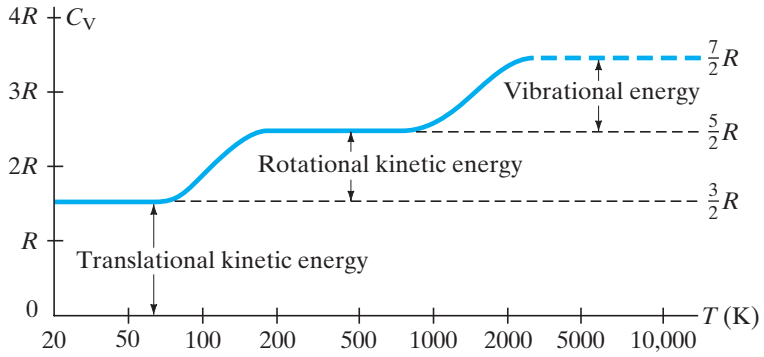

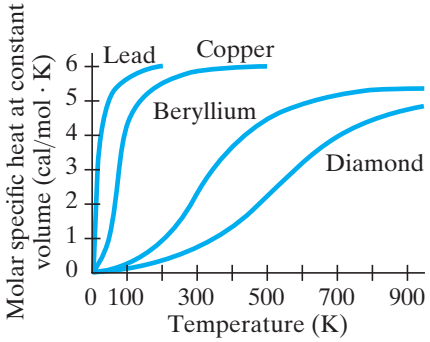

**FIGURE 19–17** Molar specific heat $C_V$ as a function of temperature for hydrogen molecules $(H_2)$. As the temperature is increased, some of the translational kinetic energy can be transferred in collisions into rotational kinetic energy and, at still higher temperature, into vibrational energy. [Note: $H_2$ dissociates into two atoms at about 3200 K, so the last part of the curve is shown dashed. Also note the temperature axis is logarithmic.]

Just why fewer degrees of freedom are "active" at lower temperatures was eventually explained by Einstein using the quantum theory. [According to quantum theory, energy does not take on continuous values but is quantized—it can have only certain values, and there is a certain minimum energy. The minimum rotational and vibrational energies are higher than for simple translational kinetic energy, so at lower temperatures and lower translational kinetic energy, there is not enough energy to excite the rotational or vibrational kinetic energy.] Calculations based on kinetic theory and the principle of equipartition of energy (as modified by the quantum theory) give numerical results in accord with experiment.

**FIGURE 19–18** Molar specific heats of solids as a function of temperature.

## *Solids

The principle of equipartition of energy can be applied to solids as well. The molar specific heat of any solid, at high temperature, is close to $3R$ $(6.0\ \text{cal/mol} \cdot \text{K})$, Fig. 19–18. This is called the *Dulong and Petit* value after the scientists who first measured it in 1819. (We are using *molar* here, not per kg as in Table 19–1.) At high temperatures, each atom apparently has six degrees of freedom, although some are not active at low temperatures. Each atom in a crystalline solid can vibrate about

its equilibrium position as if it were connected by springs to each of its neighbors (Fig. 19–19). Thus it can have three degrees of freedom for kinetic energy and three more associated with potential energy of vibration in each of the $x$, $y$, and $z$ directions, which is in accord with the measured values.

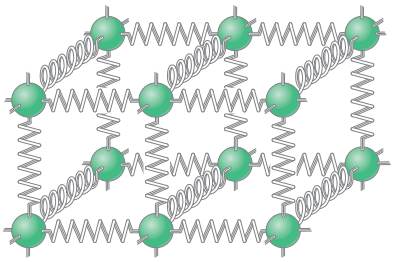

**FIGURE 19–19** The atoms in a crystalline solid can vibrate about their equilibrium positions as if they were connected to their neighbors by springs. (The forces between atoms are actually electrical in nature.)

## 19–9 Adiabatic Expansion of a Gas

The $PV$ curve for the quasistatic (slow) adiabatic expansion $(Q = 0)$ of an ideal gas was shown in Fig. 19–8 (curve AC). It is somewhat steeper than for an isothermal process $(\Delta T = 0)$, which indicates that for the same change in volume the change in pressure will be greater. Hence the temperature of the gas must drop during an adiabatic expansion. Conversely, the temperature rises during an adiabatic compression.

We can derive the relation between the pressure $P$ and the volume $V$ of an ideal gas that is allowed to slowly expand adiabatically. We begin with the first law of thermodynamics, written in differential form:

$$dE_{\text{int}} = dQ - dW = -dW = -P\,dV,$$

since $dQ = 0$ for an adiabatic process. Equation 19–13 gives us a relation between $\Delta E_{\text{int}}$ and $C_V$, which is valid for any ideal gas process since $E_{\text{int}}$ is a function only of $T$ for an ideal gas. We write this in differential form:

$$dE_{\text{int}} = nC_V\,dT.$$

When we combine these last two equations, we obtain

$$nC_V\,dT + P\,dV = 0.$$

We next take the differential of the ideal gas law, $PV = nRT$, allowing $P$, $V$, and $T$ to vary:

$$P\,dV + V\,dP = nR\,dT.$$

We solve for $dT$ in this relation and substitute it into the previous relation and get

$$nC_V\left(\frac{P\,dV + V\,dP}{nR}\right) + P\,dV = 0$$

or, multiplying through by $R$ and rearranging,

$$(C_V + R)P\,dV + C_V V\,dP = 0.$$

We note from Eq. 19–12 that $C_V + R = C_P$, so we have

$$C_P P\,dV + C_V V\,dP = 0,$$

or

$$\frac{C_P}{C_V}P\,dV + V\,dP = 0.$$

We define

$$\gamma = \frac{C_P}{C_V} \qquad \textbf{(19–15)}$$

so that our last equation becomes

$$\frac{dP}{P} + \gamma\frac{dV}{V} = 0.$$

This is integrated to become

$$\ln P + \gamma \ln V = \text{constant}.$$

This simplifies (using the rules for addition and multiplication of logarithms) to

$$PV^{\gamma} = \text{constant}. \qquad \left[\begin{array}{c}\text{quasistatic adiabatic}\\ \text{process; ideal gas}\end{array}\right] \qquad \textbf{(19–16)}$$

This equation relates $P$ and $V$ for a quasistatic adiabatic expansion or contraction.

We will find Eq. 19–16, $PV^\gamma = \text{constant}$, very useful when we discuss heat engines in the next Chapter. Table 19–4 (page 556) gives values of $\gamma$ for some real gases. Figure 19–8 compares an adiabatic expansion (Eq. 19–16) in curve AC to an isothermal expansion ($PV = \text{constant}$) in curve AB. It is important to remember that the ideal gas law, $PV = nRT$, continues to hold even for an adiabatic expansion ($PV^\gamma = \text{constant}$); clearly $PV$ is not constant, meaning $T$ is not constant.

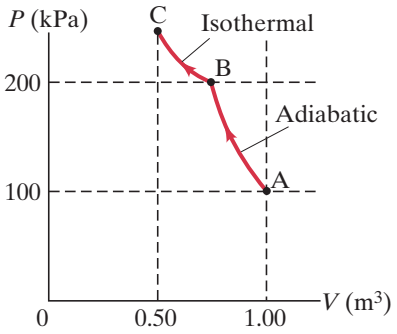

**FIGURE 19–20** Example 19–15.

**EXAMPLE 19–15 Compressing an ideal gas.** An ideal monatomic gas is compressed starting at point A in the $PV$ diagram of Fig. 19–20, where $P_A = 100\,\text{kPa}$, $V_A = 1.00\,\text{m}^3$, and $T_A = 300\,\text{K}$. The gas is first compressed adiabatically to state B ($P_B = 200\,\text{kPa}$). The gas is then further compressed from point B to point C ($V_C = 0.50\,\text{m}^3$) in an isothermal process. (*a*) Determine $V_B$. (*b*) Calculate the work done *on* the gas for the whole process.

**APPROACH** Volume $V_B$ is obtained using Eq. 19–16. The work done *by* a gas is given by Eq. 19–8, $W = \int P\,dV$. The work *on* the gas is the negative of this: $W_{on} = -\int P\,dV$.

**SOLUTION** In the adiabatic process, Eq. 19–16 tells us $PV^\gamma = \text{constant}$. Therefore, $PV^\gamma = P_A V_A^\gamma = P_B V_B^\gamma$ where for a monatomic gas $\gamma = C_P/C_V = (5/2)/(3/2) = \frac{5}{3}$.

(*a*) Equation 19–16 gives $V_B = V_A(P_A/P_B)^{\frac{1}{\gamma}} = (1.00\,\text{m}^3)(100\,\text{kPa}/200\,\text{kPa})^{\frac{3}{5}} = 0.66\,\text{m}^3$.

(*b*) The pressure $P$ at any instant during the adiabatic process is given by $P = P_A V_A^\gamma V^{-\gamma}$. The work done on the gas in going from $V_A$ to $V_B$ is

$$W_{AB} = -\int_A^B P\,dV = -P_A V_A^\gamma \int_{V_A}^{V_B} V^{-\gamma}\,dV$$
$$= -P_A V_A^\gamma \left(\frac{1}{-\gamma + 1}\right)(V_B^{1-\gamma} - V_A^{1-\gamma}).$$

Since $\gamma = \frac{5}{3}$, then $-\gamma + 1 = 1 - \gamma = -\frac{2}{3}$, so

$$W_{AB} = -\left(P_A V_A^{\frac{5}{3}}\right)\left(-\frac{3}{2}\right)\left(V_A^{-\frac{2}{3}}\right)\left[\left(\frac{V_B}{V_A}\right)^{-\frac{2}{3}} - 1\right]$$
$$= +\frac{3}{2}P_A V_A\left[\left(\frac{V_B}{V_A}\right)^{-\frac{2}{3}} - 1\right]$$
$$= +\frac{3}{2}(100\,\text{kPa})(1.00\,\text{m}^3)\left[(0.66)^{-\frac{2}{3}} - 1\right] = +48\,\text{kJ}.$$

For the isothermal process from B to C, the work is done at constant temperature, so the pressure at any instant during the process is $P = nRT_B/V$ and

$$W_{BC} = -\int_B^C P\,dV = -nRT_B\int_{V_B}^{V_C}\frac{dV}{V} = -nRT_B \ln\frac{V_C}{V_B}$$
$$= -P_B V_B \ln\frac{V_C}{V_B} = +37\,\text{kJ}.$$

The total work done on the gas is $48\,\text{kJ} + 37\,\text{kJ} = 85\,\text{kJ}$.

## 19–10 Heat Transfer: Conduction, Convection, Radiation

Heat is transferred from one place or body to another in three different ways: by *conduction*, by *convection*, and by *radiation*. We now discuss each of these in turn; but in practical situations, any two or all three may be operating at the same time. We start with conduction.

## Conduction

When a metal poker is put in a hot fire, or a silver spoon is placed in a hot bowl of soup, the exposed end of the poker or spoon soon becomes hot as well, even though it is not in the source of heat. We say that heat has been conducted from the hot end to the cold end.

Heat **conduction** in many materials can be visualized as being carried out via molecular collisions. As one end of an object is heated, the molecules there move faster and faster (= higher temperature). As these faster molecules collide with slower-moving neighbors, they transfer some of their kinetic energy to them, which in turn transfer some energy by collision with molecules still farther along the object. Thus the kinetic energy of thermal motion is transferred by molecular collision along the object. In metals, collisions of free electrons are mainly responsible for conduction. Conduction between objects in physical contact occurs similarly.

Heat conduction from one point to another takes place only if there is a difference in temperature between the two points. Indeed, it is found experimentally that the rate of heat flow through a substance is proportional to the difference in temperature between its ends. The rate of heat flow also depends on the size and shape of the object. To investigate this quantitatively, let us consider the heat flow through a uniform cylinder, as illustrated in Fig. 19–21. It is found experimentally that the heat flow $Q$ over a time interval $t$ is given by the relation

$$\frac{Q}{t} = kA\frac{T_1 - T_2}{\ell} \qquad \textbf{(19–17a)}$$

where $A$ is the cross-sectional area of the object, $\ell$ is the distance between the two ends, which are at temperatures $T_1$ and $T_2$, and $k$ is a proportionality constant called the **thermal conductivity** which is characteristic of the material. From Eq. 19–17a, we see that the rate of heat flow (units of J/s) is directly proportional to the cross-sectional area and to the temperature gradient $(T_1 - T_2)/\ell$.

In some cases (such as when $k$ or $A$ cannot be considered constant) we need to consider the limit of an infinitesimally thin slab of thickness $dx$. Then Eq. 19–17a becomes

$$\frac{dQ}{dt} = -kA\frac{dT}{dx}, \qquad \textbf{(19–17b)}$$

where $dT/dx$ is the **temperature gradient** and the negative sign is included since the heat flow is in the direction opposite to the temperature gradient.

[Equations 19–17 are quite similar to the relations describing diffusion (Section 18–8) and the flow of fluids through a pipe (Section 13–12). In those cases, the flow of matter was found to be proportional to the *concentration gradient* $dC/dx$, or to the *pressure gradient* $(P_1 - P_2)/\ell$. This close similarity is one reason we speak of the "flow" of heat. Yet we must keep in mind that no substance is flowing in the case of heat—it is energy that is being transferred.]

The thermal conductivities, $k$, for a variety of substances are given in Table 19–5. Substances for which $k$ is large conduct heat rapidly and are said to be good thermal **conductors**. Most metals fall in this category, although there is a wide range even among them, as you may observe by holding the ends of a silver spoon and a stainless-steel spoon immersed in the same hot cup of soup. Substances for which $k$ is small, such as wool, fiberglass, polyurethane, and goose down, are poor conductors of heat and are therefore good thermal **insulators**.

The relative magnitudes of $k$ can explain simple phenomena such as why a tile floor is much colder on the feet than a rug-covered floor at the same temperature. Tile is a better conductor of heat than the rug. Heat that flows from your foot to the rug is not conducted away rapidly, so the rug's surface quickly warms up to the temperature of your foot and feels good. But the tile conducts the heat away rapidly and thus can take more heat from your foot quickly, so your foot's surface temperature drops.

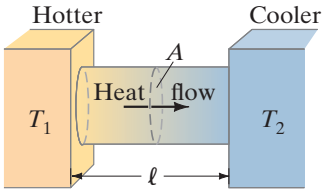

**FIGURE 19–21** Heat conduction between areas at temperatures $T_1$ and $T_2$. If $T_1$ is greater than $T_2$, the heat flows to the right; the rate is given by Eq. 19–17a.

**TABLE 19–5**
**Thermal Conductivities**

| Substance | Thermal conductivity, $k$ | |
|---|---|---|
| | J (s · m · C°) | kcal (s · m · C°) |
| Silver | 420 | $10 \times 10^{-2}$ |
| Copper | 380 | $9.2 \times 10^{-2}$ |
| Aluminum | 200 | $5.0 \times 10^{-2}$ |
| Steel | 40 | $1.1 \times 10^{-2}$ |
| Ice | 2 | $5.0 \times 10^{-4}$ |
| Glass | 0.84 | $2.0 \times 10^{-4}$ |
| Brick | 0.84 | $2.0 \times 10^{-4}$ |
| Concrete | 0.84 | $2.0 \times 10^{-4}$ |
| Water | 0.56 | $1.4 \times 10^{-4}$ |
| Human tissue | 0.2–2 | $0.5–5 \times 10^{-4}$ |
| Wood | 0.1 | $0.3 \times 10^{-4}$ |
| Fiberglass | 0.048 | $0.12 \times 10^{-4}$ |
| Cork | 0.042 | $0.10 \times 10^{-4}$ |
| Wool | 0.040 | $0.10 \times 10^{-4}$ |
| Goose down | 0.025 | $0.060 \times 10^{-4}$ |
| Polyurethane | 0.024 | $0.057 \times 10^{-4}$ |
| Air | 0.023 | $0.055 \times 10^{-4}$ |

**PHYSICS APPLIED**
*Heat loss through windows*

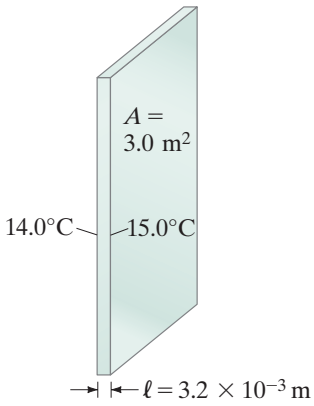

**FIGURE 19–22** Example 19–16.

**EXAMPLE 19–16 Heat loss through windows.** A major source of heat loss from a house in cold weather is through the windows. Calculate the rate of heat flow through a glass window $2.0\,\text{m} \times 1.5\,\text{m}$ in area and 3.2 mm thick, if the temperatures at the inner and outer surfaces are 15.0°C and 14.0°C, respectively (Fig. 19–22).

**APPROACH** Heat flows by conduction through the 3.2-mm thickness of glass from the higher inside temperature to the lower outside temperature. We use the heat conduction equation, Eq. 19–17a.

**SOLUTION** Here $A = (2.0\,\text{m})(1.5\,\text{m}) = 3.0\,\text{m}^2$ and $\ell = 3.2 \times 10^{-3}\,\text{m}$. Using Table 19–5 to get $k$, we have

$$\frac{Q}{t} = kA\frac{T_1 - T_2}{\ell}$$

$$= \frac{(0.84\,\text{J/s}\cdot\text{m}\cdot\text{C}^\circ)(3.0\,\text{m}^2)(15.0^\circ\text{C} - 14.0^\circ\text{C})}{(3.2 \times 10^{-3}\,\text{m})} = 790\,\text{J/s}.$$

**NOTE** This rate of heat flow is equivalent to $(790\,\text{J/s})/(4.186 \times 10^3\,\text{J/kcal}) = 0.19\,\text{kcal/s}$, or $(0.19\,\text{kcal/s}) \times (3600\,\text{s/h}) = 680\,\text{kcal/h}$.

You might notice in Example 19–16 that 15°C is not very warm for the living room of a house. The room itself may indeed be much warmer, and the outside might be colder than 14°C. But the temperatures of 15°C and 14°C were specified as those at the window surfaces, and there is usually a considerable drop in temperature of the air in the vicinity of the window both on the inside and the outside. That is, the layer of air on either side of the window acts as an insulator, and normally the major part of the temperature drop between the inside and outside of the house takes place across the air layer. If there is a heavy wind, the air outside a window will constantly be replaced with cold air; the temperature gradient across the glass will be greater and there will be a much greater rate of heat loss. Increasing the width of the air layer, such as using two panes of glass separated by an air gap, will reduce the heat loss more than simply increasing the glass thickness, since the thermal conductivity of air is much less than that for glass. Such "double-pane windows" are often called *thermal windows*.

**PHYSICS APPLIED**
*Thermal windows*

**PHYSICS APPLIED**
*Clothes insulate by trapping an air layer*

The insulating properties of clothing come from the insulating properties of air. Without clothes, our bodies in still air would heat the air in contact with the skin and would soon become reasonably comfortable because air is a very good insulator. But since air moves—there are breezes and drafts, and people move about—the warm air would (in cooler climates) be replaced by cold air, thus increasing the temperature difference and the heat loss from the body. Clothes keep us warm by trapping air so it cannot move readily. It is not the cloth that insulates us, but the air that the cloth traps. Goose down is a very good insulator because even a small amount of it fluffs up and traps a great amount of air.

**EXERCISE H** Explain why drapes in front of a window reduce heat loss from a house.

**TABLE 19–6 *R*-values**

| Material | Thickness | *R*-value ($\text{ft}^2\cdot\text{h}\cdot\text{F}^\circ/\text{Btu}$) |
|---|---|---|
| Glass | $\frac{1}{8}$ inch | 1 |
| Brick | $3\frac{1}{2}$ inches | 0.6–1 |
| Plywood | $\frac{1}{2}$ inch | 0.6 |
| Fiberglass insulation | 4 inches | 12 |

**PHYSICS APPLIED**
*R-values of thermal insulation*

## *R-Values for Building Materials

The insulating properties of building materials are often specified by *R*-values (or "thermal resistance"), defined for a given thickness $\ell$ of material as:

$$R = \frac{\ell}{k}.$$

The *R*-value of a given piece of material combines the thickness $\ell$ and the thermal conductivity $k$ in one number. Larger $R$ means better insulation from heat or cold. In the United States, *R*-values are given in British units as $\text{ft}^2\cdot\text{h}\cdot\text{F}^\circ/\text{Btu}$ (for example, *R*-19 means $R = 19\,\text{ft}^2\cdot\text{h}\cdot\text{F}^\circ/\text{Btu}$). Table 19–6 gives *R*-values for some common building materials. *R*-values increase directly with material thickness: for example, 2 inches of fiberglass is *R*-6, whereas 4 inches is *R*-12.

## Convection

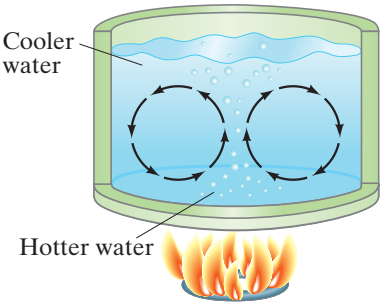
Although liquids and gases are generally not very good conductors of heat, they can transfer heat rapidly by convection. **Convection** is the process whereby heat flows by the bulk movement of molecules from one place to another. Whereas conduction involves molecules (and/or electrons) moving only over small distances and colliding, convection involves the movement of large numbers of molecules over large distances.

A forced-air furnace, in which air is heated and then blown by a fan into a room, is an example of **forced convection**. **Natural convection** occurs as well, and one familiar example is that hot air rises. For instance, the air above a radiator (or other type of heater) expands as it is heated (Chapter 17), and hence its density decreases. Because its density is less than that of the surrounding cooler air, it rises, via buoyancy, just as a log submerged in water floats upward because its density is less than that of water. Warm or cold ocean currents, such as the balmy Gulf Stream, represent natural convection on a global scale. Wind is another example of convection, and weather in general is strongly influenced by convective air currents.

When a pot of water is heated (Fig. 19–23), convection currents are set up as the heated water at the bottom of the pot rises because of its reduced density. That heated water is replaced by cooler water from above. This principle is used in many heating systems, such as the hot-water radiator system shown in Fig. 19–24. Water is heated in the furnace, and as its temperature increases, it expands and rises up along the pipes as shown. This causes the water to circulate in the heating system. Hot water then enters the radiators, heat is transferred by conduction to the air, and the cooled water returns to the furnace. Thus, the water circulates because of convection; pumps are sometimes used to improve circulation. The air throughout the room also becomes heated as a result of convection. The air heated by the radiators rises and is replaced by cooler air, resulting in convective air currents, as shown by the green arrows in Fig. 19–24.

Other types of furnaces also depend on convection. Hot-air furnaces with registers (openings) near the floor often do not have fans but depend on natural convection, which can be appreciable. In other systems, a fan is used. In either case, it is important that cool air can return to the furnace so that convective currents circulate throughout the room to keep it uniformly heated. Be sure not to block the cool air return opening.

The human body produces a great deal of thermal energy. Of the food energy transformed within the body, at best 20% is used to do work, so over 80% appears as thermal energy. During light activity, for example, if this thermal energy is not dissipated, the body temperature would rise about 3 C° per hour. Clearly, the heat generated by the body must be transferred to the outside. Is the heat transferred by conduction? The temperature of the skin in a comfortable environment is 33 to 35°C, whereas the interior of the body is at 37°C. Calculation shows (Problem 82) that, because of this small temperature difference, plus the low thermal conductivity of tissue, direct conduction from the body's interior is not responsible for much of the heat that must leave the body. Instead, the heat is carried to the skin by the blood. In addition to all its other important responsibilities, blood acts as a convective fluid to transfer heat to just beneath the surface of the skin. It is then conducted (over a very short distance) to the surface. Once at the surface, the heat is transferred to the environment by convection, evaporation, and radiation.



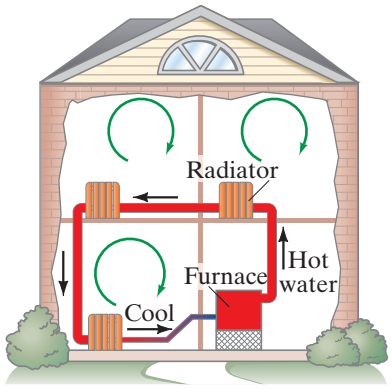


**FIGURE 19–23** Convection currents in a pot of water being heated on a stove.

**PHYSICS APPLIED**
*Body heat: convection by blood*

## Radiation

Convection and conduction require the presence of matter as a medium to carry the heat from the hotter to the colder region. But a third type of heat transfer occurs without any medium at all. All life on Earth depends on the transfer of energy from the Sun, and this energy is transferred to the Earth over empty (or nearly empty) space. This form of energy transfer is heat—since the Sun's surface temperature (6000 K) is much higher than Earth's ($\approx$ 300 K)—and is referred to as **radiation**. The warmth we receive from a fire is mainly radiant energy.

We will see in Chapter 31 that radiation consists of electromagnetic waves. Infrared (IR) wavelengths are mainly responsible for heating the Earth.

The rate at which an object radiates energy has been found to be proportional to the fourth power of the Kelvin temperature, $T$. That is, an object at 2000 K, as compared to one at 1000 K, radiates energy at a rate $2^4 = 16$ times as much. The rate of radiation is also proportional to the area $A$ of the emitting object, so the rate at which energy leaves the radiating object, $Q/t$, is

$$\frac{Q}{t} = \epsilon\sigma A T^4. \qquad \textbf{(19–18)}$$

This is called the **Stefan-Boltzmann equation**, and $\sigma$ is a universal constant called the **Stefan-Boltzmann constant** which has the value

$$\sigma = 5.67 \times 10^{-8}\,\mathrm{W/m^2 \cdot K^4}.$$

The factor $\epsilon$, called the **emissivity**, is a number[†] between 0 and 1 that is characteristic of the surface of the radiating material. Very black surfaces, such as charcoal, have emissivity close to 1, whereas shiny metal surfaces have $\epsilon$ close to zero and thus emit correspondingly less radiation. The value of $\epsilon$ depends somewhat on the temperature of the material.

**PHYSICS APPLIED**
*Dark vs. light clothing*

Not only do shiny surfaces emit less radiation, but they absorb little of the radiation that falls upon them (most is reflected). Black and very dark objects are good emitters ($\epsilon \approx 1$); they also absorb nearly all the radiation that falls on them—which is why light-colored clothing is usually preferable to dark clothing on a hot day. Thus, **a good absorber is also a good emitter**.

Any object not only emits energy by radiation but also absorbs energy radiated by other objects. If an object of emissivity $\epsilon$ and area $A$ is at a temperature $T_1$, it radiates energy at a rate $\epsilon\sigma A T_1^4$. If the object is surrounded by an environment at temperature $T_2$, the rate at which the surroundings radiate energy is proportional to $T_2^4$; then the rate that energy is *absorbed* by the object is proportional to $T_2^4$. The *net* rate of radiant heat flow from the object is given by the equation

$$\frac{Q}{t} = \epsilon\sigma A\left(T_1^4 - T_2^4\right), \qquad \textbf{(19–19)}$$

where $A$ is the surface area of the object, $T_1$ its temperature and $\epsilon$ its emissivity (at temperature $T_1$), and $T_2$ is the temperature of the surroundings. This equation is consistent with the experimental fact that equilibrium between the object and its surroundings is reached when they come to the same temperature. That is, $Q/t$ must equal zero when $T_1 = T_2$, so $\epsilon$ must be the same for emission and absorption. This confirms the idea that a good emitter is a good absorber. Because both the object and its surroundings radiate energy, there is a net transfer of energy from one to the other unless everything is at the same temperature.

From Eq. 19–19, we see that if $T_1 > T_2$, the net flow of heat is from the object to the surroundings, so the object cools. But if $T_1 < T_2$, the net heat flow is from the surroundings into the object, and the object's temperature rises. If different parts of the surroundings are at different temperatures, Eq. 19–19 becomes more complicated.

**PHYSICS APPLIED**
*The body's radiative heat loss*

**EXAMPLE 19–17** **ESTIMATE** **Cooling by radiation.** An athlete is sitting unclothed in a locker room whose dark walls are at a temperature of 15°C. Estimate the body's rate of heat loss by radiation, assuming a skin temperature of 34°C and $\epsilon = 0.70$. Take the surface area of the body not in contact with the chair to be $1.5\,\mathrm{m^2}$.

**APPROACH** We use Eq. 19–19, which requires Kelvin temperatures.

**SOLUTION** We have

$$\frac{Q}{t} = \epsilon\sigma A\left(T_1^4 - T_2^4\right)$$
$$= (0.70)\left(5.67 \times 10^{-8}\,\mathrm{W/m^2 \cdot K^4}\right)(1.5\,\mathrm{m^2})\left[(307\,\mathrm{K})^4 - (288\,\mathrm{K})^4\right] = 120\,\mathrm{W}.$$

**PROBLEM SOLVING**
*Must use the Kelvin temperature*

**NOTE** This resting person's "output" is a bit more than what a 100-W bulb uses.

**PROBLEM SOLVING**
$T_1^4 - T_2^4 \neq (T_1 - T_2)^4$

**NOTE** Avoid a common error: $(T_1^4 - T_2^4) \neq (T_1 - T_2)^4$.

[†] $\epsilon$ is the Greek letter epsilon.

A resting person naturally produces heat internally at a rate of about 100 W, which is less than the heat loss by radiation as calculated in Example 19–17. Hence, our person's temperature would drop, causing considerable discomfort. The body responds to excessive heat loss by increasing its metabolic rate, and shivering is one method by which the body increases its metabolism. Naturally, clothes help a lot. Example 19–17 illustrates that a person may be uncomfortable even if the temperature of the air is, say, 25°C, which is quite a warm room. If the walls or floor are cold, radiation to them occurs no matter how warm the air is. Indeed, it is estimated that radiation accounts for about 50% of the heat loss from a sedentary person in a normal room. Rooms are most comfortable when the walls and floor are warm and the air is not so warm. Floors and walls can be heated by means of hot-water conduits or electric heating elements. Such first-rate heating systems are becoming more common today, and it is interesting to note that 2000 years ago the Romans, even in houses in the remote province of Great Britain, made use of hot-water and steam conduits in the floor to heat their houses.

**PHYSICS APPLIED**
*Room comfort and metabolism*

**PHYSICS APPLIED**
*Warm walls, cool air are more comfortable*

**EXAMPLE 19–18** **ESTIMATE** **Two teapots.** A ceramic teapot ($\epsilon = 0.70$) and a shiny metal one ($\epsilon = 0.10$) each hold 0.75 L of tea at 95°C. (*a*) Estimate the rate of heat loss from each, and (*b*) estimate the temperature drop after 30 min for each. Consider only radiation, and assume the surroundings are at 20°C.

**APPROACH** We are given all the information necessary to calculate the heat loss due to radiation, except for the area. Each teapot holds 0.75 L, and we can approximate it as a cube 10 cm on a side (volume = 1.0 L), with five sides exposed. To estimate the temperature drop in (*b*), we use the concept of specific heat and ignore the contribution of the pots compared to that of the water.

**SOLUTION** (*a*) Each teapot, approximated by a cube 10 cm on a side with five sides exposed, has a surface area of about $5 \times (0.1\ \text{m})^2 = 5 \times 10^{-2}\ \text{m}^2$. The rate of heat loss would be about

$$\begin{aligned}\frac{Q}{t} &= \epsilon\sigma A\left(T_1^4 - T_2^4\right) \\ &= \epsilon\left(5.67 \times 10^{-8}\ \text{W/m}^2\cdot\text{K}^4\right)\left(5 \times 10^{-2}\ \text{m}^2\right)\left[(368\ \text{K})^4 - (293\ \text{K})^4\right] \\ &\approx \epsilon\,(30)\ \text{W},\end{aligned}$$

or about 20 W for the ceramic pot ($\epsilon = 0.70$) and 3 W for the shiny one ($\epsilon = 0.10$).

(*b*) To estimate the temperature drop, we use the specific heat of water and ignore the contribution of the pots. The mass of 0.75 L of water is 0.75 kg. (Recall that $1.0\ \text{L} = 1000\ \text{cm}^3 = 1 \times 10^{-3}\ \text{m}^3$ and $\rho = 1000\ \text{kg/m}^3$.) Using Eq. 19–2 and Table 19–1, we get

$$\frac{Q}{t} = mc\frac{\Delta T}{t}.$$

Then

$$\frac{\Delta T}{t} = \frac{Q/t}{mc} \approx \frac{\epsilon\,(30)\ \text{J/s}}{(0.75\ \text{kg})\left(4186\ \text{J/kg}\cdot\text{C}^\circ\right)} \approx \epsilon\,(0.01)\ \text{C}^\circ/\text{s}.$$

After 30 min (= 1800 s), $\Delta T = \epsilon\,(0.01\ \text{C}^\circ/\text{s})t = \epsilon\,(0.01\ \text{C}^\circ/\text{s})\,(1800\ \text{s}) \approx 18\epsilon\ \text{C}^\circ$, or about 12 C° for the ceramic pot ($\epsilon = 0.70$) and about 2 C° for the shiny one ($\epsilon = 0.10$). The shiny one clearly has an advantage, at least in terms of radiation.

**NOTE** Convection and conduction could play a greater role than radiation.

**PHYSICS APPLIED**
*Radiation from the Sun*

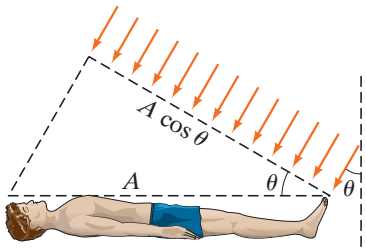

**FIGURE 19–25** Radiant energy striking a body at an angle $\theta$.

Heating of an object by radiation from the Sun cannot be calculated using Eq. 19–19 because this equation assumes a uniform temperature, $T_2$, of the environment surrounding the object, whereas the Sun is essentially a point source. Hence the Sun must be treated as a separate source of energy. About 1350 J of energy from the Sun strikes Earth's atmosphere per second per square meter of area at right angles to the Sun's rays. This number, 1350 W/m$^2$, is called the **solar constant**. The atmosphere may absorb as much as 70% of this energy before it reaches the ground, depending on the cloud cover. On a clear day, about 1000 W/m$^2$ reaches the Earth's surface. An object of emissivity $\epsilon$ with area $A$ facing the Sun absorbs energy from the Sun on a sunny day at a rate, in watts, of about

$$\frac{Q}{t} = (1000\ \text{W/m}^2)\epsilon A \cos\theta, \qquad \textbf{(19–20)}$$

where $\theta$ is the angle between the Sun's rays and a line perpendicular to the area $A$ (Fig. 19–25). That is, $A\cos\theta$ is the "effective" area, at right angles to the Sun's rays.

The explanation for the **seasons** and the polar ice caps (see Fig. 19–26) depends on this $\cos\theta$ factor in Eq. 19–20. The seasons are *not* a result of how close the Earth is to the Sun—in fact, in the Northern Hemisphere, summer occurs when the Earth is farthest from the Sun. It is the angle (i.e., $\cos\theta$) that really matters. Furthermore, the reason the Sun heats the Earth more at midday than at sunrise or sunset is also related to this $\cos\theta$ factor.

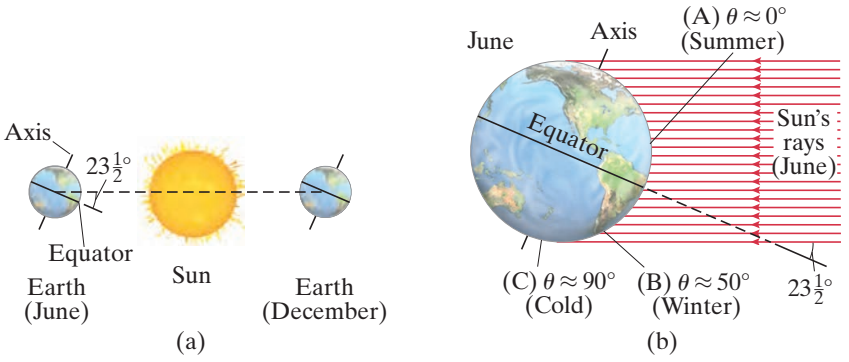

**FIGURE 19–26** (a) Earth's seasons arise from the tilt of Earth's axis relative to its orbit around the Sun. (b) June sunlight makes an angle of $23\frac{1}{2}°$ with the equator. Thus $\theta$ in the southern U.S. (label A in part b) is near 0° (direct summer sunlight), but in the Southern Hemisphere (B), $\theta$ is 50° or 60°, and less heat can be absorbed—hence it is winter. Near the poles (C), there is never strong direct sunlight; $\cos\theta$ varies from about $\frac{1}{2}$ in summer to 0 in winter; so with little heating, ice can form.

**PHYSICS APPLIED**
*Astronomy—size of a star*

**EXAMPLE 19–19** **ESTIMATE** **Star radius.** The giant star Betelgeuse emits radiant energy at a rate $10^4$ times greater than our Sun, whereas its surface temperature is only half (2900 K) that of our Sun. Estimate the radius of Betelgeuse (B), assuming $\epsilon = 1$. The radius of the Sun (S) is $r_S = 7 \times 10^8$ m.

**APPROACH** We assume both stars are spherical, with surface area $4\pi r^2$.

**SOLUTION** We solve Eq. 19–18 for $A$:

$$4\pi r^2 = A = \frac{(Q/t)}{\epsilon\sigma T^4}.$$

Then

$$\frac{r_B^2}{r_S^2} = \frac{(Q/t)_B}{(Q/t)_S}\cdot\frac{T_S^4}{T_B^4} = (10^4)(2^4) = 16 \times 10^4.$$

Hence $r_B = \sqrt{16 \times 10^4}\, r_S = (400)(7 \times 10^8\ \text{m}) \approx 3 \times 10^{11}$ m.

**NOTE** If Betelgeuse were our Sun, it would envelop us (Earth is $1.5 \times 10^{11}$ m from the Sun).

**EXERCISE I** Fanning yourself on a hot day cools you by (*a*) increasing the radiation rate of the skin; (*b*) increasing conductivity; (*c*) decreasing the mean free path of air; (*d*) increasing the evaporation of perspiration; (*e*) none of these.

(a)  (b) 

**FIGURE 19–27** Thermograms of a healthy person's arms and hands (a) before and (b) after smoking a cigarette, showing a temperature decrease due to impaired blood circulation associated with smoking. The thermograms have been color-coded according to temperature; the scale on the right goes from blue (cold) to white (hot).

**PHYSICS APPLIED**
*Thermography*

An interesting application of thermal radiation to diagnostic medicine is **thermography**. A special instrument, the thermograph, scans the body, measuring the intensity of infrared[†] radiation from many points and forming a picture that resembles an X-ray (Fig. 19–27). Areas where metabolic activity is high, such as in tumors, can often be detected on a thermogram as a result of their higher temperature and consequent increased radiation.

# Summary

**Internal energy**, $E_{\text{int}}$, refers to the total energy of all the molecules in an object. For an ideal monatomic gas,

$$E_{\text{int}} = \tfrac{3}{2}NkT = \tfrac{3}{2}nRT \qquad \textbf{(19–1)}$$

where $N$ is the number of molecules and $n$ is the number of moles.

**Heat** refers to the transfer of energy from one object to another because of a difference of temperature. Heat is thus measured in energy units, such as joules.

Heat and internal energy are also sometimes specified in calories or kilocalories (kcal), where

$$1\,\text{kcal} = 4.186\,\text{kJ}$$

is the amount of heat needed to raise the temperature of 1 kg of water by 1 C°.

The **specific heat**, $c$, of a substance is defined as the energy (or heat) required to change the temperature of unit mass of the substance by 1 degree; as an equation,

$$Q = mc\,\Delta T, \qquad \textbf{(19–2)}$$

where $Q$ is the heat absorbed or given off, $\Delta T$ is the temperature increase or decrease, and $m$ is the mass of the substance.

When heat flows between parts of an isolated system, conservation of energy tells us that the heat gained by one part of the system is equal to the heat lost by the other part of the system. This is the basis of **calorimetry**, which is the quantitative measurement of heat exchange.

Exchange of energy occurs, without a change in temperature, whenever a substance changes phase. The **heat of fusion** is the heat required to melt 1 kg of a solid into the liquid phase; it is also equal to the heat given off when the substance changes from liquid to solid. The **heat of vaporization** is the energy required to change 1 kg of a substance from the liquid to the vapor phase; it is also the energy given off when the substance changes from vapor to liquid.

The **first law of thermodynamics** states that the change in internal energy $\Delta E_{\text{int}}$ of a system is equal to the heat *added to* the system, $Q$, minus the work, $W$, done *by* the system:

$$\Delta E_{\text{int}} = Q - W. \qquad \textbf{(19–5)}$$

This important law is a broad restatement of the conservation of energy and is found to hold for all processes.

An **isothermal** process is a process carried out at constant temperature $(\Delta T = 0)$.

In an **adiabatic** process, no heat is exchanged $(Q = 0)$.

An **isobaric** process is one carried out at constant pressure. An **isovolumetric** process is one carried out at constant volume. (See Table 19–3, page 555, for a summary.)

The work done by (or on) a gas to change its volume by $dV$ is $dW = P\,dV$, where $P$ is the pressure.

Work and heat are not functions of the state of a system (as are $P$, $V$, $T$, $n$, and $E_{\text{int}}$) but depend on the type of process that takes a system from one state to another.

The **molar specific heat** of an ideal gas at constant volume, $C_{\text{V}}$, and at constant pressure, $C_{\text{P}}$, are related by

$$C_{\text{P}} - C_{\text{V}} = R, \qquad \textbf{(19–12)}$$

where $R$ is the gas constant. For a monatomic ideal gas, $C_{\text{V}} = \frac{3}{2}R$.

For ideal gases made up of diatomic or more complex molecules, $C_{\text{V}}$ is equal to $\frac{1}{2}R$ times the number of **degrees of freedom** of the molecule. Unless the temperature is very high, some of the degrees of freedom may not be active and so do not contribute. According to the **principle of equipartition of energy**, energy is shared equally among the active degrees of freedom in an amount $\frac{1}{2}kT$ per molecule on average.

When an ideal gas expands (or contracts) adiabatically $(Q = 0)$, the relation $PV^{\gamma} = \text{constant}$ holds, where

$$\gamma = \frac{C_{\text{P}}}{C_{\text{V}}}. \qquad \textbf{(19–15)}$$

Heat is transferred from one place (or object) to another in three different ways: conduction, convection, and radiation.

In **conduction**, energy is transferred through a substance by means of collisions between hotter (faster) molecules or electrons with their slower moving neighbors. The rate of heat flow through area $A$ is

$$\frac{dQ}{dt} = -kA\frac{dT}{dx} \qquad \textbf{(19–7b)}$$

where $dT/dx$ is the *temperature gradient*.

**Convection** is the transfer of energy by the mass movement of molecules over considerable distances.

**Radiation**, which does not require the presence of matter, is energy transfer by electromagnetic waves, such as from the Sun. All objects radiate energy in an amount that is proportional to the fourth power of their Kelvin temperature $(T^4)$ and to their surface area. The energy radiated (or absorbed) also depends on the nature of the surface, which is characterized by the emissivity, $\epsilon$ (dark surfaces absorb and radiate more than do bright shiny ones).

Radiation from the Sun arrives at the surface of the Earth on a clear day at a rate of about $1000\,\text{W/m}^2$.

[†]Infrared radiation is light whose wavelengths are longer than visible light (see Fig. 31–12).

# Questions

1. What happens to the work done on a bottle of orange juice when it is vigorously shaken?
2. When a hot object warms a cooler object, does temperature flow between them? Are the temperature changes of the two objects equal? Explain.
3. (*a*) If two objects of different temperature are placed in contact, will heat naturally flow from the object with higher internal energy to the object with lower internal energy? (*b*) Is it possible for heat to flow even if the internal energies of the two objects are the same? Explain.
4. The specific heat of water is quite large. Explain why this fact makes water particularly good for heating systems (that is, hot-water radiators).
5. In warm regions where tropical plants grow but the temperature may drop below freezing a few times in winter evenings, the destruction of sensitive plants due to freezing can be reduced by watering them in the evening. Explain.
6. Why does water in a metal canteen stay cooler if the cloth jacket surrounding the canteen is kept moist?
7. Explain why burns caused by steam at 100°C on the skin are often more severe than burns caused by water at 100°C.
8. Explain why water cools (its temperature drops) when it evaporates, using the concepts of latent heat and internal energy.
9. Will potatoes cook faster if the water is boiling more vigorously?
10. Very high in the Earth's atmosphere the temperature can be 700°C. Yet an animal there would freeze to death rather than roast. Explain.
11. Use the conservation of energy to explain why the temperature of a well-insulated gas increases when it is compressed—say, by pushing down on a piston—whereas the temperature decreases when the gas expands.
12. Explorers on failed Arctic expeditions have survived by covering themselves with snow. Why would they do that?
13. Why is wet sand at the beach cooler to walk on than dry sand?
14. When hot-air furnaces are used to heat a house, why is it important that there be a vent for air to return to the furnace? What happens if this vent is blocked by a bookcase?
15. Explain why the temperature of a gas increases when it is compressed adiabatically.
16. An ideal monatomic gas expands slowly to twice its volume (1) isothermally; (2) adiabatically; (3) isobarically. Plot each on a $PV$ diagram. In which process is $\Delta E_{\text{int}}$ the greatest, and in which is $\Delta E_{\text{int}}$ the least? In which is $W$ the greatest and the least? In which is $Q$ the greatest and the least?
17. Ceiling fans are sometimes reversible, so that they drive the air down in one season and pull it up in another season. Explain which way you should set the fan (*a*) for summer, (*b*) for winter.
18. Goose down sleeping bags and parkas are often specified as so many inches or centimeters of *loft*, the actual thickness of the garment when it is fluffed up. Explain.
19. Microprocessor chips have a "heat sink" glued on top that looks like a series of fins. Why are they shaped like that?
20. Sea breezes are often encountered on sunny days at the shore of a large body of water. Explain, noting that the temperature of the land rises more rapidly than that of the nearby water.
21. The Earth cools off at night much more quickly when the weather is clear than when cloudy. Why?
22. Explain why air temperature readings are always taken with the thermometer in the shade.
23. A premature baby in an incubator can be dangerously cooled even when the air temperature in the incubator is warm. Explain.
24. A 22°C day is warm, while a swimming pool at 22°C feels cool. Why?
25. In the Northern Hemisphere the amount of heat required to heat a room where the windows face north is much higher than that required where the windows face south. Explain.
26. The floor of a house on a foundation under which the air can flow is often cooler than a floor that rests directly on the ground (such as a concrete slab foundation). Explain.
27. Why is the liner of a **thermos bottle** silvered (Fig. 19–28), and why does it have a vacuum between its two walls?

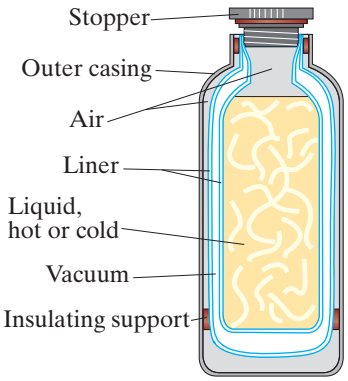

**FIGURE 19–28**
Question 27.

28. Heat loss occurs through windows by the following processes: (1) through the glass panes; (2) through the frame, particularly if it is metal; (3) ventilation leaks around edges; and (4) radiation. (*a*) For the first three, what is (are) the mechanism(s): conduction, convection, or radiation? (*b*) Heavy curtains reduce which of these heat losses? Explain in detail.
29. A paper cup placed among hot coals will burn if empty (note burn spots at top of cup in Fig. 19–29), but won't burn if filled with water. Explain. Forget the marshmallows.

**FIGURE 19–29**
Question 29.

30. On a cold windy day, a window will feel colder than on an equally cold day with no wind. This is true even if no air leaks in near the window. Why?
31. Early in the day, after the Sun has reached the slope of a mountain, there tends to be a gentle upward movement of air. Later, after a slope goes into shadow, there is a gentle downdraft. Explain.
32. A piece of wood lying in the Sun absorbs more heat than a piece of shiny metal. Yet the metal feels hotter than the wood when you pick it up. Explain.
33. An *emergency blanket* is a thin shiny (metal-coated) plastic foil. Explain how it can help to keep an immobile person warm.
34. Explain why cities situated by the ocean tend to have less extreme temperatures than inland cities at the same latitude.

# MisConceptual Questions

**1.** When you put an ice cube in a glass of warm tea, which of the following happens?
(*a*) Cold flows from the ice cube into the tea.
(*b*) Cold flows from the ice cube into the tea and heat flows from the tea into the ice cube.
(*c*) Heat flows from the tea into the ice cube.
(*d*) Neither heat nor cold flows. Only temperature flows between the ice and the tea.

**2.** Both beakers A and B in Fig. 19–30 contain a mixture of ice and water at equilibrium. Which beaker is the coldest, or are they equal in temperature?
(*a*) Beaker A.
(*b*) Beaker B.
(*c*) Equal.

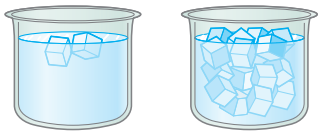

**FIGURE 19–30**
MisConceptual Question 2.

**3.** For objects at thermal equilibrium, which of the following is true?
(*a*) Each is at the same temperature.
(*b*) Each has the same internal energy.
(*c*) Each has the same heat.
(*d*) All of the above.
(*e*) None of the above.

**4.** As heat is slowly added to water, is it possible for the temperature measured by a thermometer in the water to remain constant?
(*a*) Yes, the water could be changing phase.
(*b*) No, adding heat will always change the temperature.
(*c*) Maybe; it depends on the rate at which the heat is added.
(*d*) Maybe; it depends on the initial water temperature.

**5.** Radiation is emitted
(*a*) only by glowing objects such as the Sun.
(*b*) only by objects whose temperature is greater than the temperature of the surroundings.
(*c*) only by objects with more caloric than their surroundings.
(*d*) by any object not at 0 K.[†]
(*e*) only by objects that have a large specific heat.

**6.** Ten grams of water is added to ten grams of ice in an insulated container. Will all of the ice melt?
(*a*) Yes.
(*b*) No.
(*c*) More information is needed.

**7.** Two objects are made of the same material, but they have different masses and temperatures. If the objects are brought into thermal contact, which one will have the greater temperature change?
(*a*) The one with the higher initial temperature.
(*b*) The one with the lower initial temperature.
(*c*) The one with the larger mass.
(*d*) The one with the smaller mass.
(*e*) The one with the higher specific heat.
(*f*) Not enough information.

**8.** It has been a hot summer, so when you arrive at a lake, you decide to go for a swim even though it is nighttime. The water is cold! The next day, you go swimming again during the hottest part of the day, and even though the air is warmer the water is still almost as cold. Why?
(*a*) Water is fairly dense compared with many other liquids.
(*b*) Water remains in a liquid state for a wide range of temperatures.
(*c*) Water has a high bulk modulus.
(*d*) Water has a high specific heat.

**9.** Two equal-mass liquids, initially at the same temperature, are heated for the same time over the same stove. You measure the temperatures and find that one liquid has a higher temperature than the other. Which liquid has the higher specific heat?
(*a*) The cooler one.
(*b*) The hotter one.
(*c*) Both are the same.

**10.** An ideal gas undergoes an isothermal expansion from state A to state B. In this process (use sign conventions, page 549),
(*a*) $Q = 0, \quad \Delta E_{\text{int}} = 0, \quad W > 0.$
(*b*) $Q > 0, \quad \Delta E_{\text{int}} = 0, \quad W < 0.$
(*c*) $Q = 0, \quad \Delta E_{\text{int}} > 0, \quad W > 0.$
(*d*) $Q > 0, \quad \Delta E_{\text{int}} = 0, \quad W > 0.$
(*e*) $Q = 0, \quad \Delta E_{\text{int}} < 0, \quad W < 0.$

**11.** An ideal gas undergoes an isothermal process. Which of the following statements are true? (i) No heat is added to or removed from the gas. (ii) The internal energy of the gas does not change. (iii) The average kinetic energy of the molecules does not change.
(*a*) (i) only.
(*b*) (i) and (ii) only.
(*c*) (i) and (iii) only.
(*d*) (ii) and (iii) only.
(*e*) (i), (ii), and (iii).
(*f*) None of the above.

**12.** An ideal gas is in an insulated cylinder with a movable piston on one end. The piston is slowly pushed down, compressing the gas. The piston is then released, allowing the gas to expand adiabatically. The piston accelerates, gaining kinetic energy. Where does the kinetic energy come from?
(*a*) From the heat developed by the expanding gas.
(*b*) From the decrease in internal energy of the expanding gas.
(*c*) From the increase in internal energy of the expanding gas.
(*d*) Both (*a*) and (*b*).
(*e*) Both (*a*) and (*c*).

**13.** An ideal gas undergoes an isobaric compression and then an isovolumetric process that brings it back to its initial temperature. Had the gas undergone *one isothermal* process instead of those two,
(*a*) the work done on the gas would be the same.
(*b*) the work done on the gas would be less.
(*c*) the work done on the gas would be greater.
(*d*) Need to know the temperature of the isothermal process.

[†]Which means *all* objects because 0 K is unattainable, as discussed in Section 20–10.

# Problems

## 19–1 Heat as Energy Transfer

1. (I) To what temperature will 6800 J of heat raise 3.0 kg of water that is initially at 10.0°C?
2. (II) When a diver jumps into the ocean, water leaks into the gap region between the diver's skin and her wetsuit, forming a water layer about 0.5 mm thick. Assuming the total surface area of the wetsuit covering the diver is about 1.0 $m^2$, and that ocean water enters the suit at 10°C and is warmed by the diver to skin temperature of 35°C, estimate how much energy (in units of candy bars = 300 kcal) is required by this heating process.
3. (II) An average active person consumes about 2500 Cal a day. (*a*) What is this in joules? (*b*) What is this in kilowatt-hours? (*c*) If your power company charges about 12 ¢ per kilowatt-hour, how much would your energy cost per day if you bought it from the power company? Could you feed yourself on this much money per day?
4. (II) A British thermal unit (Btu) is a unit of heat in the British system of units. One Btu is defined as the heat needed to raise 1 lb of water by 1 F°. Show that

$$1\,\text{Btu} = 0.252\,\text{kcal} = 1056\,\text{J}.$$

5. (II) How many joules and kilocalories are generated when the brakes are used to bring a 1200-kg car to rest from a speed of 95 km/h?
6. (II) A water heater can generate 32,000 kJ/h. How much water can it heat from 12°C to 42°C per hour?
7. (II) A small immersion heater is rated at 375 W. Estimate how long it will take to heat a cup of soup (assume this is 250 mL of water) from 15°C to 75°C.

## 19–3 and 19–4 Specific Heat; Calorimetry

8. (I) An automobile cooling system holds 18 L of water. How much heat does the water absorb if its temperature rises from 15°C to 95°C?
9. (I) What is the specific heat of a metal substance if 165 kJ of heat is needed to raise 4.1 kg of the metal from 18.0°C to 37.2°C?
10. (II) Samples of copper, aluminum, and water experience the same temperature rise when they absorb the same amount of heat. What is the ratio of their masses? [*Hint*: See Table 19–1.]
11. (II) (*a*) How long does it take a 750-W coffeepot to bring to a boil 0.75 L of water at sea level initially at 11°C? Assume that the part of the pot which is heated with the water is made of 250 g of aluminum, and that no water boils away. (*b*) For how long could this amount of energy run a 60-W lightbulb?
12. (II) When a 290-g piece of iron at 180°C is placed in a 95-g aluminum calorimeter cup containing 250 g of glycerin at 10°C, the final temperature is observed to be 38°C. Estimate the specific heat of glycerin.
13. (II) What will be the equilibrium temperature when a 265-g block of copper at 245°C is placed in a 145-g aluminum calorimeter cup containing 825 g of water at 12.0°C?
14. (II) A 0.40-kg iron horseshoe just forged and very hot (Fig. 19–31), is dropped into 1.35 L of water in a 0.30-kg iron pot initially at 20.0°C. If the final equilibrium temperature is 25.0°C, estimate the initial temperature of the hot horseshoe.

**FIGURE 19–31**
Problem 14.

15. (II) Estimate the *Calorie content* of 65 g of candy from the following measurements. A 15-g sample of the candy is placed in a small aluminum container of mass 0.325 kg filled with oxygen. This container is placed in 1.75 kg of water in an aluminum calorimeter cup of mass 0.624 kg at an initial temperature of 15.0°C. The oxygen-candy mixture in the small container (a *bomb calorimeter*, page 545) is ignited, and the final temperature of the whole system is 53.5°C.
16. (II) The *heat capacity, C*, of an object is defined as the amount of heat needed to raise its temperature by 1 C°. Thus, to raise the temperature by $\Delta T$ requires heat $Q$ given by

$$Q = C\,\Delta T.$$

(*a*) Write the heat capacity $C$ in terms of the specific heat, $c$, of the material. (*b*) What is the heat capacity of 1.0 kg of water? (*c*) Of 38 kg of water?

17. (II) The 1.20-kg head of a hammer has a speed of 7.5 m/s just before it strikes a nail (Fig. 19–32) and is brought to rest. Estimate the temperature rise of a 14-g iron nail generated by eight such hammer blows done in quick succession. Assume the nail absorbs all the energy.

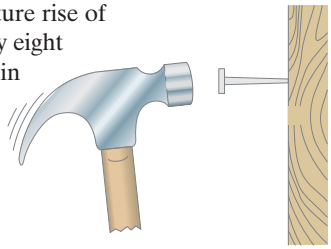

**FIGURE 19–32**
Problem 17.

18. (II) A 215-g sample of a substance is heated to 330°C and then plunged into a 105-g aluminum calorimeter cup containing 185 g of water and a 17-g glass thermometer at 10.5°C. The final temperature is 35.0°C. What is the specific heat of the substance? (Assume no water boils away.)
19. (II) A 0.095-kg aluminum sphere is dropped from the roof of a 55-m-high building. If 65% of the thermal energy produced when it hits the ground is absorbed by the sphere, what is its temperature increase?

## 19–5 Latent Heat

20. (I) If $3.40 \times 10^5$ J of energy is supplied to a container of liquid oxygen at −183°C, how much oxygen can evaporate?
21. (I) How much heat is needed to melt 26.50 kg of silver that is initially at 25°C?
22. (II) What mass of steam at 100°C must be added to 1.00 kg of ice at 0°C to yield liquid water at 30°C?

**23.** (II) During exercise, a person may give off 185 kcal of heat in 25 min by evaporation of water (at 20°C) from the skin. How much water has been lost? [*Hint*: See page 548.]

**24.** (II) A 28-g ice cube at its melting point is dropped into an insulated container of liquid nitrogen. How much nitrogen evaporates if it is at its boiling point of 77 K and has a latent heat of vaporization of 200 kJ/kg? Assume for simplicity that the specific heat of ice is a constant and is equal to its value near its melting point.

**25.** (II) High-altitude mountain climbers do not eat snow, but always melt it first with a stove. To see why, calculate the energy absorbed from your body if you (*a*) eat 1.0 kg of −15°C snow which your body warms to body temperature of 37°C; (*b*) melt 1.0 kg of −15°C snow using a stove and drink the resulting 1.0 kg of water at 2°C, which your body has to warm to 37°C.

**26.** (II) An iron boiler of mass 180 kg contains 710 kg of water at 18°C. A heater supplies energy at the rate of 58,000 kJ/h. How long does it take for the water (*a*) to reach the boiling point, and (*b*) to all have changed to steam?

**27.** (II) A bicyclist consumes 9.0 L of water over the span of 3.5 hours during a race. Making the approximation that 80% of the cyclist's energy goes into evaporating this water (at 20°C) as sweat, how much energy in kcal did the rider use during the ride? [*Hint*: See page 548].

**28.** (II) Determine the latent heat of fusion of mercury using the following calorimeter data: 1.00 kg of solid Hg at its melting point of −39.0°C is placed in a 0.620-kg aluminum calorimeter with 0.400 kg of water at 12.80°C; the resulting equilibrium temperature is 5.06°C.

**29.** (II) At a crime scene, the forensic investigator notes that the 6.2-g lead bullet that was stopped in a doorframe apparently melted completely on impact. Assuming the bullet was shot at room temperature (20°C), what does the investigator calculate as the minimum muzzle velocity of the gun?

**30.** (II) A 55-g bullet traveling at 250 m/s penetrates a block of ice at 0°C and comes to rest within the ice. Assuming that the temperature of the bullet doesn't change appreciably, how much ice is melted as a result of the collision?

**31.** (II) A cube of ice is taken from the freezer at −8.5°C and placed in an 85-g aluminum calorimeter filled with 310 g of water at room temperature of 20.0°C. The final situation is all water at 17.0°C. What was the mass of the ice cube?

## 19–6 and 19–7 First Law of Thermodynamics

[Recall sign conventions, page 549.]

**32.** (I) An ideal gas expands isothermally, performing $4.30 \times 10^3$ J of work in the process. Calculate (*a*) the change in internal energy of the gas, and (*b*) the heat absorbed during this expansion.

**33.** (I) One liter of air is cooled at constant pressure until its volume is halved, and then it is allowed to expand isothermally back to its original volume. Draw the process on a *PV* diagram.

**34.** (II) Sketch a *PV* diagram of the following process: 2.5 L of ideal gas at atmospheric pressure is cooled at constant pressure to a volume of 1.0 L, and then expanded isothermally back to 2.5 L, after which the pressure is increased at constant volume until the original pressure is reached.

**35.** (II) When $6.80 \times 10^5$ J of heat is added to a gas enclosed in a cylinder fitted with a light frictionless piston maintained at atmospheric pressure, the volume is observed to increase from 2.2 $m^3$ to 4.1 $m^3$. Calculate (*a*) the work done by the gas, and (*b*) the change in internal energy of the gas. (*c*) Graph this process on a *PV* diagram.

**36.** (II) The pressure in an ideal gas is cut in half slowly, while being kept in a container with rigid walls. In the process, 425 kJ of heat left the gas. (*a*) How much work was done during this process? (*b*) What was the change in internal energy of the gas during this process?

**37.** (II) A 64-kg ice skater moving at 8.5 m/s glides to a stop. Assuming the ice is at 0°C and that 50% of the heat generated by friction is absorbed by the ice, how much ice melts?

**38.** (II) A 1.0-L volume of air initially at 3.5 atm of (gauge) pressure is allowed to expand isothermally until the (gauge) pressure is 1.0 atm. It is then compressed at constant pressure to its initial volume, and lastly is brought back to its original pressure by heating at constant volume. (*a*) Draw the process on a *PV* diagram, including numbers and labels for the axes. (*b*) How much work does the 1.0 L of air do in this process?

**39.** (II) Consider the following two-step process. Heat is allowed to flow out of an ideal gas at constant volume so that its pressure drops from 2.2 atm to 1.4 atm. Then the gas expands at constant pressure, from a volume of 5.9 L to 9.3 L, where the temperature reaches its original value. Calculate (*a*) the total work done by the gas in the process, (*b*) the change in internal energy of the gas in the process, and (*c*) the total heat flow into or out of the gas.

**40.** (II) Suppose 3.20 mol of an ideal gas of volume $V_1 = 3.50\ m^3$ at $T_1 = 295$ K is allowed to expand isothermally to $V_2 = 7.00\ m^3$ at $T_2 = 295$ K. Determine (*a*) the work done by the gas, (*b*) the heat added to the gas, and (*c*) the change in internal energy of the gas.

**41.** (II) In an engine, an almost ideal gas is compressed adiabatically to half its volume. In doing so, 2630 J of work is done on the gas. (*a*) How much heat flows into or out of the gas? (*b*) What is the change in internal energy of the gas? (*c*) Does its temperature rise or fall?

**42.** (II) An ideal gas expands at a constant total pressure of 2.5 atm from 410 mL to 690 mL. Heat then flows out of the gas at constant volume, and the pressure and temperature are allowed to drop until the temperature reaches its original value. Calculate (*a*) the total work done by the gas in the process, and (*b*) the total heat flow into the gas.

**43.** (II) Determine (*a*) the work done and (*b*) the change in internal energy of 1.00 kg of water when it is all boiled to steam at 100°C. Assume a constant pressure of 1.00 atm.

**44.** (II) How much work is done by a pump to slowly compress, isothermally, 3.20 L of nitrogen at 0°C and 1.00 atm to 1.80 L at 0°C?

**45.** (III) Determine the work done by 1.00 mol of a van der Waals gas (Section 18–6) when it expands from volume $V_1$ to $V_2$ isothermally.

**46.** (III) When a gas is taken from a to c along the curved path in Fig. 19–33, the work done by the gas is $W = -35\,\text{J}$ and the heat added to the gas is $Q = -175\,\text{J}$. Along path abc, the work done by the gas is $W = -56\,\text{J}$. (That is, 56 J of work is done *on* the gas.) (*a*) What is $Q$ for path abc? (*b*) If $P_c = \frac{1}{2}P_b$, what is $W$ for path cda? (*c*) What is $Q$ for path cda? (*d*) What is $E_{\text{int,a}} - E_{\text{int,c}}$? (*e*) If $E_{\text{int,d}} - E_{\text{int,c}} = 42\,\text{J}$, what is $Q$ for path da?

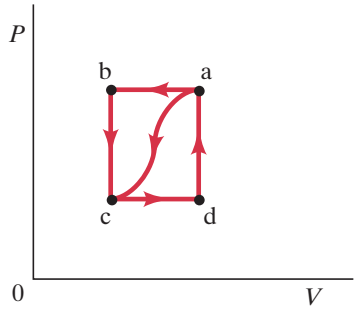

**FIGURE 19–33**
Problems 46, 47, 48.

**47.** (III) In the process of taking a gas from state a to state c along the curved path shown in Fig. 19–33, 85 J of heat leaves the system and 55 J of work is done *on* the system. (*a*) Determine the change in internal energy, $E_{\text{int,a}} - E_{\text{int,c}}$. (*b*) When the gas is taken along the path cda, the work done by the gas is $W = 38\,\text{J}$. How much heat $Q$ is added to the gas in the process cda? (*c*) If $P_a = 2.2P_d$, how much work is done by the gas in the process abc? (*d*) What is $Q$ for path abc? (*e*) If $E_{\text{int,a}} - E_{\text{int,b}} = 15\,\text{J}$, what is $Q$ for the process bc? Here is a summary of what is given:

$$\begin{aligned} Q_{a\to c} &= -85\,\text{J} \\ W_{a\to c} &= -55\,\text{J} \\ W_{cda} &= 38\,\text{J} \\ E_{\text{int,a}} - E_{\text{int,b}} &= 15\,\text{J} \\ P_a &= 2.2P_d. \end{aligned}$$

**48.** (III) Suppose a gas is taken clockwise around the rectangular cycle shown in Fig. 19–33, starting at b, then to a, to d, to c, and returning to b. Using the values given in Problem 47, (*a*) describe each leg of the process, and then calculate (*b*) the net work done during the cycle, (*c*) the total internal energy change during the cycle, and (*d*) the net heat flow during the cycle. (*e*) What percentage of the *intake* heat was turned into usable work: i.e., how efficient is this "rectangular" cycle (give as a percentage)?

## 19–8 Molecular Specific Heat for Gases; Equipartition of Energy

**49.** (I) What is the internal energy of 5.40 mol of an ideal diatomic gas at 2450 K, assuming all possible degrees of freedom are active?

**50.** (I) If a heater supplies $1.8 \times 10^6\,\text{J/h}$ to a room $3.5\,\text{m} \times 4.6\,\text{m} \times 3.0\,\text{m}$ containing air at 20°C and 1.0 atm, by how much will the temperature rise in one hour, assuming no losses of heat or air mass to the outside? Assume air is an ideal diatomic gas with molecular mass 29.

**51.** (II) Show that if the molecules of a gas have $f$ degrees of freedom, then theory predicts $C_V = \frac{1}{2}fR$ and $C_P = \frac{1}{2}(f+2)R$.

**52.** (II) A certain monatomic gas has specific heat $c_V = 0.0356\,\text{kcal/kg}\cdot\text{C}^\circ$, which changes little over a wide temperature range. What is the atomic mass of this gas? What gas is it?

**53.** (II) Show that the work done by $n$ moles of an ideal gas when it expands adiabatically is $W = nC_V(T_1 - T_2)$, where $T_1$ and $T_2$ are the initial and final temperatures, and $C_V$ is the molar specific heat at constant volume.

**54.** (II) An audience of 1600 fills a concert hall of volume $22{,}000\,\text{m}^3$. If there were no ventilation, by how much would the temperature of the air rise over a period of 2.0 h due to the metabolism of the people (70 W/person)?

**55.** (II) The specific heat at constant volume of a particular gas is $0.182\,\text{kcal/kg}\cdot\text{K}$ at room temperature, and its molecular mass is 34. (*a*) What is its specific heat at constant pressure? (*b*) What do you think is the molecular structure of this gas?

**56.** (II) A 2.00-mole sample of $N_2$ gas at 0°C is heated to 150°C at constant pressure (1.00 atm). Determine (*a*) the change in internal energy, (*b*) the work the gas does, and (*c*) the heat added to it.

**57.** (III) A 1.00-mol sample of an ideal diatomic gas at a pressure of 1.00 atm and temperature of 460 K undergoes a process in which its pressure increases linearly with temperature ($P = P_0 + aT$). The final temperature and pressure are 720 K and 1.60 atm. (*a*) First graph the process on a $PV$ diagram. Then determine (*b*) the change in internal energy, (*c*) the work done by the gas, and (*d*) the heat added to the gas. (Assume five active degrees of freedom.)

## 19–9 Adiabatic Expansion of a Gas

**58.** (II) A 1.00-mol sample of an ideal diatomic gas, originally at 1.00 atm and 20°C, expands adiabatically to 1.75 times its initial volume. What are the final pressure and temperature for the gas? (Assume no molecular vibration.)

**59.** (II) Show, using Eqs. 19–7 and 19–16, that the work done by a gas that slowly expands adiabatically from pressure $P_1$ and volume $V_1$, to $P_2$ and $V_2$, is given by $W = (P_1V_1 - P_2V_2)/(\gamma - 1)$.

**60.** (II) A 3.65-mol sample of an ideal diatomic gas expands adiabatically from a volume of $0.1210\,\text{m}^3$ to $0.750\,\text{m}^3$. Initially the pressure was 1.00 atm. Determine: (*a*) the initial and final temperatures; (*b*) the change in internal energy; (*c*) the heat lost by the gas; (*d*) the work done *on* the gas. (Assume no molecular vibration.)

**61.** (II) An ideal monatomic gas, consisting of 2.5 mol of volume $0.086\,\text{m}^3$, expands adiabatically. The initial and final temperatures are 25°C and −68°C. What is the final volume of the gas?

**62.** (III) A 1.00-mol sample of an ideal monatomic gas, originally at a pressure of 1.00 atm, undergoes a three-step process: (1) it is expanded adiabatically from $T_1 = 588\,\text{K}$ to $T_2 = 389\,\text{K}$; (2) it is compressed at constant pressure until its temperature reaches $T_3$; (3) it then returns to its original pressure and temperature by a constant-volume process. (*a*) Plot these processes on a $PV$ diagram. (*b*) Determine $T_3$. (*c*) Calculate the change in internal energy, the work done by the gas, and the heat added to the gas for each process, and (*d*) for the complete cycle.

**63.** (III) Consider a **parcel of air** moving to a different altitude $y$ in the Earth's atmosphere (Fig. 19–34). As the parcel changes altitude it acquires the pressure $P$ of the surrounding air. From Eq. 13–4 we have

$$\frac{dP}{dy} = -\rho g$$

where $\rho$ is the parcel's altitude-dependent mass density.

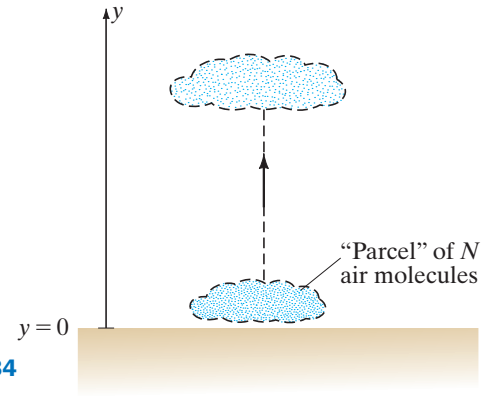

**FIGURE 19–34**
Problem 63.

During this motion, the parcel's volume will change and, because air is a poor heat conductor, we assume this expansion or contraction will take place adiabatically. (*a*) Starting with Eq. 19–16, $PV^\gamma = \text{constant}$, show that for an ideal gas undergoing an adiabatic process, $P^{1-\gamma}T^\gamma = \text{constant}$. Then show that the parcel's pressure and temperature are related by

$$(1-\gamma)\frac{dP}{dy} + \gamma\frac{P}{T}\frac{dT}{dy} = 0$$

and thus

$$(1-\gamma)(-\rho g) + \gamma\frac{P}{T}\frac{dT}{dy} = 0.$$

(*b*) Use the ideal gas law with the result from part (*a*) to show that the change in the parcel's temperature with change in altitude is given by

$$\frac{dT}{dy} = \frac{1-\gamma}{\gamma}\frac{mg}{k}$$

where $m$ is the average mass of an air molecule and $k$ is the Boltzmann constant. (*c*) Given that air is a diatomic gas with an average molecular mass of 29, show that $dT/dy = -9.8\,\text{C°/km}$. This value is called the **adiabatic lapse rate** for dry air. (*d*) In California, the prevailing westerly winds descend from one of the highest elevations (the 4000-m Sierra Nevada mountains) to one of the lowest elevations (Death Valley, $-100$ m) in the continental United States. If a dry wind has a temperature of $-5$°C at the top of the Sierra Nevada, what is the wind's temperature after it has descended to Death Valley?

## 19–10 Conduction, Convection, Radiation

**64.** (I) One end of a 64-cm-long copper rod with a diameter of 2.0 cm is kept at 460°C, and the other is immersed in water at 22°C. Calculate the heat conduction rate along the rod.

**65.** (I) Calculate the rate of heat flow by conduction through the windows of Example 19–16, assuming that there are strong gusty winds and the external temperature is $-5$°C.

**66.** (I) (*a*) How much power is radiated by a tungsten sphere (emissivity $\epsilon = 0.35$) of radius 19 cm at a temperature of 25°C? (*b*) If the sphere is enclosed in a room whose walls are kept at $-5$°C, what is the *net* flow rate of energy out of the sphere?

**67.** (II) How long does it take the Sun to melt a block of ice at 0°C with a flat horizontal area 1.0 m$^2$ and thickness 1.0 cm? Assume that the Sun's rays make an angle of 35° with the vertical and that the emissivity of ice is 0.050.

**68.** (II) **Heat conduction to skin**. Suppose 150 W of heat flows by conduction from the blood capillaries beneath the skin to the body's surface area of 1.5 m$^2$. If the temperature difference is 0.50 C°, estimate the average distance of capillaries below the skin surface.

**69.** (II) Two rooms, each a cube 4.0 m per side, share a 14-cm-thick brick wall. Because of a number of 100-W lightbulbs in one room, the air is at 30°C, while in the other room it is at 10°C. How many of the 100-W bulbs are needed to maintain the temperature difference across the wall?

**70.** (II) A ceramic teapot ($\epsilon = 0.70$) and a shiny metal one ($\epsilon = 0.10$) each hold 0.55 L of tea at 85°C. (*a*) Estimate the rate of heat loss from each, and (*b*) estimate the temperature drop after 30 min for each. Consider only radiation, and assume the surroundings are at 20°C.

**71.** (II) A copper rod and an aluminum rod of the same length and cross-sectional area are attached end to end (Fig. 19–35). The copper end is placed in a furnace maintained at a constant temperature of 205°C. The aluminum end is placed in an ice bath held at a constant temperature of 0.0°C. Calculate the temperature at the point where the two rods are joined.

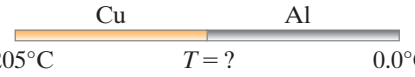

**FIGURE 19–35**
Problem 71.

**72.** (III) A cylindrical pipe has inner radius $R_1$ and outer radius $R_2$. The interior of the pipe carries hot water at temperature $T_1$. The temperature outside is $T_2$ $(< T_1)$. (*a*) Show that the rate of heat loss for a length $\ell$ of pipe is

$$\frac{dQ}{dt} = \frac{2\pi k(T_1 - T_2)\ell}{\ln(R_2/R_1)},$$

where $k$ is the thermal conductivity of the pipe. (*b*) Suppose the pipe is steel with $R_1 = 3.3$ cm, $R_2 = 4.0$ cm, and $T_2 = 18$°C. If the pipe holds still water at $T_1 = 71$°C, what will be the initial rate of change of its temperature? (*c*) Suppose water at 71°C enters the pipe and moves at a speed of 8.0 cm/s. What will be its temperature drop per centimeter of travel?

***73.** (III) Suppose the insulating qualities of the wall of a house come mainly from a 4.0-in. layer of brick and an $R$-19 layer of insulation, as shown in Fig. 19–36. What is the total rate of heat loss through such a wall, if its total area is 195 ft$^2$ and the temperature difference across it is 35 F°? Give result both in British and in SI units.

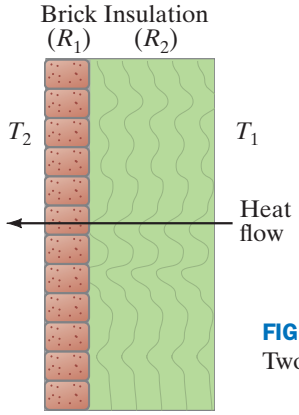

**FIGURE 19–36** Problem 73.
Two layers insulating a wall.

# General Problems

**74.** A soft-drink can contains about 0.35 kg of liquid at 5°C. Drinking this liquid can actually consume some of the fat in the body, since energy is needed to warm the liquid to body temperature (37°C). How many food Calories should the drink have so that it is in perfect balance with the heat needed to warm the liquid (essentially water)?

**75.** (*a*) Estimate the total power radiated into space by the Sun, assuming it to be a perfect emitter at $T = 5500$ K. The Sun's radius is $7.0 \times 10^8$ m. (*b*) From this, determine the power per unit area arriving at the Earth, $1.5 \times 10^{11}$ m away (Fig. 19–37).

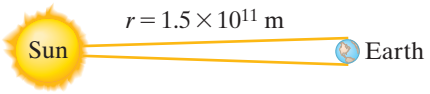

**FIGURE 19–37**
Problem 75.

**76.** To get an idea of how much thermal energy is contained in the world's oceans, estimate the heat liberated when a cube of ocean water, 1 km on each side, is cooled by 1 K. (Approximate the ocean water as pure water for this estimate.)

**77.** What will be the final result when equal masses of ice at 0°C and steam at 100°C are mixed together?

**78.** During light activity, a 70-kg person may generate 200 kcal/h. Assuming that 20% of this goes into useful work and the other 80% is converted to heat, estimate the temperature rise of the body after 45 min if none of this heat is transferred to the environment.

**79.** A mountain climber wears a goose-down jacket 3.8 cm thick with total surface area 0.95 $m^2$. The temperature at the surface of the clothing is −18°C and at the skin is 34°C. Determine the rate of heat flow by conduction through the jacket assuming (*a*) it is dry and the thermal conductivity $k$ is that of goose down, and (*b*) the jacket is wet, so $k$ is that of water and the jacket has matted to 0.50 cm thickness.

**80.** A marathon runner has an average metabolism rate of about 950 kcal/h during a race. If the runner has a mass of 62 kg, estimate how much water she would lose to evaporation from the skin for a race that lasts 2.2 h.

**81.** A house has well-insulated walls 19.5 cm thick (assume conductivity of air) and area 410 $m^2$, a roof of wood 5.5 cm thick and area 250 $m^2$, and uncovered windows 0.65 cm thick and total area 33 $m^2$. (*a*) Assuming that heat is lost only by conduction, calculate the rate at which heat must be supplied to this house to maintain its inside temperature at 23°C if the outside temperature is −15°C. (*b*) If the house is initially at 15°C, estimate how much heat must be supplied to raise the temperature to 23°C within 30 min. Assume that only the air needs to be heated and that its volume is 750 $m^3$. (*c*) If natural gas costs \$0.080/kg and its heat of combustion is $5.4 \times 10^7$ J/kg, what is the monthly cost to maintain the house as in part (*a*) for 24 h each day, assuming 90% of the heat produced is used to heat the house? Take the specific heat of air to be 0.24 kcal/kg · C°.

**82.** Estimate the rate at which heat can be conducted from the interior of the body to the surface. As a model, assume that the thickness of tissue is 4.0 cm, that the skin is at 34°C and the interior at 37°C, and that the surface area is 1.5 $m^2$. Compare this to the measured value of about 230 W that must be dissipated by a person working lightly. This clearly shows the necessity of *convective cooling* by the blood.

**83.** In a typical squash game (Fig. 19–38), two people hit a soft rubber ball at a wall. Assume that the ball hits the wall at a velocity of 22 m/s and bounces back at a velocity of 11 m/s, and that the kinetic energy lost in the process heats the ball. What will be the temperature increase of the ball after one bounce? (The specific heat of rubber is about 1200 J/kg · C°.)

**FIGURE 19–38**
Problem 83.

**84.** A bicycle pump is a cylinder 22 cm long and 3.0 cm in diameter. The pump contains air at 20.0°C and 1.0 atm. If the outlet at the base of the pump is blocked and the handle is pushed in very quickly, compressing the air to half its original volume, how hot does the air in the pump become?

**85.** A microwave oven is used to heat 250 g of water. On its maximum setting, the oven can raise the temperature of the liquid water from 20°C to 100°C in 1 min 45 s (= 105 s). (*a*) At what rate does the oven put energy into the liquid water? (*b*) If the power input from the oven to the water remains constant, determine how many grams of water will boil away if the oven is operated for 2 min (rather than just 1 min 45 s).

**86.** The temperature within the Earth's crust increases about 1.0 C° for each 30 m of depth. The thermal conductivity of the crust is 0.80 J/s · C° · m. (*a*) Determine the heat transferred from the interior to the surface for the entire Earth in 1.0 h. (*b*) Compare this heat to the 1000 W/$m^2$ that reaches the Earth's surface in 1.0 h from the Sun.

**87.** An ice sheet forms on a lake. The air above the sheet is at −18°C, whereas the water is at 0°C. Assume that the heat of fusion of the water freezing on the lower surface is conducted through the sheet to the air above. How much time will it take to form a sheet of ice 18 cm thick?

**88.** An iron meteorite melts when it enters the Earth's atmosphere. If its initial temperature was −105°C outside of Earth's atmosphere, calculate the minimum velocity the meteorite must have had before it entered Earth's atmosphere.

**89.** A 0.15-mole sample of ideal monatomic gas is in a balloon at an absolute pressure of 1.10 atm. Initially, the volume of the balloon is 3.0 liters. The balloon is gently heated until the rms speed of the atoms has increased by 16%. The pressure does not change appreciably during the expansion. How much heat flows into the gas?

**90.** A reciprocating compressor is a device that compresses air by a back-and-forth straight-line motion, like a piston in a cylinder. Consider a reciprocating compressor running at 120 rpm. During a compression stroke, 1.00 mol of air is compressed. The initial temperature of the air is 390 K, the engine of the compressor is supplying 7.5 kW of power to compress the air, and heat is being removed at the rate of 1.5 kW. Calculate the temperature change per compression stroke.

**91.** A scuba diver releases a 3.60-cm-diameter (spherical) bubble of air from a depth of 14.0 m. Assume the temperature is constant at 298 K, and that the air behaves as an ideal gas. (*a*) How large is the bubble when it reaches the surface? (*b*) Sketch a *PV* diagram for the process. (*c*) Apply the first law of thermodynamics to the bubble, and find the work done by the air in rising to the surface, the change in its internal energy, and the heat added or removed from the air in the bubble as it rises. Take the density of water to be $1000\ \text{kg/m}^3$.

**92.** Suppose 3.0 mol of neon (a monatomic gas, assume ideal) at STP are compressed slowly and isothermally to 0.22 the original volume. The gas is then allowed to expand quickly and adiabatically back to its original volume. Find the highest and lowest temperatures and pressures attained by the gas, and show on a *PV* diagram where these values occur.

**93.** The temperature of the glass surface of a 75-W lightbulb is 75°C when the room temperature is 18°C. Estimate the temperature of a 150-W lightbulb with a glass bulb the same size. Consider only radiation, and assume that 90% of the energy is emitted as heat.

**94.** A *diesel engine* accomplishes ignition without a spark plug by an adiabatic compression of air to a temperature above the ignition temperature of the diesel fuel, which is injected into the cylinder at the peak of the compression. Suppose air is taken into the cylinder at 280 K and volume $V_1$ and is compressed adiabatically to $560°\text{C} (\approx 1000°\text{F})$ and volume $V_2$. Assuming that the air behaves as an ideal gas whose ratio of $C_P$ to $C_V$ is 1.4, calculate the compression ratio $V_1/V_2$ of the engine.

**95.** At very low temperatures, the molar specific heat of many substances varies as the cube of the absolute temperature:

$$C = k\frac{T^3}{T_0^3},$$

which is sometimes called Debye's law. For rock salt, $T_0 = 281\ \text{K}$ and $k = 1940\ \text{J/mol} \cdot \text{K}$. Determine the heat needed to raise 2.75 mol of salt from 22.0 K to 46.0 K.

**96.** In a cold environment, a person can lose heat by conduction and radiation at a rate of about 200 W. Estimate how long it would take for the body temperature to drop from 36.6°C to 35.6°C if metabolism were nearly to stop. Assume a mass of 65 kg. (See Table 19–1.)

**97.** (*a*) Using the solar constant, estimate the rate at which the whole Earth receives energy from the Sun. (*b*) Assume the Earth radiates an equal amount back into space (that is, the Earth is in equilibrium). Then, assuming the Earth is a perfect emitter $(\epsilon = 1.0)$, estimate its average surface temperature. [*Hint*: Discuss why you use area $A = \pi r_E^2$ or $A = 4\pi r_E^2$ in each part.]

**98.** Approximately how long should it take 8.2 kg of ice at 0°C to melt when it is placed in a carefully sealed Styrofoam ice chest of dimensions $25\ \text{cm} \times 35\ \text{cm} \times 55\ \text{cm}$ whose walls are 1.5 cm thick? Assume that the conductivity of Styrofoam is double that of air and that the outside temperature is 34°C.

**99.** Calculate what will happen when 1000 J of heat is added to 100 grams of (*a*) ice at −20°C, (*b*) ice at 0°C, (*c*) water at 10°C, (*d*) water at 100°C, and (*e*) steam at 110°C.

**100.** A 12-g lead bullet traveling at 220 m/s passes through a thin wall and emerges at a speed of 160 m/s. If the bullet absorbs 50% of the heat generated, (*a*) what will be the temperature rise of the bullet? (*b*) If the bullet's initial temperature was 20°C, will any of the bullet melt, and if so, how much?

**101.** A leaf of area $40\ \text{cm}^2$ and mass $4.5 \times 10^{-4}\ \text{kg}$ directly faces the Sun on a clear day. The leaf has an emissivity of 0.85 and a specific heat of $0.80\ \text{kcal/kg} \cdot \text{K}$. (*a*) Estimate the energy absorbed per second by the leaf from the Sun, and then (*b*) estimate the rate of rise of the leaf's temperature. (*c*) Will the temperature rise continue for hours? Why or why not? (*d*) Calculate the temperature the leaf would reach if it lost all its heat by radiation to the surroundings at 24°C. (*e*) In what other ways can the heat be dissipated by the leaf?

**102.** Using the result of part (*a*) in Problem 101, take into account radiation from the leaf to calculate how much water must be transpired (evaporated) by the leaf per hour to maintain a temperature of 35°C.

**103.** A house thermostat is normally set to 22°C, but at night it is turned down to 16°C for 9.0 h. Estimate how much more heat would be needed (state as a percentage of daily usage) if the thermostat were not turned down at night. Assume that the outside temperature averages 0°C for the 9.0 h at night and 8°C for the remainder of the day, and that the heat loss from the house is proportional to the temperature difference inside and out. To obtain an estimate from the data, you must make other simplifying assumptions; state what these are.

**104.** *Metabolizing* 1.0 kg of fat results in about $3.7 \times 10^7\ \text{J}$ of internal energy in the body. (*a*) In one day, how much fat does the body burn to maintain the body temperature of a person staying in bed and metabolizing at an average rate of 95 W? (*b*) How long would it take to burn 1.0 kg of fat this way assuming there is no food intake?

## ANSWERS TO EXERCISES

**A:** (*b*).
**B:** (*c*).
**C:** The phase change, liquid to ice (second process). The latent heat is large.
**D:** 0.21 kg.
**E:** 700 J.
**F:** Less.
**G:** $-6.8 \times 10^3\ \text{J}$.
**H:** The drapes trap a layer of air between the inside of the window and the room, which acts as an excellent insulator.
**I:** (*d*).

There are many uses for a heat engine such as a coal or gas burning power plant, or a steam locomotive. The photograph shows an old locomotive producing steam that does work on a piston which moves linkage to turn the locomotive wheels. The efficiency of any engine is limited by nature as described in the second law of thermodynamics. This great law is best stated in terms of a quantity called entropy, which is *not* conserved, but instead is constrained always to increase in any real process. Entropy is a measure of disorder. The second law of thermodynamics tells us that as time moves forward, the disorder in the universe increases.

We also discuss practical matters such as heat engines, heat pumps, refrigerators, and air conditioners.

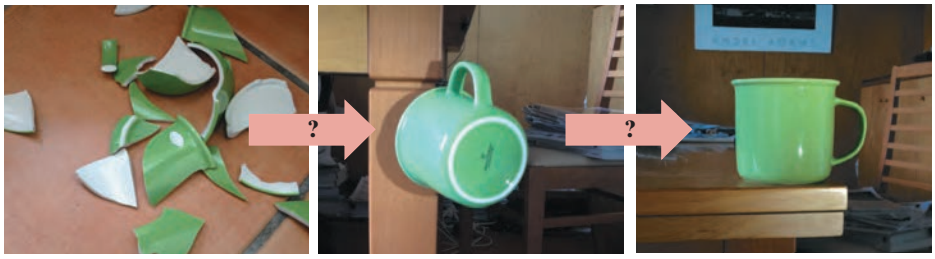
## CHAPTER-OPENING QUESTION—Guess now!

Fossil-fuel electric generating plants produce "thermal pollution." Part of the heat produced by the burning fuel is not converted to electric energy. The reason for this waste is



**(a)** the efficiency is higher if some heat is allowed to escape.
**(b)** engineering technology has not yet reached the point where 100% waste heat recovery is possible.
**(c)** when converting heat to useful work, you cannot avoid producing waste heat. This is a fundamental property of nature.
**(d)** the plants rely on fossil fuels, not nuclear fuel.
**(e)** None of the above.

In this final Chapter on heat and thermodynamics, we discuss the famous second law of thermodynamics, and the quantity "entropy" that arose from this fundamental law and is its quintessential expression. We also discuss heat engines—the useful engines that transform heat into work in power plants, trains, and motor vehicles, which first showed us that a new law was needed. Finally, we briefly discuss the third law of thermodynamics.

# 20–1 The Second Law of Thermodynamics—Introduction

The first law of thermodynamics states that energy is conserved. There are, however, many processes we can imagine that conserve energy but are not observed to occur in nature. For example, when a hot object is placed in contact with a cold object, heat flows from the hotter one to the colder one, never spontaneously from colder to hotter. If heat were to leave the colder object and pass to the hotter one, energy could still be conserved. Yet it does not happen spontaneously.[†] As a second example, consider what happens when you drop a rock and it hits the ground. The initial potential energy of the rock changes to kinetic energy as the rock falls. When the rock hits the ground, this energy in turn is transformed into internal energy of the rock and the ground in the vicinity of the impact; the molecules move faster and the temperature rises slightly. But have you seen the reverse happen—a rock at rest on the ground suddenly rise up in the air because the thermal energy of molecules is transformed into kinetic energy of the rock as a whole? Energy could be conserved in this process, yet we never see it happen.

There are many other examples of processes that occur in nature but whose reverse does not. Here are two more. (1) If you put a layer of salt in a jar and cover it with a layer of similar-sized grains of pepper, when you shake it you get a thorough mixture. But no matter how long you shake it, the mixture does not separate into two layers again. (2) Coffee cups and glasses break if you drop them. But they do not go back together spontaneously (Fig. 20–1).

(a) Initial state. (b) Later: cup reassembles and rises up. (c) Later still: cup lands on table.

**FIGURE 20–1** Have you ever observed this process, a broken cup spontaneously reassembling and rising up onto a table? This process could conserve energy and other laws of mechanics.

The first law of thermodynamics (conservation of energy) would not be violated if any of these processes occurred in reverse. To explain this lack of reversibility, scientists in the latter half of the nineteenth century formulated a new principle known as the second law of thermodynamics.

The **second law of thermodynamics** is a statement about which processes occur in nature and which do not. It can be stated in a variety of ways, all of which are equivalent. One statement, due to R. J. E. Clausius (1822–1888), is that

> **heat can flow spontaneously from a hot object to a cold object; heat will not flow spontaneously from a cold object to a hot object.**

*SECOND LAW OF THERMODYNAMICS (Clausius statement)*

Since this statement applies to one particular process, it is not obvious how it applies to other processes. A more general statement is needed that will include other possible processes in a more obvious way.

The development of a general statement of the second law of thermodynamics was based partly on the study of heat engines. A **heat engine** is any device that changes thermal energy into mechanical work, such as a steam engine or an automobile engine. We now examine heat engines, both from a practical point of view and to show their importance in developing the second law of thermodynamics.

[†]By spontaneously, we mean by itself without input of work of some sort. (A refrigerator does move heat from a cold environment to a warmer one, but only because its motor does work—Section 20–4.)

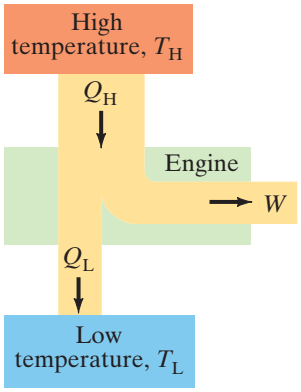


**FIGURE 20–2** Schematic diagram of energy transfers for a heat engine.

**CAUTION**

*Sign convention only for heat engines:* $Q_H > 0,\ Q_L > 0,\ W > 0$

# 20–2 Heat Engines

It is easy to produce thermal energy by doing work—for example, by simply rubbing your hands together briskly, or indeed by any frictional process. But to get work from thermal energy is more difficult, and a practical device was invented only about 1700, the steam engine.

The basic idea behind any heat engine is that mechanical energy can be obtained from thermal energy only when heat is allowed to flow from a high temperature to a low temperature. In the process, some of the heat can then be transformed to mechanical work, as diagrammed schematically in Fig. 20–2. Useful heat engines run in a *repeating cycle*: that is, the system returns repeatedly to its starting point and thus can run continuously. In each cycle the change in internal energy of the system is $\Delta E_{int} = 0$ because it returns to the starting state. Thus a heat input $Q_H$ at a high temperature $T_H$ is partly transformed into work $W$ and partly exhausted as heat $Q_L$ at a lower temperature $T_L$ (Fig. 20–2). By conservation of energy, $Q_H = W + Q_L$. The high and low temperatures, $T_H$ and $T_L$, are called the **operating temperatures** of the engine. Note that we are now using a new (and intuitive) sign convention, but only for heat engines: we take $Q_H$, $Q_L$, and $W$ as always positive. The direction of each energy transfer is shown by the arrow on the applicable diagram, such as Fig. 20–2.

**PHYSICS APPLIED**

*Engines*

## Steam Engine and Internal Combustion Engine

The operation of a steam engine is illustrated in Fig. 20–3. Steam engines are of two main types, each using steam heated by combustion of coal, oil or gas, or by nuclear energy. In a reciprocating engine, Fig. 20–3a, the heated steam passes through the intake valve and expands against a piston, forcing it to move. As the piston returns to its original position, it forces the gases out the exhaust valve. A steam turbine, Fig. 20–3b, is very similar except that the reciprocating piston is replaced by a rotating turbine that resembles a paddlewheel with many sets of blades. Most of our electricity today is generated using steam turbines.[†] The material that is heated and cooled, steam in this case, is called the **working substance**. In an old-time steam engine (see page 576), the high temperature is obtained by burning wood, coal, oil, or other fuel to heat the steam.

[†]Even nuclear power plants utilize steam turbines; the nuclear fuel—uranium—serves as fuel to heat the steam.

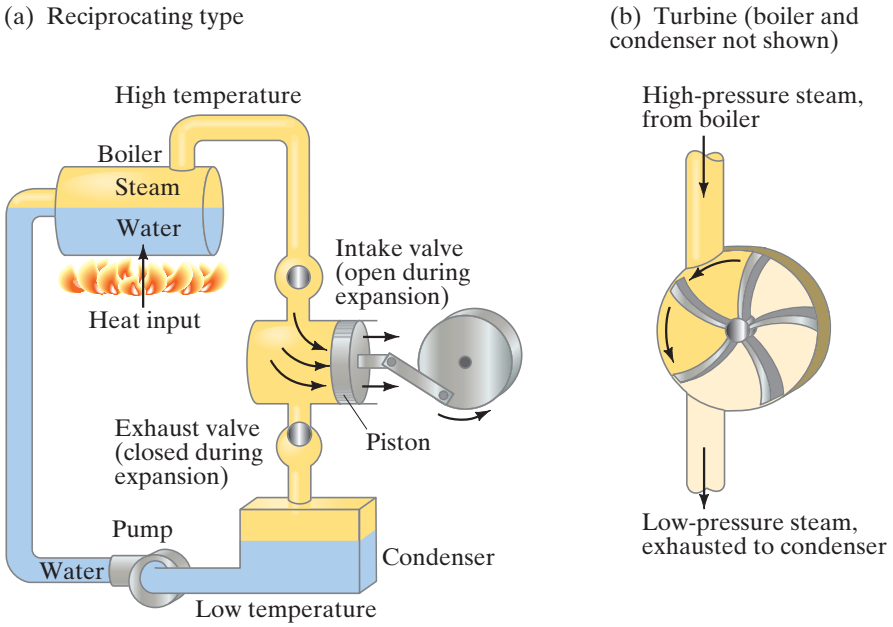

**FIGURE 20–3** Steam engines.

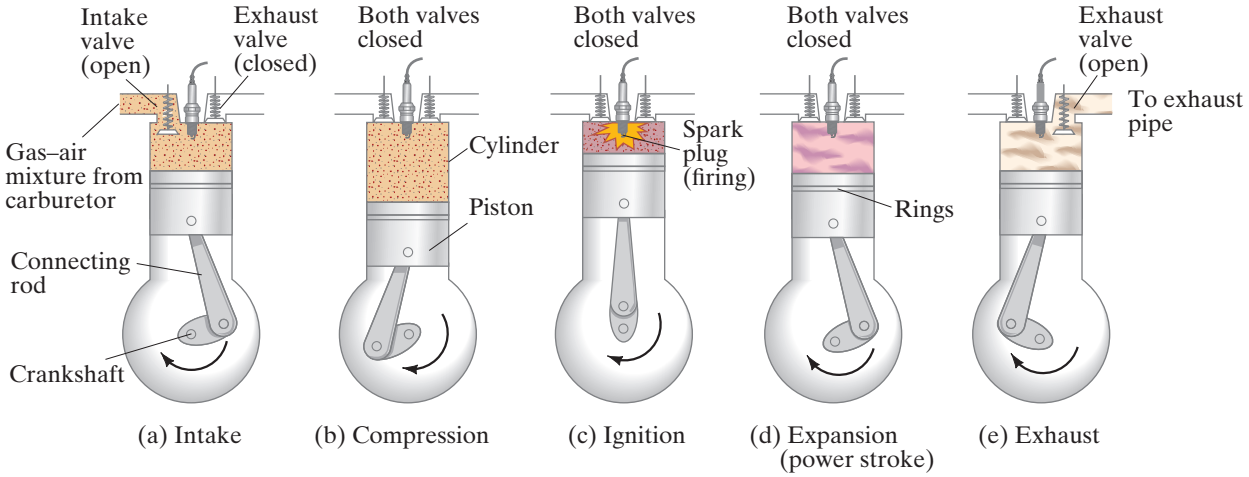

**FIGURE 20–4** Four-stroke-cycle internal combustion engine: (a) the gasoline–air mixture flows into the cylinder as the piston moves down; (b) the piston moves upward and compresses the gas; (c) the brief instant when firing of the spark plug ignites the highly compressed gasoline–air mixture, raising it to a high temperature; (d) the gases, now at high temperature and pressure, expand against the piston in this, the power stroke; (e) the burned gases are pushed out to the exhaust pipe. When the piston reaches the top, the exhaust valve closes and the intake valve opens, and the whole cycle repeats. (a), (b), (d), and (e) are the four strokes of the cycle. The piston goes down and up twice per complete cycle.

In an internal combustion engine (used in most automobiles), the high temperature is achieved by burning the gasoline–air mixture in the cylinder itself (ignited by the spark plug), as described in Fig. 20–4.

## Why a $\Delta T$ Is Needed to Drive a Heat Engine

To see why a *temperature difference* is required to run an engine, consider a steam engine. In the reciprocating engine, for example, suppose there were no condenser or pump (Fig. 20–3a), and that the steam was at the same temperature throughout the system. Then the pressure of the gas being exhausted would be the same as on intake. The work done by the gas *on* the piston when it expanded would equal the amount of work done *by* the piston to force the steam out the exhaust; hence, no net work would be done. Useless! In a real engine, the exhausted gas is cooled to a lower temperature and condensed so that the exhaust pressure is less than the intake pressure. Thus, the work the piston must do on the gas to expel it on the exhaust stroke is less than the work done by the gas on the piston during the intake. So a net amount of work can be obtained—but only if there is a difference of temperature (which allows a difference in pressure). Similarly, in the gas turbine (Fig. 20–3b) if the gas isn't cooled, the pressure on each side of the blades would be the same. By cooling the gas on the exhaust side, the pressure on the back side of the blade is less and hence the turbine turns.

## Efficiency and the Second Law

The **efficiency**, $e$, of any heat engine can be defined as the ratio of the work it does, $W$, to the heat input at the high temperature, $Q_H$ (Fig. 20–2), over a complete cycle:

$$e = \frac{W}{Q_H}. \qquad \textbf{(20–1a)}$$

This is a sensible definition since $W$ is the output (what you get from the engine), whereas $Q_H$ is what you put in and pay for in burned fuel. Since energy is conserved, the heat input $Q_H$ must equal the work done plus the heat that flows out at the low temperature $(Q_L)$:

$$Q_H = W + Q_L.$$

Thus $W = Q_H - Q_L$, and the efficiency of an engine can also be written as

$$e = \frac{W}{Q_H} = \frac{Q_H - Q_L}{Q_H}$$

or

$$e = 1 - \frac{Q_L}{Q_H}. \qquad \textbf{(20–1b)}$$

To give the efficiency as a percent, we multiply Eqs. 20–1 by 100. Note that $e$ could be 1.0 (or 100%) only if $Q_L$ were zero—that is, only if no heat were exhausted to the environment (which we will see shortly never happens).

**EXAMPLE 20–1** **Car efficiency.** An automobile engine has an efficiency of 20% and produces an average of 23,000 J of mechanical work per second (= 23 kW) during operation. (*a*) How much heat input is required, and (*b*) how much heat is discharged as waste heat from this engine, per second?

**APPROACH** We want to find the heat input $Q_H$ as well as the heat output $Q_L$, given $W = 23{,}000\ \text{J}$ each second and an efficiency $e = 0.20$. We can use the definition of efficiency, Eq. 20–1 in its various forms, to find first $Q_H$ and then $Q_L$.

**SOLUTION** (*a*) From Eq. 20–1a, $e = W/Q_H$, we solve for $Q_H$:

$$Q_H = \frac{W}{e} = \frac{23{,}000\ \text{J}}{0.20} = 1.15 \times 10^5\ \text{J} = 115\ \text{kJ}.$$

The engine requires $115\ \text{kJ/s} = 115\ \text{kW}$ of heat input.

(*b*) Now we use Eq. 20–1b $(e = 1 - Q_L/Q_H)$ and solve for $Q_L$:

$$Q_L = (1 - e)Q_H = (0.80)115\ \text{kJ} = 92\ \text{kJ}.$$

The engine discharges heat to the environment at a rate of $92\ \text{kJ/s} = 92\ \text{kW}$.

**NOTE** Of the 115 kJ that enters the engine per second, only 23 kJ (20%) does useful work whereas 92 kJ (80%) is wasted as heat output.

**NOTE** The problem was stated in terms of energy per unit time. We could just as well have stated it in terms of power, since $1\ \text{J/s} = 1\ \text{W}$.

## 20–3 The Carnot Engine; Reversible and Irreversible Processes

To explore how to increase efficiency, the French scientist Sadi Carnot (1796–1832) examined the characteristics of an ideal engine, now called a **Carnot engine**. No Carnot engine actually exists, but as a theoretical idea it played an important role in the development and understanding of the second law of thermodynamics.

The idealized Carnot engine consists of four processes done in a cycle, two of which are adiabatic $(Q = 0)$ and two are isothermal $(\Delta T = 0)$. This idealized **Carnot cycle** is shown in Fig. 20–5. Each of the processes is considered to be done **reversibly**. That is, each of the processes (such as the expansion of the gases against a piston) is considered to be carried out infinitely slowly, so that the process could be considered a series of equilibrium states, and the whole process could be done in reverse with no change in the magnitude of work done or heat exchanged.

A perfectly reversible process is not possible in reality because it would require an infinite time. Reversible processes can be approached arbitrarily closely, and are important theoretically, just as the concept of an ideal gas is. A real process, on the other hand, would occur more quickly; there would be turbulence in the gas, friction would be present, and so on. Because of these factors, a real process cannot be done precisely in reverse—the turbulence would be different and the heat lost to friction would not reverse itself.[†] Thus, **real** processes are **irreversible**.

**CAUTION**
*Real processes are always irreversible*

The isothermal processes of a Carnot engine, where heats $Q_H$ and $Q_L$ are transferred, are assumed to be done at constant temperatures $T_H$ and $T_L$. That is, the system is assumed to be in contact with idealized *heat reservoirs* (page 551) which are so large their temperatures don't change significantly when $Q_H$ and $Q_L$ are transferred. As we do for other heat engines, we take both $Q_L$ and $Q_H$ as positive.

[†]A real, irreversible process cannot be plotted on a *PV* diagram, except approximately if it approaches an ideal reversible process. But a reversible process (since it is a quasistatic series of equilibrium states) always can be plotted on a *PV* diagram. A reversible process, when done in reverse, retraces the same path on a *PV* diagram.

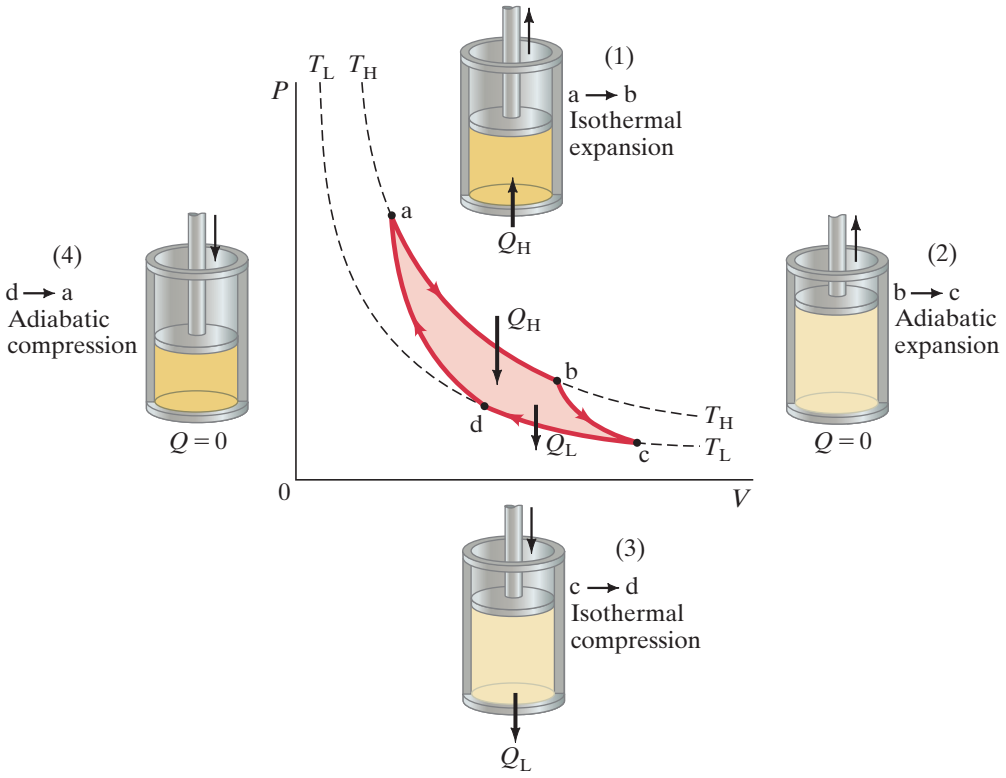

**FIGURE 20–5** The Carnot cycle. Heat engines work in a cycle, and the cycle for the hypothetical Carnot engine begins at point a on this *PV* diagram for an ideal gas. (1) The gas is first expanded isothermally, with the addition of heat $Q_H$, along the path ab at temperature $T_H$. (2) Next the gas expands adiabatically from b to c—no heat is exchanged, but the temperature drops to $T_L$. (3) The gas is then compressed at constant temperature $T_L$, path cd, and heat $Q_L$ flows out. (4) Finally, the gas is compressed adiabatically, path da, back to its original state.

The net work done in one cycle by a Carnot engine (or any other type of engine using a reversible cycle) is equal to the area enclosed by the curve representing the cycle on a *PV* diagram, the curve abcd in Fig. 20–5 (see Section 19–7, Figs. 19–11 and 19–12).

The efficiency of a Carnot engine, like any heat engine, is given by Eq. 20–1b:

$$e = 1 - \frac{Q_L}{Q_H}.$$

For a Carnot engine using an ideal gas, however, we can show that the efficiency depends only on the temperatures of the heat reservoirs, $T_H$ and $T_L$. In the first isothermal process ab in Fig. 20–5, the work done by the gas is (see Eq. 19–9)

$$W_{ab} = nRT_H \ln \frac{V_b}{V_a},$$

where $n$ is the number of moles of the ideal gas used as working substance. Because the internal energy of an ideal gas does not change when the temperature remains constant, the first law of thermodynamics ($\Delta E_{int} = Q - W$) tells us that the heat added to the gas equals the work done by the gas:

$$Q_H = nRT_H \ln \frac{V_b}{V_a}.$$

Similarly, the heat lost by the gas in the isothermal process cd is

$$Q_L = nRT_L \ln \frac{V_c}{V_d}.$$

The paths bc and da are adiabatic, so we have from Eq. 19–16:

$$P_b V_b^\gamma = P_c V_c^\gamma \quad \text{and} \quad P_d V_d^\gamma = P_a V_a^\gamma,$$

where $\gamma = C_P/C_V$ is the ratio of molar specific heats (Eq. 19–15). Also, from the ideal gas law,

$$\frac{P_b V_b}{T_H} = \frac{P_c V_c}{T_L} \quad \text{and} \quad \frac{P_d V_d}{T_L} = \frac{P_a V_a}{T_H}.$$

When we divide these last equations, term by term, into the corresponding set of equations on the line above, we obtain

$$T_H V_b^{\gamma-1} = T_L V_c^{\gamma-1} \quad \text{and} \quad T_L V_d^{\gamma-1} = T_H V_a^{\gamma-1}.$$

Next we divide the equation on the left by the one on the right and obtain

$$\left(\frac{V_b}{V_a}\right)^{\gamma-1} = \left(\frac{V_c}{V_d}\right)^{\gamma-1}.$$

So if $(V_b/V_a)^{\gamma-1} = (V_c/V_d)^{\gamma-1}$ as we just saw, then

$$\frac{V_b}{V_a} = \frac{V_c}{V_d}.$$

We insert this result into our equations for $Q_H$ and $Q_L$ on the previous page:

$$\frac{Q_L}{Q_H} = \frac{nRT_L \ln (V_c/V_d)}{nRT_H \ln (V_b/V_a)}$$

or

$$\frac{Q_L}{Q_H} = \frac{T_L}{T_H}. \qquad \text{[Carnot cycle]} \quad \textbf{(20–2)}$$

Hence the efficiency of a reversible Carnot engine can now be written

$$e_{\text{ideal}} = 1 - \frac{Q_L}{Q_H}$$

or

$$e_{\text{ideal}} = 1 - \frac{T_L}{T_H}. \qquad \left[\begin{array}{c}\text{Carnot (ideal) efficiency;}\\ \text{Kelvin temperatures}\end{array}\right] \quad \textbf{(20–3)}$$

The temperatures $T_L$ and $T_H$ are the absolute or Kelvin temperatures as measured on the ideal gas temperature scale. Thus the efficiency of a Carnot engine depends only on the temperatures $T_L$ and $T_H$.

We could imagine other possible reversible cycles that could be used for an ideal reversible engine. According to a theorem stated by Carnot:

> **All reversible engines operating between the same two constant temperatures $T_H$ and $T_L$ have the same efficiency. Any irreversible engine operating between the same two fixed temperatures will have an efficiency less than this.**

This is known as **Carnot's theorem**. It tells us that Eq. 20–3, $e = 1 - (T_L/T_H)$, applies to any ideal reversible engine with fixed input and exhaust temperatures, $T_H$ and $T_L$, and that this Eq. 20–3 expresses the fundamental upper limit to the efficiency of any heat engine. A higher efficiency would violate the second law of thermodynamics.[†] Real engines always have an efficiency lower than this because of losses due to friction and the like. Real engines that are well designed reach 60 to 80% of the Carnot efficiency.

**EXAMPLE 20–2** **Steam engine efficiency.** A steam engine operates between 500°C and 270°C. What is the maximum possible efficiency of this engine?

**APPROACH** The maximum possible efficiency is the idealized Carnot efficiency, Eq. 20–3. We must use Kelvin temperatures.

**SOLUTION** We first change the temperature to kelvins by adding 273 to the given Celsius temperatures: $T_H = 773\,\text{K}$ and $T_L = 543\,\text{K}$. Then

$$e_{\text{ideal}} = 1 - \frac{543}{773} = 0.30.$$

To get the efficiency in percent, we multiply by 100. Thus, the maximum (or Carnot) efficiency is 30%. Real engines might attain 0.70 of this value, or 21%.

**NOTE** In this Example, the exhaust temperature is still rather high, 270°C. Steam engines can be arranged in series so that the exhaust of one engine is used as intake by a second or third engine.

[†]If an engine had a higher efficiency than Eq. 20–3, it could be used in conjunction with a Carnot engine that is made to work in reverse as a refrigerator. If $W$ was the same for both, the net result would be a flow of heat at a low temperature to a high temperature without work being done. That would violate the Clausius statement of the second law (and also experience—i.e., the laboratory).

**EXAMPLE 20–3** **A phony claim?** An engine manufacturer makes the following claims: An engine's heat input per second is 9.0 kJ at 435 K. The heat output per second is 4.0 kJ at 285 K. Do you believe these claims?

**APPROACH** The engine's efficiency can be calculated from the definition, Eqs. 20–1. It must be less than the maximum possible, Eq. 20–3.

**SOLUTION** The claimed efficiency of the engine is (Eq. 20–1b)

$$e = 1 - \frac{Q_L}{Q_H} = 1 - \frac{4.0\,\text{kJ}}{9.0\,\text{kJ}} = 0.56,$$

or 56%. However, the maximum possible efficiency is given by the Carnot efficiency, Eq. 20–3:

$$e_{\text{ideal}} = 1 - \frac{T_L}{T_H} = 1 - \frac{285\,\text{K}}{435\,\text{K}} = 0.34,$$

or 34%. The manufacturer's claims violate the second law of thermodynamics and cannot be believed.

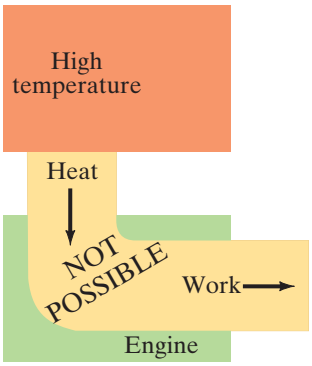
**EXERCISE A** A motor is running with an intake temperature $T_H = 400$ K and an exhaust temperature $T_L = 300$ K. Which of the following is *not* a possible efficiency for the engine? (*a*) 0.10; (*b*) 0.16; (*c*) 0.24; (*d*) 0.30.

We can see from Eq. 20–3 that a 100% efficient engine is not possible. Only if the exhaust temperature, $T_L$, were at absolute zero would 100% efficiency be reachable. But getting to absolute zero is a practical (as well as theoretical) impossibility.[†] Because no engine can be 100% efficient, it can be stated that

*SECOND LAW OF THERMODYNAMICS (Kelvin-Planck statement)*

**no device is possible whose sole effect is to transform a given amount of heat completely into work.**

This is known as the **Kelvin-Planck statement of the second law of thermodynamics**. Figure 20–6 diagrams the ideal perfect heat engine, which can not exist. If it did, remarkable things could happen. For example, if the engine of a ship did not need a low-temperature reservoir to exhaust heat into, the ship could travel across the ocean using the vast resources of the internal energy of the ocean water. Indeed, we would have no fuel problems at all!



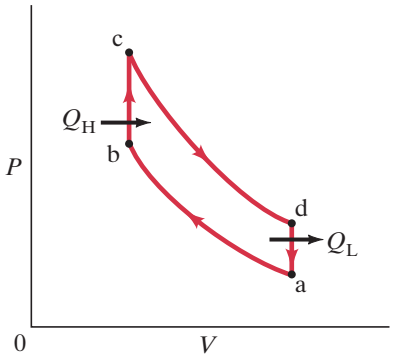


**FIGURE 20–6** Diagram of an impossible perfect heat engine in which all heat input is used to do work.

**EXERCISE B** Return to the Chapter-Opening Question, page 576, and answer it again now. Try to explain why you may have answered differently the first time.

## *The Otto Cycle

The operation of an automobile internal combustion engine (Fig. 20–4) can be approximated by a reversible cycle known as the *Otto cycle*, whose *PV* diagram is shown in Fig. 20–7. Unlike the Carnot cycle, the input and exhaust temperatures of the Otto cycle are *not* constant. Paths ab and cd are adiabatic, and paths bc and da are at constant volume. The gas (gasoline–air mixture) enters the cylinder at point a and is compressed adiabatically (compression stroke) to point b. At b ignition occurs (spark plug) and the quick burning of the gas adds heat $Q_H$ to the system at constant volume (approximately in a real engine). The temperature and pressure rise, and then in the power stroke, cd, the gas expands adiabatically. In the exhaust stroke, da, heat $Q_L$ is ejected to the environment (in a real engine, the gas leaves the engine and is replaced by a new mixture of air and fuel).

**FIGURE 20–7** The Otto cycle.

[†]This result is known as the *third law of thermodynamics*, as discussed in Section 20–10.

**EXAMPLE 20–4** **The Otto cycle.** (*a*) Show that for an ideal gas as working substance, the efficiency of an Otto cycle engine is

$$e = 1 - \left(\frac{V_a}{V_b}\right)^{1-\gamma}$$

where $\gamma$ is the ratio of specific heats ($\gamma = C_P/C_V$, Eq. 19–15) and $V_a/V_b$ is the *compression ratio*. (*b*) Calculate the efficiency for a compression ratio $V_a/V_b = 8.0$ assuming a diatomic gas like $O_2$ and $N_2$.

**APPROACH** We use the original definition of efficiency and the results from Chapter 19 for constant volume and adiabatic processes (Sections 19–8 and 19–9).

**SOLUTION** The heat exchanges take place at constant volume in the ideal Otto cycle, so from Eq. 19–11a:

$$Q_H = nC_V(T_c - T_b) \quad \text{and} \quad Q_L = nC_V(T_d - T_a).$$

Then from Eq. 20–1b,

$$e = 1 - \frac{Q_L}{Q_H} = 1 - \left[\frac{T_d - T_a}{T_c - T_b}\right].$$

To get this in terms of the compression ratio, $V_a/V_b$, we use the result from Section 19–9, Eq. 19–16, $PV^\gamma = \text{constant}$ during the adiabatic processes ab and cd. Thus

$$P_a V_a^\gamma = P_b V_b^\gamma \quad \text{and} \quad P_c V_c^\gamma = P_d V_d^\gamma.$$

We use the ideal gas law, $P = nRT/V$, and substitute $P$ into these two equations

$$T_a V_a^{\gamma-1} = T_b V_b^{\gamma-1} \quad \text{and} \quad T_c V_c^{\gamma-1} = T_d V_d^{\gamma-1}.$$

Then the efficiency (see above) is

$$e = 1 - \left[\frac{T_d - T_a}{T_c - T_b}\right] = 1 - \left[\frac{T_c(V_c/V_d)^{\gamma-1} - T_b(V_b/V_a)^{\gamma-1}}{T_c - T_b}\right].$$

But processes bc and da are at constant volume, so $V_c = V_b$ and $V_d = V_a$. Hence $V_c/V_d = V_b/V_a$ and so we achieve our desired result:

$$e = 1 - \left[\frac{(V_b/V_a)^{\gamma-1}(T_c - T_b)}{T_c - T_b}\right] = 1 - \left(\frac{V_b}{V_a}\right)^{\gamma-1} = 1 - \left(\frac{V_a}{V_b}\right)^{1-\gamma}.$$

(*b*) For diatomic molecules (Section 19–8), $\gamma = C_P/C_V = 1.4$ so

$$e = 1 - (8.0)^{1-\gamma} = 1 - (8.0)^{-0.4} = 0.56.$$

Real engines do not reach this high efficiency because they do not follow perfectly the Otto cycle, plus there is friction, turbulence, heat loss, and incomplete combustion of the gases.

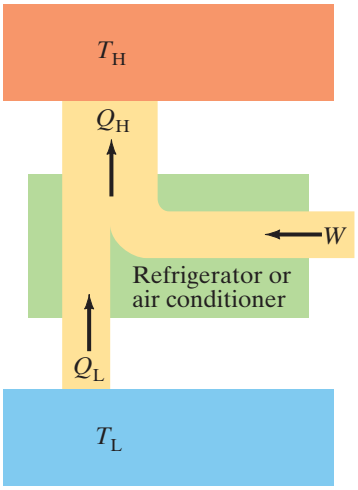

**FIGURE 20–8** Schematic diagram of energy transfers for a refrigerator or air conditioner (AC).

## 20–4 Refrigerators, Air Conditioners, and Heat Pumps

The operating principle of refrigerators, air conditioners, and heat pumps is just the reverse of a heat engine. Each operates to transfer heat *out* of a cool environment into a warm environment. As diagrammed in Fig. 20–8, by doing work $W$, heat is taken from a low-temperature region, $T_L$ (such as inside a refrigerator), and a greater amount of heat is exhausted at a high temperature, $T_H$ (the room). Heat $Q_L$ is removed from cooling coils *inside* the refrigerator and heat $Q_H$ is given off by coils *outside* the rear of the refrigerator, Fig. 20–9. You can often feel this heated air coming out beneath a refrigerator. The work $W$ is usually done by an electric motor which compresses a fluid, as illustrated in Fig. 20–9. (We assume $Q_L$, $Q_H$, and $W$ are all positive, as in Section 20–2.)

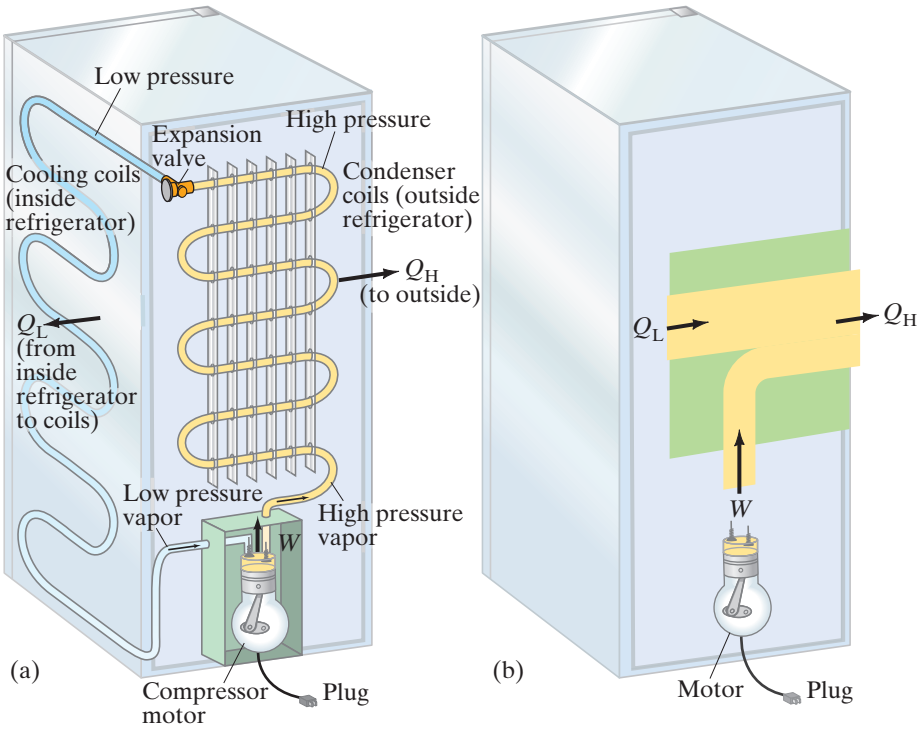

**FIGURE 20–9** (a) Typical refrigerator system. The electric compressor motor forces a gas at high pressure through a heat exchanger (condenser) on the rear *outside* wall of the refrigerator, where $Q_H$ is given off and the gas cools to become liquid. The liquid passes from a high-pressure region, via a valve, to low-pressure tubes on the *inside* walls of the refrigerator; the liquid evaporates at this lower pressure and thus absorbs heat $(Q_L)$ from the inside of the refrigerator. The fluid returns to the compressor, where the cycle begins again. (b) Schematic diagram, like Fig. 20–8.

**PHYSICS APPLIED**
*Refrigerator*

A perfect **refrigerator**—one in which no work is required to take heat from the low-temperature region to the high-temperature region—is not possible. This is the **Clausius statement of the second law of thermodynamics**, already mentioned in Section 20–1: it can be stated formally as

*SECOND LAW OF THERMODYNAMICS (Clausius statement)*

> **no device is possible whose sole effect is to transfer heat from one region at a temperature $T_L$ into a second region at a higher temperature $T_H$.**

To make heat flow from a low-temperature object (or region) to one at a higher temperature, work must be done. Thus, *there can be no perfect refrigerator*.

The **coefficient of performance** (COP) of a refrigerator is defined as the heat $Q_L$ removed from the low-temperature area (inside a refrigerator) divided by the work $W$ done to remove the heat (Fig. 20–8):

$$\text{COP} = \frac{Q_L}{W}. \qquad \left[\begin{matrix}\text{refrigerator and}\\ \text{air conditioner}\end{matrix}\right] \qquad \textbf{(20–4a)}$$

We use $Q_L$ because it is the heat removed from inside that matters from a practical point of view. This makes sense because the more heat $Q_L$ that can be removed from inside the refrigerator for a given amount of work, the better (more efficient) the refrigerator is. Energy is conserved, so from the first law of thermodynamics we can write $Q_L + W = Q_H$, or $W = Q_H - Q_L$ (see Fig. 20–8 or 20–9b). Then Eq. 20–4a becomes

$$\text{COP} = \frac{Q_L}{W} = \frac{Q_L}{Q_H - Q_L}. \qquad \left[\begin{matrix}\text{refrigerator and}\\ \text{air conditioner}\end{matrix}\right] \qquad \textbf{(20–4b)}$$

For an ideal refrigerator (not a perfect one, which is impossible), the best we could do would be

$$\text{COP}_{\text{ideal}} = \frac{T_L}{T_H - T_L}, \qquad \left[\begin{matrix}\text{refrigerator and}\\ \text{air conditioner}\end{matrix}\right] \qquad \textbf{(20–4c)}$$

analagous to an ideal (Carnot) engine (Eqs. 20–2 and 20–3).

**PHYSICS APPLIED**
*Air conditioner*

An **air conditioner** works very much like a refrigerator, although the actual construction details are different: an air conditioner takes heat $Q_L$ from inside a room or building at a low temperature, and deposits heat $Q_H$ outside to the environment at a higher temperature. Equations 20–4 also describe the coefficient of performance for an air conditioner.

**EXAMPLE 20–5** **Making ice.** A freezer has a COP of 2.8 and uses 200 watts of power. How long would it take to freeze an ice-cube tray that contains 600 g of water at 0°C?

**APPROACH** In Eq. 20–4b, $Q_L$ is the heat that must be transferred out of the water so it will become ice. To determine $Q_L$, we use the latent heat of fusion $L$ of water and Eq. 19–4, $Q = mL$.

**SOLUTION** From Table 19–2, $L = 333\,\text{kJ/kg}$ for water. Hence

$$Q_L = mL = (0.600\,\text{kg})(3.33 \times 10^5\,\text{J/kg}) = 2.0 \times 10^5\,\text{J}$$

is the total energy that needs to be removed from the water. The freezer does work at the rate of 200 watts = 200 J/s = $W/t$, which is the work $W$ it can do in $t$ seconds. We solve for $t$: $t = W/(200\,\text{J/s})$. For $W$, we can also use Eq. 20–4a: $W = Q_L/\text{COP}$. Thus

$$t = \frac{W}{200\,\text{J/s}} = \frac{Q_L/\text{COP}}{200\,\text{J/s}} = \frac{2.0 \times 10^5\,\text{J}}{(2.8)(200\,\text{J/s})} = 360\,\text{s},$$

or about 6 min.

Heat naturally flows from high temperature to low temperature. Refrigerators and air conditioners do work to accomplish the opposite: to make heat flow from cold to hot. We might say they "pump" heat from cold areas to hotter areas, against the natural tendency of heat to flow from hot to cold, just as water can be pumped uphill, against the natural tendency to flow downhill. The term **heat pump** is usually reserved for a device that can heat a house in winter by using an electric motor that does work $W$ to take heat $Q_L$ from the outside at low temperature and delivers heat $Q_H$ to the warmer inside of the house; see Fig. 20–10. As in a refrigerator, there is an indoor and an outdoor heat exchanger (coils of the refrigerator) and an electric compressor motor. The operating principle is like that for a refrigerator or air conditioner; but the objective of a heat pump is to heat (deliver $Q_H$), rather than to cool (remove $Q_L$). Thus, the coefficient of performance of a heat pump is defined differently than for an air conditioner because it is the heat $Q_H$ delivered to the inside of the house that is important now:

**PHYSICS APPLIED**
*Heat pump*

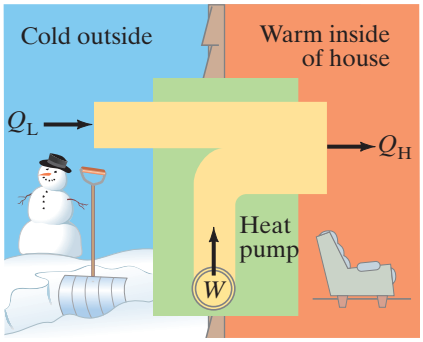

**FIGURE 20–10** A heat pump uses an electric motor to "pump" heat from the cold outside to the warm inside of a house.

$$\text{COP} = \frac{Q_H}{W}. \qquad \text{[heat pump]} \quad \textbf{(20–5)}$$

The COP is necessarily greater than 1, because $W + Q_L = Q_H$. Typical heat pumps today have COP ≈ 2.5 to 3. Most heat pumps can be "turned around" and used as air conditioners in the summer.

**EXAMPLE 20–6** **Heat pump.** A heat pump has a coefficient of performance of 3.0 and is rated to do work at 1500 watts. (*a*) How much heat can it add to a room per second? (*b*) If the heat pump were turned around to act as an air conditioner in the summer, what would you expect its coefficient of performance to be, assuming all else stays the same?

**APPROACH** We use the definitions of coefficient of performance, which are different for the two devices in (*a*) and (*b*).

**SOLUTION** (*a*) We use Eq. 20–5 for the heat pump, and, since our device does 1500 J of work per second, it can pour heat into the room at a rate of

$$Q_H = \text{COP} \times W = 3.0 \times 1500\,\text{J} = 4500\,\text{J}$$

per second, or at a rate of 4500 W [≈4 Btu/s]. That is, the heat pump works at 1500 W in order to drag 3000 W from the outdoors and deliver 4500 W indoors.

(*b*) If our device is turned around in summer, it can take heat $Q_L$ from inside the house, doing 1500 J of work per second to then dump $Q_H = 4500\,\text{J}$ per second to the hot outside. Energy is conserved, so $Q_L + W = Q_H$ (see Fig. 20–10, but reverse the inside and outside of the house). Then

$$Q_L = Q_H - W = 4500\,\text{J} - 1500\,\text{J} = 3000\,\text{J}.$$

The coefficient of performance as an air conditioner would thus be (Eq. 20–4a)

$$\text{COP} = \frac{Q_L}{W} = \frac{3000\,\text{J}}{1500\,\text{J}} = 2.0.$$

**NOTE** The coefficients of performance are defined differently for heat pumps and air conditioners.

**CAUTION**
*Heat pumps and air conditioners have different COP definitions*

**EXERCISE C** The heat pump of Example 20–6 uses 1500 W of electric power to deliver 4500 W of heat. Does this sound like we're getting something for nothing? (*a*) Explain why we aren't. (*b*) Compare to the freezer of Example 20–5 whose motor uses 200 W to extract heat at what rate?

A good heat pump can sometimes be a money saver and an energy saver, depending on the cost of the unit and installation, etc. Compare, for example, our heat pump in Example 20–6 to, say, a 1500-W electric heater. We plug the heater into the wall, it draws 1500 W of electricity, and it delivers 1500 W of heat to the room. Our heat pump when plugged into the wall also draws 1500 W of electricity (which is what we pay for), but it delivers 4500 W of heat!

### *SEER Rating

Cooling devices such as refrigerators and air conditioners are often given a rating known as SEER (Seasonal Energy Efficiency Ratio), which is defined as

**PHYSICS APPLIED**
*SEER rating*

$$\text{SEER} = \frac{(\text{heat removed in Btu})}{(\text{electrical input in watt-hours})},$$

as measured by averaging over varying (seasonal) conditions. The definition of the SEER is basically the same as the COP except for the (unfortunate) mixed units. Given that $1\ \text{Btu} = 1056\,\text{J}$ (see Section 19–1 and Problem 4 in Chapter 19), then a $\text{SEER} = 1$ is a COP equal to $(1\ \text{Btu}/1\ \text{W}\cdot\text{h}) = (1056\,\text{J})/(1\,\text{J/s} \times 3600\,\text{s}) = 0.29$. And a $\text{COP} = 1$ is a $\text{SEER} = 1/0.29 = 3.4$.

## 20–5 Entropy

Thus far we have stated the second law of thermodynamics for specific situations. What we really need is a general statement of the second law of thermodynamics that will cover all situations, including processes discussed earlier in this Chapter, processes that are not observed in nature even though they would not violate the first law of thermodynamics. It was not until the latter half of the nineteenth century that the second law of thermodynamics was finally stated in a general way—namely, in terms of a quantity called **entropy**, introduced by Clausius in the 1860s. Entropy is a state variable, as we will see, and in Section 20–7 we will see that entropy can be interpreted as a measure of the order or disorder of a system.

When we deal with entropy—as with potential energy—it is the *change* in entropy during a process that is important, not the absolute amount. According to Clausius, when an amount of heat $Q$ is *added* to a system by a reversible process at constant temperature, the change in entropy $S$ of the system is given by

$$\Delta S = \frac{Q}{T}, \qquad \textbf{(20–6)}$$

where $T$ is the Kelvin temperature. If heat is lost, $Q$ is *negative* in this equation, as we now resume our *original sign conventions* on page 549.

**CAUTION**
*Sign conventions for Q and W (page 549) in use from now on*

**EXAMPLE 20–7** **Entropy change in melting.** An ice cube of mass 56 g is taken from a storage compartment at 0°C and placed in a paper cup. After a few minutes, exactly half of the mass of the ice cube has melted, becoming water at 0°C. Find the change in entropy of the 56 grams of ice/water.

**APPROACH** We consider the 56 g of water, initially in the form of ice, as our system. To determine the entropy change, we first must find the heat needed to melt the ice, which we do using the latent heat of fusion of water, $L = 333\ \text{kJ/kg}$ (Section 19–5). The heat $Q$ required comes from the surroundings.

**SOLUTION** The heat required to melt 28 g of ice (half of the 56-g ice cube) is

$$Q = mL = (0.028\ \text{kg})(333\ \text{kJ/kg}) = 9.3\ \text{kJ}.$$

The temperature remains constant in our process, so the change in entropy using Eq. 20–6 is:

$$\Delta S = \frac{Q}{T} = \frac{9.3\ \text{kJ}}{273\ \text{K}} = 34\ \text{J/K}.$$

**NOTE** The change in entropy of the surroundings (cup, air) has not been computed.

If the temperature is not constant, we define entropy $S$ by the relation

$$dS = \frac{dQ}{T}. \qquad \textbf{(20–7)}$$

Then the change in entropy of a system taken reversibly between two equilibrium states a and b is given by[†]

$$\Delta S = S_\text{b} - S_\text{a} = \int_\text{a}^\text{b} dS = \int_\text{a}^\text{b} \frac{dQ}{T}. \quad \text{[reversible process]} \qquad \textbf{(20–8)}$$

**PROBLEM SOLVING**
*Entropy is a state variable*

A careful analysis (next page) shows that the change in entropy when a system is moved by a reversible process from any state a to another state b does not depend on the process. That is, $\Delta S = S_\text{b} - S_\text{a}$ depends only on the states a and b of the system. Thus entropy (unlike heat) is a **state variable**. Any system in a given state has a mass, a temperature, a volume, a pressure, and also has a particular value of entropy. Therefore the change in entropy $\Delta S$ for a real process, which is always irreversible (page 580), can be determined by calculating $\Delta S$ for an idealized reversible process between the same two states. (We used this fact in Example 20–7.)

For now, we can see why entropy is a state variable for a Carnot cycle. In Eq. 20–2 we saw that $Q_\text{L}/Q_\text{H} = T_\text{L}/T_\text{H}$, which we rewrite as

$$\frac{Q_\text{L}}{T_\text{L}} = \frac{Q_\text{H}}{T_\text{H}}.$$

This relation shows that in the *PV* diagram for a Carnot cycle, Fig. 20–5, the entropy change $\Delta S = Q/T$ in going from state a to state c along path abc $(= Q_\text{H}/T_\text{H} + 0)$ is thus the same as going along the path adc $(0 + Q_\text{L}/T_\text{L})$. That is, the change in entropy is *path independent*—it depends only on the initial and final states of the system.

## *Showing Entropy Is a State Variable

In our study of the Carnot cycle we found (Eq. 20–2) that $Q_\text{L}/Q_\text{H} = T_\text{L}/T_\text{H}$. We rewrite this as

$$\frac{Q_\text{H}}{T_\text{H}} = \frac{Q_\text{L}}{T_\text{L}}.$$

In this relation, both $Q_\text{H}$ and $Q_\text{L}$ are positive. But now let us recall our original convention

[†]Equation 20–8 says nothing about the value of $S$. It only gives the change in $S$. This is much like potential energy (Chapter 8). However, one form of the *third law of thermodynamics* (see also Section 20–10) states that as $T \to 0$, $S \to 0$.

as used in the first law (Section 19–6, page 549), that $Q$ is positive when it represents a heat flow into the system (as $Q_H$) and negative for a heat flow out of the system (as $-Q_L$). Then this last relation becomes

$$\frac{Q_H}{T_H} + \frac{Q_L}{T_L} = 0. \qquad \text{[Carnot cycle]} \quad \textbf{(20–9)}$$

Now consider *any* reversible cycle, as represented by the smooth (oval-shaped) curve in Fig. 20–11. Any reversible cycle can be approximated as a series of Carnot cycles. Figure 20–11 shows only six—the isotherms (dashed lines) are connected by adiabatic paths for each—and the approximation becomes better and better if we increase the number of Carnot cycles. Equation 20–9 is valid for each of these cycles, so we can write

$$\Sigma \frac{Q}{T} = 0 \qquad \text{[Carnot cycles]} \quad \textbf{(20–10)}$$

for the sum of all these cycles. But note that the heat output $Q_L$ of one cycle crosses the boundary below it and is approximately equal to the negative of the heat input, $Q_H$, of the cycle below it (actual equality occurs in the limit of an infinite number of infinitely thin Carnot cycles). Hence the heat flows on the inner paths of all these Carnot cycles cancel out, so the net heat transferred, and the work done, is the same for the series of Carnot cycles as for the original cycle. Hence, in the limit of infinitely many Carnot cycles, Eq. 20–10 applies to any reversible cycle. In this case Eq. 20–10 becomes

$$\oint \frac{dQ}{T} = 0, \qquad \text{[reversible cycle]} \quad \textbf{(20–11)}$$

where $dQ$ represents an infinitesimal heat flow. The symbol $\oint$ means that the integral is taken around a closed path; the integral can be started at any point on the path such as at a or b in Fig. 20–11, and proceed in either direction. If we divide the cycle of Fig. 20–11 into two parts as indicated in Fig. 20–12, then

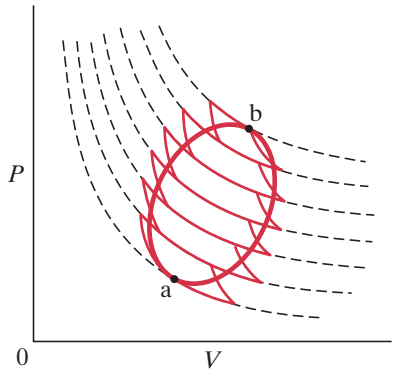
$$\int_{a\,\mathrm{I}}^{b} \frac{dQ}{T} + \int_{b\,\mathrm{II}}^{a} \frac{dQ}{T} = 0.$$

The first term is the integral from point a to point b along path I in Fig. 20–12, and the second term is the integral from b back to a along path II. If path II is taken in reverse, $dQ$ at each point becomes $-dQ$, since the path is reversible. Therefore

$$\int_{a\,\mathrm{I}}^{b} \frac{dQ}{T} = \int_{a\,\mathrm{II}}^{b} \frac{dQ}{T}. \qquad \text{[reversible paths]} \quad \textbf{(20–12)}$$

The integral of $dQ/T$ between any two equilibrium states, a and b, does not depend on the path of the process. By defining entropy as $dS = dQ/T$ (Eq. 20–7), we see from Eq. 20–12 that the change in entropy between any two states along a reversible path is *independent of the path between two points a and b*. Thus *entropy is a state variable*—its value depends only on the state of the system, and not on the process or the past history of how it got there. This is in clear distinction to $Q$ and $W$ which are *not* state variables; their values do depend on the processes undertaken.

Real processes are irreversible. But because entropy is a state variable, the change in entropy $\Delta S$ for an irreversible process can be determined by calculating $\Delta S$ for a reversible process between the same two states.



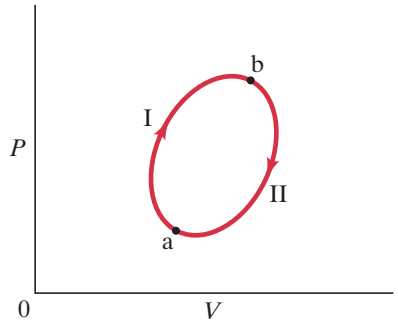


**FIGURE 20–11** Any reversible cycle (the arbitrary red oval shown here) can be approximated as a series of Carnot cycles. (The dashed lines represent isotherms.)

**FIGURE 20–12** The integral, $\oint dS$, of the entropy for a reversible cycle is zero. Hence the difference in entropy between states a and b, $S_b - S_a = \int_a^b dS$, is the same for path I as for path II.

## 20–6 Entropy and the Second Law of Thermodynamics

We have defined a new quantity, $S$, the entropy, which is a state variable and can be used to describe the state of the system, along with $P$, $T$, $V$, $E_{\text{int}}$, and $n$. But what does this rather abstract quantity have to do with the second law of thermodynamics? To answer this, let us take some examples in which we calculate the entropy changes during particular processes. But note first that Eq. 20–8 can be applied only to reversible processes. How then do we calculate $\Delta S = S_b - S_a$ for a real process that is irreversible? What we can do is this. We figure out some other *reversible* process that takes the system between the same two states, and calculate $\Delta S$ for this reversible process. This will equal $\Delta S$ for the irreversible process because $\Delta S$ depends only on the initial and final states of the system.

If the temperature varies during a process, a summation of the heat flow over the changing temperature can often be calculated using calculus or a computer. However, if the temperature change is not too great, a reasonable approximation can be made using the average value of the temperature, as indicated in the next Example.

**EXAMPLE 20–8** **ESTIMATE** **Entropy change when water samples are mixed.** A sample of 50.00 kg of water at 20.00°C is mixed with 50.00 kg of water at 24.00°C. Estimate the change in entropy.

**APPROACH** The final temperature of the mixture will be 22.00°C, since we started with equal amounts of water. We use the specific heat of water and the methods of calorimetry (Sections 19–3 and 19–4) to determine the heat transferred. Then we use the average temperature of each sample of water to estimate the entropy change $(Q/T)$ for the two samples, as if the processes were reversible.

**SOLUTION** A quantity of heat,

$$Q = mc\,\Delta T = (50.00\,\text{kg})\,(4186\,\text{J/kg}\cdot\text{C}^\circ)\,(2.00\,\text{C}^\circ) = 4.186\times10^5\,\text{J},$$

flows out of the hot water as it cools down from 24°C to 22°C, and this heat flows into the cold water as it warms from 20°C to 22°C. The total change in entropy, $\Delta S$, will be the sum of the changes in entropy of the hot water, $\Delta S_H$, and that of the cold water, $\Delta S_C$:

$$\Delta S = \Delta S_H + \Delta S_C.$$

We estimate entropy changes by writing $\Delta S = Q/\overline{T}$, where $\overline{T}$ is an "average" temperature for each process, which ought to give a reasonable estimate since the temperature change is small. For the hot water we use an average temperature of 23°C (296 K), and for the cold water an average temperature of 21°C (294 K). Thus

$$\Delta S_H \approx -\frac{4.186\times10^5\,\text{J}}{296\,\text{K}} = -1414\,\text{J/K}$$

which is negative because this heat flows out (sign conventions, page 549) whereas heat is added to the cold water:

$$\Delta S_C \approx \frac{4.186\times10^5\,\text{J}}{294\,\text{K}} = 1424\,\text{J/K}.$$

The entropy of the hot water $(S_H)$ decreases since heat flows out of the hot water. But the entropy of the cold water $(S_C)$ increases by a greater amount. The total change in entropy is

$$\Delta S = \Delta S_H + \Delta S_C \approx -1414\,\text{J/K} + 1424\,\text{J/K} \approx 10\,\text{J/K}.$$

We see that although the entropy of one part of the system decreased, the entropy of the other part increased by a greater amount so that the net change in entropy of the whole system is positive.

We can now show in general that for an isolated system of two objects, the flow of heat from the higher-temperature $(T_H)$ object to the lower-temperature $(T_L)$ object always results in an increase in the total entropy. The two objects eventually come to some intermediate temperature, $T_M$. The heat lost by the hotter object $(Q_H = -Q,$ where $Q$ is positive$)$ is equal to the heat gained by the colder one $(Q_L = Q)$, so the total change in entropy is

$$\Delta S = \Delta S_H + \Delta S_L = -\frac{Q}{T_{HM}} + \frac{Q}{T_{LM}},$$

where $T_{HM}$ is some intermediate temperature between $T_H$ and $T_M$ for the hot object as it cools from $T_H$ to $T_M$, and $T_{LM}$ is the counterpart for the cold object. Since the temperature of the hot object is, at all times during the process, greater than that of the cold object, then $T_{HM} > T_{LM}$. Hence

$$\Delta S = Q\left(\frac{1}{T_{LM}} - \frac{1}{T_{HM}}\right) > 0.$$

One object decreases in entropy, while the other gains in entropy, but the *total* change is positive.

**EXAMPLE 20–9** **Entropy changes in a free expansion.** Consider the *adiabatic free expansion* of $n$ moles of an ideal gas from volume $V_1$ to volume $V_2$, where $V_2 > V_1$ as was discussed in Section 19–7, Fig. 19–14 (repeated below). Calculate the change in entropy $(a)$ of the gas and $(b)$ of the surrounding environment. $(c)$ Evaluate $\Delta S$ for 1.00 mole, with $V_2 = 2.00\, V_1$.

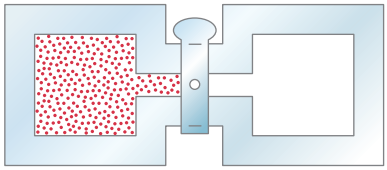

**FIGURE 19–14** (Repeated.) Free expansion.

**APPROACH** We saw in Section 19–7 that the gas is initially in a closed container of volume $V_1$, and, with the opening of a valve, it expands adiabatically into a previously empty container. The total volume of the two containers is $V_2$. The whole apparatus is thermally insulated from the surroundings, so no heat flows into the gas, $Q = 0$. The gas does no work, $W = 0$, so there is no change in internal energy, $\Delta E_{int} = 0$, and the temperature of the initial and final states is the same, $T_2 = T_1 = T$. The process takes place very quickly, and is irreversible. Thus we cannot apply Eq. 20–8 to this process. Instead we must think of a reversible process that will take the gas from volume $V_1$ to $V_2$ at the same temperature, and use Eq. 20–8 on this reversible process to get $\Delta S$. A reversible isothermal process will do the trick; in such a process, the internal energy does not change, so from the first law,

$$dQ = dW = P\,dV.$$

**SOLUTION** $(a)$ For the gas,

$$\Delta S_{gas} = \int \frac{dQ}{T} = \frac{1}{T}\int_{V_1}^{V_2} P\,dV.$$

The ideal gas law tells us $P = nRT/V$, so

$$\Delta S_{gas} = \left(\frac{1}{T}\right)(nRT)\int_{V_1}^{V_2}\frac{dV}{V} = nR\ln\frac{V_2}{V_1}.$$

Since $V_2 > V_1$, $\Delta S_{gas} > 0$.

$(b)$ Since no heat is transferred to the surrounding environment, there is no change of the state of the environment due to this process. Hence $\Delta S_{env} = 0$. Note that the total change in entropy, $\Delta S_{gas} + \Delta S_{env}$, is greater than zero.

$(c)$ Since $n = 1.00$ and $V_2 = 2.00\, V_1$, then $\Delta S_{gas} = R\ln 2.00 = 5.76\ \text{J/K}$.

**EXAMPLE 20–10 Heat transfer.** A red-hot 2.00-kg piece of iron at temperature $T_1 = 880\,\text{K}$ is thrown into a huge lake whose temperature is $T_2 = 280\,\text{K}$. Assume the lake is so large that its temperature rise is insignificant. Determine the change in entropy (*a*) of the iron and (*b*) of the surrounding environment (the lake).

**APPROACH** The process is irreversible, but the same entropy change will occur for a reversible process, and we use the concept of specific heat, Eq. 19–2.

**SOLUTION** (*a*) We assume the specific heat of the iron is constant at $c = 450\,\text{J/kg}\cdot\text{K}$. Then $dQ = mc\,dT$ and in a quasistatic reversible process

$$\Delta S_{\text{iron}} = \int \frac{dQ}{T} = mc\int_{T_1}^{T_2}\frac{dT}{T} = mc\ln\frac{T_2}{T_1} = -mc\ln\frac{T_1}{T_2}.$$

Putting in numbers, we find

$$\Delta S_{\text{iron}} = -(2.00\,\text{kg})(450\,\text{J/kg}\cdot\text{K})\ln\frac{880\,\text{K}}{280\,\text{K}} = -1030\,\text{J/K}.$$

(*b*) The initial and final temperatures of the lake are the same, $T = 280\,\text{K}$. The lake receives from the iron an amount of heat

$$Q = mc(T_2 - T_1) = (2.00\,\text{kg})(450\,\text{J/kg}\cdot\text{K})(880\,\text{K} - 280\,\text{K}) = 540\,\text{kJ}.$$

Strictly speaking, this is an irreversible process (the lake heats up locally before equilibrium is reached), but is equivalent to a reversible isothermal transfer of heat $Q = 540\,\text{kJ}$ at $T = 280\,\text{K}$. Hence

$$\Delta S_{\text{env}} = \frac{540\,\text{kJ}}{280\,\text{K}} = 1930\,\text{J/K}.$$

Thus, although the entropy of the iron actually decreases, the *total* change in entropy of iron plus environment is positive: $1930\,\text{J/K} - 1030\,\text{J/K} = 900\,\text{J/K}$.

In each of these Examples, the entropy of our system plus that of the environment (or surroundings) either stayed constant or increased. For any *reversible* process, the total entropy change is zero. This is because any reversible process can be considered as a series of quasistatic isothermal transfers of heat $\Delta Q$ between a system and the environment, which differ in temperature only by an infinitesimal amount. Hence the change in entropy of either the system or environment is $\Delta Q/T$ and that of the other is $-\Delta Q/T$, so the total is

$$\Delta S = \Delta S_{\text{syst}} + \Delta S_{\text{env}} = 0. \qquad \text{[any reversible process]}$$

In Examples 20–8, 20–9, and 20–10, we found that the total entropy of system plus environment increases. Indeed, it has been found that for all real (irreversible) processes, the total entropy increases. No exceptions have been found. We can thus make the *general statement of the second law of thermodynamics* as follows:

**The entropy of an isolated system never decreases. It either stays constant (reversible processes) or increases (irreversible processes).**

Since all real processes are irreversible, we can equally well state the second law as:

*SECOND LAW OF THERMODYNAMICS (general statement)*

**The total entropy of any system plus that of its environment increases as a result of any natural process:**

$$\Delta S = \Delta S_{\text{syst}} + \Delta S_{\text{env}} > 0. \qquad \textbf{(20–13)}$$

Although the entropy of one part of the universe may decrease in any process (see the last few Examples we have done), the entropy of some other part of the universe always increases by a greater amount, so the total entropy always increases.

Now that we finally have a quantitative general statement of the second law of thermodynamics, we can see that it is an unusual law. It differs considerably

from other laws of physics, which are typically equalities (such as $F = ma$) or conservation laws (such as for energy and momentum). The second law of thermodynamics introduces a new quantity, the entropy, $S$, but does not tell us it is conserved. Quite the opposite. Entropy is not conserved in natural processes. Entropy always increases in time for real processes.

### "Time's Arrow"

The second law of thermodynamics summarizes which processes are observed in nature, and which are not. Or, said another way, it tells us about the *direction* processes go. For the reverse of any of the processes in the last few Examples, the entropy would decrease; and we never observe those processes. For example, we never observe heat flowing spontaneously from a cold object to a hot object, the hot one getting hotter and the cold one colder. Nor do we ever observe a gas spontaneously compressing itself into a smaller volume, the reverse of Example 20–9 (gases always expand to fill their containers). Nor do we see thermal energy transform into kinetic energy of a rock so the rock rises spontaneously from the ground. Any of these processes would be consistent with the first law of thermodynamics (conservation of energy). But they are not consistent with the second law of thermodynamics, and this is why we need the second law. If you were to see a movie run backward, you would probably realize it immediately because you would see odd occurrences—such as rocks rising spontaneously from the ground, or air rushing in from the atmosphere to fill an empty balloon (the reverse of free expansion). When watching a movie or video, we are tipped off to a faked reversal of time by observing whether entropy is increasing or decreasing. Hence entropy has been called **time's arrow**, for it can tell us in which direction time is going.

## 20–7 Order to Disorder

The concept of entropy, as we have discussed it so far, may seem rather abstract. But we can relate it to the more ordinary concepts of *order* and *disorder*. In fact, the entropy of a system can be considered a *measure of the disorder of the system*. Then the second law of thermodynamics can be stated simply as:

*SECOND LAW OF THERMODYNAMICS (general statement)*

**natural processes tend to move toward a state of greater disorder.**

Exactly what we mean by **disorder** may not always be clear, so we now consider a few examples. Some of these will show us how this very general statement of the second law applies beyond what we usually consider as thermodynamics.

Let us look at the simple processes mentioned in Section 20–1. First, a jar containing separate layers of salt and pepper is more orderly than a jar in which the salt and pepper are all mixed up. Shaking a jar containing separate layers results in a mixture, and no amount of shaking brings the layers back again. The natural process is from a state of relative order (layers) to one of relative disorder (a mixture), not the reverse. That is, disorder increases. Second, a solid coffee cup is a more "orderly" and useful object than the pieces of a broken cup. Cups break when they fall, but they do not spontaneously mend themselves (as faked in Fig. 20–1). Again, the normal course of events is an increase of disorder.

Let us consider some processes for which we have actually calculated the entropy change, and see that an increase in entropy results in an increase in disorder (or vice versa). When ice melts to water at 0°C, the entropy of the water increases (Example 20–7). Intuitively, we can think of solid water, ice, as being more ordered than the less orderly fluid state which can flow all over the place. This change from order to disorder can be seen more clearly from the molecular point of view: the orderly arrangement of water molecules in an ice crystal has changed to the disorderly and somewhat random motion of the molecules in the fluid state.

When a hot substance is put in contact with a cold substance, heat flows from the high temperature to the low until the two substances reach the same intermediate temperature. Entropy increases, as we saw in Example 20–8. At the beginning of the process we can distinguish two classes of molecules: those with a high average kinetic energy (the hot object), and those with a low average kinetic energy (the cooler object). After the process in which heat flows, all the molecules are in one class with the same average kinetic energy; we no longer have the more orderly arrangement of molecules in two classes. Order has gone to disorder. Furthermore, the separate hot and cold objects could serve as the hot- and cold-temperature regions of a heat engine, and thus could be used to obtain useful work. But once the two objects are put in contact and reach the same temperature, no work can be obtained. Disorder has increased, because a system that has the ability to perform work must surely be considered to have a higher order than a system no longer able to do work.

When a stone falls to the ground, its macroscopic kinetic energy is transformed to thermal energy. (We noted earlier that the reverse never happens: a stone never absorbs thermal energy and rises into the air of its own accord.) This is another example of order changing to disorder. Thermal energy is associated with the disorderly random motion of molecules, but the molecules in the falling stone all have the same velocity downward in addition to their own random velocities. Thus, the more orderly kinetic energy of the stone as a whole (which could do useful work) is changed to disordered thermal energy when the stone strikes the ground. Disorder increases in this process, as it does in all processes that occur in nature.

### Biological Development

**PHYSICS APPLIED**
*Biological development*

An interesting example of the increase in entropy relates to the biological development and growth of organisms. Clearly, a human being is a highly ordered organism. The development of an individual from a single cell to a grown person is a process of increasing order. Evolution too might be seen as an increase in order. Do these processes violate the second law of thermodynamics? No, they do not. In the processes of growth and evolution, and even during the mature life of an individual, waste products are eliminated. These small molecules that remain as a result of metabolism are simple molecules without much order. Thus they represent relatively higher disorder or entropy. Indeed, the total entropy of the molecules cast aside by organisms during the processes of development and growth is greater than the decrease in entropy associated with the order of the growing individual or evolving species.

## 20–8 Unavailability of Energy; Heat Death

In the process of heat conduction from a hot object to a cold one, we have seen that entropy increases and that order goes to disorder. The separate hot and cold objects could serve as the high- and low-temperature regions for a heat engine and thus could be used to obtain useful work. But after the two objects are put in contact with each other and reach the same uniform temperature, no work can be obtained from them. With regard to being able to do useful work, order has gone to disorder in this process.

The same can be said about a falling rock that comes to rest upon striking the ground. Before hitting the ground, all the kinetic energy of the rock could have been used to do useful work. But once the rock's mechanical kinetic energy becomes thermal energy, doing useful work is no longer possible.

Both examples illustrate an important aspect of the second law of thermodynamics:

**in any natural process, some energy becomes unavailable to do useful work.**

In any process, no energy is ever lost (it is always conserved). Rather, energy becomes less useful—it can do less useful work. As time goes on, **energy is degraded**, in a sense. It goes from more orderly forms (such as mechanical) eventually to the least orderly form: internal, or thermal, energy. Entropy is a factor here because the amount of energy that becomes unavailable to do work is proportional to the change in entropy during any process.[†]

[†]It can be shown that the amount of energy that becomes unavailable to do useful work is equal to $T_L \Delta S$, where $T_L$ is the lowest available temperature and $\Delta S$ is the total increase in entropy during the process.

A natural outcome of the degradation of energy is the prediction that as time goes on, the universe is expected to approach a state of maximum disorder. Matter would become a uniform mixture, and heat would have flowed from high-temperature regions to low-temperature regions until the whole universe is at one temperature. No work could then be done. All the energy of the universe would have degraded to thermal energy. This prediction, called the **heat death** of the universe, has been much discussed, but it would lie *very* far in the future. It is a complicated subject, and some scientists question whether thermodynamics, as we now understand it, actually applies to the universe as a whole, which is at a much larger scale.

## 20–9 Statistical Interpretation of Entropy and the Second Law

The ideas of entropy and disorder are made clearer with the use of a statistical or probabilistic analysis of the molecular state of a system. This statistical approach, which was first applied toward the end of the nineteenth century by Ludwig Boltzmann (1844–1906), makes a clear distinction between the "macrostate" and the "microstate" of a system. The **microstate** of a system would be specified by giving the position and velocity of every particle (or molecule). The **macrostate** of a system is specified by giving the far fewer macroscopic properties of the system—the temperature, pressure, number of moles, and so on. In reality, we can know only the macrostate of a system. There are generally far too many molecules in a system to be able to know the velocity and position of every one at a given moment. Nonetheless, we can hypothesize a great many different microstates that can correspond to the *same* macrostate.

Let us take a very simple example. Suppose you repeatedly shake four coins in your hand and drop them on a table. Specifying the *number* of heads and the number of tails that appear on a given throw is the *macrostate* of this system. Specifying *each coin* as being a head or a tail is the *microstate* of the system. In Table 20–1 we see how many microstates correspond to each macrostate:

**TABLE 20–1 Microstates per Macrostates (4 coins)**

| Macrostate | Possible Microstates (H = heads, T = tails) | Number of Microstates |
|---|---|---|
| 4 heads | HHHH | 1 |
| 3 heads, 1 tail | HHHT, HHTH, HTHH, THHH | 4 |
| 2 heads, 2 tails | HHTT, HTHT, THHT, HTTH, THTH, TTHH | 6 |
| 1 head, 3 tails | TTTH, TTHT, THTT, HTTT | 4 |
| 4 tails | TTTT | 1 |

A basic assumption behind the statistical approach is that *each microstate is equally probable*. Thus the number of microstates that give the same macrostate corresponds to the relative probability of that macrostate occurring. The macrostate of two heads and two tails is the most probable one in our case of tossing four coins; out of the total of 16 possible microstates, six correspond to two heads and two tails, so the probability of throwing two heads and two tails is 6 out of 16, or 38%. The probability of throwing one head and three tails is 4 out of 16, or 25%. The probability of four heads is only 1 in 16, or 6%. If you threw the coins 16 times, you might not find that two heads and two tails appear exactly 6 times, or four tails exactly once. These are only probabilities or averages. But if you made 1600 throws, very nearly 38% of them would be two heads and two tails. The greater the number of tries, the closer the percentages are to the calculated probabilities.

**CAUTION**
*Careful use of probability*

**EXERCISE D** In Table 20–1, what is the probability that there will be at least two heads? (*a*) $\frac{1}{2}$; (*b*) $\frac{1}{16}$; (*c*) $\frac{1}{8}$; (*d*) $\frac{3}{8}$; (*e*) $\frac{11}{16}$.

If we toss more coins—say, 100 all at the same time—the relative probability of throwing all heads (or all tails) is greatly reduced. There is only one microstate corresponding to all heads. For 99 heads and 1 tail, there are 100 microstates because each of the coins could be the one tail. The relative probabilities for other macrostates are given in Table 20–2. About $1.3 \times 10^{30}$ microstates are possible.[†] Thus the relative probability of finding all heads is about 1 in $10^{30}$, an incredibly unlikely event! The probability of obtaining 50 heads and 50 tails (see Table 20–2) is $(1.0 \times 10^{29})/(1.3 \times 10^{30}) = 0.08$ or 8%. The probability of obtaining anything between 45 and 55 heads is about 70%.

**TABLE 20–2 Probabilities of Various Macrostates for 100 Coin Tosses**

| Macrostate | | Number of Microstates | Probability |
|---|---|---|---|
| Heads | Tails | | |
| 100 | 0 | 1 | $7.9 \times 10^{-31}$ |
| 99 | 1 | $1.0 \times 10^{2}$ | $7.9 \times 10^{-29}$ |
| 90 | 10 | $1.7 \times 10^{13}$ | $1.4 \times 10^{-17}$ |
| 80 | 20 | $5.4 \times 10^{20}$ | $4.2 \times 10^{-10}$ |
| 60 | 40 | $1.4 \times 10^{28}$ | 0.011 |
| 55 | 45 | $6.1 \times 10^{28}$ | 0.047 |
| 50 | 50 | $1.0 \times 10^{29}$ | 0.077 |
| 45 | 55 | $6.1 \times 10^{28}$ | 0.047 |
| 40 | 60 | $1.4 \times 10^{28}$ | 0.011 |
| 20 | 80 | $5.4 \times 10^{20}$ | $4.2 \times 10^{-10}$ |
| 10 | 90 | $1.7 \times 10^{13}$ | $1.4 \times 10^{-17}$ |
| 1 | 99 | $1.0 \times 10^{2}$ | $7.9 \times 10^{-29}$ |
| 0 | 100 | 1 | $7.9 \times 10^{-31}$ |

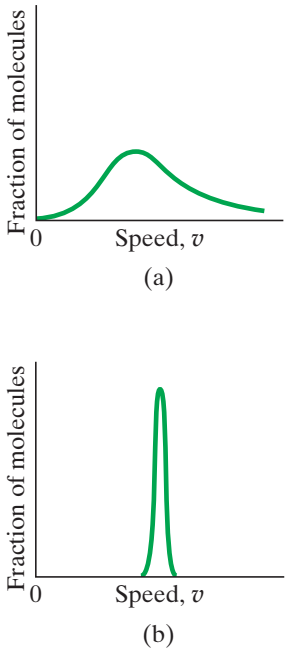

**FIGURE 20–13** (a) Most probable distribution of molecular speeds in a gas (Maxwellian, or random). (b) Orderly, but highly unlikely, distribution of speeds in which all molecules have nearly the same speed.

Thus we see that as the number of coins increases, the probability of obtaining the most orderly arrangement (all heads or all tails) becomes extremely unlikely. The least orderly arrangement (half heads, half tails) is the most probable, and the probability of being within, say, 5% of the most probable arrangement greatly increases as the number of coins increases. These same ideas can be applied to the molecules of a system. For example, the most probable state of a gas (say, the air in a room) is one in which the molecules take up the whole space and move about randomly; this corresponds to the Maxwellian distribution, Fig. 20–13a (and see Section 18–2). On the other hand, the very orderly arrangement of all the molecules located in one corner of the room and all moving with the same velocity (Fig. 20–13b) is extremely unlikely.

From these examples, we see that probability is directly related to disorder and hence to entropy. That is, the most probable state is the one with greatest entropy or greatest disorder and randomness; it is also the macrostate that corresponds to the *most microstates*. Boltzmann showed, consistent with Clausius's definition $(dS = dQ/T)$, that the entropy of a system in a given (macro) state can be written

$$S = k \ln \mathcal{W}, \tag{20–14}$$

where $k$ is Boltzmann's constant $(k = R/N_A = 1.38 \times 10^{-23}\,\text{J/K})$ and $\mathcal{W}$ is the number of microstates corresponding to the given macrostate. That is, $\mathcal{W}$ is proportional to the probability of occurrence of that state. $\mathcal{W}$ is called the **thermodynamic probability**, or, sometimes, the disorder parameter.

[†]Each coin has two possibilities, heads or tails. Then the possible number of microstates is $2 \times 2 \times 2 \times \cdots = 2^{100} \approx 1.3 \times 10^{30}$ (using a calculator or logarithms).

**EXAMPLE 20–11** **Free expansion—statistical determination of entropy.** Use Eq. 20–14 to determine the change in entropy for the adiabatic *free expansion* of a gas, a calculation we did macroscopically in Example 20–9. Assume $\mathcal{W}$, the number of microstates for each macrostate, is the number of possible positions.

**APPROACH** We assume the number of moles is $n = 1$, and then the number of molecules is $N = nN_A = N_A$, Avogadro's number. We let the volume double, just as in Example 20–9. Because the volume doubles, the number of possible positions for each molecule doubles.

**SOLUTION** When the volume doubles, each molecule has two times as many positions (microstates) available. For two molecules, the number of total microstates increases by $2 \times 2 = 2^2$. For $N_A$ molecules, the total number of microstates increases by a factor of $2 \times 2 \times 2 \times \cdots = 2^{N_A}$. That is

$$\frac{\mathcal{W}_2}{\mathcal{W}_1} = 2^{N_A}.$$

The change in entropy is, from Eq. 20–14,

$$\Delta S = S_2 - S_1 = k(\ln \mathcal{W}_2 - \ln \mathcal{W}_1) = k \ln \frac{\mathcal{W}_2}{\mathcal{W}_1} = k \ln 2^{N_A}$$
$$= kN_A \ln 2 = R \ln 2$$

which is the same result we obtained in Example 20–9.

In terms of probability, the second law of thermodynamics—which tells us that entropy increases in any process—reduces to the statement that **those processes occur which are most probable**.

There is an additional element, however. The second law in terms of probability does not *forbid* a decrease in entropy. Rather, it says the probability is extremely low. It is not impossible that salt and pepper could separate spontaneously into layers, or that a broken cup could mend itself (Fig. 20–1). It is even possible that a lake could freeze over on a hot summer day (that is, for heat to flow out of the cold lake into the warmer surroundings). But the probability for such events occurring is extremely small. In our coin examples, we saw that increasing the number of coins from 4 to 100 drastically reduced the probability of large deviations from the average, or most probable, arrangement. In ordinary systems we are not dealing with only 100 molecules, but with extremely large numbers of molecules: in 1 mol alone there are $6 \times 10^{23}$ molecules. Hence the probability of deviation far from the average is incredibly tiny. For example, it has been calculated that the probability that a stone resting on the ground could transform 1 cal of thermal energy into mechanical energy and rise up into the air is much less likely than the probability that a group of monkeys typing randomly would by chance produce the complete works of Shakespeare. Put another way, the probability is less than once in the entire age of the universe; this could be what "never" means.

## *20–10 Thermodynamic Temperature; Third Law of Thermodynamics

In Section 20–3 we saw for a Carnot cycle that the ratio of the heat absorbed $Q_H$ from the high-temperature reservoir and the heat exhausted $Q_L$ to the low-temperature reservoir is equal to the ratio of the temperatures of the two reservoirs (Eq. 20–2):

$$\frac{Q_L}{Q_H} = \frac{T_L}{T_H}.$$

This result is valid for any reversible engine and does not depend on the working substance. It can thus serve as the basis for the **Kelvin** or **thermodynamic temperature scale**.

We use this relation and the ideal gas temperature scale (Section 17–10) to complete the definition of the thermodynamic scale: we assign the value $T_{tp} = 273.16\,\text{K}$ to the triple point of water so that

$$T = (273.16\,\text{K})\left(\frac{Q}{Q_{tp}}\right),$$

where $Q$ and $Q_{tp}$ are the magnitudes of the heats exchanged by a Carnot engine with reservoirs at temperatures $T$ and $T_{tp}$. Then the thermodynamic scale is identical to the ideal gas scale over the latter's range of validity.

Very low temperatures are difficult to obtain experimentally. The closer the temperature is to absolute zero, the more difficult it is to reduce the temperature further, and it is generally accepted that *it is not possible to reach absolute zero in any finite number of processes*. This last statement is one way to state the **third law of thermodynamics**. Since the maximum efficiency that any heat engine can have is the Carnot efficiency

$$e = 1 - \frac{T_L}{T_H},$$

and since $T_L$ can never be zero, we see that a 100% efficient heat engine is not possible.

**FIGURE 20–15** Mechanical energy is transformed to electric energy with a turbine and generator.

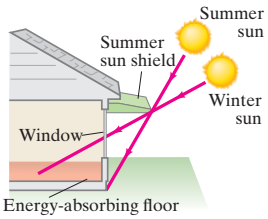
**PHYSICS APPLIED**

*Heat engines and thermal pollution*

## 20–11 Thermal Pollution, Global Warming, and Energy Resources

Much of the energy we use in everyday life—from motor vehicles to most of the electricity produced by power plants—uses a heat engine. About $\frac{2}{3}$ of the electric energy produced in the U.S. is generated at fossil-fuel steam plants (coal, oil, or gas—see Fig. 20–14a), and they make use of a heat engine (steam engines). In electric power plants, the steam drives the turbines and generators (Fig. 20–15) whose output is electric energy. The various means to turn the turbine are shown in Table 20–3, along with some of the advantages and disadvantages of each. Even nuclear power plants use a steam engine, run on nuclear fuel. Electricity produced by falling water at dams, by windmills, or by solar cells (Fig. 20–14b) does not involve a heat engine.

The heat output $Q_L$ from every heat engine, from power plants to cars, is referred to as **thermal pollution** because this heat $(Q_L)$ must be absorbed by the environment—such as by water from rivers or lakes, or by the air using large cooling towers (Fig. 20–14c). When water is the coolant, this heat raises the temperature of the water, altering the natural ecology of aquatic life (warmer water holds less oxygen). In air cooling towers, the output heat $Q_L$ raises the temperature of the atmosphere, which affects climate.



**Air pollution**—the chemicals released in the burning of fossil fuels in cars, power plants, heating, and industrial furnaces—gives rise to smog and other problems. Buildup of $CO_2$ in the Earth's atmosphere, due to the burning of fossil fuels (carbon in the fuel combines with $O_2$ of the air) absorbs infrared radiation the Earth naturally emits, and thus contributes to **global warming**.

Electric energy production (Table 20–3) is responsible for only about $\frac{1}{4}$ of fossil-fuel pollution. The other $\frac{3}{4}$ is due to direct burning of fossil fuels in cars, trucks, airplanes, manufacturing furnaces, and heating houses and buildings.

The **carbon footprint** of these activities refers to the negative impact on the environment due to the burning of fossil fuels releasing $CO_2$ (and other noxious products) into the atmosphere, contributing to **climate change**. A carbon footprint can be expressed in kg or tons of carbon (in the $CO_2$). Limiting the burning of fossil fuels can help reduce these problems.

And do not be fooled that electric cars do not pollute. They do. When you plug them in to charge, that electricity is produced at power plants which mostly burn very polluting fossil fuels (Table 20–3). So *your electric car is no cleaner than the power plant that supplies your electricity*. Furthermore, to make an electric car includes massive energy storage batteries which require very large amounts of energy (and pollution) to manufacture, and later to recycle (or dispose of) when worn out.

**TABLE 20–3 Electric Energy Resources**

| Form of Electric Energy Production | % of Production (approx.) U.S. | % of Production (approx.) World | Advantages | Disadvantages |
|---|---|---|---|---|
| **Fossil-fuel steam plants:** burn coal, oil, or natural gas to boil water, producing high-pressure steam that turns a turbine of a generator (Figs. 20–3b, 20–15); uses heat engine. | 64 | 65 | We know how to build them; for now relatively inexpensive. | Air pollution; thermal pollution; limited efficiency; land devastation from extraction of raw materials (mining); global warming; accidents such as oil spills at sea or on land; limited fuel supply (estimates range from a few decades to maybe a century). |
| **Nuclear energy:** | | | | |
| **Fission:** nuclei of uranium or plutonium atoms split ("fission") with release of energy (Chapter 42) that heats steam; uses heat engine. | 19 | 10 | Normally almost no air pollution; less contribution to global warming; relatively inexpensive.  | Thermal pollution; accidents can release damaging radioactivity; difficult disposal of radioactive by-products; possible diversion of nuclear material by terrorists; limited fuel supply. |
| **Fusion:** energy released when isotopes of hydrogen (or other small nuclei) combine or "fuse" (Chapter 42). | 0 | 0 | Relatively "clean"; vast fuel supply (hydrogen in water molecules in oceans); less contribution to global warming. | Not yet workable. |
| **Hydroelectric:** falling water turns turbines at the base of a dam.  | 7 | 16 | No heat engine needed; no air, water, or thermal pollution; relatively inexpensive; high efficiency; dams can control flooding. | Reservoirs behind dams inundate scenic or inhabited land; they fill with silt over time and become useless; dams block upstream migration of salmon and other fish for reproduction; few locations remain for new dams; drought. |
| **Geothermal:** natural steam from inside the Earth comes to the surface (hot springs, geysers, steam vents); or cold water passed down into contact with hot, dry rock is heated to steam. | <1 | 1 | No heat engine needed; little air pollution; good efficiency; relatively inexpensive and "clean." | Few appropriate sites; small production; mineral content of spent hot water can pollute. |
| **Wind power:** 3-kW to 5-MW windmills (vanes up to 50 m long) turn a generator.  | 7 | 5 | No heat engine; no air, water, or thermal pollution; relatively inexpensive. | Large array of big windmills might affect weather and be eyesores; slows down cooling winds; hazardous to migratory birds; winds not always strong. |
| **Solar energy:** | | | | |
| **Active solar heating:** rooftop solar panels absorb the Sun's rays, heating water in tubes for inside heating and hot water supply. (See also Fig. 20–14b.) | 1 | >1 | No heat engine needed; no air or thermal pollution; unlimited fuel supply.  | Space limitations; may require back-up; relatively expensive; less effective when cloudy. |
| **Passive solar heating:** architectural devices—windows along southern exposure, sunshade over windows to keep Sun's rays out in summer. | | | No heat engine needed; no air or thermal pollution; relatively inexpensive. | Almost none, but other methods needed too.   |
| **Solar cells (photovoltaic cells):** convert sunlight directly into electricity without use of heat engine. | 2 [California ≈ 20%] | 3 | No heat engine; thermal, air, and water pollution very low; good efficiency (>30% and improving). | Expensive; chemical pollution at manufacture; much land needed as Sun's energy not concentrated; absorption (dark color) without reemission = global warming. |

**PHYSICS APPLIED**

*Thermal pollution unavoidable*
*Best = use less energy!*
*[Avoid also plastic especially in packaging: protect our oceans.]*

Thermal pollution, however, is unavoidable. Engineers can try to design and build engines that are more efficient, but they cannot surpass the Carnot efficiency and must live with $T_L$ being at best the ambient temperature of water or air. The second law of thermodynamics tells us the limit imposed by nature. Even alternative energy sources like wind and solar cells can contribute to global warming: windmills slow down cooling winds; solar cells are "dark" and absorb more of the Sun's energy, thus warming the Earth more. The best we can do, in the light of the second law of thermodynamics, is use less energy and conserve our fuel resources.

PROBLEM SOLVING

## Thermodynamics

1. Define the **system** you are dealing with; distinguish the system under study from its surroundings.
2. When applying the first law of thermodynamics, be careful of **signs** associated with **work** and **heat**. In the first law, work done *by* the system is positive; work done *on* the system is negative. Heat *added* to the system is positive, but heat *removed* from it is negative. With heat engines, we usually consider the heat intake, the heat exhausted, and the work done as positive.
3. Watch the **units** used for work and heat; work is most often expressed in joules, and heat can be in calories, kilocalories, or joules. Be consistent: choose only one unit for use throughout a given problem.
4. **Temperatures** must generally be expressed in kelvins; temperature *differences* may be expressed in C° or K.
5. **Efficiency** (or coefficient of performance) is a ratio of two energy transfers: useful output divided by required input. Efficiency (but *not* coefficient of performance) is always less than 1 in value, and hence is often stated as a percentage.
6. The **entropy** of a system increases when heat is added to the system, and decreases when heat is removed. If heat is transferred from system A to system B, the change in entropy of A is negative and the change in entropy of B is positive.

# Summary

A **heat engine** is a device for changing thermal energy, by means of heat flow, partially into useful work.

The **efficiency** $e$ of a heat engine is defined as the ratio of the work $W$ done by the engine to the high temperature heat input $Q_H$. Because of conservation of energy, the work output equals $Q_H - Q_L$, where $Q_L$ is the heat exhausted at low temperature to the environment; hence

$$e = \frac{W}{Q_H} = \frac{Q_H - Q_L}{Q_H} = 1 - \frac{Q_L}{Q_H}. \quad \textbf{(20–1)}$$

$Q_H$, $Q_L$, $W$, as defined for heat engines, are positive.

A **Carnot engine** consists of two isothermal and two adiabatic processes in an idealized reversible cycle.

The *upper limit* on the efficiency (the *Carnot efficiency*) can be written in terms of the higher and lower operating temperatures (in kelvins) of the engine, $T_H$ and $T_L$, as

$$e_{\text{ideal}} = 1 - \frac{T_L}{T_H}. \quad \textbf{(20–3)}$$

Real (irreversible) engines always have an efficiency less than this.

The operation of **refrigerators** and **air conditioners** is the reverse of a heat engine: work is done to extract heat $Q_L$ from a cool region and exhaust it to a region at a higher temperature. The coefficient of performance (COP) for either is

$$\text{COP} = \frac{Q_L}{W}, \quad \begin{bmatrix}\text{refrigerator or}\\ \text{air conditioner}\end{bmatrix} \quad \textbf{(20–4a)}$$

where $W$ is the work needed to remove heat $Q_L$ from the area with the low temperature, which is the purpose of these devices.

A **heat pump** uses work $W$ to bring heat $Q_L$ from the cold outside and deliver heat $Q_H$ to warm the interior. The coefficient of performance of a heat pump is

$$\text{COP} = \frac{Q_H}{W}, \quad \text{[heat pump]} \quad \textbf{(20–5)}$$

because it is the heat $Q_H$ delivered inside the building that counts.

The **second law of thermodynamics** can be stated in several equivalent ways:

(a) heat flows spontaneously from a hot object to a cold one, but not the reverse;
(b) there can be no 100% efficient heat engine—that is, one that can change a given amount of heat completely into work;
(c) natural processes tend to move toward a state of greater disorder or greater **entropy**.

Statement (c) is the most general statement of the second law of thermodynamics, and can be restated as: the total entropy, $S$, of any system plus that of its environment increases as a result of any natural process:

$$\Delta S > 0. \quad \textbf{(20–13)}$$

The change in entropy in a process that transfers heat $Q$ at a constant temperature $T$ is

$$\Delta S = \frac{Q}{T}. \quad \textbf{(20–6)}$$

In general for a reversible process, $\Delta S = \int dQ/T$.

Entropy is a quantitative measure of the **disorder** of a system. The second law of thermodynamics also indicates that as time goes on, energy is **degraded** to less useful forms—that is, it is less available to do useful work.

The second law of thermodynamics tells us in which direction processes tend to proceed; hence entropy is called **time's arrow**.

Entropy can be examined from a statistical point of view, considering **macrostates** (for example, $P$, $V$, $T$) and **microstates** (state of each molecule). The most probable processes are the ones we observe, and they are the macrostates that have the most microstates. They are the ones that increase entropy the most. Processes that violate the second law "could" occur, but only with *extremely* low probability.

[*All heat engines give rise to **thermal pollution** because they exhaust heat to the environment.]

# Questions

1. Can mechanical energy ever be transformed completely into heat or internal energy? Can the reverse happen? In each case, if your answer is no, explain why not; if yes, give one or two examples.
2. Can you warm a kitchen in winter by leaving the oven door open? Can you cool the kitchen on a hot summer day by leaving the refrigerator door open? Explain.
3. Would a definition of heat engine efficiency as $e = W/Q_L$ be useful? Explain.
4. What are the high-temperature and the low-temperature areas for (*a*) an internal combustion engine, and (*b*) a steam engine? Are they, strictly speaking, heat reservoirs?
5. What exactly is a Carnot engine and why is it important? How practical is it?
6. The oceans contain a tremendous amount of thermal (internal) energy. Why, in general, is it not possible to put this energy to useful work?
7. Discuss the factors that keep real engines from reaching Carnot efficiency.
8. The expansion valve in a refrigeration system, Fig. 20–9, is crucial for cooling the fluid. Explain how the cooling occurs.
9. (*a*) Describe how heat could be added to a system reversibly. (*b*) Could you use a stove burner to add heat to a system reversibly? Explain.
10. (*a*) What happens if you remove the lid of a bottle containing chlorine gas? (*b*) Does the reverse process ever happen? Why or why not? (*c*) Can you think of two other examples of irreversibility?
11. The COPs are defined differently for heat pumps and air conditioners. Explain why.
12. A gas is allowed to expand (*a*) adiabatically and (*b*) isothermally. In each process, does the entropy increase, decrease, or stay the same? Explain.
13. Give three examples, other than those mentioned in this Chapter, of naturally occurring processes in which order goes to disorder. Discuss the observability of the reverse process.
14. Which do you think has the greater entropy, 1 kg of solid iron or 1 kg of liquid iron? Why?
15. (*a*) Make up an advertisement for a refrigerator or an air conditioner that violates the first law of thermodynamics (see Section 20–4). (*b*) Make up an ad for a car engine that violates the second law of thermodynamics (see Section 20–2).
16. Think up several processes (other than those already mentioned) that would obey the first law of thermodynamics, but, if they actually occurred, would violate the second law.
17. Suppose a lot of papers are strewn all over the floor; then you stack them neatly. Does this violate the second law of thermodynamics? Explain.
18. The first law of thermodynamics is sometimes whimsically stated as, "You can't get something for nothing," and the second law as, "You can't even break even." Explain how these statements could be equivalent to the formal statements.
19. Powdered milk is very slowly (quasistatically) added to water while being stirred. Is this a reversible process? Explain.
20. Two identical systems are taken from state a to state b by two different *irreversible* processes. Will the change in entropy for the system be the same for each process? For the environment? Answer carefully and completely.
21. It can be said that the *total change in entropy during a process is a measure of the irreversibility of the process*. Discuss why this is valid, starting with the fact that $\Delta S_{\text{total}} = \Delta S_{\text{system}} + \Delta S_{\text{environment}} = 0$ for a reversible process.
22. Entropy is often called "time's arrow" because it tells us in which direction natural processes occur. If a movie were run backward, name some processes that you might see that would tell you that time was "running backward."
23. Living organisms, as they grow, convert relatively simple food molecules into a complex structure. Is this a violation of the second law of thermodynamics? Explain your answer.

# MisConceptual Questions

1. Which is possible: converting (i) 100 J of work entirely into 100 J of heat, (ii) 100 J of heat entirely into 100 J of work?
   (*a*) Only (i) is possible.
   (*b*) Only (ii) is possible.
   (*c*) Both (i) and (ii) are possible.
   (*d*) Neither (i) nor (ii) is possible.
2. A heat engine operates between a high temperature of about 600°C and a low temperature of about 300°C. What is the maximum theoretical efficiency for this engine?
   (*a*) = 100%. (*b*) ≈ 66%. (*c*) ≈ 50%. (*d*) ≈ 34%.
   (*e*) Cannot be determined from the given information.
3. On a very hot day, could you cool your kitchen by leaving the refrigerator door open?
   (*a*) Yes, but it would be very expensive.
   (*b*) Yes, but only if the humidity is below 50%.
   (*c*) No, the refrigerator would exhaust the same amount of heat into the room as it takes out of the room.
   (*d*) No, the heat exhausted by the refrigerator into the room is more than the heat the refrigerator takes out of the room.
4. Which of the following possibilities could increase the efficiency of a heat engine or an internal combustion engine?
   (*a*) Increase the temperature of the hot part of the system and reduce the temperature of the exhaust.
   (*b*) Increase the temperatures of both the hot part and the exhaust part of the system by the same amount.
   (*c*) Decrease the temperatures of both the hot part and the exhaust part of the system by the same amount.
   (*d*) Decrease the temperature of the hot part and increase the temperature of the exhaust part by the same amount.
   (*e*) None of the above; only redesigning the engine or using better gas could improve the engine's efficiency.
5. About what percentage of the heat produced by burning gasoline is turned into useful work by a typical automobile?
   (*a*) 20%.
   (*b*) 50%.
   (*c*) 80%.
   (*d*) 90%.
   (*e*) Nearly 100%.

6. An engine manufacturer makes the claim that the engine they have developed will, on each cycle, take 100 J of heat out of boiling water at 100°C, do mechanical work of 80 J, and exhaust 20 J of heat at 10°C. What, if anything, is wrong with this claim?
   (*a*) The heat exhausted must always be greater than the work done according to the second law of thermodynamics.
   (*b*) There is nothing wrong with this claim because 100 J = 20 J + 80 J.
   (*c*) The efficiency of this engine is greater than the ideal Carnot cycle efficiency.
   (*d*) This engine violates the first law of thermodynamics because 100 J + 20 J ≠ 80 J.
   (*e*) An engine would operate by taking in heat at the lower temperature and exhausting heat at the higher temperature.

7. Which statement is true regarding the entropy change of an ice cube that melts?
   (*a*) Since melting occurs at the melting point temperature, there is no temperature change so there is no entropy change.
   (*b*) Entropy increases.
   (*c*) Entropy decreases.

8. A piece of ice at 0°C melts very slowly at 0°C. Assume that the ice is in contact with a heat reservoir whose temperature is only infinitesimally greater than 0°C. What are the entropy changes of the ice cube and the heat reservoir, respectively?
   (*a*) Both entropy changes are negative.
   (*b*) Both entropy changes are 0.
   (*c*) Both entropy changes are positive.
   (*d*) The changes are the same magnitude, but the ice gains entropy and the reservoir loses entropy.
   (*e*) The changes are the same magnitude, but the ice loses entropy and the reservoir gains entropy.

9. When a gas is compressed isothermally, its entropy
   (*a*) increases.
   (*b*) decreases.
   (*c*) stays the same.

10. There are three coins on a table—one head and two tails. How many microstates would give this macrostate?
   (*a*) 1 (*b*) 2 (*c*) 3 (*d*) 6
   (*e*) None of the above.

11. Which of the processes shown in Fig. 20–16 results in the least entropy change for an ideal gas changing from state S (start) to state F (finish)?
   (*a*) Process A.
   (*b*) Process B.
   (*c*) Process C.
   (*d*) Process D.
   (*e*) All 4 processes produce the same entropy change of the gas.

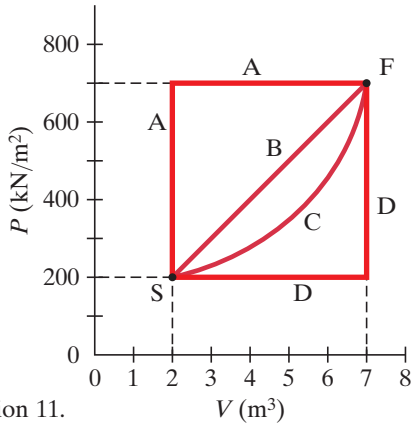


**FIGURE 20–16**
MisConceptual Question 11.

12. Which of the following are not subject to the second law?
   (*a*) Electric cars.
   (*b*) Electricity-producing windmills.
   (*c*) Hydroelectric power stations.
   (*d*) Nuclear power stations.
   (*e*) Coal-fired power stations.
   (*f*) None of the above. All are subject to the second law.

# Problems

## 20–2 Heat Engines

1. (I) A heat engine exhausts 7600 J of heat while performing 2600 J of useful work. What is the efficiency of this engine?
2. (I) The exhaust temperature of a heat engine is 230°C. What is the high temperature if the Carnot efficiency is 34%?
3. (II) A certain power plant puts out 680 MW of electric power. Estimate the heat discharged per second, assuming that the plant has an efficiency of 32%.
4. (II) A typical compact car experiences a total drag force of about 350 N at 55 mi/h. If this car gets 32 miles per gallon of gasoline at this speed, and a liter of gasoline (1 gal = 3.8 L) releases about $3.2 \times 10^7$ J when burned, what is the car's efficiency?
5. (II) A four-cylinder gasoline engine has an efficiency of 0.22 and delivers 180 J of work per cycle per cylinder. If the engine runs at 25 cycles per second (1500 rpm), determine (*a*) the work done per second, and (*b*) the total heat input per second from the gasoline. (*c*) If the energy content of gasoline is 120 MJ per gallon, how far can the car go on one gallon (or on one liter), assuming 1500 rpm in high gear corresponds to a speed of 80 km/h?
6. (III) Figure 20–17 is a *PV* diagram for a reversible heat engine in which 1.0 mol of argon, a nearly ideal monatomic gas, is initially at STP (point a). Points b and c are on an isotherm at $T = 423$ K. Process ab is at constant volume, process ac at constant pressure. (*a*) Is the path of the cycle carried out clockwise or counterclockwise? (*b*) What is the efficiency of this engine?

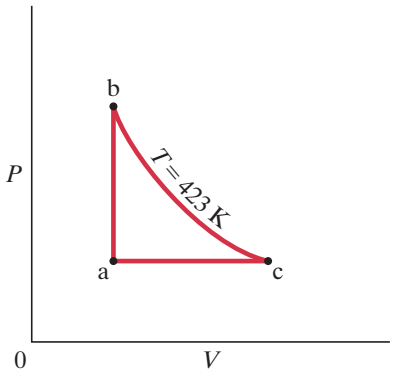

**FIGURE 20–17** Problem 6.

## 20–3 Carnot Engine

7. (I) What is the maximum efficiency of a heat engine whose operating temperatures are 530°C and 345°C?

8. (II) Nitrogen liquefies at 77 K (Fig. 20–18) and is relatively cheap to produce. (*a*) Estimate the efficiency of an ideal engine that operated between room temperature (293 K) and liquid nitrogen as the low temperature reservoir. (*b*) Discuss the issues for why this high efficiency may not be practical.

**FIGURE 20–18**
Problem 8.

9. (II) A heat engine exhausts its heat at 340°C and has a Carnot efficiency of 36%. What exhaust temperature would enable it to achieve a Carnot efficiency of 45%?

10. (II) A heat engine uses a heat source at 540°C and has an ideal (Carnot) efficiency of 22%. To increase the ideal efficiency to 42%, what must be the temperature of the heat source?

11. (II) (*a*) Show that the work done by a Carnot engine is equal to the area enclosed by the Carnot cycle on a *PV* diagram, Fig. 20–5. (See Section 19–7.) (*b*) Generalize this to any reversible cycle.

12. (II) A Carnot engine's operating temperatures are 210°C and 45°C. The engine's power output is 960 W. Calculate the rate of heat output.

13. (II) A nuclear power plant operates at 65% of its maximum theoretical (Carnot) efficiency between temperatures of 660°C and 330°C. If the plant produces electric energy at the rate of 1.4 GW, how much exhaust heat is discharged per hour?

14. (II) Which will improve the efficiency of a Carnot engine more: a 10 C° increase in the high-temperature reservoir, or a 10 C° decrease in the low-temperature reservoir? Give detailed results. Can you state a generalization?

15. (II) Assume that a 65-kg hiker needs to eat $4.0 \times 10^3$ kcal of energy to supply a day's worth of metabolism ($= Q_H$). Estimate the elevation change the person can climb in one day, using only this amount of energy. As a fun and rough prediction, treat the person as an isolated heat engine, operating between the internal temperature of 37°C (98.6°F) and the ambient air temperature of 20°C.

16. (II) A Carnot engine performs work at the rate of 520 kW with an input of 950 kcal of heat per second. If the temperature of the heat source is 480°C, at what temperature is the waste heat exhausted?

17. (II) A particular car does work at the rate of about 7.0 kJ/s when traveling at a steady 21.8 m/s along a level road. This is the work done against friction. The car can travel 17 km on 1.0 L of gasoline at this speed (about 40 mi/gal). What is the minimum value for $T_H$ if $T_L$ is 25°C? The energy available from 1.0 L of gas is $3.2 \times 10^7$ J.

18. (II) The working substance of a certain Carnot engine is 1.0 mol of an ideal monatomic gas. During the isothermal expansion portion of this engine's cycle, the volume of the gas doubles, while during the adiabatic expansion the volume increases by a factor of 6.2. The work output of the engine is 920 J in each cycle. Compute the temperatures of the two reservoirs between which this engine operates.

19. (III) A Carnot cycle, shown in Fig. 20–5, has the following conditions: $V_a = 7.5$ L, $V_b = 15.0$ L, $T_H = 470$°C, and $T_L = 260$°C. The gas used in the cycle is 0.50 mol of a diatomic gas, $\gamma = 1.4$. Calculate (*a*) the pressures at a and b; (*b*) the volumes at c and d. (*c*) What is the work done along process ab? (*d*) What is the heat lost along process cd? (*e*) Calculate the net work done for the whole cycle. (*f*) What is the efficiency of the cycle, using the definition $e = W/Q_H$? Show that this is the same as given by Eq. 20–3.

20. (III) One mole of monatomic gas undergoes a Carnot cycle with $T_H = 350$°C and $T_L = 210$°C. The initial pressure is 8.8 atm. During the isothermal expansion, the volume doubles. (*a*) Find the values of the pressure and volume at the points a, b, c, and d of Fig. 20–5. (*b*) Determine $Q$, $W$, and $\Delta E_{int}$ for each segment of the cycle. (*c*) Calculate the efficiency of the cycle using Eqs. 20–1 and 20–3.

*21. (III) In an engine that approximates the Otto cycle (Fig. 20–7), gasoline vapor must be ignited at the end of the cylinder's adiabatic compression by the spark from a spark plug. The ignition temperature of 87-octane gasoline vapor is about 430°C. Assuming that the working gas is diatomic and enters the cylinder at 25°C, determine the maximum compression ratio of the engine.

## 20–4 Refrigerators, Air Conditioners, Heat Pumps

22. (I) If an ideal refrigerator keeps its contents at 2.5°C when the house temperature is 22°C, what is its COP?

23. (I) The low temperature of a freezer cooling coil is −8°C and the discharge temperature is 33°C. What is the maximum theoretical coefficient of performance?

24. (I) A Carnot heat pump supplies 3900 W to keep a room at 23°C while drawing energy from the outside air at the rate of 3400 W. What is the outside air temperature?

25. (II) What is the temperature inside an ideal refrigerator-freezer that operates with a COP = 7.0 in a 22°C room?

26. (II) A *heat pump* is used to keep a house warm at 22°C. How much work is required of the pump to deliver 2800 J of heat into the house if the outdoor temperature is (*a*) 0°C, (*b*) −15°C? Assume a COP of 3.0. (*c*) Redo for both temperatures assuming an ideal Carnot heat pump, first deriving the ideal (Carnot) coefficient of performance as

$$\text{COP} = \frac{T_H}{T_H - T_L}.$$

27. (II) (*a*) What is the coefficient of performance of an ideal heat pump that extracts heat from 6°C air outside and deposits heat inside a house at 24°C? (*b*) If this heat pump operates on 1200 W of electrical power, what is the maximum heat it can deliver into your house each hour? See Problem 26.

28. (II) (*a*) Given that the coefficient of performance of a *refrigerator* is defined (Eq. 20–4a) as

$$\text{COP} = \frac{Q_L}{W},$$

show that Eqs. 20–4c is valid for an ideal (Carnot) refrigerator,

$$\text{COP}_{\text{ideal}} = \frac{T_L}{T_H - T_L}.$$

(*b*) Write the COP in terms of the efficiency $e$ of the reversible heat engine obtained by running the refrigerator backward. (*c*) What is the coefficient of performance for an ideal refrigerator that maintains a freezer compartment at −18°C when the condenser's temperature is 24°C?

**29.** (II) An ideal heat pump is used to maintain the inside temperature of a house at $T_{in} = 22°C$ when the outside temperature is $T_{out}$. Assume the heat pump does work at a rate of 1700 W. Also assume that the house loses heat via conduction through its walls and other surfaces at a rate given by $(650\ W/C°)(T_{in} - T_{out})$. (*a*) For what outside temperature would the heat pump have to operate at all times in order to maintain the house at an inside temperature of 22°C? (*b*) If the outside temperature is less than you just calculated, what happens? (*c*) If the outside temperature is 8°C, what percentage of the time does the heat pump have to operate in order to maintain the house at an inside temperature of 22°C?

**30.** (II) An ideal (Carnot) engine has an efficiency of 33%. If it were possible to run it backward as a heat pump, what would be its coefficient of performance?

**31.** (II) What volume of water at 0°C can a freezer make into ice cubes in 1.0 h, if the coefficient of performance of the cooling unit is 6.0 and the power input is 1.2 kilowatt?

**32.** (II) A central heat pump operating as an air conditioner draws 33,000 Btu per hour from a building and operates between the temperatures of 24°C and 38°C. (*a*) If its coefficient of performance is only 25% of a Carnot air conditioner, what is the effective coefficient of performance? (*b*) What is the power (kW) required of the compressor motor? (*c*) What is the power in terms of hp?

**33.** (II) How much less per year would it cost a family to operate a heat pump that has a coefficient of performance of 2.9 than an electric heater that costs $2100 to heat their home for a year? If the conversion to the heat pump costs $15,000, how long would it take the family to break even on heating costs? How much would the family save in 20 years?

## 20–5 and 20–6 Entropy

**34.** (I) What is the change in entropy of 280 g of steam at 100°C when it is condensed to water at 100°C?

**35.** (I) 1.0 kg of water is heated from 0°C to 100°C. Estimate the change in entropy of the water.

**36.** (I) What is the change in entropy of 1.00 $m^3$ of water at 0°C when it is frozen to ice at 0°C?

**37.** (II) A 6.8-kg box having an initial speed of 4.0 m/s slides along a rough table and comes to rest. Estimate the total change in entropy of the universe. Assume all objects are at room temperature (293 K).

**38.** (II) If 0.45 kg of water at 100°C is changed by a reversible process to steam at 100°C, determine the change in entropy of (*a*) the water, (*b*) the surroundings, and (*c*) the universe as a whole. (*d*) How would your answers differ if the process were irreversible?

**39.** (II) If 1.00 $m^3$ of water at 0°C is frozen and cooled to −8.0°C by being in contact with a great deal of ice at −8.0°C, estimate the total change in entropy of the process.

**40.** (II) A 2.8-kg piece of aluminum at 36.5°C is placed in 1.0 kg of water in a Styrofoam container at room temperature (20.0°C). Determine the net change in entropy of the system when it comes to equilibrium.

**41.** (II) An aluminum rod conducts 8.25 cal/s from a heat source maintained at 225°C to a large body of water at 22°C. Calculate the rate at which entropy increases in this process.

**42.** (II) A falling rock has kinetic energy $K$ just before striking the ground and coming to rest. What is the total change in entropy of rock plus environment as a result of this collision?

**43.** (II) An ideal gas expands isothermally $(T = 440\ K)$ from a volume of 2.50 L and a pressure of 7.5 atm to a pressure of 1.0 atm. What is the entropy change for this process?

**44.** (II) When 2.0 kg of water at 12.0°C is mixed with 3.0 kg of water at 38.0°C in a well-insulated container, what is the change in entropy of the system? (*a*) Make an estimate; (*b*) use the integral $\Delta S = \int dQ/T$.

**45.** (II) A real heat engine working between heat reservoirs at 970 K and 650 K produces 550 J of work per cycle for a heat input of 2500 J. (*a*) Compare the efficiency of this real engine to that of an ideal (Carnot) engine. (*b*) Calculate the total entropy change of the universe per cycle of the real engine, and (*c*) also if the engine is ideal (Carnot).

**46.** (II) The temperature of 1.6 mol of an ideal diatomic gas goes from 25°C to 55°C at a constant volume. What is the change in entropy? Use $\Delta S = \int dQ/T$.

**47.** (II) (*a*) An ice cube of mass $m$ at 0°C is placed in a large 20°C room. Heat flows (from the room to the ice cube) such that the ice cube melts and the liquid water warms to 20°C. The room is so large that its temperature remains nearly 20°C at all times. Calculate the change in entropy for the (water + room) system due to this process. Will this process occur naturally? (*b*) A mass $m$ of liquid water at 20°C is placed in a large 20°C room. Heat flows (from the water to the room) such that the liquid water cools to 0°C and then freezes into a 0°C ice cube. The room is so large that its temperature remains 20°C at all times. Calculate the change in entropy for the (water + room) system due to this process. Will this process occur naturally?

**48.** (II) An ideal gas of $n$ moles undergoes the reversible process ab shown in the $PV$ diagram of Fig. 20–19. The temperature $T$ of the gas is the same at points a and b. Determine the change in entropy of the gas due to this process. [*Hint*: Recall that entropy is a state variable.]

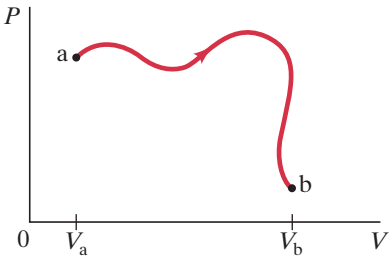

**FIGURE 20–19**
Problem 48.

**49.** (II) Calculate the change in entropy of 1.00 kg of water when it is heated from 0°C to 85°C. (*a*) Make an estimate; (*b*) use the integral $\Delta S = \int dQ/T$. (*c*) Does the entropy of the surroundings change? If so, by how much?

**50.** (II) A 110-g insulated aluminum cup at 35°C is filled with 150 g of water at 45°C. After a few minutes, equilibrium is reached. Determine (*a*) the final temperature, and (*b*) the total change in entropy as a result of the mixing process (use $\Delta S = \int dQ/T$).

**51.** (II) Two samples of an ideal gas are initially at the same temperature and pressure. They are each compressed reversibly from a volume $V$ to volume $V/2$, one isothermally, the other adiabatically. (*a*) In which sample is the final pressure greater? (*b*) Determine the change in entropy of the gas for each process by integration. (*c*) What is the entropy change of the environment for each process? (*d*) Entropy is a state variable. Why then don't the two processes give the same $\Delta S$?

**52.** (II) 1.00 mole of nitrogen $(N_2)$ gas and 1.00 mole of argon (Ar) gas are in separate, equal-sized, insulated containers at the same temperature. The containers are then connected and the gases (assumed ideal) allowed to mix. What is the change in entropy (*a*) of the system and (*b*) of the environment? (*c*) Repeat part (*a*) but assume one container is twice as large as the other.

**53.** (II) (*a*) Why would you expect the total entropy change in a Carnot cycle to be zero? (*b*) Do a calculation to show that it is zero.

**54.** (II) Thermodynamic processes are sometimes represented on *TS* (temperature–entropy) diagrams, rather than *PV* diagrams. Determine the slope of a constant-volume process on a *TS* diagram when a system with $n$ moles of an ideal gas with constant-volume molar specific heat $C_V$ is at temperature $T$.

**55.** (III) The specific heat per mole of potassium at low temperatures is given by $C_V = aT + bT^3$, where $a = 2.08\,\text{mJ/mol}\cdot\text{K}^2$ and $b = 2.57\,\text{mJ/mol}\cdot\text{K}^4$. Determine (by integration) the entropy change of 0.15 mol of potassium when its temperature is lowered from 5.0 K to 1.0 K.

**56.** (III) Consider an ideal gas of $n$ moles with molar specific heats $C_V$ and $C_P$. (*a*) Starting with the first law, show that when the temperature and volume of this gas are changed by a reversible process, its change in entropy is given by

$$dS = nC_V\frac{dT}{T} + nR\frac{dV}{V}.$$

(*b*) Show that the expression in part (*a*) can be written as

$$dS = nC_V\frac{dP}{P} + nC_P\frac{dV}{V}.$$

(*c*) Using the expression from part (*b*), show that if $dS = 0$ for the reversible process (that is, the process is adiabatic), then $PV^\gamma = \text{constant}$, where $\gamma = C_P/C_V$.

## 20–8 Unavailability of Energy

**57.** (III) A general theorem states that the amount of energy that becomes unavailable to do useful work in any process is equal to $T_L\,\Delta S$, where $T_L$ is the lowest temperature available and $\Delta S$ is the total change in entropy during the process. Show that this is valid in the specific cases of: (*a*) a falling rock that comes to rest when it hits the ground; (*b*) the free adiabatic expansion of an ideal gas; and (*c*) the conduction of heat, $Q$, from a high-temperature $(T_H)$ reservoir to a low-temperature $(T_L)$ reservoir. [*Hint*: In part (*c*) compare to a Carnot engine.]

**58.** (III) Determine the work available in a 2.2-kg block of copper at 490 K if the surroundings are at 290 K. Use results of Problem 57.

## 20–9 Statistical Interpretation of Entropy

**59.** (I) Use Eq. 20–14 to determine the entropy of each of the five macrostates listed in Table 20–1 on page 595.

**60.** (II) Suppose that you repeatedly shake six coins in your hand and drop them on the floor. Construct a table showing the number of microstates that correspond to each macrostate. What is the probability of obtaining (*a*) three heads and three tails and (*b*) six heads?

**61.** (II) (*a*) Suppose you have four coins, all with tails up. You now rearrange them so two heads and two tails are up. What was the change in entropy of the coins? (*b*) Suppose your system is the 100 coins of Table 20–2; what is the change in entropy of the coins if they are mixed randomly initially, 50 heads and 50 tails, and you arrange them so all 100 are heads? (*c*) Compare these entropy changes to ordinary thermodynamic entropy changes, such as Examples 20–7, 20–8, 20–9, and 20–10.

**62.** (II) Calculate the probabilities, when you throw two dice, of obtaining (*a*) a 7, and (*b*) an 11.

**63.** (III) Consider an isolated gas-like system consisting of a box that contains $N = 10$ distinguishable atoms, each moving at the same speed $v$. The number of unique ways that these atoms can be arranged so that $N_L$ atoms are within the left-hand half of the box and $N_R$ atoms are within the right-hand half of the box is given by

$$\frac{N!}{N_L!\,N_R!},$$

where, for example, the factorial $4! = 4\cdot3\cdot2\cdot1$ (the only exception is that $0! = 1$). Define each unique arrangement of atoms within the box to be a microstate of this system. Now imagine the following two possible macrostates: state A where all of the atoms are within the left-hand half of the box and none are within the right-hand half; and state B where the distribution is uniform (that is, there is the same number in each half). See Fig. 20–20. (*a*) Assume the system is initially in state A and, at a later time, is found to be in state B. Determine the system's change in entropy. Can this process occur naturally? (*b*) Assume the system is initially in state B and, at a later time, is found to be in state A. Determine the system's change in entropy. Can this process occur naturally?

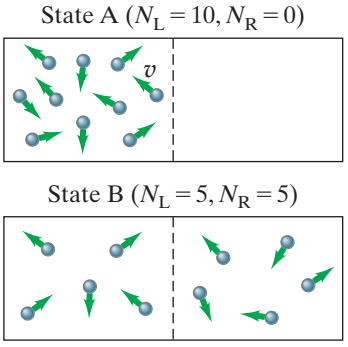

**FIGURE 20–20** Problem 63.

## 20–11 Energy Resources

**64.** (I) *Photovoltaic cells* (Fig. 20–21) can produce about 170 W of electricity per square meter of surface area if directly facing the Sun. How large an area is required to supply the needs of a house that requires 28 kWh/day? Would this fit on the roof of an average house? (Assume the Sun shines about 9 h/day.)

**FIGURE 20–21** Problem 64.

**65.** (II) Energy may be stored by pumping water to a high reservoir when demand is low and then releasing it to drive turbines (Fig. 20–15) during peak demand. Suppose water is pumped to a lake 105 m above the turbines at a rate of $1.00\times10^5\,\text{kg/s}$ for 10.0 h at night. (*a*) How much energy (kWh) is needed to do this each night? (*b*) If all this energy is released during a 14-h day, at 75% efficiency, what is the average power output?

**66.** (II) Water is stored in an artificial lake created by a dam (Fig. 20–22). The water depth is 48 m at the dam, and a steady flow rate of 35 $m^3/s$ is maintained through hydroelectric turbines installed near the base of the dam. (*a*) How much electrical power can be produced? (*b*) What are the environmental implications of such a dam?

**FIGURE 20–22** Problem 66. Flaming Gorge Dam on the Green River in Utah.

# General Problems

**67.** An inventor claims to have built an engine that produces 2.00 MW of usable work while taking in 3.00 MW of thermal energy at 425 K, and rejecting 1.00 MW of thermal energy at 215 K. Is there anything fishy about his claim? Explain.

**68.** It has been suggested that a heat engine could be developed that made use of the temperature difference between water at the surface of the ocean and water several hundred meters deep. In the tropics, the temperatures may be 27°C and 4°C, respectively. (*a*) What is the maximum efficiency such an engine could have? (*b*) Why might such an engine be feasible in spite of the low efficiency? (*c*) Can you imagine any adverse environmental effects that might occur?

**69.** A heat engine takes a diatomic gas around the cycle shown in Fig. 20–23. (*a*) Using the ideal gas law, determine how many moles of gas are in this engine. (*b*) Determine the temperature at point c. (*c*) Calculate the heat input into the gas during the constant volume process from points b to c. (*d*) Calculate the work done on the gas during the isothermal compression from points a to b. (*e*) Calculate the work done by the gas during the adiabatic process from points c to a. (*f*) Determine the engine's efficiency. (*g*) What is the maximum efficiency possible for an engine working between $T_a$ and $T_c$?

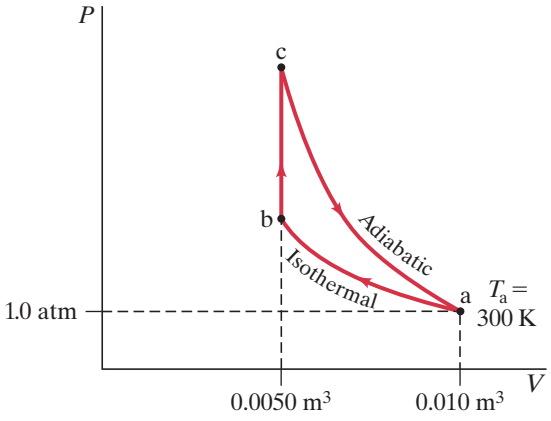

**FIGURE 20–23** Problem 69.

**70.** Refrigeration units can be rated in "tons." A 1-ton air conditioning system can remove sufficient energy to freeze 1 ton (2000 pounds = 909 kg) of 0°C water into 0°C ice in one 24-h day. Assume the hot part of a day averages 35°C and the interior of a house is maintained at 22°C by the continuous operation of a 6-ton air conditioning system for 6 hours a day. How much does this cooling cost the homeowner per day, and per month? Assume the work done by the refrigeration unit is powered by electricity that costs \$0.13 per kWh and that the unit's coefficient of performance is only 18% of an ideal refrigerator. 1 kWh = $3.60 \times 10^6$ J.

**71.** (*a*) At a steam power plant, *steam engines* work in pairs, the heat output of the first one being the approximate heat input of the second. The operating temperatures of the first are 750°C and 440°C, and of the second 415°C and 240°C. If the heat of combustion of coal is $2.8 \times 10^7$ J/kg, at what rate must coal be burned if the plant is to put out 950 MW of power? Assume the efficiency of the engines is 65% of the ideal (Carnot) efficiency. (*b*) Water is used to cool the power plant. If the water temperature is allowed to increase by no more than 4.5 C°, estimate how much water must pass through the plant per hour.

**72.** A 38% efficient power plant puts out 850 MW of electrical power. Cooling towers take away the exhaust heat. (*a*) If the air temperature is allowed to rise 7.0 C°, estimate what volume of air ($km^3$) is heated per day. Will the local climate be heated significantly? (*b*) If the heated air were to form a layer 150 m thick, estimate how large an area it would cover for 24 h of operation. Assume the air has density 1.3 $kg/m^3$ and has specific heat of about 1.0 kJ/kg · C° at constant pressure.

**73.** The operation of a certain heat engine takes an ideal monatomic gas through a cycle shown as the rectangle on the *PV* diagram of Fig. 20–24. (*a*) Determine the efficiency of this engine. Let $Q_H$ and $Q_L$ be the total heat input and total heat exhausted during one cycle of this engine. (*b*) Compare (as a ratio) the efficiency of this engine to that of a Carnot engine operating between $T_H$ and $T_L$, where $T_H$ and $T_L$ are the highest and lowest temperatures achieved.

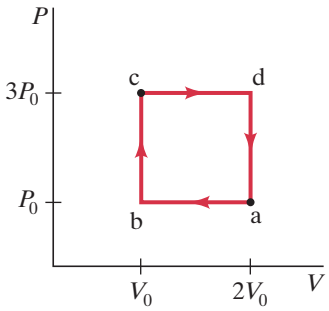

**FIGURE 20–24** Problem 73.

**74.** A "Carnot" refrigerator (the reverse of a Carnot engine) absorbs heat from the freezer compartment at a temperature of −17°C and exhausts it into the room at 25°C. (*a*) How much work would the refrigerator do to change 0.65 kg of water at 25°C into ice at −17°C? (*b*) If the compressor output is 105 W and runs 25% of the time, how long will this take?

**75.** A car engine whose output power is 145 hp operates at about 15% efficiency. Assume the engine's water temperature of 85°C is its cold-temperature (exhaust) reservoir and 495°C is its thermal "intake" temperature (the temperature of the exploding gas–air mixture). (*a*) What is the ratio of its efficiency relative to its maximum possible (Carnot) efficiency? (*b*) Estimate how much power (in watts) goes into moving the car, and how much heat, in joules and in kcal, is exhausted to the air in 1.0 h.

**76.** 1.00 mole of an ideal monatomic gas at STP first undergoes an isothermal expansion so that the volume at b is 2.5 times the volume at a (Fig. 20–25). Next, heat is extracted at a constant volume so that the pressure drops. The gas is then compressed adiabatically back to the original state. (*a*) Calculate the pressures at b and c. (*b*) Determine the temperature at c. (*c*) Determine the work done, heat input or extracted, and the change in entropy for each process. (*d*) What is the efficiency of this cycle?

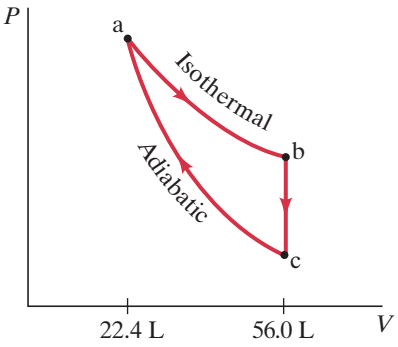

**FIGURE 20–25**
Problem 76.

**77.** Suppose a power plant delivers energy at 880 MW using steam turbines. The steam goes into the turbines superheated at 625 K and deposits its unused heat in river water at 285 K. Assume that the turbine operates as an ideal Carnot engine. (*a*) If the river flow rate is 37 $m^3/s$, estimate the average temperature increase of the river water immediately downstream from the power plant. (*b*) What is the entropy increase per kilogram of the downstream river water in $J/kg \cdot K$?

**78.** An ideal air conditioner keeps the temperature inside a room at 21°C when the outside temperature is 32°C. If 4.8 kW of power enters a room through the windows in the form of direct radiation from the Sun, how much electrical power would be saved if the windows were shaded so only 500 W enters?

**79.** The operation of a **diesel engine** can be idealized by the cycle shown in Fig. 20–26. Air is drawn into the cylinder during the intake stroke (not part of the idealized cycle). The air is compressed adiabatically, path ab. At point b diesel fuel is injected into the cylinder and immediately burns since the temperature is very high. Combustion is slow, and during the first part of the power stroke, the gas expands at (nearly) constant pressure, path bc. After burning, the rest of the power stroke is adiabatic, path cd. Path da corresponds to the exhaust stroke. (*a*) Show that, for a quasistatic reversible engine undergoing this cycle using an ideal gas, the ideal efficiency is

$$e = 1 - \frac{(V_a/V_c)^{-\gamma} - (V_a/V_b)^{-\gamma}}{\gamma[(V_a/V_c)^{-1} - (V_a/V_b)^{-1}]},$$

where $V_a/V_b$ is the "compression ratio," $V_a/V_c$ is the "expansion ratio," and $\gamma$ is defined by Eq. 19–15 $\left(\gamma = \frac{C_P}{C_V}\right)$. (*b*) If $V_a/V_b = 16$ and $V_a/V_c = 4.5$, calculate the efficiency assuming the gas is diatomic (like $N_2$ and $O_2$) and ideal.

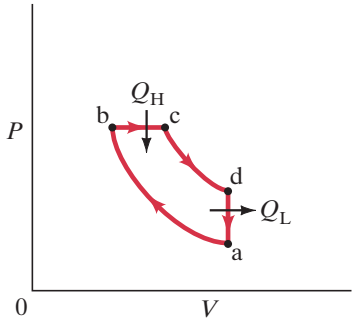

**FIGURE 20–26**
Problem 79.

**80.** Two 1100-kg cars are traveling 75 km/h in opposite directions when they collide and are brought to rest. Estimate the change in entropy of the universe as a result of this collision. Assume $T = 20°C$.

**81.** A cooling unit for a new freezer has an inner surface area of 8.0 $m^2$, and is bounded by walls 12 cm thick with a thermal conductivity of 0.050 $W/m \cdot K$. The inside must be kept at −15°C in a room that is at 22°C. The motor for the cooling unit must run no more than 18% of the time. What is the minimum power requirement of the cooling motor?

**82.** Suppose a heat pump has a stationary bicycle attachment that allows *you* to provide the work instead of using an electrical wall outlet. If your heat pump has a coefficient of performance of 2.0 and you can cycle at a racing pace output of about 200 W for a half hour, how much heat can you provide?

**83.** The **Stirling cycle**, shown in Fig. 20–27, is useful to describe some heat engines. Find the efficiency of the cycle in terms of the parameters shown, assuming an ideal monatomic gas as the working substance. The processes ab and cd are isothermal whereas bc and da are at constant volume. How does it compare to the Carnot efficiency?

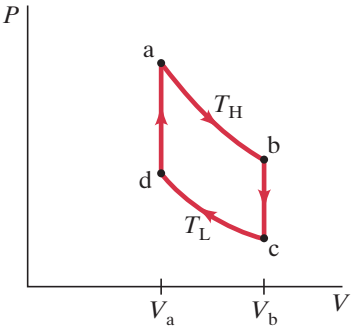

**FIGURE 20–27**
Problem 83.
Stirling cycle.

**84.** The **Brayton cycle**, depicted in the *PV* diagram of Fig. 20–28, can describe a *jet engine* gas turbine. In process ab the air–fuel mixture undergoes an adiabatic compression. This is followed, in process bc, with an isobaric (constant pressure) heating, by combustion. Process cd is an adiabatic expansion with expulsion of the products to the atmosphere. The return step, da, takes place at constant pressure. If the working gas behaves like an ideal gas, show that the efficiency of the Brayton cycle is

$$e = 1 - \left(\frac{P_b}{P_a}\right)^{\frac{1-\gamma}{\gamma}}.$$

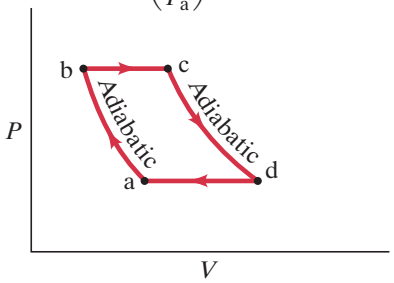

**FIGURE 20–28** Problem 84. Brayton cycle.

**85.** A restaurant refrigerator has a coefficient of performance of 5.0. If the temperature in the kitchen outside the refrigerator is 32°C, what is the lowest temperature that could be obtained inside the refrigerator if it were ideal?

**86.** Thermodynamic processes can be represented not only on *PV* and *PT* diagrams, but also on a *TS* (temperature–entropy) diagram. (*a*) Draw a *TS diagram* for a Carnot cycle. (*b*) What does the area within the curve represent?

**87.** An aluminum can, with negligible heat capacity, is filled with 450 g of water at 0°C and then is brought into thermal contact with a similar can filled with 450 g of water at 50°C. Find the change in entropy of the system if no heat is allowed to exchange with the surroundings. Use $\Delta S = \int dQ/T$.

**88.** A **dehumidifier** removes water vapor from air and has been referred to as a "refrigerator with an open door." The humid air is pulled in by a fan and passes over a cold coil, whose temperature is less than the dew point, and some of the air's water condenses. After this water is extracted, the air is warmed back to its original temperature and sent into the room. In a well-designed dehumidifier, the heat that is removed by the cooling coil mostly comes from the condensation of water vapor to liquid, and this heat is used to re-warm the air. Estimate how much water is removed in 1.0 h by an ideal dehumidifier, if the temperature of the room is 25°C, the water condenses at 8°C, and the dehumidifier does work at the rate of 550 W of electrical power.

**89.** A bowl contains many red, orange, and green jelly beans, in equal numbers. You are to make a line of 3 jelly beans by randomly taking 3 beans from the bowl. (*a*) Construct a table showing the number of microstates that correspond to each macrostate. Then determine the probability of (*b*) all 3 beans red, and (*c*) 2 greens, 1 orange.

**90.** Rank the following five-card hands in order of increasing probability: (*a*) four aces and a king; (*b*) six of hearts, eight of diamonds, queen of clubs, three of hearts, jack of spades; (*c*) two jacks, two queens, and an ace; and (*d*) any hand having no two equal-value cards (no pairs, etc.). Discuss your ranking in terms of microstates and macrostates.

**91.** A particular 1.5-$m^2$ photovoltaic panel operating in direct sunlight produces electricity at 22% efficiency. The resulting electricity is used to operate an electric stove that can be used to heat water. A second system uses a 1.5-$m^2$ curved mirror to concentrate the Sun's energy directly onto a container of water. Estimate how long it takes each system to heat 1.0 kg of water from 25°C to 95°C. (See also Chapter 19.)

**92.** At low temperature the specific heat of diamond varies with absolute temperature $T$ according to the Debye equation $C_V = 1.88 \times 10^3 \left(T/T_D\right)^3 \text{J} \cdot \text{mol}^{-1} \cdot \text{K}^{-1}$ where the Debye temperature for diamond is $T_D = 2230$ K. Determine the entropy change of 1.00 mol of diamond when it is heated at constant volume from 4 K to 40 K. [*Hint*: $dS = nC_V\, dT/T$, where $n$ is the number of moles.]

**93.** **Trees offsetting $CO_2$.** Trees can help a bit to offset the buildup of $CO_2$ due to burning coal and other fossil fuels. $CO_2$ can be absorbed by tree foliage. Trees use the carbon to grow, and release $O_2$ into the atmosphere. Suppose a refrigerator uses 600 kWh of electricity per year (about $2 \times 10^9$ J) from a 33% efficient coal-fired power plant. Burning 1 kg of coal releases about $2 \times 10^7$ J of energy. Assume coal is all carbon, which when burned in air becomes $CO_2$. (*a*) How much coal is burned per year to run this refrigerator? (*b*) Assuming a forest can capture 1700 kg of carbon per hectare ($= 10{,}000\ m^2$) per year, estimate how many square meters of forest are needed to capture the carbon (in the form now of $CO_2$) emitted by the refrigerator in (*a*).

## ANSWERS TO EXERCISES

**A:** (*d*).
**B:** (*c*).
**C:** (*a*) Heat $Q_L$ comes from outside to conserve energy; (*b*) 560 W.
**D:** (*e*) 11/16.

This comb has acquired a static electric charge, either from passing through hair, or being rubbed by a cloth or paper towel. The electrical charge on the comb induces a polarization (separation of charge) in scraps of paper, and thus attracts them.

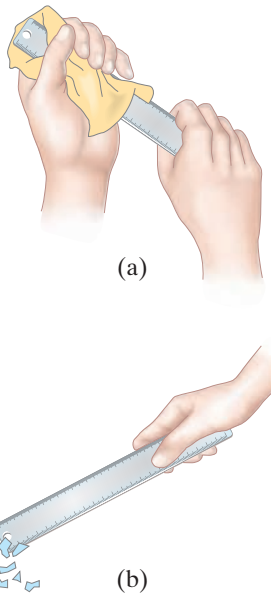
Our introduction to electricity in this Chapter covers conductors and insulators, and Coulomb's law which relates the force between two point charges as a function of their distance apart. We also introduce the powerful concept of electric field.

CHAPTER 21

# Electric Charge and Electric Field

**CHAPTER-OPENING QUESTION—Guess now!**

Two identical tiny spheres have the same electric charge. If their separation is doubled, the force each exerts on the other will be



**(a)** half.
**(b)** double.
**(c)** four times larger.
**(d)** one-quarter as large.
**(e)** unchanged.

The word "electricity" may evoke an image of complex modern technology: lights, motors, electronics, and computers. But the electric force plays an even deeper role in our lives. According to atomic theory, electric forces between atoms and molecules hold them together to form liquids and solids, and electric forces are also involved in the metabolic processes that occur within our bodies. Many of the forces we have dealt with so far, such as elastic forces, the normal force, and friction and other contact forces (pushes and pulls), are now considered to result from electric forces acting at the atomic level. Gravity, on the other hand, is a separate force.[†]

[†]As we discussed in Section 6–7, physicists in the twentieth century came to recognize four different fundamental forces in nature: (1) gravitational force, (2) electromagnetic force (we will see later that electric and magnetic forces are intimately related), (3) strong nuclear force, and (4) weak nuclear force. The last two forces operate at the level of the nucleus of an atom. Recent theory has combined the electromagnetic and weak nuclear forces so they are now considered to have a common origin known as the electroweak force. We discuss the other forces in later Chapters.

**FIGURE 21–1** (a) Rub a plastic ruler with a cloth or paper towel, and (b) bring it close to some tiny pieces of paper.

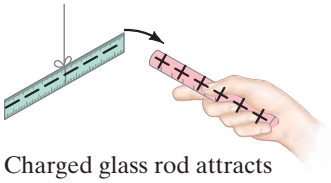

**FIGURE 21–2** Like charges repel one another; unlike charges attract. (Note color coding: we color positive charged objects pink or red, and negative charges blue-green. We use these colors especially for point charges, and most of the time for real objects.)

(a) Two charged plastic rulers repel

(b) Two charged glass rods repel

(c) Charged glass rod attracts charged plastic ruler

The earliest studies on electricity date back to the ancients, but only since the late 1700s has electricity been studied in detail. We will discuss the development of ideas about electricity, including practical devices, as well as its relation to magnetism, in the next eleven Chapters.

# 21–1 Static Electricity; Electric Charge and Its Conservation

The word *electricity* comes from the Greek word *elektron*, which means "amber." Amber is petrified tree resin, and the ancients knew that if you rub a piece of amber with a cloth, the amber attracts small pieces of leaves or dust. A piece of hard rubber, a glass rod, or a plastic ruler rubbed with a cloth will also display this "amber effect," or **static electricity** as we call it today. You can readily pick up small pieces of paper with a plastic comb or ruler that you have just vigorously rubbed with even a paper towel. See the photo on the previous page and Fig. 21–1. You have probably experienced static electricity when combing your hair or when taking a synthetic blouse or shirt from a clothes dryer. And you may have felt a shock when you touched a metal doorknob after sliding across a car seat or walking across a synthetic carpet. In each case, an object becomes "charged" as a result of rubbing, and is said to possess a net **electric charge**.

Is all electric charge the same, or is there more than one type? In fact, there are *two* types of electric charge, as the following simple experiments show. A plastic ruler suspended by a thread is vigorously rubbed with a cloth to charge it. When a second plastic ruler, which has been charged in the same way, is brought close to the first, it is found that one ruler *repels* the other. This is shown in Fig. 21–2a. Similarly, if a rubbed glass rod is brought close to a second charged glass rod, again a repulsive force is seen to act, Fig. 21–2b. However, if the charged glass rod is brought close to the charged plastic ruler, it is found that they *attract* each other, Fig. 21–2c. The charge on the glass must therefore be different from that on the plastic. Indeed, it is found experimentally that all charged objects fall into one of two categories. Either they are attracted to the plastic and repelled by the glass; or they are repelled by the plastic and attracted to the glass. Thus there seem to be two, and only two, types of electric charge. Each type of charge repels the same type but attracts the opposite type. That is: **unlike charges attract; like charges repel**.

The two types of electric charge were referred to as *positive* and *negative* by the American statesman, philosopher, and scientist Benjamin Franklin (1706–1790). The choice of which name went with which type of charge was arbitrary. Franklin's choice set the charge on the rubbed glass rod to be positive charge, so the charge on a rubbed plastic ruler (or amber) is called negative charge. We still follow this convention today.

Franklin argued that whenever a certain amount of charge is produced on one object, an equal amount of the opposite type of charge is produced on another object. The positive and negative are to be treated *algebraically*, so during any process, the net change in the amount of charge produced is zero. For example, when a plastic ruler is rubbed with a paper towel, the plastic acquires a negative charge and the towel acquires an equal amount of positive charge. The charges are separated, but the sum of the two is zero.

This is an example of a law that is now well established: the **law of conservation of electric charge**, which states that

*LAW OF CONSERVATION OF ELECTRIC CHARGE*

**the net amount of electric charge produced in any process is zero;**

or, said another way,

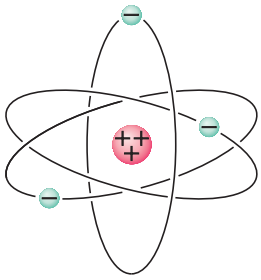
**no net electric charge can be created or destroyed.**

If one object (or a region of space) acquires a positive charge, then an equal amount of negative charge will be found in neighboring areas or objects. No violations have ever been found, and the law of conservation of electric charge is as firmly established as those for energy and momentum.

## 21–2 Electric Charge in the Atom

Only within the past century has it become clear that an explanation of electricity originates inside the atom itself. In later Chapters we will discuss atomic structure and the ideas that led to our present view of the atom in more detail. But it will help our understanding of electricity if we discuss it briefly now.

A simplified model of an atom shows it as having a tiny but massive nucleus, positively charged, surrounded by one or more negatively charged electrons (Fig. 21–3). The nucleus contains protons, which are positively charged, and neutrons, which have no net electric charge. All protons and all electrons have exactly the same magnitude of electric charge; but their signs are opposite. Hence neutral atoms, having no net charge, contain equal numbers of protons and electrons. Sometimes an atom may lose one or more of its electrons, or may gain one or more electrons, in which case it will have a net positive or negative charge and is called an **ion**.



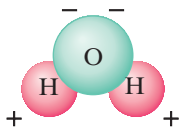


**FIGURE 21–3** Simple model of the atom.

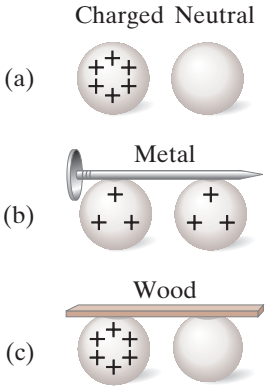
In solid materials the nuclei tend to remain close to fixed positions, whereas some of the electrons may move quite freely. When an object is *neutral*, it contains equal amounts of positive and negative charge. The charging of a solid object by rubbing can be explained by the transfer of electrons from one object to the other. When a plastic ruler becomes negatively charged by rubbing with a paper towel, electrons are transfered from the towel to the plastic, leaving the towel with a positive charge equal in magnitude to the negative charge acquired by the plastic. In liquids and gases, nuclei or ions can move as well as electrons.

Normally when objects are charged by rubbing, they hold their charge only for a limited time and eventually return to the neutral state. Where does the charge go? Usually the excess charge "leaks off" onto water molecules in the air. This is because water molecules are **polar**—that is, even though they are neutral, their charge is not distributed uniformly, Fig. 21–4. Thus the extra electrons on, say, a charged plastic ruler can "leak off" into the air because they are attracted to the positive end of water molecules. A positively charged object, on the other hand, can be neutralized by transfer of loosely held electrons from water molecules in the air. On dry days, static electricity is much more noticeable because the air contains fewer water molecules to allow leakage of charge. On humid or rainy days, it is difficult to make any object hold a net charge for long.

**FIGURE 21–4** Diagram of a water molecule. Because it has opposite charges on different ends, it is called a "polar" molecule.



## 21–3 Insulators and Conductors

Suppose we have two metal spheres, one highly charged and the other electrically neutral (Fig. 21–5a). If we now place a metal object, such as a nail, so that it touches both spheres (Fig. 21–5b), the previously uncharged sphere quickly becomes charged. If, instead, we had connected the two spheres by a wooden rod or a piece of rubber (Fig. 21–5c), the uncharged ball would not become noticeably charged. Materials like the iron nail are said to be **conductors** of electricity, whereas wood and rubber are **nonconductors** or **insulators**.

Metals are generally good conductors, whereas most other materials are insulators (although even insulators conduct electricity very slightly). Nearly all natural materials fall into one or the other of these two distinct categories. However, a few materials (notably silicon and germanium) fall into an intermediate category known as **semiconductors**.

From the atomic point of view, the electrons in an insulating material are bound very tightly to the nuclei. In a good metal conductor, on the other hand, some of the electrons are bound very loosely and can move about freely within the metal (although they cannot *leave* the metal easily) and are often referred to as *free electrons* or *conduction electrons*. When a positively charged object is brought close to or touches a conductor, the free electrons in the conductor are attracted by this positively charged object and move quickly toward it. If a negatively charged object is brought close to the conductor, the free electrons in the conductor move swiftly away from it. In a semiconductor, there are many fewer free electrons, and in an insulator, almost none.

**FIGURE 21–5** (a) A charged metal sphere and a neutral metal sphere. (b) The two spheres connected by a conductor (a metal nail), which conducts charge from one sphere to the other. (c) The original two spheres connected by an insulator (wood); almost no charge is conducted.

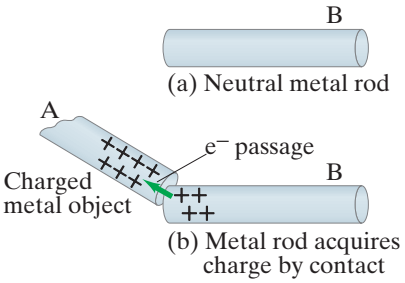


**FIGURE 21–6** A neutral metal rod in (a) will acquire a positive charge if placed in contact (b) with a positively charged metal object. (Electrons move as shown by the green arrow.) This is called charging by conduction.

# 21–4 Induced Charge; the Electroscope

Suppose a positively charged metal object A is brought close to an uncharged metal object B. If the two touch, the free electrons in the neutral one are attracted to the positively charged object and some of those electrons will pass over to it, Fig. 21–6. Since object B, originally neutral, is now missing some of its negative electrons, it will have a net positive charge. This process is called **charging by conduction**, or "by contact," and the two objects end up with the same sign of charge.

Now suppose a positively charged object is brought close to a neutral metal rod, but does not touch it. Although the free electrons of the metal rod do not leave the rod, they still move within the metal toward the external positive charge, leaving a positive charge at the opposite end of the rod (Fig. 21–7b). A charge is said to have been *induced* at the two ends of the metal rod. No net charge has been created in the rod: charges have merely been *separated*. The net charge on the metal rod is still zero. However, if the metal is cut into two pieces, we would have two charged objects: one charged positively and one charged negatively. This is **charging by induction**.

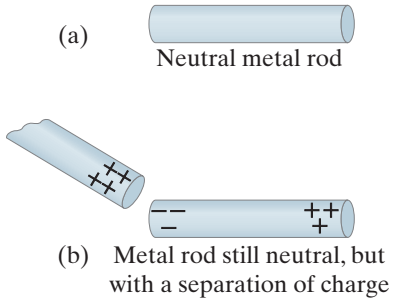

**FIGURE 21–7** Charging by induction: if the rod in (b) is cut into two parts, each part will have a net charge.

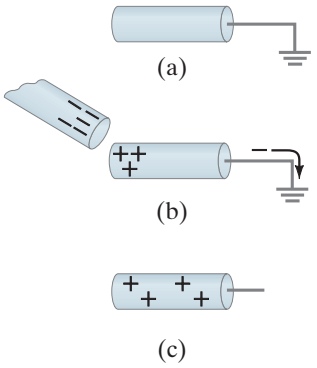

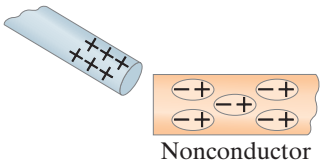

**FIGURE 21–8** Inducing a charge on an object connected to ground.

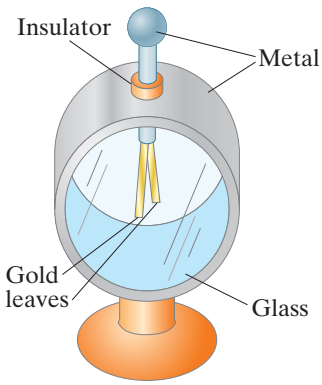

**FIGURE 21–9** A charged object brought near a nonconductor causes a charge separation within the nonconductor's molecules.

Another way to induce a net charge on a metal object is to first connect it with a conducting wire to the ground (or a conducting pipe leading into the ground) as shown in Fig. 21–8a (the symbol ⏚ means connected to "ground"). The object is then said to be **grounded** or "earthed." The Earth, because it is so large and can conduct, easily accepts or gives up electrons; hence it acts like a reservoir for charge. If a charged object—say negative this time—is brought up close to the metal object, free electrons in the metal are repelled and many of them move down the wire into the Earth, Fig. 21–8b. This leaves the metal positively charged. If the wire is now cut, the metal object will have a positive induced charge on it (Fig. 21–8c). If the wire is cut *after* the negative object is moved away, the electrons would all have moved from the ground back into the metal object and it would be neutral again.

Charge separation can also be done in nonconductors. If you bring a positively charged object close to a neutral nonconductor as shown in Fig. 21–9, almost no electrons can move about freely within the nonconductor. But they can move slightly within their own atoms or molecules. Each oval in Fig. 21–9 represents a molecule (not to scale); the negatively charged electrons, attracted to the external positive charge, tend to move in its direction within their molecules. Because the negative charges in the nonconductor are nearer to the external positive charge, the nonconductor as a whole is attracted to the external positive charge (see the Chapter-Opening Photo, page 609).

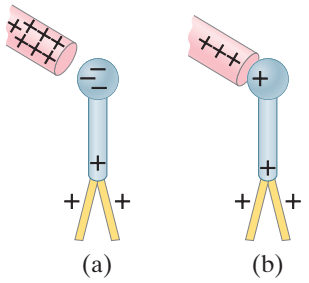
**FIGURE 21–10** (below) Electroscope.

An **electroscope** is a device that can be used for detecting charge. As shown in Fig. 21–10, inside a case are two movable metal leaves, often made of gold foil, attached to a metal rod with a knob on the outside. (Sometimes only one leaf is movable.)

If a positively charged object is brought close to the knob, a separation of charge is induced: electrons are attracted up into the knob, and the leaves become positively charged, Fig. 21–11a. The two leaves repel each other as shown, because they are both positively charged. If, instead, the knob is charged by conduction (touching), the whole apparatus acquires a net charge as shown in Fig. 21–11b. In either case, the greater the amount of charge, the greater the separation of the leaves.

Note that you cannot tell the sign of the charge in this way, since negative charge will cause the leaves to separate just as much as an equal amount of positive charge; in either case, the two leaves repel each other. An electroscope can, however, be used to determine the sign of the charge if it is first charged by conduction: say, negatively, as in Fig. 21–12a. Now if a negative object is brought close, as in Fig. 21–12b, more electrons are repelled and "induced" to move down into the leaves, which separate further. If a positive charge is brought close instead, the electrons are induced to flow upward, so the leaves are less negative and their separation is reduced, Fig. 21–12c.

The electroscope was used in the early studies of electricity. The same principle, aided by some electronics, is used in much more sensitive modern **electrometers**.



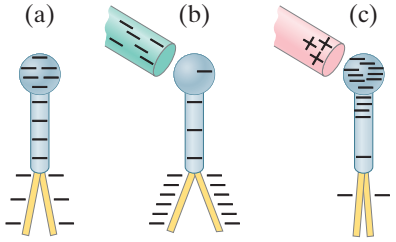


**FIGURE 21–11** Electroscope charged (a) by induction, (b) by conduction.

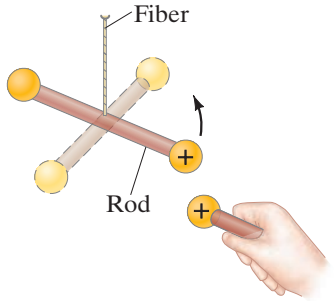
**FIGURE 21–12** A previously charged electroscope can be used to determine the sign of a charged object.

## 21–5 Coulomb's Law



We have seen that an electric charge exerts a force of attraction or repulsion on other electric charges. What factors affect the magnitude of this force? To find an answer, the French physicist Charles Coulomb (1736–1806) investigated electric forces in the 1780s using a torsion balance (Fig. 21–13) much like that used by Cavendish for his studies of the gravitational force (Chapter 6).

Precise instruments for the measurement of electric charge were not available in Coulomb's time. Nonetheless, Coulomb was able to prepare small spheres with different magnitudes of charge in which the *ratio* of the charges was known.[†] Although he had some difficulty with induced charges, Coulomb was able to argue that the electric force one tiny charged object exerts on a second tiny charged object is directly proportional to the charge on each of them. That is, if the charge on either one of the objects is doubled, the force is doubled; and if the charge on both of the objects is doubled, the force increases to four times the original value. This was the case when the distance between the two charges remained the same. If the distance between the two charges was allowed to increase, he found that the force decreased with the *square of the distance* between them. That is, if the distance was doubled, the force fell to one-fourth of its original value. Thus, Coulomb concluded, the magnitude of the force $F$ that one small charged object exerts on a second one is proportional to the product of the magnitude of the charge on one, $Q_1$, times the magnitude of the charge on the other, $Q_2$, and inversely proportional to the square of the distance $r$ between them (Fig. 21–14). As an equation, we can write **Coulomb's law** as

$$F = k\frac{Q_1 Q_2}{r^2}, \qquad \text{[magnitudes]} \quad \textbf{(21–1)}$$

where $k$ is a proportionality constant.[‡] Equation 21–1 gives the *magnitude* of the electric force that either charge exerts on the other.

**FIGURE 21–13** Coulomb's apparatus: when an external charged sphere is placed close to the charged one on the suspended bar, the bar rotates slightly. The suspending fiber resists the twisting motion, and the angle of twist is proportional to the force applied. With this apparatus, Coulomb investigated how the electric force varies as a function of the magnitude of the charges and of the distance between them.

*COULOMB'S LAW*

**FIGURE 21–14** Coulomb's law, Eq. 21–1, gives the force between two point charges, $Q_1$ and $Q_2$, a distance $r$ apart.

[†]Coulomb reasoned that if a charged conducting sphere is placed in contact with an identical uncharged sphere, the charge on the first would be shared equally by the two of them because of symmetry. He thus had a way to produce charges equal to $\frac{1}{2}$, $\frac{1}{4}$, and so on, of the original charge.

[‡]The validity of Coulomb's law today rests on precision measurements that are much more sophisticated than Coulomb's original experiment. The exponent 2 on $r$ in Coulomb's law has been shown to be accurate to 1 part in $10^{16}$ [that is, $2 \pm (1 \times 10^{-16})$].

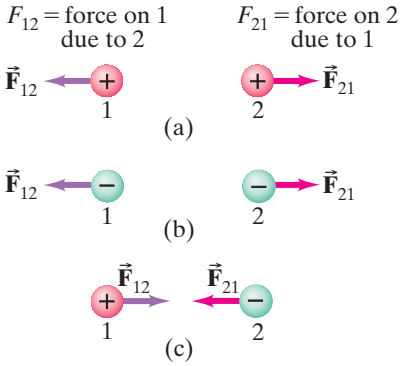


**FIGURE 21–15** The direction of the static electric force one point charge exerts on another is always along the line joining the two charges, and depends on whether the charges have the same sign as in (a) and (b), or opposite signs (c).

The *direction* of the electric force *is always along the line joining the two charges*. If the two charges have the same sign, the force on either charge is directed away from the other (they repel each other). If the two charges have opposite signs, the force on one is directed toward the other (they attract). See Fig. 21–15. Notice that the force one charge exerts on the second is equal but opposite to that exerted by the second on the first, in accord with Newton's third law.

The SI unit of charge is the **coulomb** (C), and its standard definition is in terms of electric current and magnetic field, as discussed later (Section 28–3). In SI units, the constant $k$ in Coulomb's law has the value[†]

$$k = 8.988 \times 10^9\,\mathrm{N \cdot m^2/C^2}$$

or, when we only need two significant figures,

$$k \approx 9.0 \times 10^9\,\mathrm{N \cdot m^2/C^2}.$$

We rarely encounter charges as large as a coulomb. Charges produced by rubbing ordinary objects (such as a comb or plastic ruler) are typically around a microcoulomb $(1\,\mu\mathrm{C} = 10^{-6}\,\mathrm{C})$ or less. Everyday objects that have a positive charge have a deficit of electrons, whereas negatively charged objects have an excess of electrons. The charge on one electron has a magnitude of about $1.6022 \times 10^{-19}\,\mathrm{C}$, and is negative. This is the smallest charge observed in nature, and because it is fundamental, it is given the symbol $e$ and is often referred to as the **elementary charge**:[‡]

$$e = 1.6022 \times 10^{-19}\,\mathrm{C} \approx 1.6 \times 10^{-19}\,\mathrm{C}.$$

Note that $e$ is defined as a positive number, so the charge on the electron is $-e$. Since an object cannot gain or lose a fraction of an electron, the net charge on any object must be an integral multiple of this charge. Electric charge is thus said to be **quantized** (existing only in discrete amounts: $1e$, $2e$, $3e$, etc.). Because $e$ is so small, however, we normally do not notice this discreteness in macroscopic charges ($1\,\mu\mathrm{C}$ requires about $10^{13}$ electrons), which thus seem continuous.

The charge on a proton, a basic constituent in the nucleus of atoms (Section 21–2), is precisely $+e$, the same magnitude charge as an electron but opposite sign. (The mass of a proton is almost 2000 times greater than the electron mass.)

Coulomb's law looks a lot like the *law of universal gravitation*, $F = Gm_1m_2/r^2$, which expresses the magnitude of the gravitational force a mass $m_1$ exerts on a mass $m_2$ (Eq. 6–1). Both are **inverse square laws** $(F \propto 1/r^2)$. Both also have a proportionality to a property of each object—mass for gravity, electric charge for electricity. And both act over a distance (that is, there is no need for contact). A major difference between the two laws is that gravity is always an attractive force, whereas the electric force can be either attractive or repulsive. Electric charge comes in two types, positive and negative; gravitational mass is only positive.

The constant $k$ in Eq. 21–1 is often written in terms of another constant, $\epsilon_0$, called the **permittivity of free space**. It is related to $k$ by $k = 1/4\pi\epsilon_0$. Coulomb's law can be written

*COULOMB'S LAW (in terms of $\epsilon_0$)*

$$F = \frac{1}{4\pi\epsilon_0}\frac{Q_1 Q_2}{r^2}, \qquad \textbf{(21–2)}$$

[†]In the once common cgs system of units, $k$ is set equal to 1, and the unit of electric charge is called the *electrostatic unit* (esu) or the statcoulomb. One esu is defined as that charge, on each of two point objects 1 cm apart, that gives rise to a force of 1 dyne.

[‡]See inside front cover for precise value. (In the new SI, Section 1–4, the charge on the electron $e$ is defined as exact, and the Coulomb defined in terms of $e$, details that don't concern us here.) According to the Standard Model of elementary particle physics, subnuclear particles called quarks have a smaller charge than the electron, equal to $\frac{1}{3}e$ or $\frac{2}{3}e$. Quarks have not been detected directly as isolated objects, and theory indicates that free quarks may not be detectable.

where[†]

$$\epsilon_0 = \frac{1}{4\pi k} = 8.85 \times 10^{-12}\,\mathrm{C^2/N \cdot m^2}.$$

Equation 21–2 looks more complicated than Eq. 21–1, but other fundamental equations we haven't seen yet are simpler in terms of $\epsilon_0$ rather than $k$. It doesn't matter which form we use since Eqs. 21–1 and 21–2 are the same. (The precise value of $\epsilon_0$ is given inside the front cover.)

Equations 21–1 and 21–2 apply to objects whose size is much smaller than the distance between them. Ideally, it is precise for **point charges** (spatial size negligible compared to other distances). For finite-sized objects, it is not always clear what value to use for $r$, particularly since the charge may not be distributed uniformly on the objects. If the two objects are spheres and the charge is known to be distributed uniformly on each, then $r$ is the distance between the centers of the spheres (we show this in Examples 22–3 and 22–4).

Coulomb's law describes the force one electrically charged particle $(Q_1)$ exerts on a second one $(Q_2)$, when they are at rest. We call this the **electrostatic force** or the **Coulomb force**. Additional forces come into play when charges are in motion, and will be discussed in later Chapters. In this Chapter we discuss only charges at rest, the study of which is called **electrostatics**.

**EXERCISE A** Return to the Chapter-Opening Question, page 609, and answer it again now. Try to explain why you may have answered differently the first time.

**EXAMPLE 21–1** **Electric force on electron by proton.** Determine the magnitude and direction of the electric force on the electron of a hydrogen atom exerted by the single proton $(Q_2 = +e)$ that is the atom's nucleus. Assume the average distance between the revolving electron and the proton is $r = 0.53 \times 10^{-10}\,\mathrm{m}$, Fig. 21–16.

**APPROACH** To find the force magnitude we use Coulomb's law, $F = k\,Q_1 Q_2/r^2$ (Eq. 21–1), with $r = 0.53 \times 10^{-10}\,\mathrm{m}$. The electron and proton have the same *magnitude* of charge, $e$, so $Q_1 = Q_2 = 1.6 \times 10^{-19}\,\mathrm{C}$.

**SOLUTION** The magnitude of the force is

$$F = k\frac{Q_1 Q_2}{r^2} = \frac{(9.0 \times 10^9\,\mathrm{N \cdot m^2/C^2})(1.6 \times 10^{-19}\,\mathrm{C})(1.6 \times 10^{-19}\,\mathrm{C})}{(0.53 \times 10^{-10}\,\mathrm{m})^2}$$
$$= 8.2 \times 10^{-8}\,\mathrm{N}.$$

The direction of the force on the electron is toward the proton, because the charges have opposite signs so the force is attractive.

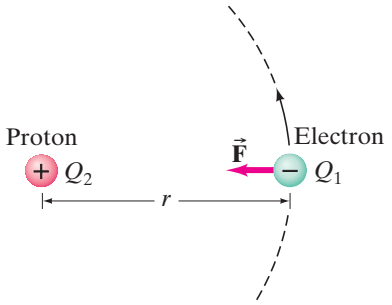

**FIGURE 21–16** Example 21–1.

**CONCEPTUAL EXAMPLE 21–2** **Which charge exerts the greater force?** Two positive point charges, $Q_1 = 50\,\mu\mathrm{C}$ and $Q_2 = 1\,\mu\mathrm{C}$, are separated by a distance $\ell$, Fig. 21–17. Which is larger in magnitude, the force that $Q_1$ exerts on $Q_2$, or the force that $Q_2$ exerts on $Q_1$?

**RESPONSE** From Coulomb's law, the force on $Q_1$ exerted by $Q_2$ is

$$F_{12} = k\frac{Q_1 Q_2}{\ell^2}.$$

The force on $Q_2$ exerted by $Q_1$ is

$$F_{21} = k\frac{Q_2 Q_1}{\ell^2}$$

which is the same magnitude. The equation is symmetric with respect to the two charges, so $F_{21} = F_{12}$.

**NOTE** Newton's third law also tells us that these two forces must have equal magnitude.

**FIGURE 21–17** Example 21–2.

**EXERCISE B** In Example 21–2, how is the direction of $F_{12}$ related to the direction of $F_{21}$?

[†]Our convention for units, such as $\mathrm{C^2/N \cdot m^2}$ for $\epsilon_0$, means $\mathrm{m^2}$ is in the denominator. That is, $\mathrm{C^2/N \cdot m^2}$ means $\mathrm{C^2/(N \cdot m^2)}$ and does *not* mean $\mathrm{(C^2/N) \cdot m^2 = C^2 \cdot m^2/N}$.

Coulomb's law, Eq. 21–1 or 21–2, gives the force on a charge due to only *one* other charge. This Coulomb force is a vector, with magnitude and direction. If several (or many) charges are present, the *net force on any one of them will be the vector sum of the forces due to each of the others*. This **principle of superposition** is based on experiment, and tells us that electric force vectors add like any other vector. For example, if you have a system of four charges, the net force on charge 1 is the vector sum of the forces exerted on charge 1 by charges 2, 3, and 4: $\vec{\mathbf{F}}_{1\text{net}} = \vec{\mathbf{F}}_2 + \vec{\mathbf{F}}_3 + \vec{\mathbf{F}}_4$. The magnitudes of these three forces are determined from Coulomb's law, and then are added vectorially, as discussed in Chapter 3. For continuous distributions of charge, the sum becomes an integral (Section 21–7).

As in all problem solving, it is important to draw a free-body diagram (Chapter 4) for each object, showing all the forces acting *on* that object. In applying Coulomb's law, we can start with charge magnitudes only (leaving out minus signs) to get the *magnitude* of each force. Then determine separately the *direction* of the force physically (along the line joining the two particles: like charges repel, unlike charges attract), and show the force on the diagram. Finally, add all the forces on one object together as vectors to obtain the net force on that object.

**PROBLEM SOLVING**
*Use magnitudes in Coulomb's law; find force direction from signs of charges*

It can be helpful to use double subscripts on each of the forces involved. The first subscript refers to the particle *on* which the force acts; the second refers to the particle that exerts the force. For example, if we have three charges, $\vec{\mathbf{F}}_{31}$ means the force exerted *on* particle 3 *by* particle 1.

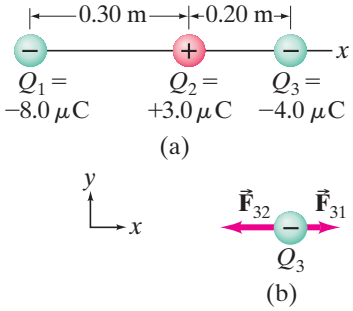

**FIGURE 21–18** Example 21–3.

**EXAMPLE 21–3** **Three charges in a line.** Three charged particles are arranged in a line, as shown in Fig. 21–18a. Calculate the net electrostatic force on particle 3 (the $-4.0\,\mu\text{C}$ on the right) due to the other two charges.

**APPROACH** The net force on particle 3 is the vector sum of the force $\vec{\mathbf{F}}_{31}$ exerted on particle 3 by particle 1 and the force $\vec{\mathbf{F}}_{32}$ exerted on particle 3 by particle 2: $\vec{\mathbf{F}} = \vec{\mathbf{F}}_{31} + \vec{\mathbf{F}}_{32}$.

**SOLUTION** The magnitudes of these two forces are obtained using Coulomb's law, Eq. 21–1:

$$F_{31} = k\frac{Q_3 Q_1}{r_{31}^2} = \frac{(9.0 \times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(4.0 \times 10^{-6}\,\text{C})(8.0 \times 10^{-6}\,\text{C})}{(0.50\,\text{m})^2} = 1.2\,\text{N},$$

where $r_{31} = 0.50\,\text{m}$ is the distance from $Q_3$ to $Q_1$. Similarly,

$$F_{32} = k\frac{Q_3 Q_2}{r_{32}^2} = \frac{(9.0 \times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(4.0 \times 10^{-6}\,\text{C})(3.0 \times 10^{-6}\,\text{C})}{(0.20\,\text{m})^2} = 2.7\,\text{N}.$$

Since we were calculating the magnitudes of the forces, we omitted the signs of the charges. But we must be aware of them to get the direction of each force. Let the line joining the particles be the $x$ axis, and we take it positive to the right. Then, because $\vec{\mathbf{F}}_{31}$ is repulsive and $\vec{\mathbf{F}}_{32}$ is attractive, the directions of the forces are as shown in Fig. 21–18b: $F_{31}$ points in the positive $x$ direction (away from $Q_1$) and $F_{32}$ points in the negative $x$ direction (toward $Q_2$). The net force on particle 3 is then

$$F = -F_{32} + F_{31} = -2.7\,\text{N} + 1.2\,\text{N} = -1.5\,\text{N}.$$

The magnitude of the net force is 1.5 N, and it points to the left.

**NOTE** Charge $Q_1$ acts on charge $Q_3$ just as if $Q_2$ were not there (this is the principle of superposition). That is, the charge in the middle, $Q_2$, in no way blocks the effect of charge $Q_1$ acting on $Q_3$. Naturally, $Q_2$ exerts its own force on $Q_3$.

**CAUTION**
*Each charge exerts its own force. No charge blocks the effect of the others*

**EXERCISE C** Determine the magnitude and direction of the net force on charge $Q_2$ in Fig. 21–18a.

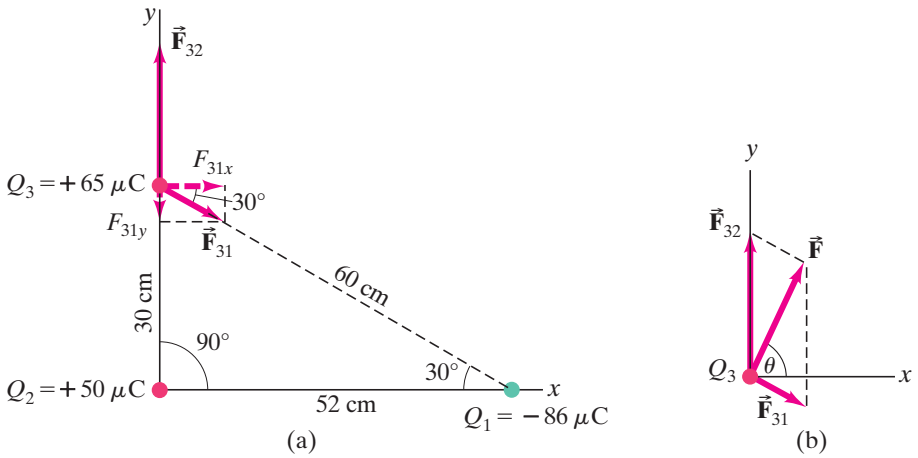

**FIGURE 21–19** Determining the forces for Example 21–4. (a) The directions of the individual forces are as shown because $\vec{\mathbf{F}}_{32}$ is repulsive (the force on $Q_3$ is in the direction away from $Q_2$ because $Q_3$ and $Q_2$ are both positive) whereas $\vec{\mathbf{F}}_{31}$ is attractive ($Q_3$ and $Q_1$ have opposite signs), so $\vec{\mathbf{F}}_{31}$ points toward $Q_1$. (b) Adding $\vec{\mathbf{F}}_{32}$ to $\vec{\mathbf{F}}_{31}$ to obtain the net force $\vec{\mathbf{F}}$.

**EXAMPLE 21–4** **Electric force using vector components.** Calculate the net electrostatic force on charge $Q_3$ shown in Fig. 21–19a due to the charges $Q_1$ and $Q_2$.

**APPROACH** We use Coulomb's law to find the magnitudes of the individual forces. The direction of each force will be along the line connecting $Q_3$ to $Q_1$ or $Q_2$. The forces $\vec{\mathbf{F}}_{31}$ and $\vec{\mathbf{F}}_{32}$ have the directions shown in Fig. 21–19a, since $Q_1$ exerts an attractive force on $Q_3$, and $Q_2$ exerts a repulsive force. Figure 21–19a also shows the $x$ and $y$ components of $\vec{\mathbf{F}}_{31}$. $\vec{\mathbf{F}}_{32}$ is along the $+y$ axis so has no $x$ component. $\vec{\mathbf{F}}_{31}$ and $\vec{\mathbf{F}}_{32}$ are *not* along the same line, so to find the resultant force on $Q_3$ we add $x$ and $y$ components of $\vec{\mathbf{F}}_{31}$ and $\vec{\mathbf{F}}_{32}$ separately and perform the vector addition.

**SOLUTION** The magnitudes of $\vec{\mathbf{F}}_{31}$ and $\vec{\mathbf{F}}_{32}$ are (ignoring signs of the charges since we know the directions)

$$F_{31} = k\frac{Q_3 Q_1}{r_{31}^2} = \frac{(9.0\times10^9\,\mathrm{N\cdot m^2/C^2})(6.5\times10^{-5}\,\mathrm{C})(8.6\times10^{-5}\,\mathrm{C})}{(0.60\,\mathrm{m})^2} = 140\,\mathrm{N},$$

$$F_{32} = k\frac{Q_3 Q_2}{r_{32}^2} = \frac{(9.0\times10^9\,\mathrm{N\cdot m^2/C^2})(6.5\times10^{-5}\,\mathrm{C})(5.0\times10^{-5}\,\mathrm{C})}{(0.30\,\mathrm{m})^2} = 325\,\mathrm{N}.$$

(We keep 3 significant figures until the end, and then keep 2 because only 2 are given.) We determine the $x$ and $y$ components of $\vec{\mathbf{F}}_{31}$ (Fig. 21–19a) using trigonometric functions (as we discussed in Section 3–4):

$$F_{31x} = F_{31}\cos 30^\circ = (140\,\mathrm{N})\cos 30^\circ = 120\,\mathrm{N},$$
$$F_{31y} = -F_{31}\sin 30^\circ = -(140\,\mathrm{N})\sin 30^\circ = -70\,\mathrm{N}.$$

The force $\vec{\mathbf{F}}_{32}$ has only a $y$ component. So the net force $\vec{\mathbf{F}}$ on $Q_3$ has components

$$F_x = F_{31x} = 120\,\mathrm{N},$$
$$F_y = F_{32} + F_{31y} = 325\,\mathrm{N} - 70\,\mathrm{N} = 255\,\mathrm{N}.$$

The magnitude of the net force is

$$F = \sqrt{F_x^2 + F_y^2} = \sqrt{(120\,\mathrm{N})^2 + (255\,\mathrm{N})^2} = 280\,\mathrm{N};$$

and it acts at an angle $\theta$ (see Fig. 21–19b) given by

$$\tan\theta = \frac{F_y}{F_x} = \frac{255\,\mathrm{N}}{120\,\mathrm{N}} = 2.13,$$

so $\theta = \tan^{-1}(2.13) = 65^\circ$.

**NOTE** Because $\vec{\mathbf{F}}_{31}$ and $\vec{\mathbf{F}}_{32}$ are not along the same line, the magnitude of $\vec{\mathbf{F}}_3$ is not equal to the sum (or difference as in Example 21–3) of the separate magnitudes.

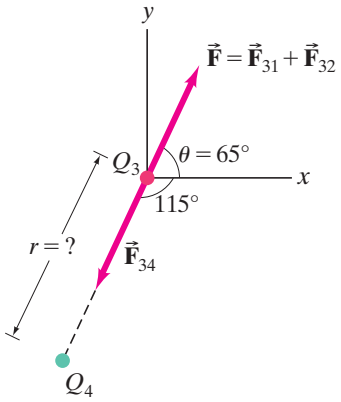

**FIGURE 21–20** Example 21–5: $Q_4$ exerts force $(\vec{\mathbf{F}}_{34})$ that makes the net force on $Q_3$ zero.

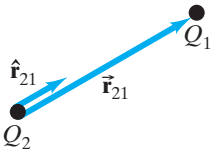
**CONCEPTUAL EXAMPLE 21–5** **Make the force on $Q_3$ zero.** In Fig. 21–19, where could you place a fourth charge, $Q_4 = -50\,\mu\text{C}$, so that the net force on $Q_3$ would be zero?

**RESPONSE** By the principle of superposition, we need a force in exactly the opposite direction to the resultant $\vec{\mathbf{F}}$ $(= \vec{\mathbf{F}}_{31} + \vec{\mathbf{F}}_{32})$ due to $Q_2$ and $Q_1$ that we calculated in Example 21–4, Fig. 21–19b. This new force must have the same magnitude, 280 N, and must point down and to the left of $Q_3$ in Fig. 21–19b, in the direction opposite to $\vec{\mathbf{F}}$. So $Q_4$ must be along this line as shown in Fig. 21–20. The distance $r$ of $Q_4$ from $Q_3$ should be (using Coulomb's law $F_{34} = k\,Q_3\,Q_4/r^2$)

$$r = \sqrt{kQ_3Q_4/F_{34}} = \sqrt{(9.0\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(50\times10^{-6}\,\text{C})(65\times10^{-6}\,\text{C})/280\,\text{N}} = 0.32\,\text{m}.$$

**EXERCISE D** (*a*) Consider two point charges, $+Q$ and $-Q$, which are fixed a distance $d$ apart. Can you find a location where a third positive charge $Q$ could be placed so that the net electric force on this third charge is zero? (*b*) What if the first two charges were both $+Q$?



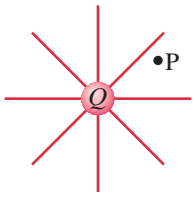
## *Vector Form of Coulomb's Law

Coulomb's law can be written in vector form (as we did for Newton's law of universal gravitation in Chapter 6, Section 6–2) as

$$\vec{\mathbf{F}}_{12} = k\frac{Q_1 Q_2}{r_{21}^2}\hat{\mathbf{r}}_{21},$$

where $\vec{\mathbf{F}}_{12}$ is the vector force on charge $Q_1$ due to $Q_2$ and $\hat{\mathbf{r}}_{21}$ is the unit vector pointing from $Q_2$ toward $Q_1$. That is, $\vec{\mathbf{r}}_{21}$ points from the "source" charge $(Q_2)$ toward the charge on which we want to know the force $(Q_1)$. See Fig. 21–21. The charges $Q_1$ and $Q_2$ can be either positive or negative, and this will affect the direction of the electric force. If $Q_1$ and $Q_2$ have the same sign, the product $Q_1 Q_2 > 0$ and the force on $Q_1$ points away from $Q_2$: that is, it is repulsive. If $Q_1$ and $Q_2$ have opposite signs, $Q_1 Q_2 < 0$ and $\vec{\mathbf{F}}_{12}$ points toward $Q_2$, it is attractive.

**FIGURE 21–21** Determining the force on $Q_1$ due to $Q_2$, showing the direction of the unit vector $\hat{\mathbf{r}}_{21}$.



# 21–6 The Electric Field

Many common forces might be referred to as "contact forces," such as your hands pushing or pulling a cart, or a tennis racket hitting a tennis ball.

In contrast, both the gravitational force and the electrical force act over a distance: there is a force between two objects even when the objects are not touching. The idea of a force *acting at a distance* was a difficult one for early thinkers. Newton himself felt uneasy with this idea when he published his law of universal gravitation (Chapter 6). A helpful way to look at the situation uses the idea of the **field**, developed by the British scientist Michael Faraday (1791–1867). In the electrical case, according to Faraday, an *electric field* extends outward from every charge and permeates all of space (Fig. 21–22). If a second charge (call it $q$) is placed near the first charge $(Q)$, then $q$ feels a force exerted by the electric field that is there (say, at point P in Fig. 21–22).

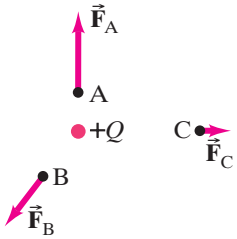


**FIGURE 21–22** An electric field surrounds every charge $(Q)$. The red lines indicate the electric field extending out from charge $Q$, and P is an arbitrary point.

**The electric field at point P is considered to interact directly with charge $q$ to produce the force on $q$.**

We can in principle investigate the electric field surrounding a charge or group of charges by measuring the force on a small positive **test charge**, which is at rest. By a test charge we mean a charge so small that the force it exerts on other nearby charges does not significantly move or affect the other charges that create the field. If a tiny positive test charge $q$ is placed at various locations in the vicinity of a single positive charge $Q$ as shown in Fig. 21–23 (points A, B, C), the force exerted on $q$ is as shown. The force at B is less than at A because B's distance from $Q$ is greater (Coulomb's law); and the force at C is smaller still. In each case, the force on $q$ is directed radially away from $Q$. *The electric field is defined in terms of the force on such a positive test charge.*

**FIGURE 21–23** Force exerted by charge $+Q$ on a small positive test charge, $q$, placed at points A, B, and C.

In particular, the **electric field**, $\vec{\mathbf{E}}$, at any point in space is defined as the force $\vec{\mathbf{F}}$ exerted on a tiny positive test charge placed at that point divided by the magnitude of the test charge $q$:

$$\vec{\mathbf{E}} = \frac{\vec{\mathbf{F}}}{q}. \qquad [q \to 0] \qquad \textbf{(21–3)}$$

More precisely, $\vec{\mathbf{E}}$ is defined as the limit of $\vec{\mathbf{F}}/q$ as $q$ is taken smaller and smaller, approaching zero. That is, $q$ is so tiny that it exerts essentially no force on the other charges which created the field. From this definition (Eq. 21–3), we see that the electric field at any point in space is a vector whose direction is the direction of the force on a tiny positive test charge at that point, and whose magnitude is the *force per unit charge*. Thus $\vec{\mathbf{E}}$ has SI units of newtons per coulomb (N/C).

The reason for defining $\vec{\mathbf{E}}$ as $\vec{\mathbf{F}}/q$ (with $q \to 0$) is so that $\vec{\mathbf{E}}$ does not depend on the magnitude of the test charge $q$. This means that $\vec{\mathbf{E}}$ describes only the effect of the charges creating the electric field at that point.

The electric field at any point in space can be measured, based on the definition, Eq. 21–3. For simple situations involving one or several point charges, we can calculate $\vec{\mathbf{E}}$. For example, the electric field at a distance $r$ from a single point charge $Q$ would have magnitude

$$E = \frac{F}{q} = \frac{kqQ/r^2}{q}$$

$$E = k\frac{Q}{r^2}; \qquad [\text{single point charge}] \qquad \textbf{(21–4a)}$$

or, in terms of $\epsilon_0$ as in Eq. 21–2 $\left(k = 1/4\pi\epsilon_0\right)$:

$$E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2}. \qquad [\text{single point charge}] \qquad \textbf{(21–4b)}$$

Notice that $E$ is independent of the test charge $q$—that is, $E$ depends only on the charge $Q$ which produces the field, and not on the value of the test charge $q$. Equations 21–4 are referred to as the *electric field form of Coulomb's law*.

If we are given the electric field $\vec{\mathbf{E}}$ at a given point in space, then we can calculate the force $\vec{\mathbf{F}}$ that $\vec{\mathbf{E}}$ exerts on any charge $q$ placed at that point (see Eq. 21–3):

$$\vec{\mathbf{F}} = q\vec{\mathbf{E}}. \qquad \textbf{(21–5)}$$

This is valid even if $q$ is not small as long as $q$ does not cause the charges creating $\vec{\mathbf{E}}$ to move. If $q$ is positive, $\vec{\mathbf{F}}$ and $\vec{\mathbf{E}}$ point in the same direction. If $q$ is negative, $\vec{\mathbf{F}}$ and $\vec{\mathbf{E}}$ point in opposite directions. See Fig. 21–24.

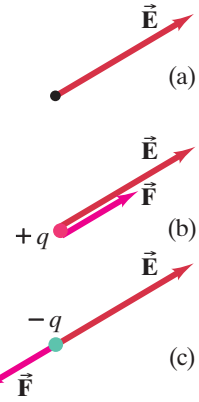

**FIGURE 21–24** (a) Electric field at a given point in space. (b) Force on a positive charge at that point. (c) Force on a negative charge at that point.

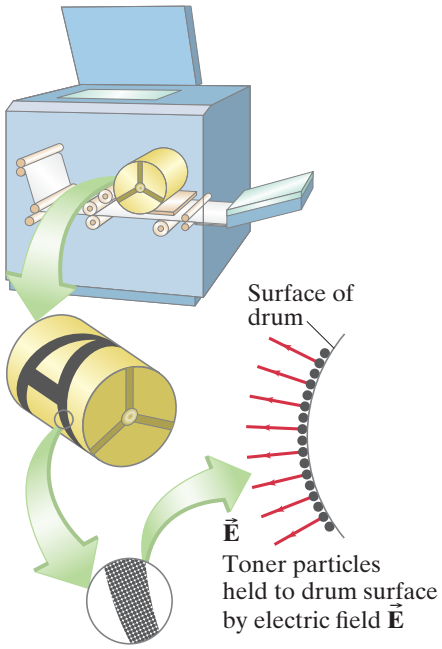
**EXAMPLE 21–6** **Printing and copying.** Many computer printers and photocopiers work by arranging positive charges (in the pattern to be copied) on the surface of a drum, then gently sprinkling negatively charged dry toner (ink) particles onto the drum. The toner particles temporarily stick to the pattern on the drum (Fig. 21–25). Suppose each toner particle has a mass of $9.0 \times 10^{-16}$ kg and carries an average of 20 extra electrons to provide an electric charge. Assuming that the electric force on a toner particle must exceed twice its weight in order to ensure sufficient attraction, compute the required electric field strength near the surface of the drum.

**APPROACH** The electric force on a toner particle of charge $q = 20e$ is $F = qE$, where $E$ is the needed electric field. This force needs to be at least as great as twice the weight $(mg)$ of the particle.



**SOLUTION** The minimum value of electric field satisfies the relation

$$qE = 2mg$$

where $q = 20e$. Hence

$$E = \frac{2mg}{q} = \frac{2\left(9.0 \times 10^{-16}\,\text{kg}\right)\left(9.8\,\text{m/s}^2\right)}{20\left(1.6 \times 10^{-19}\,\text{C}\right)} = 5.5 \times 10^3\,\text{N/C}.$$

**FIGURE 21–25** Example 21–6

**PHYSICS APPLIED**
*Photocopiers and printers*

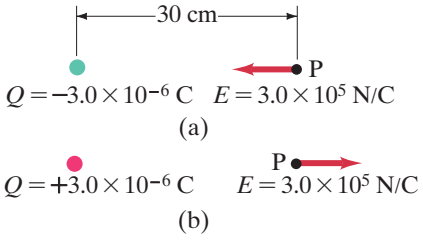


**FIGURE 21–26** Example 21–7. Electric field at point P (a) due to a negative charge $Q$, and (b) due to a positive charge $Q$, each 30 cm from P.

**EXAMPLE 21–7** **Electric field of a single point charge.** Calculate the magnitude and direction of the electric field at a point P which is 30 cm to the right of a point charge $Q = -3.0 \times 10^{-6}$ C.

**APPROACH** The magnitude of the electric field due to a single point charge is given by Eq. 21–4. The direction is found using the sign of the charge $Q$.

**SOLUTION** The magnitude of the electric field is:

$$E = k\frac{Q}{r^2} = \frac{(9.0 \times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(3.0 \times 10^{-6}\,\text{C})}{(0.30\,\text{m})^2} = 3.0 \times 10^5\,\text{N/C}.$$

The direction of the electric field is *toward* the charge $Q$, to the left as shown in Fig. 21–26a, since we defined the direction as that of the force on a positive test charge which here would be attractive. If $Q$ had been positive, the electric field would have pointed away, as in Fig. 21–26b.

**NOTE** There is no electric charge at point P. But there is an electric field there. The only charge here is $Q$.

This Example illustrates a general result: The electric field $\vec{\mathbf{E}}$ due to a positive charge points away from the charge, whereas $\vec{\mathbf{E}}$ due to a negative charge points toward that charge.

If the electric field at a given point in space is due to more than one charge, the individual fields (call them $\vec{\mathbf{E}}_1$, $\vec{\mathbf{E}}_2$, etc.) due to each charge are added vectorially to get the total field at that point:

$$\vec{\mathbf{E}} = \vec{\mathbf{E}}_1 + \vec{\mathbf{E}}_2 + \cdots.$$

The validity of this **superposition principle** for electric fields is fully confirmed by experiment.

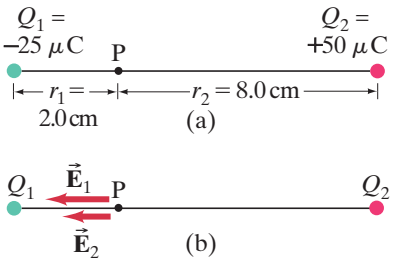

**FIGURE 21–27** Example 21–8. In (b), we don't know the relative magnitudes of $\vec{\mathbf{E}}_1$ and $\vec{\mathbf{E}}_2$ until we do the calculation.

**EXAMPLE 21–8** **$\vec{\mathbf{E}}$ at a point between two charges.** Two point charges are separated by a distance of 10.0 cm. One has a charge of $-25\,\mu$C and the other $+50\,\mu$C. (*a*) Determine the direction and magnitude of the electric field at a point P between the two charges that is 2.0 cm from the negative charge (Fig. 21–27a). (*b*) If an electron $(\text{mass} = 9.11 \times 10^{-31}\,\text{kg})$ is placed at rest at P and then released, what will be its initial acceleration (direction and magnitude)?

**APPROACH** The electric field at P will be the vector sum of the fields created separately by $Q_1$ and $Q_2$. The field due to the negative charge $Q_1$ points toward $Q_1$, and the field due to the positive charge $Q_2$ points away from $Q_2$. Thus both fields point to the left as shown in Fig. 21–27b, and we can add the magnitudes of the two fields together algebraically, ignoring the signs of the charges. In (*b*) we use Newton's second law ($\Sigma\vec{\mathbf{F}} = m\vec{\mathbf{a}}$) to determine the acceleration, where $\Sigma\vec{\mathbf{F}} = q\Sigma\vec{\mathbf{E}}$.

**SOLUTION** (*a*) Each field is due to a point charge as given by Eq. 21–4, $E = kQ/r^2$. The total field points to the left and has magnitude

$$E = k\frac{Q_1}{r_1^2} + k\frac{Q_2}{r_2^2} = k\left(\frac{Q_1}{r_1^2} + \frac{Q_2}{r_2^2}\right)$$

$$= (9.0 \times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)\left(\frac{25 \times 10^{-6}\,\text{C}}{(2.0 \times 10^{-2}\,\text{m})^2} + \frac{50 \times 10^{-6}\,\text{C}}{(8.0 \times 10^{-2}\,\text{m})^2}\right)$$

$$= 6.3 \times 10^8\,\text{N/C}.$$

(*b*) The electric field points to the left, so the electron will feel a force to the *right* since it is negatively charged. Therefore the acceleration $a = F/m$ (Newton's second law) will be to the right. The force on a charge $q$ in an electric field $E$ is $F = qE$ (Eq. 21–5). Hence the magnitude of the electron's initial acceleration is

$$a = \frac{F}{m} = \frac{qE}{m} = \frac{(1.60 \times 10^{-19}\,\text{C})(6.3 \times 10^8\,\text{N/C})}{9.11 \times 10^{-31}\,\text{kg}} = 1.1 \times 10^{20}\,\text{m/s}^2.$$

**NOTE** By considering the directions of *each* field ($\vec{\mathbf{E}}_1$ and $\vec{\mathbf{E}}_2$) before doing any calculations, we made sure our calculation could be done simply and correctly.

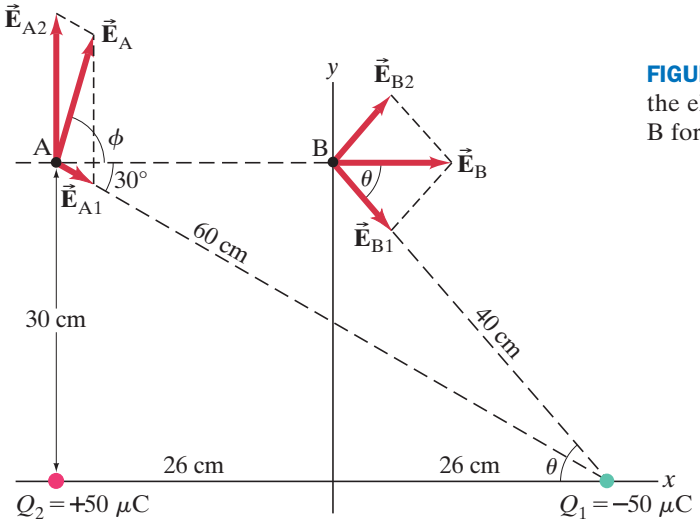

**FIGURE 21–28** Calculation of the electric field at points A and B for Example 21–9.

**EXAMPLE 21–9** **$\vec{E}$ above two point charges.** Calculate the total electric field (*a*) at point A and (*b*) at point B in Fig. 21–28 due to both charges, $Q_1$ and $Q_2$.

**APPROACH** The calculation is much like that of Example 21–4, except now we are dealing with electric fields instead of force. The electric field at point A is the vector sum of the fields $\vec{E}_{A1}$ due to $Q_1$, and $\vec{E}_{A2}$ due to $Q_2$. We find the magnitude of the field produced by each point charge, then we add their components to find the total field at point A. We do the same for point B.

**SOLUTION** (*a*) The magnitude of the electric field produced at point A by each of the charges $Q_1$ and $Q_2$ is given by $E = kQ/r^2$, so

$$E_{A1} = \frac{(9.0 \times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(50 \times 10^{-6}\,\text{C})}{(0.60\,\text{m})^2} = 1.25 \times 10^6\,\text{N/C},$$

$$E_{A2} = \frac{(9.0 \times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(50 \times 10^{-6}\,\text{C})}{(0.30\,\text{m})^2} = 5.0 \times 10^6\,\text{N/C}.$$

**PROBLEM SOLVING**
*Ignore signs of charges and determine direction physically, showing directions on diagram*

The direction of $E_{A1}$ points from A toward $Q_1$ (negative charge), whereas $E_{A2}$ points from A away from $Q_2$, as shown; so the total electric field at A, $\vec{E}_A$, has components

$$E_{Ax} = E_{A1}\cos 30° = 1.1 \times 10^6\,\text{N/C},$$
$$E_{Ay} = E_{A2} - E_{A1}\sin 30° = 4.4 \times 10^6\,\text{N/C}.$$

Thus the magnitude of $\vec{E}_A$ is

$$E_A = \sqrt{(1.1)^2 + (4.4)^2} \times 10^6\,\text{N/C} = 4.5 \times 10^6\,\text{N/C},$$

and its direction is $\phi$ given by $\tan\phi = E_{Ay}/E_{Ax} = 4.4/1.1 = 4.0$, so $\phi = 76°$.

(*b*) Because B is equidistant from the two equal charges (40 cm by the Pythagorean theorem), the magnitudes of $E_{B1}$ and $E_{B2}$ are the same; that is,

$$E_{B1} = E_{B2} = \frac{kQ}{r^2} = \frac{(9.0 \times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(50 \times 10^{-6}\,\text{C})}{(0.40\,\text{m})^2}$$
$$= 2.8 \times 10^6\,\text{N/C}.$$

**PROBLEM SOLVING**
*Use symmetry to save work, when possible*

Also, because of the symmetry, the $y$ components are equal and opposite, and so cancel out. Hence the total field $E_B$ is horizontal and equals $E_{B1}\cos\theta + E_{B2}\cos\theta = 2E_{B1}\cos\theta$. From the diagram, $\cos\theta = 26\,\text{cm}/40\,\text{cm} = 0.65$. Then

$$E_B = 2E_{B1}\cos\theta = 2(2.8 \times 10^6\,\text{N/C})(0.65) = 3.6 \times 10^6\,\text{N/C},$$

and the direction of $\vec{E}_B$ is along the $+x$ direction.

**NOTE** We could have done part (*b*) in the same way we did part (*a*). But symmetry allowed us to solve the problem with less effort.

**EXERCISE E** Four charges of equal magnitude, but possibly different sign, are placed on the corners of a square. What arrangement of charges will produce an electric field with the greatest magnitude at the center of the square? (*a*) All four positive charges; (*b*) all four negative charges; (*c*) three positive and one negative; (*d*) two positive and two negative; (*e*) three negative and one positive.

PROBLEM SOLVING

### Electrostatics: Electric Forces and Electric Fields

Whether you use electric field or electrostatic forces, the procedure for solving electrostatics problems is similar:

1. **Draw** a careful **diagram**—namely, a free-body diagram for each object, showing all the forces acting on that object, or showing the electric field at a point due to all significant charges present. Determine the **direction** of each force or electric field physically: like charges repel each other, unlike charges attract; fields point away from a + charge, and toward a − charge. Show and label each vector force or field on your diagram.
2. **Apply Coulomb's law** to calculate the magnitude of the force that each contributing charge exerts on a charged object, or the magnitude of the electric field each charge produces at a given point. Deal only with magnitudes of charges (leaving out minus signs), and obtain the magnitude of each force or electric field.
3. **Add vectorially** all the forces on an object, or the contributing fields at a point, to get the resultant. Use **symmetry** (say, in the geometry) whenever possible.
4. **Check** your answer. Is it **reasonable**? If a function of distance, does it give reasonable results in limiting cases?

## 21–7 Electric Field Calculations for Continuous Charge Distributions

In many cases we can treat charge as being distributed continuously.† We can divide up a charge distribution into infinitesimal charges $dQ$, each of which will act as a tiny point charge. The contribution to the electric field at a distance $r$ from each $dQ$ is

$$dE = \frac{1}{4\pi\epsilon_0}\frac{dQ}{r^2}. \qquad \textbf{(21–6a)}$$

Then the electric field, $\vec{\mathbf{E}}$, at any point is obtained by summing over all the infinitesimal contributions, which is the integral

$$\vec{\mathbf{E}} = \int d\vec{\mathbf{E}}. \qquad \textbf{(21–6b)}$$

Note that $d\vec{\mathbf{E}}$ is a vector (Eq. 21–6a gives its magnitude). Sometimes Eq. 21–6b is difficult to evaluate, but often we can use other techniques as we will see. (Numerical integration, discussed in Appendix C, can also be used in many cases.)

**EXAMPLE 21–10** **A ring of charge.** A thin, ring-shaped object of radius $a$ holds a total charge $+Q$ distributed uniformly around it. Determine the electric field at a point P on its axis, a distance $x$ from the center. See Fig. 21–29. Let $\lambda$ be the charge per unit length (C/m).

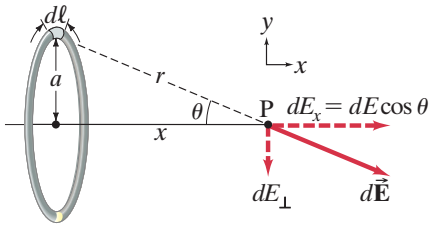

**FIGURE 21–29** Example 21–10.

†Because we believe there is a minimum charge ($e$), the treatment here is only for convenience; it is nonetheless useful and accurate since $e$ is usually very much smaller than macroscopic charges.

**APPROACH AND SOLUTION** We explicitly follow the steps of the Problem Solving Strategy on page 622.

1. **Draw** a careful **diagram**, which is Fig. 21–29. The **direction** of the electric field due to one infinitesimal length $d\ell$ of the charged ring is shown in Fig. 21–29.
2. **Apply Coulomb's law**. The electric field, $d\vec{\mathbf{E}}$, due to this particular segment of the ring of length $d\ell$ has magnitude

$$dE = \frac{1}{4\pi\epsilon_0}\frac{dQ}{r^2}.$$

The whole ring has circumference of $2\pi a$, so the charge on a length $d\ell$ is

$$dQ = Q\left(\frac{d\ell}{2\pi a}\right) = \lambda\, d\ell$$

where $\lambda = Q/2\pi a$ is the charge per unit length (or the linear charge density). Now we write $dE$ as

$$dE = \frac{1}{4\pi\epsilon_0}\frac{\lambda\, d\ell}{r^2}.$$

3. Add **vectorially** and use **symmetry**: The vector $d\vec{\mathbf{E}}$ has components $dE_x$ along the $x$ axis and $dE_\perp$ perpendicular to the $x$ axis (Fig. 21–29). We are going to sum (integrate) around the entire ring. We note that an equal-length segment $d\ell$, diametrically opposite the $d\ell$ shown, will produce a $d\vec{\mathbf{E}}$ whose component perpendicular to the $x$ axis will just cancel the $dE_\perp$ shown. This is true for all segments of the ring, so by symmetry $\vec{\mathbf{E}}$ will have zero $y$ components, and so we need only sum the $x$ components, $dE_x$. The total field is then

**PROBLEM SOLVING**
*Use symmetry when possible*

$$E = E_x = \int dE_x = \int dE\cos\theta = \frac{1}{4\pi\epsilon_0}\lambda\int\frac{d\ell}{r^2}\cos\theta.$$

Because $r^2 = x^2 + a^2$, where we treat $x$ as fixed (not a variable), and $\cos\theta = x/r$, we have

$$E = \frac{\lambda}{(4\pi\epsilon_0)}\frac{x}{(x^2+a^2)^{\frac{3}{2}}}\int_0^{2\pi a} d\ell = \frac{1}{4\pi\epsilon_0}\frac{\lambda x(2\pi a)}{(x^2+a^2)^{\frac{3}{2}}} = \frac{1}{4\pi\epsilon_0}\frac{Qx}{(x^2+a^2)^{\frac{3}{2}}}.$$

4. To **check reasonableness**, note that at great distances, $x \gg a$, this result reduces to $E = Q/(4\pi\epsilon_0 x^2)$. We would expect this result because at great distances the ring would appear to be a point charge ($1/r^2$ dependence). Also note that our result gives $E = 0$ at $x = 0$, as we might expect because all components will cancel at the center of the circle.

**PROBLEM SOLVING**
*Check result by noting that at a great distance the ring looks like a point charge*

Note in this Example three important problem-solving techniques that can be used elsewhere: (1) using symmetry to reduce the complexity of the problem; (2) expressing the charge $dQ$ in terms of a charge density (here linear, $\lambda = Q/2\pi a$); and (3) checking the answer at the limit of large $r$, which serves as an indication (but not proof) of the correctness of the answer—if the result does not check at large $r$, your result has to be wrong.

**PROBLEM SOLVING**
*Use symmetry, charge density, and values at $r = 0$ and $\infty$*

**CONCEPTUAL EXAMPLE 21–11** **Charge at the center of a ring.** Imagine a small positive charge placed at the center of a nonconducting ring carrying a uniformly distributed negative charge. Is the positive charge in equilibrium if it is displaced slightly from the center along the axis of the ring, and if so is it stable? What if the small charge is negative? Neglect gravity, as it is much smaller than the electrostatic forces.

**RESPONSE** A positive charge at the center of the ring is in equilibrium because there is no net force on it, by *symmetry*. If the positive charge is moved away from the center of the negative ring along the axis in either direction, the attractive force acts back towards the center of the ring and so the charge is in *stable* equilibrium. A negative charge at the center of the ring feels no net force, but is in *unstable* equilibrium because if it is moved along the ring's axis, the repulsive force acts away from the ring, pushing the charge farther away.

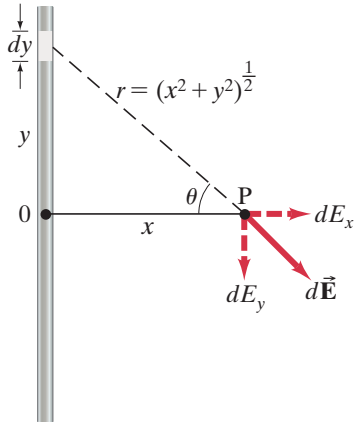

**FIGURE 21–30** Example 21–12.

**EXAMPLE 21–12 Long line of charge.** Determine the magnitude of the electric field at any point P a distance $x$ from the midpoint 0 of a very long straight wire of uniformly distributed positive charge, Fig. 21–30. Assume $x$ is much smaller than the length of the wire, and let $\lambda$ be the charge per unit length (C/m).

**APPROACH** We set up a coordinate system so the wire is on the $y$ axis with origin 0 as shown. A segment of wire $dy$ has charge $dQ = \lambda\, dy$. The field $d\vec{\mathbf{E}}$ at point P due to this length $dy$ of wire (at $y$) has magnitude

$$dE = \frac{1}{4\pi\epsilon_0}\frac{dQ}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{\lambda\, dy}{(x^2 + y^2)},$$

where $r = (x^2 + y^2)^{\frac{1}{2}}$ as shown in Fig. 21–30. The vector $d\vec{\mathbf{E}}$ has components $dE_x$ and $dE_y$ as shown, where $dE_x = dE\cos\theta$ and $dE_y = dE\sin\theta$.

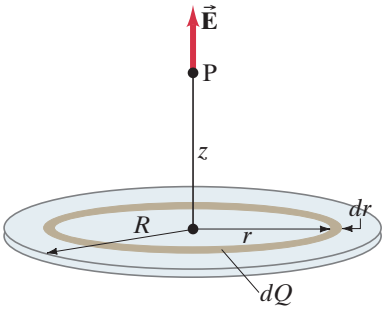
**SOLUTION** Because 0 is at the midpoint of the wire, the $y$ component of $\vec{\mathbf{E}}$ will be zero since there will be equal contributions to $E_y = \int dE_y$ from above and below point 0:

$$E_y = \int dE\sin\theta = 0.$$

Thus we have

$$E = E_x = \int dE\cos\theta = \frac{\lambda}{4\pi\epsilon_0}\int \frac{\cos\theta\, dy}{x^2 + y^2}.$$

The integration here is over $y$, along the wire, with $x$ treated as constant. We must now write $\theta$ as a function of $y$, or $y$ as a function of $\theta$. We do the latter: since $y = x\tan\theta$, then $dy = x\, d\theta/\cos^2\theta$. Furthermore, because $\cos\theta = x/\sqrt{x^2 + y^2}$, then $1/(x^2 + y^2) = \cos^2\theta/x^2$ and our integrand above is $(\cos\theta)(x\, d\theta/\cos^2\theta)(\cos^2\theta/x^2) = \cos\theta\, d\theta/x$. Hence



$$E = \frac{\lambda}{4\pi\epsilon_0}\frac{1}{x}\int_{-\pi/2}^{\pi/2}\cos\theta\, d\theta = \frac{\lambda}{4\pi\epsilon_0 x}(\sin\theta)\Big|_{-\pi/2}^{\pi/2} = \frac{1}{2\pi\epsilon_0}\frac{\lambda}{x},$$

where we have assumed the wire is extremely long in both directions ($y \to \pm\infty$) which corresponds to the limits $\theta = \pm\pi/2$. Thus the field near a long straight wire of uniform charge decreases inversely as the first power of the distance from the wire. Compare to a point charge where $E$ decreases as the *square* of the distance.

**NOTE** This result, obtained for an infinite wire, is a good approximation for a wire of finite length as long as $x$ is small compared to the distance of P from the ends of the wire.

**EXAMPLE 21–13 Uniformly charged disk.** Charge is distributed uniformly over a thin circular disk of radius $R$. The charge per unit area ($C/m^2$) is $\sigma$. Calculate the electric field at a point P on the axis of the disk, a distance $z$ above its center, Fig. 21–31.

**FIGURE 21–31** Example 21–13; a uniformly charged thin flat disk of radius $R$.

**APPROACH** We can think of the disk as a set of concentric rings. We can then apply the result of Example 21–10 to each of these rings, and then sum over all the rings.

**SOLUTION** For the ring of radius $r$ shown in Fig. 21–31, the electric field has magnitude (see result of Example 21–10)

$$dE = \frac{1}{4\pi\epsilon_0}\frac{z\, dQ}{(z^2 + r^2)^{\frac{3}{2}}}$$

where we have written $dE$ (instead of $E$) for this thin ring of total charge $dQ$. The ring has area $(dr)(2\pi r)$ and charge per unit area $\sigma = dQ/(2\pi r\, dr)$, which we call the surface charge density. We solve this for $dQ$ $(= \sigma\, 2\pi r\, dr)$ and insert it in the equation above for $dE$:

$$dE = \frac{1}{4\pi\epsilon_0}\frac{z\sigma 2\pi r\, dr}{(z^2 + r^2)^{\frac{3}{2}}} = \frac{z\sigma r\, dr}{2\epsilon_0(z^2 + r^2)^{\frac{3}{2}}}.$$

Now we integrate[†] over all the rings, starting at $r = 0$ out to the largest with $r = R$:

$$E = \frac{z\sigma}{2\epsilon_0}\int_0^R \frac{r\,dr}{(z^2 + r^2)^{\frac{3}{2}}} = \frac{z\sigma}{2\epsilon_0}\left[-\frac{1}{(z^2 + r^2)^{\frac{1}{2}}}\right]_0^R = \frac{\sigma}{2\epsilon_0}\left[1 - \frac{z}{(z^2 + R^2)^{\frac{1}{2}}}\right].$$

This gives the magnitude of $\vec{\mathbf{E}}$ at any point $z$ along the axis of the disk. The direction of each $d\vec{\mathbf{E}}$ due to each ring is along the $z$ axis (as in Example 21–10), and therefore the direction of $\vec{\mathbf{E}}$ is along $z$. If $Q$ (and $\sigma$) are positive, $\vec{\mathbf{E}}$ points away from the disk; if $Q$ (and $\sigma$) are negative, $\vec{\mathbf{E}}$ points toward the disk.

If the radius of the disk in Example 21–13 is much greater than the distance of our point P from the disk (i.e., $z \ll R$) then we can obtain a very useful result: the second term in the solution above becomes very small, so

$$E = \frac{\sigma}{2\epsilon_0}. \qquad \text{[infinite plane]} \quad \textbf{(21–7)}$$

This result is valid for any point above (or below) an infinite plane of any shape holding a uniform surface charge density $\sigma$ (charge per unit area). It is also valid for points close to a finite plane, as long as the point is close to the plane compared to the distance to the edges of the plane. Thus the field near a large uniformly charged plane is uniform, and directed outward if the plane is positively charged.

It is interesting to compare here the distance dependence of the electric field (1) due to a point charge $(E \sim 1/r^2)$, (2) due to a very long uniform line of charge $(E \sim 1/r)$, and (3) due to a very large uniform plane of charge ($E$ does not depend on $r$).

**CAUTION**
*Comparing dependence of E on distance*

**EXAMPLE 21–14 Two parallel plates.** Two large parallel plates are very thin and are separated by a distance $d$ which is small compared to their height and width. One plate carries a positive charge, with uniform charge density $\sigma$, and the other carries a uniform negative charge density, $-\sigma$. Determine the electric field between the plates near their center where the field is assumed to be uniform.

**APPROACH** From Eq. 21–7, each plate sets up an electric field of magnitude $\sigma/2\epsilon_0$. The field due to the positive plate points away from that plate whereas the field due to the negative plate points toward that plate. See Fig. 21–32, which is a zoom-in view of the central portion of the two plates.

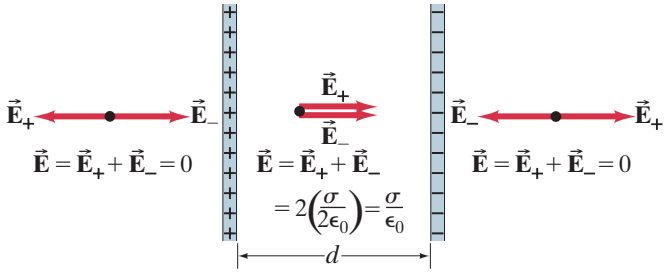


**FIGURE 21–32** Example 21–14. Two large flat parallel plates very close together, oppositely charged. Shown here is only the central portion for calculating the uniform electric field between the plates.

**SOLUTION** In the region between the plates, the fields add together as shown:

$$E = E_+ + E_- = \frac{\sigma}{2\epsilon_0} + \frac{\sigma}{2\epsilon_0} = \frac{\sigma}{\epsilon_0}. \quad \left[\begin{array}{c}\text{2 large flat plates, oppositely}\\ \text{charged, close together}\end{array}\right] \quad \textbf{(21–8)}$$

The field is uniform, since the plates are very large compared to their separation, so this result is valid for any point, whether near one or the other of the plates, or midway between them as long as the point is far from the ends. Outside the plates, the fields cancel,

$$E = E_+ + E_- = \frac{\sigma}{2\epsilon_0} - \frac{\sigma}{2\epsilon_0} = 0,$$

as shown in Fig. 21–32. These results are valid ideally for infinitely large plates; they are a good approximation for finite plates if the separation is much less than the dimensions of the plate and for points not too close to the edge.

**NOTE** These useful and extraordinary results illustrate the *principle of superposition* and its great power.

[†]You should confirm this integral by taking the derivation of the result and seeing that it equals the integrand. You might also take a look at Appendix B.

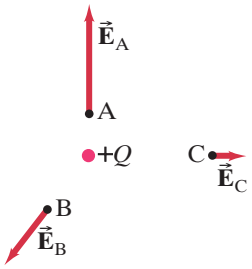

**FIGURE 21–33** Electric field vector at three points, due to one point charge $Q$.

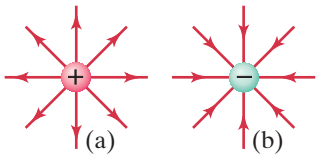
**FIGURE 21–34** Electric field lines near (a) a single positive point charge, (b) a single negative point charge.



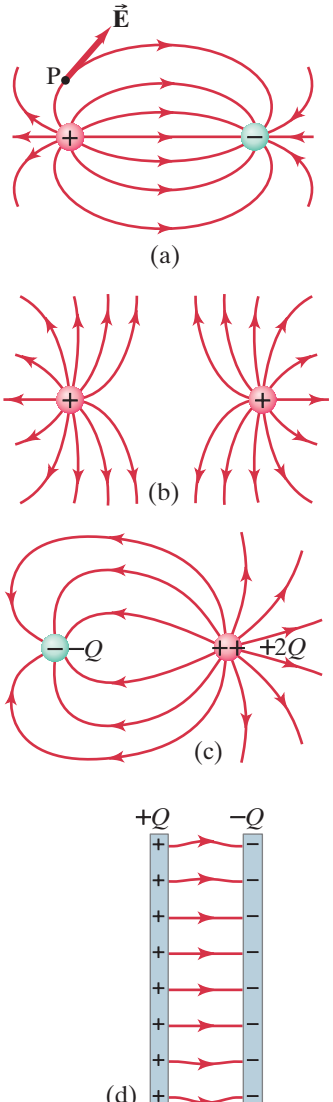


**FIGURE 21–35** Electric field lines for four arrangements of charges.

# 21–8 Field Lines

Since the electric field is a vector, it is sometimes referred to as a **vector field**. We could indicate the electric field with arrows at various points in a given situation, such as at A, B, and C in Fig. 21–33. The directions of $\vec{\mathbf{E}}_A$, $\vec{\mathbf{E}}_B$, and $\vec{\mathbf{E}}_C$ are the same as for the forces shown earlier in Fig. 21–23, but the magnitudes (arrow lengths) are different since we divide $\vec{\mathbf{F}}$ by $q$ to get $\vec{\mathbf{E}}$. However, the relative magnitudes of $\vec{\mathbf{E}}_A$, $\vec{\mathbf{E}}_B$, and $\vec{\mathbf{E}}_C$ are the same as for the forces since we divide by the same $q$ each time. To indicate the electric field in such a way at *many* points, however, would result in many arrows, which would become cluttered and confusing. To avoid this, we use another technique, that of field lines.

To visualize the electric field, we draw a series of lines to indicate the direction of the electric field at various points in space. These **electric field lines** (or **lines of force**) are drawn to indicate the direction of the force due to the given field on a positive test charge. The lines of force due to a single isolated positive charge are shown in Fig. 21–34a, and for a negative charge in Fig. 21–34b. In part (a) the lines point radially outward from the charge, and in part (b) they point radially inward toward the charge because that is the direction the force would be on a positive test charge in each case (as in Fig. 21–26). Only a few representative lines are shown. We could draw lines in between those shown since the electric field exists there as well. We can draw the lines so that the *number of lines starting on a positive charge, or ending on a negative charge, is proportional to the magnitude of the charge*. Notice that nearer the charge, where the electric field is greater $(F \propto 1/r^2)$, the lines are closer together. This is a general property of electric field lines: *the closer together the lines are, the stronger the electric field in that region*. In fact, field lines can be drawn so that the *number of lines crossing unit area perpendicular to* $\vec{\mathbf{E}}$ *is proportional to the magnitude of the electric field*.

Figure 21–35a shows the electric field lines due to two equal charges of opposite sign, a combination known as an **electric dipole**. The electric field lines are curved in this case and are directed from the positive charge to the negative charge. The direction of the electric field at any point is tangent to the field line at that point as shown by the vector arrow $\vec{\mathbf{E}}$ at point P. To satisfy yourself that this is the correct pattern for the electric field lines, you can make a few calculations such as those done in Example 21–9 for just this case (see Fig. 21–28). Figure 21–35b shows the electric field lines for two equal positive charges, and Fig. 21–35c for unequal charges, $-Q$ and $+2Q$. Note that twice as many lines leave $+2Q$, as enter $-Q$ (number of lines is proportional to magnitude of $Q$). Finally, in Fig. 21–35d, we see the field lines between two parallel plates carrying equal but opposite charges. Notice that the electric field lines between the two plates start out perpendicular to the surface of the metal plates (Example 21–14 and the next Section) and go directly from one plate to the other, as we expect because a positive test charge placed between the plates would feel a strong repulsion from the positive plate and a strong attraction to the negative plate. The field lines between two close plates are parallel and equally spaced in the central region, but fringe outward near the edges. Thus, in the central region, the electric field has the same magnitude at all points, and we can write (see Example 21–14)

$$E = \text{constant} = \frac{\sigma}{\epsilon_0} = \frac{Q}{\epsilon_0 A}. \quad \left[\begin{array}{l}\text{between two closely spaced,}\\ \text{oppositely charged, parallel plates}\end{array}\right] \qquad \textbf{(21–8)}$$

where $Q = \sigma A$ is the charge on one plate of area $A$. The fringing of the field near the edges can often be ignored, particularly if the separation of the plates is small compared to their height and width. We summarize the properties of field lines as:

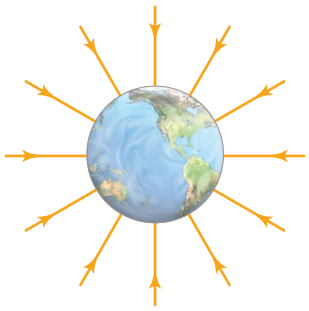
1. Electric field lines indicate the direction of the electric field; the field points in the direction tangent to the field line at any point.
2. The lines are drawn so that the magnitude of the electric field, $E$, is proportional to the number of lines crossing unit area perpendicular to the lines. The closer together the lines, the stronger the field.
3. Electric field lines start on positive charges and end on negative charges; and the number starting or ending is proportional to the magnitude of the charge.

Also note that field lines never cross. Why not? Because it would not make sense for the electric field to have two directions at the same point.

Our diagrams for electric field lines, as Figs. 21–34 and 21–35, are 2-dimensional. It is hard to show them in 3 dimensions, but the Chapter-opening drawing for Chapter 22, page 643, is an attempt to suggest field lines in 3-D.

### Gravitational Field

The field concept can also be applied to the gravitational force (Chapter 6). Thus we can say that a **gravitational field** exists for every object that has mass. One object attracts another by means of the gravitational field. The Earth, for example, can be said to possess a gravitational field (Fig. 21–36) which is responsible for the gravitational force on objects. The force that keeps Earth satellites and the Moon revolving around Earth is exerted by the gravitational field produced at their position by the Earth. The *gravitational field* is defined as the *force per unit mass*. The magnitude of the Earth's gravitational field at any point above the Earth's surface is $GM_E/r^2$, where $M_E$ is the mass of the Earth, $r$ is the distance of the point from the Earth's center, and $G$ is the gravitational constant (Chapter 6). At the Earth's surface, $r$ is the radius of the Earth and the gravitational field is equal to $g$, the acceleration due to gravity. Beyond the Earth, the gravitational field can be calculated at any point as a sum of terms due to Earth, Sun, Moon, and other bodies that contribute significantly.



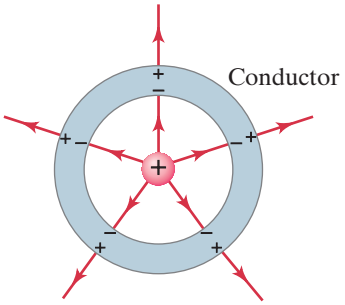


**FIGURE 21–36** The Earth's gravitational field, which at any point is directed toward the Earth's center (the force on any mass points toward the Earth's center).

## 21–9 Electric Fields and Conductors

We now discuss some properties of conductors. First, *the electric field inside a conductor is zero in the static situation*—that is, when the charges are at rest. If there were an electric field within a conductor, there would be a force on the free electrons. The electrons would move until they reached positions where the electric field, and therefore the electric force on them, did become zero.

This reasoning has some interesting consequences. For one, *any net charge on a conductor distributes itself on the surface*. For a negatively charged conductor, you can imagine that the negative charges repel one another and race to the surface to get as far from one another as possible. Another consequence is the following. Suppose that a positive charge $Q$ is surrounded by an isolated uncharged metal conductor whose shape is a spherical shell, Fig. 21–37. Because there can be no field within the metal, the lines leaving the central positive charge must end on negative charges on the inner surface of the metal shell. That is, the encircled charge $+Q$ induces an equal amount of negative charge, $-Q$, on the inner surface of the spherical shell. Since the shell is neutral, a positive charge of the same magnitude, $+Q$, must exist on the outer surface of the shell. Thus, although no field exists in the metal shell itself, an electric field exists outside of it, as shown in Fig. 21–37, as if the metal were not even there.

**FIGURE 21–37** A charge inside a neutral spherical metal shell induces charge on the shell's surfaces. The electric field exists even beyond the shell, but not within the conducting shell itself.

A related property of static electric fields and conductors is that *the electric field is always perpendicular to the surface outside of a conductor*. If there were a component of $\vec{\mathbf{E}}$ parallel to the surface (Fig. 21–38), it would exert a force on free electrons at the surface, causing the electrons to move along the surface until they reached positions where no net force was exerted on them parallel to the surface—that is, until the electric field was perpendicular to the surface. [These results will be confirmed in the next Chapter, Section 22–3, Example 22–8.]

These properties apply only to conductors. Inside a nonconductor, which does not have free electrons, a static electric field can exist as we will see in the next Chapter (Examples 22–4 and 22–5). Also, the electric field outside a *non*conductor does not necessarily make an angle of 90° to the surface.

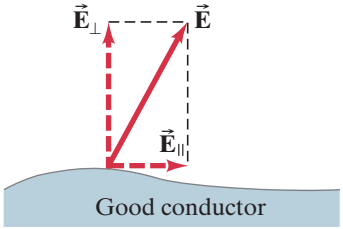

**FIGURE 21–38** If the electric field $\vec{\mathbf{E}}$ at the surface of a conductor had a component parallel to the surface, $\vec{\mathbf{E}}_\parallel$, the latter would accelerate electrons into motion (no longer static). In the static case, $\vec{\mathbf{E}}_\parallel$ must be zero, and the electric field must be perpendicular to the conductor's surface: $\vec{\mathbf{E}} = \vec{\mathbf{E}}_\perp$.

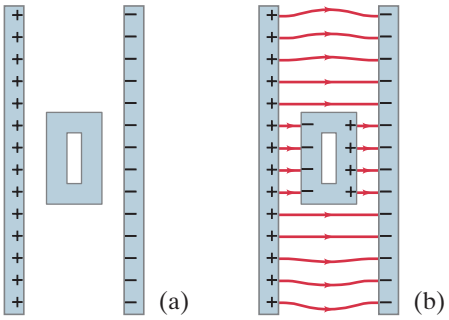

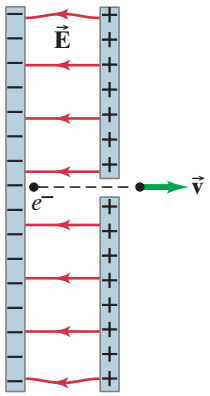

**FIGURE 21–39** Example 21–15.

**PHYSICS APPLIED**
*Electrical shielding*

**FIGURE 21–40** High-voltage "Van de Graaff" generators create strong electric fields in the vicinity of the "Faraday cage" below. The strong field accelerates stray electrons in the atmosphere to the high kinetic energy needed to knock electrons out of air atoms, causing an avalanche of charge which flows to (or from) the metal cage. The metal cage protects the person inside it.

**FIGURE 21–41** Example 21–16.

**CONCEPTUAL EXAMPLE 21–15** **Shielding, and safety in a storm.** A neutral hollow metal box is placed between two parallel charged plates as shown in Fig. 21–39a. What is the field like inside the box?

**RESPONSE** If our metal box had been solid, and not hollow, free electrons in the box would have redistributed themselves along the surface until all their individual fields would have canceled each other inside the box. The net field inside the box would have been zero. For a hollow box, the external field is not changed since the electrons in the metal can move just as freely as before to the surface. Hence the field inside the hollow metal box is also zero, and the field lines are shown in Fig. 21–39b. A conducting box is an effective device for shielding delicate instruments and electronic circuits from unwanted external electric fields. We also can see that a relatively safe place to be during a lightning storm is inside a parked car, surrounded by metal. See also Fig. 21–40, where a person inside a porous "cage" is protected from a strong electric discharge. (It is not safe in a lightning storm to be near a tree which can conduct, or out in the open where you are taller than the surroundings.)

## 21–10 Motion of a Charged Particle in an Electric Field

If an object having an electric charge $q$ is at a point in space where the electric field is $\vec{\mathbf{E}}$, the force on the object exerted by that electric field is given by

$$\vec{\mathbf{F}} = q\vec{\mathbf{E}}$$

(see Eq. 21–5). In the past few Sections we have seen how to determine $\vec{\mathbf{E}}$ for some particular situations. Now let us suppose we know $\vec{\mathbf{E}}$ and we want to find the force on a charged object and the object's subsequent motion. (We assume no other forces act.)

**EXAMPLE 21–16** **Electron accelerated by electric field.** An electron (mass $m = 9.1 \times 10^{-31}\,\text{kg}$) is accelerated in the uniform field $\vec{\mathbf{E}}\,(E = 2.0 \times 10^4\,\text{N/C})$ between two parallel charged plates. The separation of the plates is 1.5 cm. The electron is accelerated from rest near the negative plate and passes through a tiny hole in the positive plate, Fig. 21–41. (*a*) With what speed does it leave the hole? (*b*) Show that the gravitational force can be ignored. Assume the hole is so small that it does not affect the uniform field between the plates.

**APPROACH** We can obtain the electron's velocity using the kinematic equations of Chapter 2, after first finding its acceleration from Newton's second law, $F = ma$. The magnitude of the force on the electron is $F = qE$ and is directed to the right.

**SOLUTION** (*a*) The magnitude of the electron's acceleration is

$$a = \frac{F}{m} = \frac{qE}{m}.$$

Between the plates $\vec{\mathbf{E}}$ is uniform so the electron undergoes uniformly accelerated motion with acceleration

$$a = \frac{(1.6 \times 10^{-19}\,\text{C})(2.0 \times 10^4\,\text{N/C})}{(9.1 \times 10^{-31}\,\text{kg})} = 3.5 \times 10^{15}\,\text{m/s}^2.$$

It travels a distance $x = 1.5 \times 10^{-2}\,\text{m}$ before reaching the hole, and since its initial speed was zero, we can use the kinematic equation, $v^2 = v_0^2 + 2ax$ (Eq. 2–12c), with $v_0 = 0$:

$$v = \sqrt{2ax} = \sqrt{2(3.5 \times 10^{15}\,\text{m/s}^2)(1.5 \times 10^{-2}\,\text{m})} = 1.0 \times 10^7\,\text{m/s}.$$

There is no electric field outside the plates, so after passing through the hole, the electron moves with this speed, which is now constant.

(*b*) The magnitude of the electric force on the electron is

$$qE = (1.6 \times 10^{-19}\,\text{C})(2.0 \times 10^{4}\,\text{N/C}) = 3.2 \times 10^{-15}\,\text{N}.$$

The gravitational force is

$$mg = (9.1 \times 10^{-31}\,\text{kg})(9.8\,\text{m/s}^2) = 8.9 \times 10^{-30}\,\text{N},$$

which is $10^{14}$ times smaller! Note that the electric field due to the electron does not come into it (a particle cannot exert a force on itself).

**EXAMPLE 21–17** **Electron moving perpendicular to $\vec{\mathbf{E}}$.** Suppose an electron traveling with speed $v_0$ enters a uniform electric field $\vec{\mathbf{E}}$, which is at right angles to $\vec{\mathbf{v}}_0$ as shown in Fig. 21–42. Describe its motion by giving the equation of its path while in the electric field. Ignore gravity.

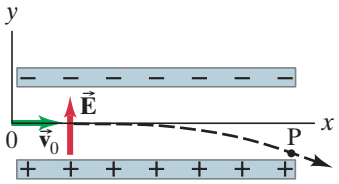

**FIGURE 21–42** Example 21–17.

**APPROACH** Again we use Newton's second law, with $F = qE$, and the kinematic equations from Chapter 2.

**SOLUTION** When the electron enters the electric field (at $x = y = 0$) it has velocity $\vec{\mathbf{v}}_0 = v_0\hat{\mathbf{i}}$ in the $x$ direction. The electric field $\vec{\mathbf{E}}$, pointing vertically upward, imparts a uniform vertical acceleration to the electron of

$$a_y = \frac{F}{m} = \frac{qE}{m} = -\frac{eE}{m},$$

where we set $q = -e$ for the electron. The electron's vertical position is given by Eq. 2–12b,

$$y = \frac{1}{2}a_y t^2 = -\frac{eE}{2m}t^2$$

since the motion is at constant acceleration. The horizontal position is given by

$$x = v_0 t$$

since $a_x = 0$. We eliminate $t$ between these two equations and obtain

$$y = -\frac{eE}{2mv_0^2}x^2,$$

which is the equation of a parabola (just as in projectile motion, Section 3–7).

# 21–11 Electric Dipoles

The combination of two equal charges of opposite sign, $+Q$ and $-Q$, separated by a distance $\ell$, is referred to as an **electric dipole**. The quantity $Q\ell$ is called the **dipole moment** and is represented[†] by the symbol $p$. The dipole moment can be considered to be a vector $\vec{\mathbf{p}}$, of magnitude $Q\ell$, that points from the negative to the positive charge as shown in Fig. 21–43. Many molecules, such as the diatomic molecule CO, have a dipole moment (C has a small positive charge and O a small negative charge of equal magnitude), and are referred to as **polar molecules**.

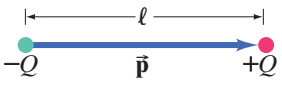

**FIGURE 21–43** A dipole consists of equal but opposite charges, $+Q$ and $-Q$, separated by a distance $\ell$. The dipole moment is $\vec{\mathbf{p}} = Q\vec{\boldsymbol{\ell}}$ and points from the negative to the positive charge (violet arrow).

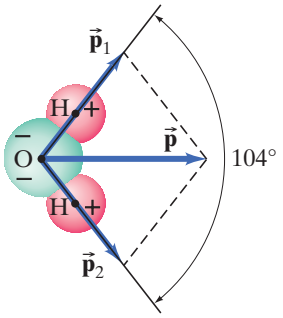
[†]Be careful not to confuse this $p$ for dipole moment with $p$ for momentum.



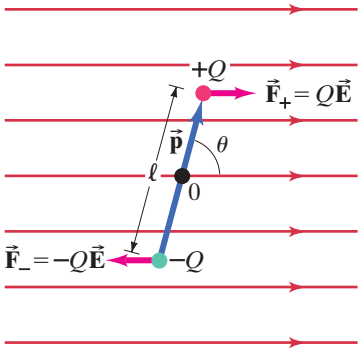


**FIGURE 21–44** In the water molecule $(H_2O)$, the electrons spend more time around the oxygen atom than around the two hydrogen atoms. The net dipole moment $\vec{\mathbf{p}}$ can be considered as the vector sum of two dipole moments $\vec{\mathbf{p}}_1$ and $\vec{\mathbf{p}}_2$ that point from the O toward each H as shown: $\vec{\mathbf{p}} = \vec{\mathbf{p}}_1 + \vec{\mathbf{p}}_2$.

**FIGURE 21–45** An electric dipole in a uniform electric field.

Even though a molecule as a whole may be neutral, there can be a separation of charge that results from an uneven sharing of electrons by the two atoms.[†] (Symmetric diatomic molecules, like $O_2$, have no dipole moment.) The water molecule, with its uneven sharing of electrons (O is negative, the two H are positive), also has a dipole moment—see Fig. 21–44.

## Dipole in an External Field

First let us consider a dipole, of dipole moment $p = Q\ell$, that is placed in a uniform electric field $\vec{\mathbf{E}}$, as shown in Fig. 21–45. If the field is uniform, the force $Q\vec{\mathbf{E}}$ on the positive charge and the force $-Q\vec{\mathbf{E}}$ on the negative charge result in no net force on the dipole. There will, however, be a *torque* on the dipole (Fig. 21–45) which has magnitude (calculated about the center, 0, of the dipole)

$$\tau = QE\frac{\ell}{2}\sin\theta + QE\frac{\ell}{2}\sin\theta = pE\sin\theta. \qquad \textbf{(21–9a)}$$

This can be written in vector notation as

$$\vec{\boldsymbol{\tau}} = \vec{\mathbf{p}} \times \vec{\mathbf{E}}. \qquad \textbf{(21–9b)}$$

The effect of the torque is to try to turn the dipole so $\vec{\mathbf{p}}$ is parallel to $\vec{\mathbf{E}}$. The work done on the dipole by the electric field to change the angle $\theta$ from $\theta_1$ to $\theta_2$ is (see Eq. 10–22)

$$W = \int_{\theta_1}^{\theta_2} \tau\, d\theta.$$

We need to write the torque as $\tau = -pE\sin\theta$ because its direction is opposite to the direction of increasing $\theta$ (right-hand rule). Then

$$W = \int_{\theta_1}^{\theta_2} \tau\, d\theta = -pE\int_{\theta_1}^{\theta_2} \sin\theta\, d\theta = pE\cos\theta\Big|_{\theta_1}^{\theta_2} = pE(\cos\theta_2 - \cos\theta_1).$$

Positive work done by the field decreases the potential energy, $U$, of the dipole in this field. (Recall the relation between work and potential energy, Eq. 8–4, $\Delta U = -W$.) If we choose $U = 0$ when $\vec{\mathbf{p}}$ is perpendicular to $\vec{\mathbf{E}}$ (that is, choosing $\theta_1 = 90°$ so $\cos\theta_1 = 0$), and setting $\theta_2 = \theta$, then

$$U = -W = -pE\cos\theta = -\vec{\mathbf{p}}\cdot\vec{\mathbf{E}}. \qquad \textbf{(21–10)}$$

If the electric field is *not* uniform, the force on the $+Q$ of the dipole may not have the same magnitude as on the $-Q$, so there may be a net force as well as a torque.

**EXAMPLE 21–18 Dipole in a field.** The dipole moment of a water molecule is $6.1 \times 10^{-30}\ \text{C}\cdot\text{m}$. A water molecule is placed in a uniform electric field with magnitude $2.0 \times 10^5\ \text{N/C}$. (*a*) What is the magnitude of the maximum torque that the field can exert on the molecule? (*b*) What is the potential energy when the torque is at its maximum? (*c*) In what position will the potential energy take on its greatest value? Why is this different than the position where the torque is maximum?

**APPROACH** The torque is given by Eq. 21–9 and the potential energy by Eq. 21–10.

**SOLUTION** (*a*) From Eq. 21–9 we see that $\tau$ is maximized when $\theta$ is 90°. Then $\tau = pE = (6.1 \times 10^{-30}\ \text{C}\cdot\text{m})(2.0 \times 10^5\ \text{N/C}) = 1.2 \times 10^{-24}\ \text{m}\cdot\text{N}$.

(*b*) The potential energy for $\theta = 90°$ is zero (Eq. 21–10). Note that the potential energy is negative for smaller values of $\theta$, so $U$ is not a minimum for $\theta = 90°$.

(*c*) The potential energy $U$ will be a maximum when $\cos\theta = -1$ in Eq. 21–10, so $\theta = 180°$, meaning $\vec{\mathbf{E}}$ and $\vec{\mathbf{p}}$ are antiparallel. The potential energy is maximized when the dipole is oriented so that it has to rotate through the largest angle, 180°, to reach the equilibrium position at $\theta = 0°$. The torque, on the other hand, is maximized when the electric forces are perpendicular to $\vec{\mathbf{p}}$.

[†]The value of the separated charges may be a fraction of $e$ (say $\pm 0.2e$ or $\pm 0.4e$) but note that such charges do not violate what we said about $e$ being the smallest charge. These charges less than $e$ cannot be isolated and merely represent how much time electrons spend around one atom or the other. The charge on any normal (macroscopic) object is always an integer times $+e$ or $-e$.

## Electric Field Produced by a Dipole

We have just seen how an external electric field affects an electric dipole. Now let us suppose that there is no external field, and we want to determine the electric field produced *by* the dipole. For brevity, we restrict ourselves to points that are on the perpendicular bisector of the dipole, such as point P in Fig. 21–46 which is a distance $r$ above the midpoint of the dipole. Note that $r$ in Fig. 21–46 is not the distance from either charge to point P; the latter distance is $(r^2 + \ell^2/4)^{\frac{1}{2}}$ and this is what must be used in Eq. 21–4. The total field at P is

$$\vec{\mathbf{E}} = \vec{\mathbf{E}}_+ + \vec{\mathbf{E}}_-,$$

where $\vec{\mathbf{E}}_+$ and $\vec{\mathbf{E}}_-$ are the fields due to the + and − charges respectively. The magnitudes $E_+$ and $E_-$ are equal:

$$E_+ = E_- = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2 + \ell^2/4}.$$

Their $y$ components cancel at point P (*symmetry* again), so the magnitude of the total field $\vec{\mathbf{E}}$ is

$$E = 2E_+\cos\phi = \frac{1}{2\pi\epsilon_0}\left(\frac{Q}{r^2 + \ell^2/4}\right)\frac{\ell}{2(r^2 + \ell^2/4)^{\frac{1}{2}}}$$

or, setting $Q\ell = p$,

$$E = \frac{1}{4\pi\epsilon_0}\frac{p}{(r^2 + \ell^2/4)^{\frac{3}{2}}}. \quad \left[\begin{array}{c}\text{on perpendicular bisector}\\ \text{of dipole}\end{array}\right] \quad \textbf{(21–11)}$$

Far from the dipole, $r \gg \ell$, this reduces to

$$E = \frac{1}{4\pi\epsilon_0}\frac{p}{r^3}. \quad \left[\begin{array}{c}\text{on perpendicular bisector}\\ \text{of dipole; } r \gg \ell\end{array}\right] \quad \textbf{(21–12)}$$

So the field decreases more rapidly for a dipole than for a single point charge $(1/r^3$ versus $1/r^2)$, which we expect since at large distances the two opposite charges appear so close together as to neutralize each other. This $1/r^3$ dependence also applies for points not on the perpendicular bisector (see Problem 64).

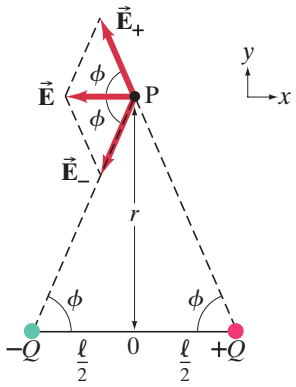

**FIGURE 21–46** Electric field due to an electric dipole.

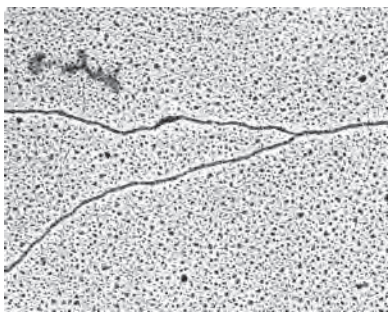
# *21–12 Electric Forces in Molecular Biology: DNA Structure and Replication

The study of the structure and functioning of a living cell at the molecular level is known as *molecular biology*. It is an important area for application of physics. The interior of every biological cell is mainly water. We can imagine a cell as a thick soup of molecules continually in motion (kinetic theory, Chapter 18), colliding with one another with various amounts of kinetic energy. These molecules interact with one another because of the *electrostatic force* between molecules.



Indeed, cellular processes are now considered to be the result of *random ("thermal") molecular motion plus the ordering effect of the electrostatic force*. As an example, we look at DNA structure and replication. The picture we present is a model of what happens based on physical theories and experiment.

The genetic information that is passed on from generation to generation in all living cells is contained in the chromosomes, which are made up of genes. Each gene contains the information needed to produce a particular type of protein molecule, and that information is built into the principal molecule of a chromosome, DNA (deoxyribonucleic acid), Fig. 21–47. DNA molecules are made up of many small molecules known as nucleotide bases which are each *polar* (Section 21–2) due to unequal sharing of electrons. There are four types of nucleotide bases in DNA: adenine (A), cytosine (C), guanine (G), and thymine (T).

**PHYSICS APPLIED**

*Inside a cell: kinetic theory plus electrostatic force*

**FIGURE 21–47** Image of DNA replicating, made by a transmission electron microscope.

**PHYSICS APPLIED**
*DNA structure*

The DNA of a chromosome generally consists of two long DNA strands wrapped about one another in the shape of a "double helix." The genetic information is contained in the specific order of the four bases (A, C, G, T) along each strand. As shown in Fig. 21–48, the two strands are attracted by electrostatic forces—that is, by the attraction of positive charges to negative charges that exist on parts of the molecules. We see in Fig. 21–48a that an A (adenine) on one strand is always opposite a T (thymine) on the other strand; similarly, a G (guanine) is always opposite a C (cytosine). This important ordering effect occurs because the shapes of A, T, C, and G are such that a T fits closely only into an A, and a G into a C. Only in the case of this close proximity of the charged portions can the electrostatic force (recall Coulomb's law, $F \propto 1/r^2$) be great enough to hold them together even for a short time (Fig. 21–48b), forming what are referred to as "weak bonds."

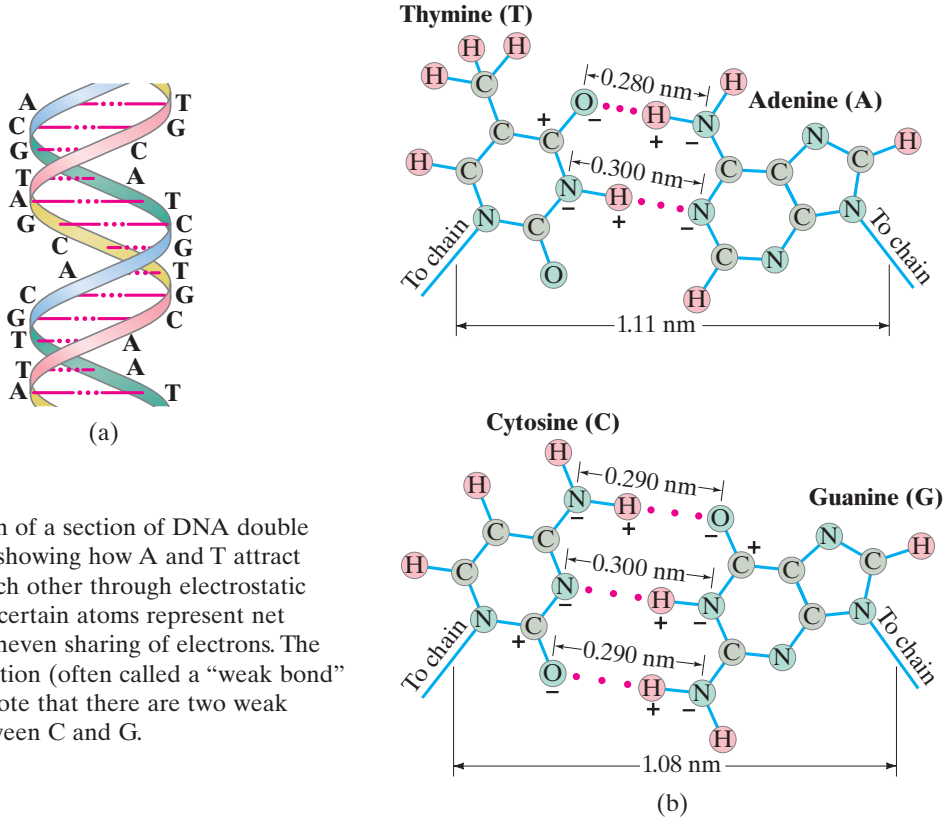


**FIGURE 21–48** (a) Schematic diagram of a section of DNA double helix. (b) "Close-up" view of the helix, showing how A and T attract each other and how G and C attract each other through electrostatic forces. The + and − signs indicated on certain atoms represent net charges, usually a fraction of $e$ due to uneven sharing of electrons. The red dots indicate the electrostatic attraction (often called a "weak bond" or "hydrogen bond"—Section 40–3). Note that there are two weak bonds between A and T, and three between C and G.

The electrostatic force between A and T, and between C and G, exists because these molecules have charged parts. These charges are due to some electrons in each of these molecules spending more time orbiting one atom than another. For example, the electron normally on the H atom of adenine (upper part of Fig. 21–48b) spends some of its time orbiting the adjacent N atom (more on this in Chapter 40), so the N has a net negative charge and the H is left with a net positive charge. This $H^+$ atom of adenine is then attracted to the $O^-$ atom of thymine. These net + and − charges usually have magnitudes of a fraction of $e$ (charge on the electron) such as $0.2e$ or $0.4e$. (This is what we mean by "polar" molecules.)

[When $H^+$ is involved, the weak bond it can make with a nearby negative charge, such as $O^-$, is relatively strong (partly because $H^+$ is so small) and is referred to as a **hydrogen bond** (Section 40–3).]

**PHYSICS APPLIED**
*DNA replication*

When the DNA replicates (duplicates) itself just before cell division, the arrangement of A opposite T and G opposite C is crucial for ensuring that the genetic information is passed on accurately to the next generation, Fig. 21–49. The two strands of DNA separate (with the help of enzymes, which also operate via the electrostatic force), leaving the charged parts of the bases exposed.

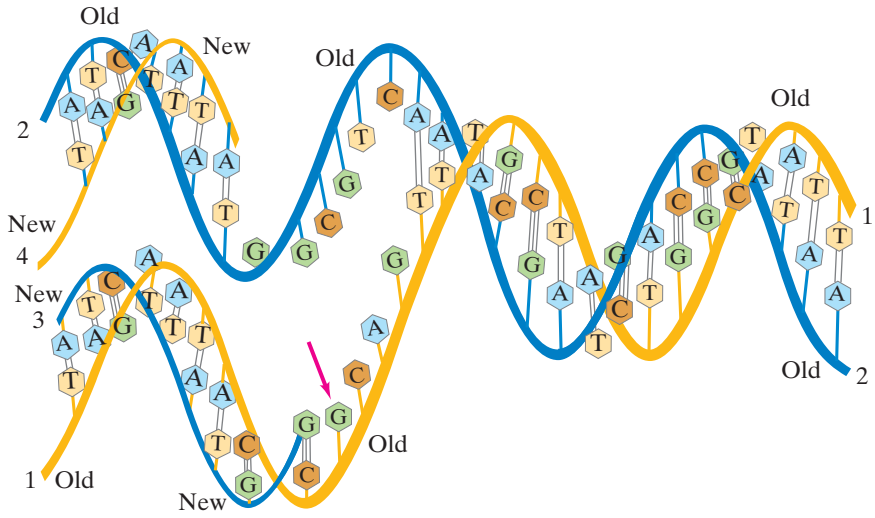

**FIGURE 21–49** Replication of DNA.

Once replication starts, let us see how the correct order of bases occurs by looking at the G molecule indicated by the red arrow in Fig. 21–49. Many unattached nucleotide bases of all four kinds are bouncing around in the cellular fluid, and the only type that will experience enough attraction to our G, if it comes close to it, will be a C. The charges on the other three bases can not get close enough to those on the G to provide a significant attractive force—remember that the electrostatic (Coulomb) force decreases rapidly with distance $(\propto 1/r^2)$. Because the G does not attract an A, T, or G appreciably, an A, T, or G will be knocked away by collisions with other molecules in the cellular fluid before enzymes can attach it to the growing chain (number 3 in Fig. 21–49). But the electrostatic force will often hold a C opposite our G long enough so that an enzyme can attach the C to the growing end of the new chain. Thus electrostatic forces are responsible for selecting the bases in the proper order during replication. Note in Fig. 21–49 that the new number 4 strand has the same order of bases as the old number 1 strand; and the new number 3 strand is the same as the old number 2. So the two new double helixes, 1–3 and 2–4, are identical to the original 1–2 helix. This is how the genetic information is passed on accurately to the next generation. Rarely, errors are made, possibly causing a *mutation* (a noticeable change in the expression of that gene).

This process of DNA replication is often presented as if it occurred in clockwork fashion—as if each molecule knew its role and went to its assigned place. But this is not the case. The forces of attraction are rather weak and become significant only when charged parts of two molecules have "complementary shapes," meaning they can get close enough so that the electrostatic force $(\propto 1/r^2)$ is strong enough to form weak bonds. If the molecular shapes are not just right, there is almost no electrostatic attraction, which is why there are so few mistakes. Thus, out of the random motion of the molecules, the electrostatic force acts to bring order out of chaos.

The random (thermal) velocities of molecules in a cell affect *cloning*. When a bacterial cell divides, the two new bacteria have nearly identical DNA. Even if the DNA were perfectly identical, the two new bacteria would not end up behaving in exactly the same way. Long protein, DNA, and RNA molecules get bumped into different shapes, and even the expression[†] of genes can thus be different. Loosely held parts of large molecules such as a methyl group $(CH_3)$ can also be knocked off by a strong collision with another molecule. Hence, cloned organisms are not identical, even when their DNA is identical. Indeed, there can not really be genetic determinism.

[†]The separate genes of a DNA double helix can be covered by protein molecules, keeping those genes from being "expressed"—that is, translated into the proteins they code for (see Section 40–3).

# Summary

There are two kinds of **electric charge**, positive and negative. These designations are to be taken algebraically—that is, any charge is plus or minus so many coulombs (C), in SI units.

Electric charge is **conserved**: if a certain amount of one type of charge is produced in a process, an equal amount of the opposite type is also produced; thus the *net* charge produced is zero.

According to atomic theory, electricity originates in the atom, which consists of a positively charged nucleus surrounded by negatively charged electrons. Each electron has a charge $-e = -1.6 \times 10^{-19}$ C.

Electric **conductors** are those materials in which many electrons are relatively free to move, whereas electric **insulators** or **nonconductors** are those in which very few electrons are free to move.

An object is negatively charged when it has an excess of electrons, and positively charged when it has less than its normal number of electrons. The charge on any object is a whole number times $+e$ or $-e$. That is, charge is **quantized**.

An object can become charged by rubbing (in which electrons are transferred from one material to another), **by conduction** (which is transfer of charge from one charged object to another by touching), or **by induction** (the separation of charge within an object because of the close approach of another charged object but without touching).

Electric charges exert a force on each other. If two charges are of opposite types, one positive and one negative, they each exert an attractive force on the other. If the two charges are the same type, each repels the other.

The magnitude of the force one point charge exerts on another is proportional to the product of their charges, and inversely proportional to the square of the distance between them:

$$F = k\frac{Q_1 Q_2}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{Q_1 Q_2}{r^2}; \qquad \textbf{(21–1, 21–2)}$$

this is **Coulomb's law**. In SI units, $k$ is often written as $1/4\pi\epsilon_0$.

We think of an **electric field** as existing in space around any charge or group of charges. The force on another charged object is then said to be due to the electric field present at that charge's location.

The *electric field*, $\vec{\mathbf{E}}$, at any point in space due to one or more charges, is defined as the force per unit charge that would act on a tiny positive test charge $q$ placed at that point:

$$\vec{\mathbf{E}} = \frac{\vec{\mathbf{F}}}{q}. \qquad \textbf{(21–3)}$$

The magnitude of the electric field a distance $r$ from a point charge $Q$ is

$$E = k\frac{Q}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{Q_1 Q_2}{r^2} \qquad \textbf{(21–4)}$$

The total electric field at a point in space is equal to the vector sum of the individual fields due to each contributing charge. This is the **principle of superposition**.

Electric fields are represented by **electric field lines** that start on positive charges and end on negative charges. Their direction indicates the direction the force would be on a tiny positive test charge placed at each point. The lines can be drawn so that the number per unit area is proportional to the magnitude of $E$.

The static electric field inside a conductor is zero, and the electric field lines just outside a charged conductor are perpendicular to its surface.

An **electric dipole** is a combination of two equal but opposite charges, $+Q$ and $-Q$, separated by a distance $\ell$. The **dipole moment** is $p = Q\ell$. A dipole placed in a uniform electric field feels no net force but does feel a net torque (unless $\vec{\mathbf{p}}$ is parallel to $\vec{\mathbf{E}}$). The electric field produced by a dipole decreases as the third power of the distance $r$ from the dipole $(E \propto 1/r^3)$ for $r$ large compared to $\ell$.

[*In the replication of DNA, the electrostatic force plays a crucial role in selecting the proper molecules so that the genetic information is passed on accurately from generation to generation.]

# Questions

1. If you charge a pocket comb by rubbing it with a silk scarf, how can you determine if the comb is positively or negatively charged?
2. Why does a shirt or blouse taken from a clothes dryer sometimes cling to your body?
3. Explain why fog or rain droplets tend to form around ions or electrons in the air.
4. A positively charged rod is brought close to a neutral tiny piece of paper, which it attracts. Draw a diagram showing the separation of charge in the paper, and explain why attraction occurs.
5. Why does a plastic ruler that has been rubbed with a cloth have the ability to pick up small pieces of paper? Why is this difficult to do on a humid day?
6. Contrast the *net charge* on a conductor to the "free charges" in the conductor.
7. Figures 21–7 and 21–8 show how a charged rod placed near an uncharged metal object can attract (or repel) electrons. There are a great many electrons in the metal, yet only some of them move as shown. Why not all of them?
8. When an electroscope is charged, the two leaves repel each other and remain at an angle. What balances the electric force of repulsion so that the leaves don't separate further?

**9.** The balloon in Fig. 21–50 was rubbed on a student's hair. Explain why the water drip curves instead of falling vertically.

**FIGURE 21–50** Question 9.

**10.** What happens to the separation of the leaves of an electroscope (Fig. 21–10) when the charging object is removed from an electroscope (*a*) charged by induction and (*b*) charged by conduction? (*c*) Is it possible to tell whether the electroscope in Fig. 21–12a has been charged by induction or by conduction? If so, which way was it charged?

**11.** The form of Coulomb's law is very similar to that for Newton's law of universal gravitation. What are the differences between these two laws? Compare also gravitational mass and electric charge.

**12.** We are not normally aware of the gravitational or electric force between two ordinary objects. What is the reason in each case? Give an example where we are aware of each one and why.

**13.** What experimental observations, mentioned in the text, rule out the possibility that the numerator in Coulomb's law contains the sum $(Q_1 + Q_2)$ rather than the product $Q_1 Q_2$?

**14.** When a charged ruler attracts small pieces of paper, sometimes a piece jumps quickly away after touching the ruler. Explain.

**15.** Explain why the test charges we use when measuring electric fields must be small.

**16.** When determining an electric field, must we use a *positive* test charge, or would a negative one do as well? Explain.

**17.** Draw the electric field lines surrounding two negative electric charges a distance $\ell$ apart.

**18.** Assume that the two opposite charges in Fig. 21–35a are 12.0 cm apart. Consider the magnitude of the electric field 2.5 cm from the positive charge. On which side of this charge—top, bottom, left, or right—is the electric field the strongest? The weakest?

**19.** Consider the electric field at the three points indicated by the letters A, B, and C in Fig. 21–51. First draw an arrow at each point indicating the direction of the net force that a positive test charge would experience if placed at that point, then list the letters in order of *decreasing* field strength (strongest first). Explain.

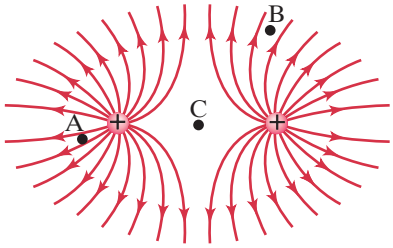

**FIGURE 21–51** Question 19.

**20.** Why can electric field lines never cross?

**21.** Show, using the three properties of field lines given in Section 21–8, page 626, that the electric field lines starting or ending on a single point charge must be symmetrically spaced around the charge.

**22.** Given two point charges, of magnitude $Q$ and $2Q$, a distance $\ell$ apart, is there a point along the straight line that passes through them where $E = 0$? Give answers for when their signs are (*a*) opposite, (*b*) the same. If yes, state roughly where this point will be.

**23.** Suppose the ring of Fig. 21–29 has a uniformly distributed negative charge $Q$. What are the magnitude and direction of $\vec{\mathbf{E}}$ at point P?

**24.** Consider a small positive test charge located on an electric field line at some point, such as point P in Fig. 21–35a. Is the direction of the velocity and/or acceleration of the test charge along this line? Discuss.

**25.** We wish to determine the electric field at a point P near a positively charged metal sphere (a good conductor). We do so by bringing a small test charge, $q_0$, to this point P and measure the force $F_0$ on it. Will $F_0/q_0$ at that point be greater than, less than, or equal to the electric field $\vec{\mathbf{E}}$ compared to before the test charge was present? Explain.

**26.** In what ways does the electron motion in Example 21–17 resemble projectile motion (Section 3–7)? In which ways does it not?

**27.** Explain why there can be a net force on an electric dipole placed in a nonuniform electric field.

**28.** Describe the motion of the dipole shown in Fig. 21–45 if it is released from rest at the position shown. Assume (*a*) uniform $\vec{\mathbf{E}}$, (*b*) $\vec{\mathbf{E}}$ increasing in magnitude going downward.

## MisConceptual Questions

**1.** $Q_1 = -0.10\,\mu\text{C}$ is located at the origin. $Q_2 = +0.10\,\mu\text{C}$ is located on the positive $x$ axis at $x = 1.0\,\text{m}$. Which of the following is true of the force on $Q_1$ due to $Q_2$?
(*a*) It is attractive and directed in the $+x$ direction.
(*b*) It is attractive and directed in the $-x$ direction.
(*c*) It is repulsive and directed in the $+x$ direction.
(*d*) It is repulsive and directed in the $-x$ direction.

**2.** Swap the positions of $Q_1$ and $Q_2$ of MisConceptual Question 1. Which of the following is true of the force on $Q_1$ due to $Q_2$?
(*a*) It does not change.
(*b*) It changes from attractive to repulsive.
(*c*) It changes from repulsive to attractive.
(*d*) It changes from the $+x$ direction to the $-x$ direction.
(*e*) It changes from the $-x$ direction to the $+x$ direction.

3. Fred the lightning bug has a mass $m$ and a charge $+q$. Jane, his lightning-bug wife, has a mass of $\frac{3}{4}m$ and a charge $-2q$. Because they have charges of opposite sign, they are attracted to each other. Which is attracted more to the other, and by how much?
(*a*) Fred, twice as much.
(*b*) Jane, twice as much.
(*c*) Fred, four times as much.
(*d*) Jane, four times as much.
(*e*) They are attracted to each other by the same amount.

4. Figure 21–52 shows electric field lines due to a point charge. What can you say about the field at point 1 compared with the field at point 2?
(*a*) The field at point 2 is larger, because point 2 is on a field line.
(*b*) The field at point 1 is larger, because point 1 is not on a field line.
(*c*) The field at point 1 is zero, because point 1 is not on a field line.
(*d*) The field at point 1 is larger, because the field lines are closer together in that region.

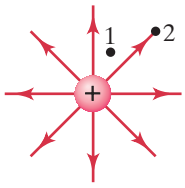

**FIGURE 21–52**
MisConceptual Question 4.

5. A negative point charge is in an electric field created by a positive point charge. Which of the following is true?
(*a*) The field points away from the positive charge, and the force on the negative charge is in the same direction as the field.
(*b*) The field points away from the positive charge, and the force on the negative charge is in the opposite direction to the field.
(*c*) The field points toward the positive charge, and the force on the negative charge is in the same direction as the field.
(*d*) The field points toward the positive charge, and the force on the negative charge is in the opposite direction to the field.

6. A small object with charge $+Q$ is placed a distance $d$ from another small object with charge $+4Q$. Is it possible to place a third charge on the line between them such that the net force on the third charge will be zero?
(*a*) Yes, but only if the third charge is positive.
(*b*) Yes, but only if the third charge is negative.
(*c*) Yes, independent of the sign of the third charge.
(*d*) No, it is not possible.

7. Refer to Fig. 21–35d. If the two charged plates were moved until they are half the distance shown without changing the charge on the plates, the electric field near the center of the plates would
(*a*) remain almost exactly the same.
(*b*) increase by a factor of 2.
(*c*) increase, but not by a factor of 2.
(*d*) decrease by a factor of 2.
(*e*) decrease, but not by a factor of 2.

8. A proton and an electron are fixed at rest 1.0 m apart, and then let go. Where do they meet?
(*a*) Halfway between their original positions.
(*b*) Closer to the electron's original position.
(*c*) Closer to the proton's original position.

9. To be safe during a lightning storm, it is best to be
(*a*) in the middle of a grassy meadow.
(*b*) inside a metal car.
(*c*) next to a tall tree in a forest.
(*d*) inside a wooden building.
(*e*) on a metal observation tower.

10. Which are the worst places in MisConceptual Question 9?

11. Which vector best represents the direction of the electric field at the fourth corner of the square due to the three charges shown in Fig. 21–53?

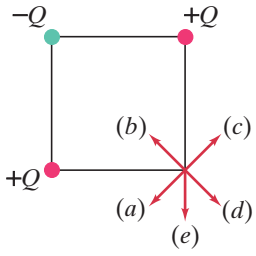

**FIGURE 21–53**
MisConceptual Question 11.

12. A small metal ball hangs from the ceiling by an insulating thread. The ball is attracted to a positively charged rod held near the ball. The charge of the ball must be
(*a*) positive.
(*b*) negative.
(*c*) neutral.
(*d*) positive or neutral.
(*e*) negative or neutral.

# Problems

## 21–5 Coulomb's Law

$[1\,\text{mC} = 10^{-3}\,\text{C},\ 1\,\mu\text{C} = 10^{-6}\,\text{C},\ 1\text{nC} = 10^{-9}\,\text{C},\ 1\text{pC} = 10^{-12}\,\text{C}.]$

1. (I) What is the magnitude of the electric force of attraction between an iron nucleus $(q = +26e)$ and its innermost electron if the distance between them is $1.5 \times 10^{-12}\,\text{m}$?

2. (I) How many electrons make up a charge of $-58.0\,\mu\text{C}$?

3. (I) What is the magnitude of the force a $+25\,\mu\text{C}$ charge exerts on a $+2.5\,\text{mC}$ charge 22 cm away?

4. (I) What is the repulsive electrical force between two protons $3.5 \times 10^{-15}\,\text{m}$ apart from each other in an atomic nucleus?

5. (II) When an object such as a plastic comb is charged by rubbing it with a cloth, the net charge is typically a few microcoulombs. If that charge is $2.4\,\mu\text{C}$, by what percentage does the mass of a 9.0-g comb change during charging?

6. (II) Two charged dust particles exert a force of $4.6 \times 10^{-2}\,\text{N}$ on each other. What will be the force if they are moved so they are only one-eighth as far apart?

7. (II) Two small charged spheres are 6.22 cm apart. They are moved, and the force each exerts on the other is found to have tripled. How far apart are they now?

8. (II) A person scuffing her feet on a wool rug on a dry day accumulates a net charge of $-34\,\mu C$. How many excess electrons does she get, and by how much does her mass increase?

9. (II) What is the total charge of all the electrons in a 12-kg bar of gold? What is the net charge of the bar? (Gold has 79 electrons per atom and an atomic mass of 197 u.)

10. (II) Compare the electric force holding the electron in orbit $(r = 0.53 \times 10^{-10}\,\text{m})$ around the proton nucleus of the hydrogen atom, with the gravitational force between the same electron and proton. Give the ratio of these two forces.

11. (II) Two positive point charges are a fixed distance apart. The sum of their charges is $Q_T$. What charge must each have in order to (*a*) maximize the electric force between them, and (*b*) minimize it?

12. (II) Particles of charge $+82$, $+48$, and $-95\,\mu C$ are placed in a line (Fig. 21–54). The center one is 0.35 m from each of the others. Calculate the net force on each charge due to the other two.

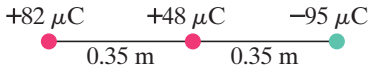

**FIGURE 21–54** Problem 12.

13. (II) Three positive particles of equal charge, $+17.0\,\mu C$, are located at the corners of an equilateral triangle of side 15.0 cm (Fig. 21–55). Calculate the magnitude and direction of the net force on each particle due to the other two.

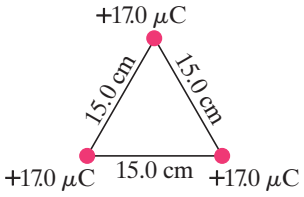

**FIGURE 21–55**
Problem 13.

14. (II) Two small nonconducting spheres have a total charge of $82.0\,\mu C$. (*a*) When placed 28.0 cm apart, the force each exerts on the other is 12.0 N and is repulsive. What is the charge on each? (*b*) What if the force is attractive?

15. (II) A charge of 6.45 mC is placed at each corner of a square 0.100 m on a side. Determine the magnitude and direction of the force on each charge.

16. (II) Two negative and two positive point charges (magnitude $Q = 4.15$ mC) are placed on opposite corners of a square as shown in Fig. 21–56. Determine the magnitude and direction of the force on each charge.

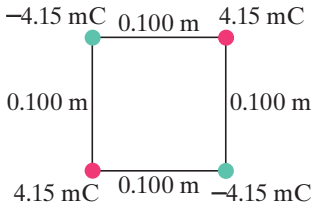

**FIGURE 21–56**
Problem 16.

17. (II) At each corner of a square of side $\ell$ there are point charges of magnitude $Q$, $2Q$, $3Q$, and $4Q$ (Fig. 21–57). Determine the magnitude and direction of the force on the charge $2Q$.

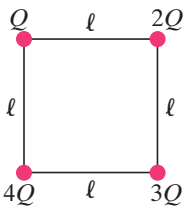

**FIGURE 21–57**
Problem 17.

18. (II) A large electroscope is made with "leaves" that are 66-cm-long wires with tiny 21-g spheres at the ends. When charged, nearly all the charge resides on the spheres. If the wires each make a 26° angle with the vertical (Fig. 21–58), what total charge $Q$ must have been applied to the electroscope? Ignore the mass of the wires.

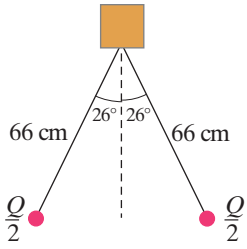

**FIGURE 21–58**
Problem 18.

19. (II) A charge $Q$ is transferred from an initially uncharged plastic ball to an identical ball 21 cm away. The force of attraction is then 17 mN. How many electrons were transferred from one ball to the other?

20. (III) Two charges, $-2Q$ and $-3Q$, are a distance $\ell$ apart. These two charges are free to move but do not because there is a third (fixed) charge nearby. What must be the magnitude of the third charge and its placement in order for the first two to be in equilibrium?

21. (III) Two positive charges $+Q$ are affixed rigidly to the $x$ axis, one at $x = +d$ and the other at $x = -d$. A third charge $+q$ of mass $m$, which is constrained to move only along the $x$ axis, is displaced from the origin by a small distance $s \ll d$ and then released from rest. (*a*) Show that (to a good approximation) $+q$ will execute simple harmonic motion and determine an expression for its oscillation period $T$. (*b*) If these three charges are each singly ionized sodium atoms $(q = Q = +e)$ at the equilibrium spacing $d = 3 \times 10^{-10}\,\text{m}$ typical of the atomic spacing in a solid, find $T$ in picoseconds.

## 21–6 to 21–8 Electric Field, Field Lines

22. (I) Determine the magnitude and direction of the electric force on an electron in a uniform electric field of strength 2260 N/C that points due east.

23. (I) A proton is released in a uniform electric field, and it experiences an electric force of $1.68 \times 10^{-14}\,\text{N}$ toward the south. Find the magnitude and direction of the electric field.

24. (I) Determine the magnitude and direction of the electric field 27.4 cm directly above an isolated $33.0 \times 10^{-6}\,\text{C}$ charge.

25. (I) The electric force on a $+3.70$-$\mu C$ charge is $\vec{\mathbf{F}} = (7.22 \times 10^{-4}\,\text{N})\,\hat{\mathbf{j}}$. What is the electric field at the position of the charge?

26. (II) What is the electric field at a point when the force on a $-1.25$-$\mu C$ charge placed at that point is $\vec{\mathbf{F}} = (4.0\,\hat{\mathbf{i}} - 5.2\,\hat{\mathbf{j}}) \times 10^{-3}\,\text{N}$?

27. (II) Determine the magnitude of the acceleration experienced by an electron in an electric field of 756 N/C. How does the direction of the acceleration depend on the direction of the field at that point?

28. (II) Determine the magnitude and direction of the electric field at a point midway between a $-9.2$ pC and a $+5.8$ pC charge 6.0 cm apart. Assume no other charges are nearby.

**29.** (II) What is the electric field strength at a point in space where a proton experiences an acceleration of 2.4 million "$g$'s"?

**30.** (II) A very long uniformly charged wire (linear charge density $\lambda = 2.5\,\text{C/m}$) lies along the $x$ axis in Fig. 21–59. A small charged sphere ($Q = -2.0\,\text{C}$) is at the point $x = 0\,\text{cm}$, $y = -5.0\,\text{cm}$. What is the electric field at the point $x = 7.0\,\text{cm}$, $y = 7.0\,\text{cm}$? $\vec{\mathbf{E}}_{\text{wire}}$ and $\vec{\mathbf{E}}_{\text{Q}}$ represent fields due to the long wire and the charge $Q$, respectively.

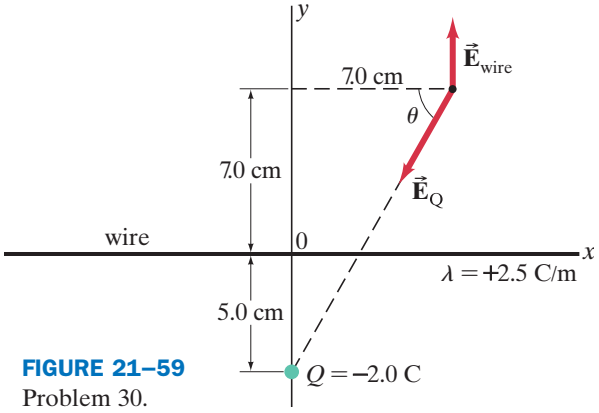

**FIGURE 21–59** Problem 30.

**31.** (II) The electric field midway between two equal but opposite point charges is 326 N/C, and the distance between the charges is 16.0 cm. What is the magnitude of the charge on each?

**32.** (II) Calculate the electric field at one corner of a square 1.22 m on a side if the other three corners are occupied by $3.25 \times 10^{-6}\,\text{C}$ charges.

**33.** (II) Calculate the electric field at the center of a square 42.5 cm on a side if one corner is occupied by a $-33.8\,\mu\text{C}$ charge and the other three are occupied by $-22.0\,\mu\text{C}$ charges.

**34.** (II) Determine the direction and magnitude of the electric field at the point P in Fig. 21–60. The charges are separated by a distance $2a$, and point P is a distance $x$ from the midpoint between the two charges. Express your answer in terms of $Q$, $x$, $a$, and $k$.

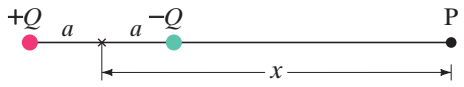

**FIGURE 21–60** Problem 34.

**35.** (II) Two point charges, $Q_1 = -32\,\mu\text{C}$ and $Q_2 = +45\,\mu\text{C}$, are separated by a distance of 12 cm. The electric field at the point P (see Fig. 21–61) is zero. How far from $Q_1$ is P?

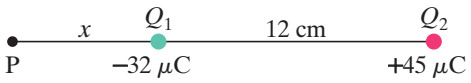

**FIGURE 21–61** Problem 35.

**36.** (II) A very thin line of charge lies along the $x$ axis from $x = -\infty$ to $x = +\infty$. Another similar line of charge lies along the $y$ axis from $y = -\infty$ to $y = +\infty$. Both lines have a uniform charge per length $\lambda$. Determine the resulting electric field magnitude and direction (relative to the $x$ axis) at a point $(x, y)$ in the first quadrant of the $xy$ plane.

**37.** (II) ($a$) Determine the electric field $\vec{\mathbf{E}}$ at the origin 0 in Fig. 21–62 due to the two charges at A and B. ($b$) Repeat, but let the charge at B be reversed in sign.

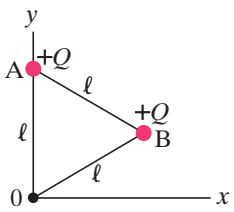

**FIGURE 21–62** Problem 37.

**38.** (II) Draw, approximately, the electric field lines emanating from a uniformly charged straight wire whose length $\ell$ is not great. The spacing between lines near the wire should be much less than $\ell$. [*Hint*: Also consider points very far from the wire up to $4\ell$.]

**39.** (II) Two parallel circular rings of radius $R$ have their centers on the $x$ axis separated by a distance $\ell$ as shown in Fig. 21–63. If each ring carries a uniformly distributed charge $Q$, find the electric field, $\vec{\mathbf{E}}(x)$, at points along the $x$ axis.

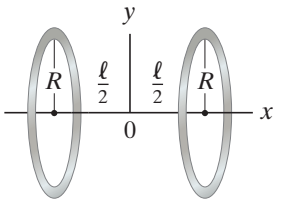

**FIGURE 21–63** Problem 39.

**40.** (II) You are given two unknown point charges, $Q_1$ and $Q_2$. At a point on the line joining them, one-third of the way from $Q_1$ to $Q_2$, the electric field is zero (Fig. 21–64). What is the ratio $Q_1/Q_2$?

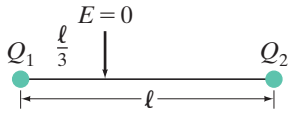

**FIGURE 21–64** Problem 40.

**41.** (II) Use Coulomb's law to determine the magnitude and direction of the electric field at points A and B in Fig. 21–65 due to the two positive charges ($Q = 4.7\,\mu\text{C}$) shown. Are your results consistent with Fig. 21–35b?

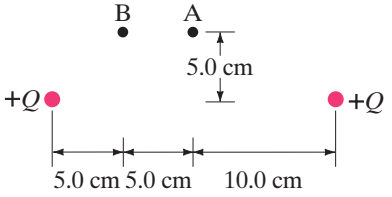

**FIGURE 21–65** Problem 41.

**42.** (II) ($a$) Two equal charges $Q$ are positioned at points $(x = \ell,\ y = 0)$ and $(x = -\ell,\ y = 0)$. Determine the electric field as a function of $y$ for points along the $y$ axis. ($b$) Show that the field is a maximum at $y = \pm\ell/\sqrt{2}$.

**43.** (II) At what position, $x = x_{\text{M}}$, is the magnitude of the electric field along the axis of the ring of Example 21–10 a maximum?

**44.** (II) Estimate the electric field at a point 2.40 cm perpendicular to the midpoint of a uniformly charged 2.00-m-long thin wire carrying a total charge of 7.45 $\mu$C.

**45.** (II) The uniformly charged straight wire in Fig. 21–30 has the length $\ell$, where point 0 is at the midpoint. Show that the field at point P, a perpendicular distance $x$ from 0, is given by

$$E = \frac{\lambda}{2\pi\epsilon_0}\frac{\ell}{x(\ell^2 + 4x^2)^{1/2}},$$

where $\lambda$ is the charge per unit length.

**46.** (II) Determine the direction and magnitude of the electric field at the point P shown in Fig. 21–66. The two point charges are separated by a distance of $2a$. Point P is on the perpendicular bisector of the line joining the charges, a distance $x$ from the midpoint between them. Express your answers in terms of $Q$, $x$, $a$, and $k$.

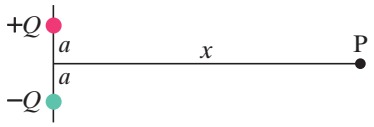

**FIGURE 21–66** Problem 46.

**47.** (III) Use the result given in Problem 45 to find the electric field (magnitude and direction) a distance $z$ above the center of a square loop of wire, each of whose sides has length $\ell$ and uniform charge per length $\lambda$ (Fig. 21–67).

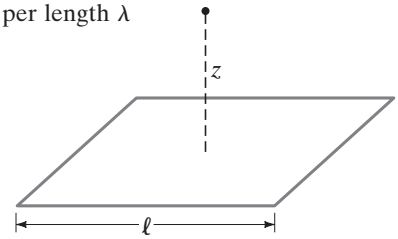

**FIGURE 21–67**
Problem 47.

**48.** (III) A thin rod bent into the shape of an arc of a circle of radius $R$ carries a uniform charge per unit length $\lambda$. The arc subtends a total angle $2\theta_0$, symmetric about the $x$ axis, as shown in Fig. 21–68. Determine the electric field $\vec{\mathbf{E}}$ at the origin 0.

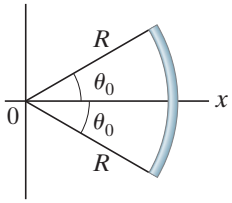

**FIGURE 21–68**
Problem 48.

**49.** (III) Suppose a uniformly charged wire has one end at point 0 and rises vertically along the positive $y$ axis to a length $\ell$. (*a*) Determine the components of the electric field $E_x$ and $E_y$ at point $(x, 0)$. That is, calculate $\vec{\mathbf{E}}$ near one end of a long wire, in the plane perpendicular to the wire. (*b*) If the wire extends from $y = 0$ to $y = \infty$, so that $\ell = \infty$, show that $\vec{\mathbf{E}}$ makes a 45° angle to the horizontal for any $x$ in the plane where $y = 0$. [*Hint*: See Example 21–12 and Fig. 21–30.]

**50.** (III) Suppose in Example 21–12 that $x = 0.250\,\text{m}$, $Q = 2.85\,\mu\text{C}$, and that the uniformly charged wire is only 6.50 m long and extends along the $y$ axis from $y = -4.00\,\text{m}$ to $y = +2.50\,\text{m}$. (*a*) Calculate $E_x$ and $E_y$ at point P. (*b*) Determine what the error would be if you simply used the result of Example 21–12, $E = \lambda/2\pi\epsilon_0 x$. Express this error as $(E_x - E)/E$ and $E_y/E$, and as percent.

**51.** (III) A thin rod of length $\ell$ carries a total charge $Q$ distributed uniformly along its length. See Fig. 21–69. Determine the electric field along the axis of the rod starting at one end—that is, find $E(x)$ for $x \geq 0$ in Fig. 21–69.

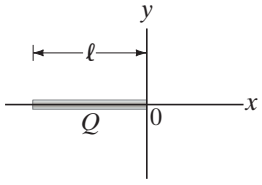

**FIGURE 21–69** Problem 51.

**52.** (III) *Uniform plane of charge*. Charge is distributed uniformly over a large square plane of side $\ell$, as shown in Fig. 21–70. The charge per unit area $(\text{C/m}^2)$ is $\sigma$. Determine the electric field at a point P a distance $z$ above the center of the plane, in the limit $\ell \to \infty$. [*Hint*: Divide the plane into long narrow strips of width $dy$, and use the result of Example 21–12; then sum the fields due to each strip to get the total field at P.]

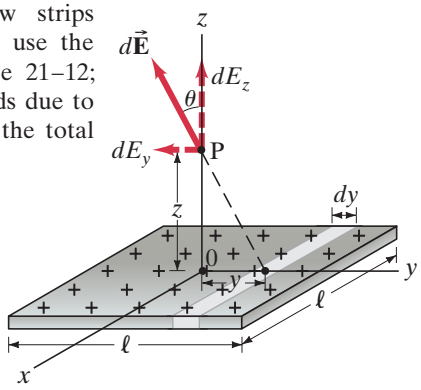

**FIGURE 21–70**
Problem 52.

## 21–10 Motion of Charges in an Electric Field

**53.** (II) An electron with speed $v_0 = 4.16 \times 10^6\,\text{m/s}$ is traveling parallel to a uniform electric field of magnitude $E = 8.65 \times 10^3\,\text{N/C}$. (*a*) How far will the electron travel before it stops? (*b*) How much time will elapse before it returns to its starting point?

**54.** (II) An electron has an initial velocity $\vec{\mathbf{v}}_0 = (8.0 \times 10^4\,\text{m/s})\,\hat{\mathbf{j}}$. It enters a region where $\vec{\mathbf{E}} = (2.0\hat{\mathbf{i}} + 7.0\hat{\mathbf{j}}) \times 10^4\,\text{N/C}$. (*a*) Determine the vector acceleration of the electron. (*b*) At what angle $\theta$ is it moving (relative to its initial direction) at $t = 1.0\,\text{ns}$?

**55.** (II) An electron moving to the right at $7.5 \times 10^5\,\text{m/s}$ enters a uniform electric field parallel to its direction of motion. If the electron is to be brought to rest in the space of 5.0 cm, (*a*) what direction is required for the electric field, and (*b*) what is the strength of the field?

**56.** (II) At what angle will the electrons in Example 21–17 leave the uniform electric field at the end of the parallel plates (point P in Fig. 21–42)? Assume the plates are 4.6 cm long, $E = 5.0 \times 10^3\,\text{N/C}$, and $v_0 = 1.00 \times 10^7\,\text{m/s}$. Ignore fringing of the field.

**57.** (II) An electron is traveling through a uniform electric field. The field is constant and given by $\vec{\mathbf{E}} = (2.00 \times 10^{-11}\,\text{N/C})\,\hat{\mathbf{i}} - (1.20 \times 10^{-11}\,\text{N/C})\,\hat{\mathbf{j}}$. At $t = 0$, the electron is at the origin and traveling in the $x$ direction with a speed of 1.90 m/s. What is its position 3.00 s later?

**58.** (II) A positive charge $q$ is placed at the center of a circular ring of radius $R$. The ring carries a uniformly distributed negative charge of total magnitude $-Q$. (*a*) If the charge $q$ is displaced from the center a small distance $x$ as shown in Fig. 21–71, show that it will undergo simple harmonic motion when released. (*b*) If its mass is $m$, what is its period?

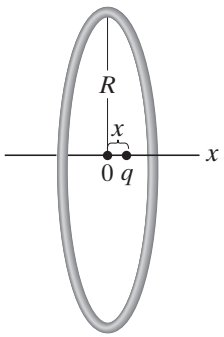

**FIGURE 21–71**
Problem 58.

### 21–11 Electric Dipoles

**59.** (II) A dipole consists of charges $+e$ and $-e$ separated by 0.68 nm. It is in an electric field $E = 2.2 \times 10^4$ N/C. (*a*) What is the value of the dipole moment? (*b*) What is the torque on the dipole when it is perpendicular to the field? (*c*) What is the torque on the dipole when it is at an angle of 45° to the field? (*d*) What is the work required to rotate the dipole from being oriented parallel to the field to being antiparallel to the field?

**60.** (II) The HCl molecule has a dipole moment of about $3.4 \times 10^{-30}$ C · m. The two atoms are separated by about $1.0 \times 10^{-10}$ m. (*a*) What is the net charge on each atom? (*b*) Is this equal to an integral multiple of $e$? If not, explain. (*c*) What maximum torque would this dipole experience in a $2.5 \times 10^4$ N/C electric field? (*d*) How much energy would be needed to rotate one molecule 45° from its equilibrium position of lowest potential energy?

**61.** (II) An electric dipole, of dipole moment $p$ and moment of inertia $I$, is placed in a uniform electric field $\vec{\mathbf{E}}$. (*a*) If displaced by an angle $\theta$ as shown in Fig. 21–45 and released, under what conditions will it oscillate in simple harmonic motion? (*b*) What will be its frequency?

**62.** (II) Suppose both charges in Fig. 21–46 (for a dipole) are positive. (*a*) Show that the field on the perpendicular bisector, for $r \gg \ell$, is given by $(1/4\pi\epsilon_0)(2Q/r^2)$. (*b*) Explain why the field decreases as $1/r^2$ here for 2 positive charges, whereas for a dipole it decreases as $1/r^3$.

**63.** (III) Suppose a dipole $\vec{\mathbf{p}}$ is placed in a nonuniform electric field $\vec{\mathbf{E}} = E\hat{\mathbf{i}}$ that points along the $x$ axis. If $\vec{\mathbf{E}}$ depends only on $x$, show that the net force on the dipole is

$$\vec{\mathbf{F}} = \left(\vec{\mathbf{p}} \cdot \frac{d\vec{\mathbf{E}}}{dx}\right)\hat{\mathbf{i}},$$

where $d\vec{\mathbf{E}}/dx$ is called the gradient of the field in the $x$ direction.

**64.** (III) For the dipole shown in Fig. 21–46, let the $x$ axis be horizontal along the line joining the $-Q$ and $+Q$ charges, with origin midway between the two charges. (*a*) Show that the electric field at any point $x$ ($x \gg \ell$) has magnitude

$$E = \frac{1}{4\pi\epsilon_0}\frac{2p}{x^3}.$$

(*b*) In what direction does $\vec{\mathbf{E}}$ point?

### *21–12 DNA

***65.** (III) The two strands of the helix-shaped DNA molecule are held together by electrostatic forces as shown in Fig. 21–48. Assume that the net average charge (due to electron sharing) indicated on H and N atoms has magnitude $0.2e$ and on the indicated C and O atoms is $0.4e$. Assume also that atoms on each molecule are separated by $1.0 \times 10^{-10}$ m. Estimate the net force between (*a*) a thymine and an adenine, and (*b*) a cytosine and a guanine. For each bond (red dots) consider only the three atoms in a line (two atoms on one molecule, one atom on the other). (*c*) Estimate the total force for a DNA molecule containing $10^5$ pairs of such molecules. Assume half are A–T pairs and half are C–G pairs.

## General Problems

**66.** How close must two electrons be if the magnitude of the electric force between them is equal to the weight of either at the Earth's surface?

**67.** Given that the human body is mostly made of water, estimate the total amount of positive charge in a 72-kg person.

**68.** A water droplet of radius 0.018 mm remains stationary in the air. If the downward-directed electric field of the Earth is 150 N/C, how many excess electron charges must the water droplet have?

**69.** Estimate the net force between the CO group and the HN group shown in Fig. 21–72. The C and O have charges $\pm 0.40e$, and the H and N have charges $\pm 0.20e$, where $e = 1.6 \times 10^{-19}$ C. [*Hint*: Do not include the "internal" forces between C and O, or between H and N.]

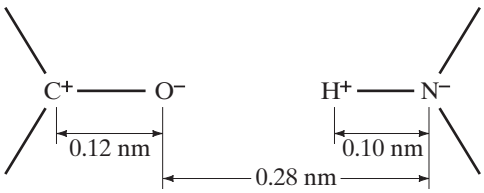

**FIGURE 21–72** Problem 69.

**70.** Suppose that electrical attraction, rather than gravity, was responsible for holding the Moon in orbit around the Earth. If equal and opposite charges $Q$ were placed on the Earth and the Moon, what should be the value of $Q$ to maintain the present orbit? Use data given on the inside front cover of this book. Treat the Earth and Moon as point particles.

**71.** In a simple model of the hydrogen atom, the electron revolves in a circular orbit around the proton with a speed of $2.2 \times 10^6$ m/s. Determine the radius of the electron's orbit. [*Hint*: See Chapter 5 on circular motion.]

**72.** A positive point charge $Q_1 = 2.5 \times 10^{-5}$ C is fixed at the origin of coordinates, and a negative point charge $Q_2 = -5.0 \times 10^{-6}$ C is fixed to the $x$ axis at $x = +3.2$ m. Find the location of the place(s) along the $x$ axis where the electric field due to these two charges is zero.

**73.** When clothes are removed from a dryer, a 40-g sock is stuck to a sweater, by "static electricity". Estimate the minimum attractive force between the sock and the sweater. Then estimate the minimum charge on the sock and the sweater. Assume the charging came entirely from the sock rubbing against the sweater so that they have equal and opposite charges, and approximate the sweater as a flat sheet of uniform charge.

**74.** A small lead sphere carrying an electric charge $Q = -3.00 \times 10^{-6}$ C is suspended vertically from an ideal spring (spring constant $k = 115$ N/m) as in Fig. 21–73. The total mass of the sphere is 0.650 kg, and its center lies 15.0 cm above a tabletop when in equilibrium. The sphere is pulled down 5.00 cm below equilibrium, and then it is released. Using what you know about harmonic oscillation, write an expression for the electric field strength as a function of time that would be measured at the point on the tabletop (P) directly below the sphere.

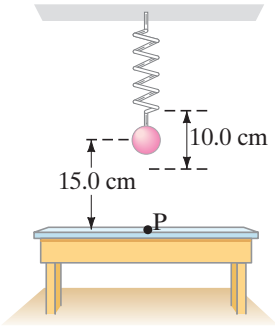

**FIGURE 21–73**
Problem 74.

**75.** Dry air will break down and generate a spark if the electric field exceeds about $3 \times 10^6$ N/C. How much charge could be packed onto a small green pea (diameter 0.75 cm) before the pea spontaneously discharges?

**76.** Two point charges, $Q_1 = -6.7\,\mu$C and $Q_2 = 2.6\,\mu$C, are located between two oppositely charged parallel plates, as shown in Fig. 21–74. The two charges are separated by a distance of $x = 0.47$ m. Assume that the electric field produced by the charged plates is uniform and equal to $E = 53{,}000$ N/C. Calculate the net electrostatic force on $Q_1$ and give its direction.

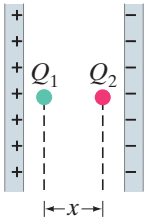

**FIGURE 21–74**
Problem 76.

**77.** Packing material made of pieces of foamed polystyrene can easily become charged and stick to each other. Given that the density of this material is about 35 kg/m$^3$, estimate how much charge might be on a 2.0-cm-diameter foamed polystyrene sphere, assuming the electric force between two spheres stuck together is equal to the weight of one sphere.

**78.** One type of *electric quadrupole* consists of two dipoles placed end to end with their negative charges (say) overlapping; that is, in the center is $-2Q$ flanked (on a line) by a $+Q$ to either side (Fig. 21–75). Determine the electric field $\vec{\mathbf{E}}$ at points along the perpendicular bisector and show that $E$ decreases as $1/r^4$ for $r \gg \ell$. Measure $r$ from the $-2Q$ charge.

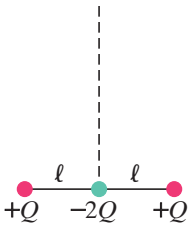

**FIGURE 21–75**
Problem 78.

**79.** Suppose electrons enter a uniform electric field midway between two plates (1.0 cm apart) at an angle $\theta_0$ to the horizontal, as shown in Fig. 21–76. The path is symmetrical, so they leave at the same angle $\theta_0$ and just barely miss the top plate. What is $\theta_0$? Ignore fringing of the field.

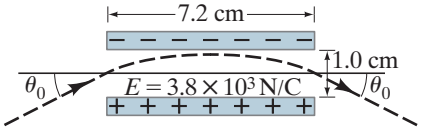

**FIGURE 21–76** Problem 79.

**80.** An electron moves in a circle of radius $r$ around a very long uniformly charged wire in a vacuum chamber, as shown in Fig. 21–77. The linear charge density on the wire is $\lambda = 0.18\,\mu$C/m. (*a*) What is the electric field at the electron (magnitude and direction) in terms of $r$ and $\lambda$? (*b*) What is the speed of the electron?

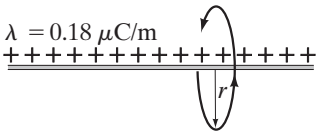

**FIGURE 21–77**
Problem 80.

**81.** Three very large square charged planes are arranged as shown (on edge) in Fig. 21–78. From left to right, the planes have charge densities per unit area of $-0.50\,\mu$C/m$^2$, $+0.25\,\mu$C/m$^2$, and $-0.35\,\mu$C/m$^2$. Find the total electric field (direction and magnitude) at the points A, B, C, and D. Assume the plates are much larger than the distance AD.

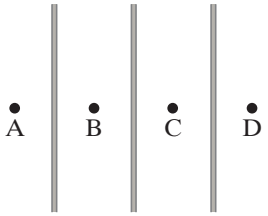

**FIGURE 21–78**
Problem 81.

**82.** A point charge ($m = 1.5$ gram) at the end of an insulating cord of length 55 cm is observed to be in equilibrium in a uniform horizontal electric field of 9500 N/C, when the pendulum's position is as shown in Fig. 21–79, with the charge 12 cm above the lowest (vertical) position. If the field points to the right in Fig. 21–79, determine the magnitude and sign of the point charge.

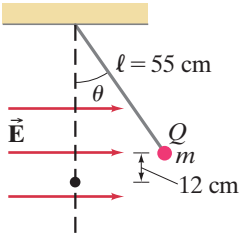

**FIGURE 21–79**
Problem 82.

**83.** Four equal positive point charges, each of charge 5.8 $\mu$C, are at the corners of a square of side 9.2 cm. What charge should be placed at the center of the square so that all charges are at equilibrium? Is this a stable or an unstable equilibrium (Section 12–4) in the plane?

**84.** Two small, identical conducting spheres A and B are a distance $R$ apart; each carries the same charge $Q$. (*a*) What is the force sphere B exerts on sphere A? (*b*) An identical sphere with zero charge, sphere C, makes contact with sphere B and is then moved very far away. What is the net force now acting on sphere A? (*c*) Sphere C is brought back and now makes contact with sphere A and is then moved far away. What is the force now on sphere A?

**85.** A point charge of mass 0.145 kg, and net charge $+3.40\,\mu$C, hangs at rest at the end of an insulating cord above a large sheet of charge. The horizontal sheet of fixed uniform charge creates a uniform vertical electric field in the vicinity of the point charge. The tension in the cord is measured to be 5.18 N. (*a*) Calculate the magnitude and direction of the electric field due to the sheet of charge (Fig. 21–80). (*b*) What is the surface charge density $\sigma$ $(\text{C/m}^2)$ on the sheet?

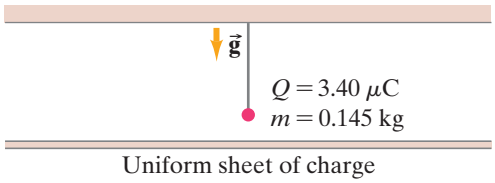

**FIGURE 21–80** Problem 85.

**86.** A one-dimensional row of positive ions, each with charge $+Q$ and separated from its neighbors by a distance $d$, occupies the right-hand half of the $x$ axis. That is, there is a $+Q$ charge at $x = 0$, $x = +d$, $x = +2d$, $x = +3d$, and so on out to $\infty$. (*a*) If an electron is placed at the position $x = -d$, determine $F$, the magnitude of the electric force that this row of charges exerts on the electron. (*b*) If the electron is instead placed at $x = -3d$, what is the value of $F$? [*Hint*: The infinite sum $\sum_{n=1}^{n=\infty} \frac{1}{n^2} = \frac{\pi^2}{6}$, where $n$ is a positive integer.]

**87.** (*a*) How many electrons are there in 1.00 mole of carbon atoms? (*b*) Two electrically neutral carbon spheres, each containing 1.00 mole of carbon, are separated by 18.0 cm (center to center). What fraction of electrons would have to be transferred from one sphere to the other for the electric force and the gravitational force between the spheres to be equal? Assume uniform charge distribution.

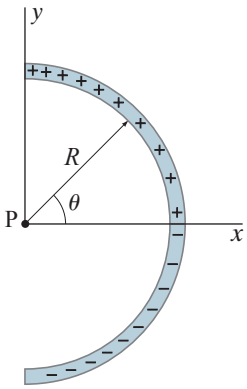
**88.** Near the surface of the Earth, there is a downward electric field of 150 N/C and a downward gravitational field of 9.8 N/kg. A charged 1.0-kg mass is observed to fall with acceleration $8.0\ \text{m/s}^2$. Determine the magnitude and sign of its charge.

**89.** Draw, approximately, the electric field lines about two point charges, $+Q$ and $-3Q$, which are a distance $\ell$ apart.

**90.** (*a*) The electric field near the Earth's surface has magnitude of about 150 N/C. What is the acceleration experienced by an electron due to this electric field near the surface of the Earth? (*b*) What about a proton? (*c*) Calculate the ratio of each acceleration to $g = 9.8\ \text{m/s}^2$.

**91.** Suppose the charge $Q$ on the ring of Fig. 21–29 was all distributed uniformly on only the upper half of the ring, and no charge was on the lower half. Determine the electric field $\vec{\mathbf{E}}$ at P in terms of $x$, $a$, $Q$, and $\lambda$. (Take $y$ vertically upward.)

**92.** A thin glass rod is a semicircle of radius $R$, Fig. 21–81. A charge is nonuniformly distributed along the semicircle with a linear charge density given by $\lambda = \lambda_0 \sin\theta$, where $\lambda_0$ is a positive constant. Point P is at the center of the semicircle. (*a*) Find the electric field $\vec{\mathbf{E}}$ (magnitude and direction) at point P. [*Hint:* Remember $\sin(-\theta) = -\sin\theta$, so the two halves of the rod are oppositely charged.] (*b*) Determine the acceleration (magnitude and direction) of an electron placed at point P, assuming $R = 1.0$ cm and $\lambda_0 = 1.0\ \mu\text{C/m}$.



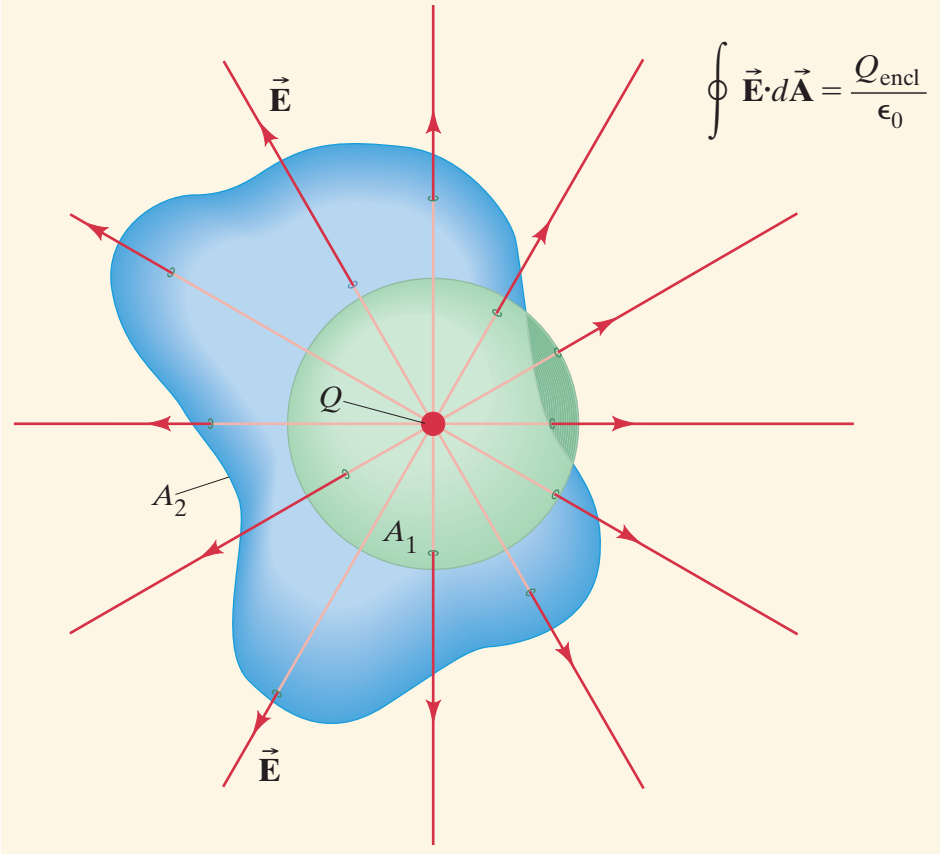


**FIGURE 21–81** Problem 92.

## ANSWERS TO EXERCISES

**A:** (*d*).
**B:** Opposite.
**C:** 0.3 N, to the right.
**D:** (*a*) No; (*b*) yes, midway between them.
**E:** (*d*), if the two + charges are not at opposite corners.

Gauss's law is an elegant relation between electric charge and electric field. It is more general than Coulomb's law. Gauss's law involves an integral of the electric field $\vec{\mathbf{E}}$ at each point on a closed surface. The surface is only imaginary, and we choose the shape and placement of the surface so that evaluating the integral is doable. In this drawing, two different 3-D surfaces are shown (one green, one blue), both enclosing a point charge $Q$. Gauss's law states that the product $\vec{\mathbf{E}} \cdot d\vec{\mathbf{A}}$, where $d\vec{\mathbf{A}}$ is an infinitesimal area of the surface, integrated over the entire surface, equals the charge enclosed by the surface $Q_{\text{encl}}$ divided by $\epsilon_0$. Both surfaces here enclose the same charge $Q$. Hence $\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}}$ will give the same result for both surfaces.

CHAPTER 22

# Gauss's Law

**CHAPTER-OPENING QUESTION—Guess now!**

A nonconducting sphere has a uniform charge density throughout. How does the magnitude of the electric field vary inside with distance from the center?

**(a)** The electric field is zero throughout.
**(b)** The electric field is constant but nonzero throughout.
**(c)** The electric field increases linearly from the center to the outer edge.
**(d)** The electric field decreases linearly from the center to the outer edge.
**(e)** The electric field increases exponentially from the center to the outer edge.
**(d)** The electric field decreases quadratically from the center to the outer edge.

The great mathematician Karl Friedrich Gauss (1777–1855) developed an important relation, now known as Gauss's law, which we develop and discuss in this Chapter. It is a statement of the relation between electric charge and electric field and is a more general and elegant form of Coulomb's law.

We can, in principle, determine the electric field due to any given distribution of electric charge using Coulomb's law. The total electric field at any point will be the vector sum (or integral) of contributions from all charges present (see Eq. 21–6). Except for some simple cases, the sum or integral can be quite complicated to evaluate. For situations in which an analytic solution (such as we carried out in the Examples of Sections 21–6 and 21–7) is not possible, a computer can be used.

In some cases, however, the electric field due to a given charge distribution can be calculated more easily or more elegantly using Gauss's law, as we shall see in this Chapter. But the major importance of Gauss's law is that it gives us additional insight into the nature of electrostatic fields, and a more general relationship between charge and field.

Before discussing Gauss's law itself, we first discuss the concept of *flux*.

## CONTENTS

22–1 Electric Flux
22–2 Gauss's Law
22–3 Applications of Gauss's Law
*22–4 Experimental Basis of Gauss's and Coulomb's Laws

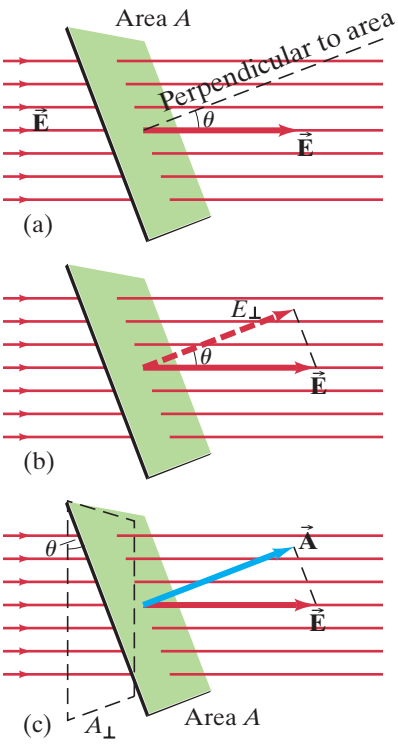

**FIGURE 22–1** (a) A uniform electric field $\vec{\mathbf{E}}$ passing through a flat area $A$. (b) $E_\perp = E\cos\theta$ is the component of $\vec{\mathbf{E}}$ perpendicular to the plane of area $A$. (c) $A_\perp = A\cos\theta$ is the projection (dashed) of the area $A$ perpendicular to the field $\vec{\mathbf{E}}$.

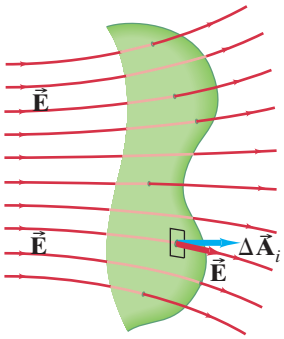
**FIGURE 22–2** Electric flux through a curved surface. One small area of the surface, $\Delta\vec{\mathbf{A}}_i$, is indicated.



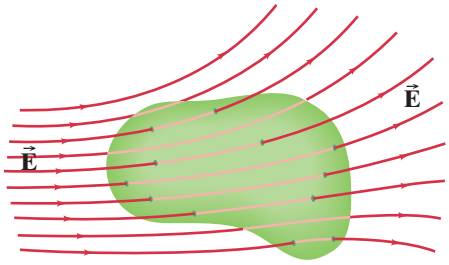


**FIGURE 22–3** (below) Electric flux through a closed surface.

# 22–1 Electric Flux

Gauss's law involves the concept of **electric flux**, which refers to the electric field passing through a given area. For a uniform electric field $\vec{\mathbf{E}}$ passing through an area $A$, as shown in Fig. 22–1a, the electric flux $\Phi_E$ is defined as

$$\Phi_E = EA\cos\theta,$$

where $\theta$ is the angle between the electric field direction and a line drawn perpendicular to the area. The flux can be written equivalently as

$$\Phi_E = E_\perp A = EA_\perp = EA\cos\theta, \qquad [\vec{\mathbf{E}} \text{ uniform}] \quad \textbf{(22–1a)}$$

where $E_\perp = E\cos\theta$ is the component of $\vec{\mathbf{E}}$ along the perpendicular to the area (Fig. 22–1b) and, similarly, $A_\perp = A\cos\theta$ is the projection of the area $A$ perpendicular to the field $\vec{\mathbf{E}}$ (Fig. 22–1c).

The area $A$ of a surface can be represented by a vector $\vec{\mathbf{A}}$ whose magnitude is $A$ and whose direction is perpendicular to the surface, as shown in Fig. 22–1c. The angle $\theta$ is the angle between $\vec{\mathbf{E}}$ and $\vec{\mathbf{A}}$, so the electric flux can also be written

$$\Phi_E = \vec{\mathbf{E}}\cdot\vec{\mathbf{A}}. \qquad [\vec{\mathbf{E}} \text{ uniform}] \quad \textbf{(22–1b)}$$

Electric flux can be interpreted in terms of field lines. We mentioned in Section 21–8 that field lines can always be drawn so that the number $(N)$ passing through unit area perpendicular to the field $(A_\perp)$ is proportional to the magnitude of the field $(E)$: that is, $E \propto N/A_\perp$. Hence,

$$N \propto EA_\perp = \Phi_E,$$

so the flux through an area is proportional to the number of lines passing through that area.

**EXAMPLE 22–1** **Electric flux.** Calculate the electric flux through the rectangle shown in Fig. 22–1a. The rectangle is 10 cm by 20 cm, the electric field is uniform at 200 N/C, and the angle $\theta$ is 30°.

**APPROACH** We use the definition of flux, $\Phi_E = \vec{\mathbf{E}}\cdot\vec{\mathbf{A}} = EA\cos\theta$.

**SOLUTION** The electric flux is

$$\Phi_E = (200\,\text{N/C})(0.10\,\text{m} \times 0.20\,\text{m})\cos 30° = 3.5\,\text{N}\cdot\text{m}^2/\text{C}.$$

**EXERCISE A** Which of the following would cause a change in the electric flux through a circle lying in the $xz$ plane where the electric field is $(10\,\text{N})\hat{\mathbf{j}}$? (*a*) Changing the magnitude of the electric field. (*b*) Changing the size of the circle. (*c*) Tipping the circle so that it is lying in the $xy$ plane. (*d*) All of the above. (*e*) None of the above.

In the more general case, when the electric field $\vec{\mathbf{E}}$ is not uniform and the surface is not flat, Fig. 22–2, we divide up the chosen surface into $n$ tiny areas, $\Delta A_1, \Delta A_2, \cdots, \Delta A_n$. We choose the division so that each $\Delta A_i$ is small enough that (1) it can be considered flat, and (2) the electric field varies so little over this small area that it can be considered uniform. Then the *total* electric flux through the entire surface is approximately

$$\Phi_E \approx \sum_{i=1}^{n} \vec{\mathbf{E}}_i\cdot\Delta\vec{\mathbf{A}}_i,$$

where $\vec{\mathbf{E}}_i$ is the field passing through $\Delta\vec{\mathbf{A}}_i$. In the limit as we let $\Delta\vec{\mathbf{A}}_i \to 0$, the sum becomes an integral over the entire surface and the relation becomes mathematically exact:

$$\Phi_E = \int \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}}. \qquad \textbf{(22–2)}$$

Gauss's law involves the *total* flux through a *closed* surface—a surface of any shape that completely encloses a volume of space, such as that shown in Fig. 22–3. In this case, the net flux through the enclosing surface is given by

$$\Phi_E = \oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}}, \qquad \textbf{(22–3)}$$

where the integral sign is written $\oint$ to indicate that the integral is over the value of $\vec{\mathbf{E}}$ at every point on a *closed* surface: one that fully encloses a volume.

Up to now we have not been concerned with an ambiguity in the direction of the vector $\vec{\mathbf{A}}$ or $d\vec{\mathbf{A}}$ that represents a surface. For example, in Fig. 22–1c, the vector $\vec{\mathbf{A}}$ could point upward and to the right (as shown) or downward to the left and still be perpendicular to the surface. For a closed surface, we define (arbitrarily) the direction of $\vec{\mathbf{A}}$, or of $d\vec{\mathbf{A}}$, to point *outward* from the enclosed volume, Fig. 22–4. For an electric field line leaving the enclosed volume (on the right in Fig. 22–4), the angle $\theta$ between $\vec{\mathbf{E}}$ and $d\vec{\mathbf{A}}$ must be less than $\pi/2$ $(= 90°)$; hence $\cos\theta > 0$. For a line entering the volume (on the left in Fig. 22–4) $\theta > \pi/2$; hence $\cos\theta < 0$. Thus, flux *entering* the enclosed volume is *negative* $\left(\int E\cos\theta\, dA < 0\right)$, whereas flux *leaving* the volume is *positive*. Consequently, Eq. 22–3 gives the net flux *out* of the volume. If $\Phi_E$ is negative, there is a net flux *into* the volume.

In Figs. 22–3 and 22–4, each field line that enters the volume also leaves the volume. Hence $\Phi_E = \oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = 0$. There is no net flux into or out of this enclosed surface. The flux, $\oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}}$, will be nonzero only if one or more lines start or end within the surface. Since electric field lines start and stop only on electric charges, the flux will be nonzero only if the surface encloses a net charge. For example, the surface labeled $A_1$ in Fig. 22–5 encloses a positive charge and there is a net outward flux through this surface $(\Phi_E > 0)$. In fact *all* the electric field lines are *leaving* surface $A_1$. The surface $A_2$ encloses an equal magnitude negative charge and there is a net inward flux $(\Phi_E < 0)$. For the configuration shown in Fig. 22–6, some lines enter the surface, others leave. But the net flux through the surface shown is negative (count the lines). The value of $\Phi_E$ depends on the charge enclosed by the surface, and this is what Gauss's law is all about.

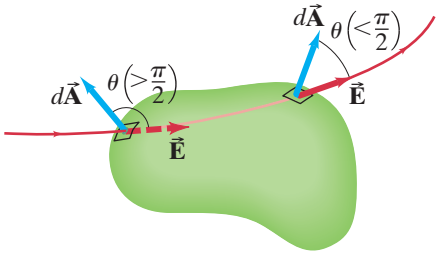

**FIGURE 22–4** The direction of an element of area $d\vec{\mathbf{A}}$ is taken to point outward from an enclosed surface.

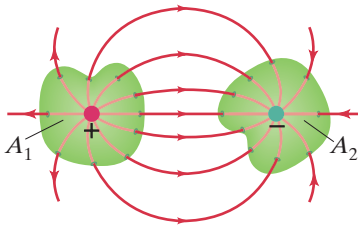
**FIGURE 22–5** An electric dipole. Flux through surface $A_1$ is positive. Flux through $A_2$ is negative.



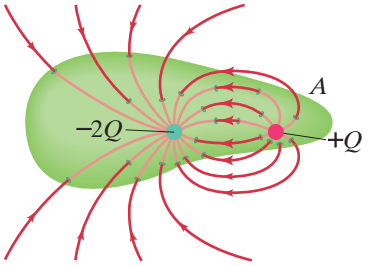


**FIGURE 22–6** (below) Net flux through surface $A$ is negative.

## 22–2 Gauss's Law

The precise relation between the electric flux through a closed surface and the net charge $Q_{\text{encl}}$ enclosed within that surface is given by **Gauss's law**:

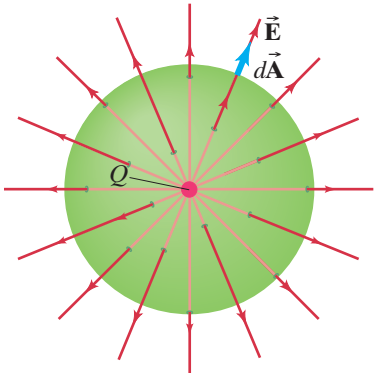
$$\oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = \frac{Q_{\text{encl}}}{\epsilon_0}, \qquad \textbf{(22–4)}$$

where $\epsilon_0$ is the same constant (permittivity of free space) that appears in Coulomb's law, $\epsilon_0 = 8.85 \times 10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2$. The integral on the left is over the value of $\vec{\mathbf{E}}$ on any closed surface, and we choose that imaginary surface for our convenience in any given situation. The charge $Q_{\text{encl}}$ is the net charge *enclosed* by that surface. It doesn't matter where or how the charge is distributed inside the surface. Any charge outside this surface must not be included. A charge outside the chosen surface may affect the position of the electric field lines, but will not affect the net number of lines entering or leaving the surface. For example, $Q_{\text{encl}}$ for the imaginary gaussian surface $A_1$ in Fig. 22–5 would be the positive charge enclosed by $A_1$; the negative charge on the right does contribute to the electric field at $A_1$ but it is *not* enclosed by surface $A_1$ and so is *not* included in $Q_{\text{encl}}$.

Now let us see how Gauss's law is related to Coulomb's law. First, we show that Coulomb's law follows from Gauss's law. In Fig. 22–7 we have a single isolated charge $Q$. For our "gaussian surface," we choose an imaginary sphere of radius $r$ centered on the charge. Because Gauss's law is supposed to be valid for any surface, we have chosen one that will make our calculation easy. Because of the *symmetry* of this (imaginary) sphere about the charge at its center, we know (1) that $\vec{\mathbf{E}}$ must have the same magnitude at any point on this spherical surface, and (2) that $\vec{\mathbf{E}}$ points radially outward (inward for a negative charge) perpendicular to the surface and parallel to $d\vec{\mathbf{A}}$, an element of the surface area. Hence, we write the integral in Gauss's law as

$$\oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = \oint E\, dA = E\oint dA = E(4\pi r^2)$$

since the magnitude of $\vec{\mathbf{E}}$ is the same at all points on this spherical surface, and the surface area of a sphere of radius $r$ is $4\pi r^2$. Then Gauss's law becomes, with $Q_{\text{encl}} = Q$,



$$\frac{Q}{\epsilon_0} = \oint \vec{\mathbf{E}}\cdot d\vec{\mathbf{A}} = E(4\pi r^2).$$

So

$$E = \frac{Q}{4\pi\epsilon_0 r^2},$$

which is the electric field form of Coulomb's law, Eq. 21–4b.

**FIGURE 22–7** A single point charge $Q$ at the center of an imaginary sphere of radius $r$ (our "gaussian surface"—that is, the closed surface we choose to use for applying Gauss's law in this case).

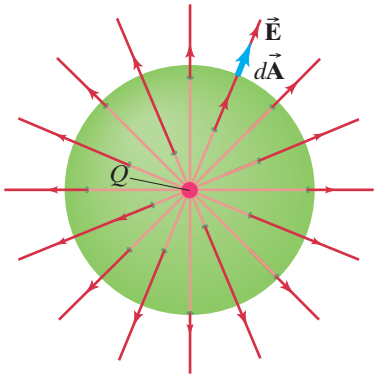


**FIGURE 22–7** (Repeated.) A single point charge $Q$ at the center of an imaginary sphere of radius $r$ (our "gaussian surface"—that is, the closed surface we choose to use for applying Gauss's law in this case).

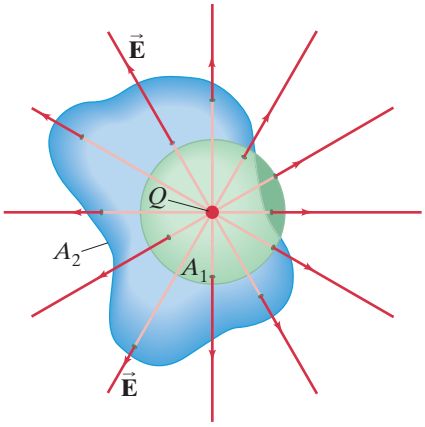
**FIGURE 22–8** A single point charge surrounded by a spherical surface, $A_1$ (green color), and an irregular surface, $A_2$ (blue).



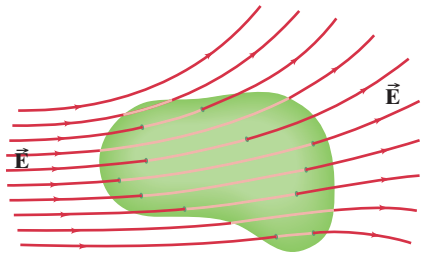


**FIGURE 22–9** Electric flux through a closed surface. (Same as Fig. 22–3.) No electric charge is enclosed by this surface $(Q_{\text{encl}} = 0)$.

Now let us do the reverse, and derive Gauss's law from Coulomb's law for static electric charges.† First we consider a single point charge $Q$ surrounded by an imaginary spherical surface as in Fig. 22–7 (and shown again, green, in Fig. 22–8). Coulomb's law tells us that the electric field at the spherical surface is $E = (1/4\pi\epsilon_0)(Q/r^2)$. Reversing the argument we just used, we have

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \oint \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2}\,dA = \frac{Q}{4\pi\epsilon_0 r^2}(4\pi r^2) = \frac{Q}{\epsilon_0}.$$

This is Gauss's law, with $Q_{\text{encl}} = Q$, and we derived it for the special case of a spherical surface enclosing a point charge at its center. But what about some other surface, such as the irregular surface labeled $A_2$ in Fig. 22–8? The same number of field lines (due to our charge $Q$) pass through surface $A_2$, as pass through the spherical surface, $A_1$. Therefore, because the flux through a surface is proportional to the number of lines through it as we saw in Section 22–1, the flux through $A_2$ is the same as through $A_1$:

$$\oint_{A_2} \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \oint_{A_1} \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \frac{Q}{\epsilon_0}.$$

Hence, we can expect that

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \frac{Q}{\epsilon_0}$$

would be valid for *any* surface surrounding a single point charge $Q$.

Finally, let us look at the case of more than one charge. For each charge, $Q_i$, enclosed by the chosen surface,

$$\oint \vec{\mathbf{E}}_i \cdot d\vec{\mathbf{A}} = \frac{Q_i}{\epsilon_0},$$

where $\vec{\mathbf{E}}_i$ refers to the electric field produced by $Q_i$ alone. By the superposition principle for electric fields (Section 21–6), the total field $\vec{\mathbf{E}}$ is equal to the sum of the fields due to each separate charge, $\vec{\mathbf{E}} = \Sigma\vec{\mathbf{E}}_i$. Hence

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \oint (\Sigma\vec{\mathbf{E}}_i) \cdot d\vec{\mathbf{A}} = \Sigma\frac{Q_i}{\epsilon_0} = \frac{Q_{\text{encl}}}{\epsilon_0},$$

where $Q_{\text{encl}} = \Sigma Q_i$ is the total net charge enclosed within the surface. Thus we see, based on this simple argument, that Gauss's law follows from Coulomb's law for any distribution of static electric charge enclosed within a closed surface of any shape.

The derivation of Gauss's law from Coulomb's law is valid for electric fields produced by static electric charges. We will see later that electric fields can also be produced by changing magnetic fields. Coulomb's law cannot be used to describe such electric fields. But Gauss's law *is* found to hold also for electric fields produced in any of these ways. Hence *Gauss's law is a more general law than Coulomb's law*. It holds for any electric field whatsoever.

Even for the case of static electric fields that we are considering in this Chapter, it is important to recognize that $\vec{\mathbf{E}}$ on the left side of Gauss's law is not necessarily due only to the charge $Q_{\text{encl}}$ that appears on the right. For example, in Fig. 22–9 there is an electric field $\vec{\mathbf{E}}$ at all points on the imaginary gaussian surface, but it is not due to the charge enclosed by the surface (which is $Q_{\text{encl}} = 0$ in this case). The electric field $\vec{\mathbf{E}}$ which appears on the left side of Gauss's law is the *total* electric field at each point, on the gaussian surface chosen, not just that due to the charge $Q_{\text{encl}}$, which appears on the right side. Gauss's law has been found to be valid for the total field at any surface. It tells us that any *difference* between the input and output flux of the electric field over any surface is due to charge within that surface.

†Note that Gauss's law would look more complicated in terms of the constant $k = 1/4\pi\epsilon_0$ that we originally used in Coulomb's law (Eqs. 21–1 or 21–4a), $\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = 4\pi kQ$. We prefer $\epsilon_0$ to $k$ so as to make Gauss's law simpler, which is considered more general than Coulomb's law.

**CONCEPTUAL EXAMPLE 22–2** **Flux from Gauss's law.** Consider the two imaginary gaussian surfaces, $A_1$ and $A_2$, shown in Fig. 22–10. The only charge present is the charge $Q$ at the center of surface $A_1$. What is the net flux through each surface, $A_1$ and $A_2$?

**RESPONSE** The surface $A_1$ encloses the charge $+Q$. By Gauss's law, the net flux through $A_1$ is then $Q/\epsilon_0$. For surface $A_2$, the charge $+Q$ is outside the surface. Surface $A_2$ encloses zero net charge, so the net electric flux through $A_2$ is zero, by Gauss's law. Note that all field lines that enter the volume enclosed by surface $A_2$ also leave it.

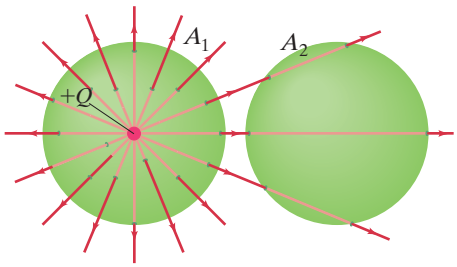

**FIGURE 22–10** Example 22–2. Two gaussian surfaces.

**EXERCISE B** A point charge $Q$ is at the center of a spherical gaussian surface $A$. When a second charge $Q$ is placed just outside $A$, the total flux through this spherical surface $A$ is (*a*) unchanged, (*b*) doubled, (*c*) halved, (*d*) none of these.

**EXERCISE C** Three 2.95 $\mu$C charges are in a small box. What is the net flux leaving the box? (*a*) $3.3 \times 10^{12}\,\mathrm{N \cdot m^2/C}$, (*b*) $3.3 \times 10^{5}\,\mathrm{N \cdot m^2/C}$, (*c*) $1.0 \times 10^{12}\,\mathrm{N \cdot m^2/C}$, (*d*) $1.0 \times 10^{6}\,\mathrm{N \cdot m^2/C}$, (*e*) $6.7 \times 10^{6}\,\mathrm{N \cdot m^2/C}$.

# 22–3 Applications of Gauss's Law

Gauss's law is a very compact and elegant way to write the relation between electric charge and electric field. It also offers a simple way to determine the electric field when the charge distribution is simple and/or possesses a high degree of *symmetry*. In order to apply Gauss's law, however, we must choose the "gaussian" surface very carefully (for the integral on the left side of Gauss's law) so we can determine $\vec{\mathbf{E}}$. We normally try to think of a surface that has just the symmetry needed so that $E$ will be constant on all or on parts of its surface. Sometimes we choose a surface so the flux through part of the surface is zero.

**EXAMPLE 22–3** **Charged spherical conducting shell.** A thin spherical shell of radius $r_0$ possesses a total net charge $Q$ that is uniformly distributed on it, Fig. 22–11. Determine the electric field at points (*a*) outside the shell, and (*b*) inside the shell. (*c*) What if the conductor were a solid sphere?

**APPROACH** Because the charge is distributed symmetrically, the electric field must also be *symmetric*. Thus the field outside the shell must be directed radially outward (inward if $Q < 0$) and must depend only on $r$, not on angle (spherical coordinates).

**SOLUTION** (*a*) We choose our imaginary gaussian surface as a sphere of radius $r$ $(r > r_0)$ outside and concentric with our charged shell, shown in Fig. 22–11 as the dashed green circle $A_1$. Then, by symmetry, the electric field will have the same magnitude at all points on this gaussian surface. Because $\vec{\mathbf{E}}$ is perpendicular to this surface, the cosine of the angle between $\vec{\mathbf{E}}$ and $d\vec{\mathbf{A}}$ is always 1. Gauss's law then gives (with $Q_{\text{encl}} = Q$ in Eq. 22–4)

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = E(4\pi r^2) = \frac{Q}{\epsilon_0},$$

where $4\pi r^2$ is the surface area of our imaginary sphere (gaussian surface) of radius $r$. Thus

$$E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2}. \qquad [r > r_0]$$

We see that the field outside a uniformly charged spherical shell is the same as if *all the charge were concentrated at the center as a point charge*.

(*b*) Inside the shell, the electric field must also be symmetric. So $E$ must again have the same value at all points on an imaginary spherical gaussian surface ($A_2$ in Fig. 22–11) concentric with our charged shell. Thus $E$ can be factored out of the integral and, with $Q_{\text{encl}} = 0$ because the charge inside surface $A_2$ is zero, we have

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = E\oint dA = E(4\pi r^2) = 0.$$

Hence

$$E = 0 \qquad [r < r_0]$$

inside a uniform spherical shell of charge (as claimed in Section 21–9).

(*c*) These same results also apply to a uniformly charged solid spherical conductor, because all the charge would lie in a thin layer at the surface.

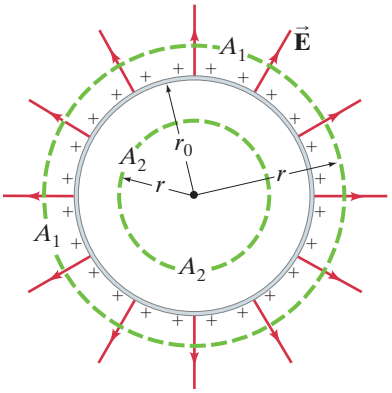

**FIGURE 22–11** Cross-sectional drawing of a thin spherical shell (grey) of radius $r_0$, carrying a net charge $Q$ uniformly distributed. $A_1$ and $A_2$ represent two gaussian surfaces we use to determine $\vec{\mathbf{E}}$. Example 22–3.

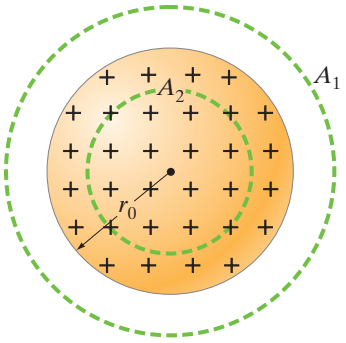

**FIGURE 22–12** A solid sphere of uniform charge density. Example 22–4.

**EXAMPLE 22–4 Solid sphere of charge.** An electric charge $Q$ is distributed uniformly throughout a nonconducting sphere of radius $r_0$, Fig. 22–12. Determine the electric field (*a*) outside the sphere $(r > r_0)$ and (*b*) inside the sphere $(r < r_0)$.

**APPROACH** Since the charge is distributed symmetrically in the sphere, the electric field at all points must again be *symmetric*. $\vec{\mathbf{E}}$ depends only on $r$ and is directed radially outward (or inward if $Q < 0$).

**SOLUTION** (*a*) For our gaussian surface we choose a sphere of radius $r$ $(r > r_0)$, labeled $A_1$ in Fig. 22–12. Since $E$ depends only on $r$, Gauss's law gives, with $Q_{\text{encl}} = Q$,

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = E(4\pi r^2) = \frac{Q}{\epsilon_0}$$

or

$$E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2}.$$

Again, the field outside a spherically symmetric distribution of charge is the same as that for a point charge of the same magnitude located at the center of the sphere.

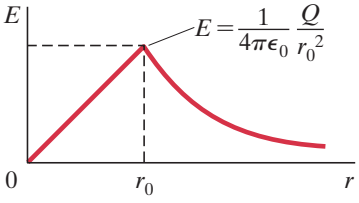
(*b*) Inside the sphere, we choose for our gaussian surface a concentric sphere of radius $r$ $(r < r_0)$, labeled $A_2$ in Fig. 22–12. From symmetry, the magnitude of $\vec{\mathbf{E}}$ is the same at all points on $A_2$, and $\vec{\mathbf{E}}$ is perpendicular to the gaussian surface, so

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = E(4\pi r^2).$$

We must equate this to $Q_{\text{encl}}/\epsilon_0$ where $Q_{\text{encl}}$ is the charge enclosed by $A_2$. $Q_{\text{encl}}$ is not the total charge $Q$ but only a portion of it. We define the **charge density**, $\rho_{\text{E}}$, as the charge per unit volume $(\rho_{\text{E}} = dQ/dV)$, and here we are given that $\rho_{\text{E}} =$ constant. So the charge enclosed by the gaussian surface $A_2$, a sphere of radius $r$, is

$$Q_{\text{encl}} = \left(\frac{\frac{4}{3}\pi r^3 \rho_{\text{E}}}{\frac{4}{3}\pi r_0^3 \rho_{\text{E}}}\right) Q = \frac{r^3}{r_0^3} Q.$$

Hence, from Gauss's law,



$$E(4\pi r^2) = \frac{Q_{\text{encl}}}{\epsilon_0} = \frac{r^3}{r_0^3}\frac{Q}{\epsilon_0}$$

or

$$E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r_0^3} r. \qquad [r < r_0]$$

Thus the field increases linearly with $r$, until $r = r_0$. It then decreases as $1/r^2$, as plotted in Fig. 22–13.

**FIGURE 22–13** Magnitude of the electric field as a function of the distance $r$ from the center of a uniformly charged solid sphere, Example 22–4.

**EXERCISE D** Return to the Chapter-Opening Question, page 643, and answer it again now. Try to explain why you may have answered differently the first time.

Examples 22–3 and 22–4a tell us that

$$E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2} \qquad \left[\begin{array}{c}\text{outside uniformly charged}\\ \text{sphere or spherical shell}\end{array}\right]$$

outside a sphere or spherical shell carrying uniform charge $Q$. The electric field outside a spherically symmetric distribution of charge is thus the same as for a point charge of the same magnitude at the center of the sphere, confirming what we said in Section 21–5, and applies for both a uniformly charged conductor or nonconductor.

The *gravitational force* is also a $1/r^2$ force, so this same result applies: The gravitational force exerted by a uniform sphere is the same as if all the mass were at the center, as stated at the end of Section 6–1, and derived by integration in Appendix E. Furthermore, the last equation in Example 22–4 tells us that the *gravitational field* at a point *inside* the Earth is $\propto r$, if we assume uniform mass density (again see Appendix E).

The results in Example 22–4 would have been difficult to obtain from Coulomb's law by integrating over the sphere (as we do for gravity in Appendix E). Using Gauss's law and the *symmetry* of the situation, these results are obtained rather easily, and show the great power of Gauss's law. Gauss's law holds for any surface, but is practically useful mainly when the charge distribution has a high degree of symmetry. Carrying out the integral in Gauss's law can be difficult. We try to *choose* a simple surface on which $E$ = constant, so the integration is simple.

**EXAMPLE 22–5** **Nonuniformly charged solid sphere.** Suppose the charge density of the solid sphere in Fig. 22–12, Example 22–4, is given by $\rho_E = \alpha r^2$, where $\alpha$ is a constant. (*a*) Find $\alpha$ in terms of $Q$ and $r_0$, the total charge on the sphere and its radius. (*b*) Find the electric field as a function of $r$ inside the sphere.

**APPROACH** We divide the sphere up into concentric thin shells of thickness $dr$ as shown in Fig. 22–14, and (*a*) integrate $Q = \int \rho_E \, dV$ and (*b*) use Gauss's law.

**SOLUTION** (*a*) A thin shell of radius $r$ and thickness $dr$ (Fig. 22–14) has volume $dV = 4\pi r^2 \, dr$. The total charge is given by

$$Q = \int \rho_E \, dV = \int_0^{r_0} (\alpha r^2)(4\pi r^2 \, dr) = 4\pi\alpha \int_0^{r_0} r^4 \, dr = \frac{4\pi\alpha}{5} r_0^5.$$

Thus $\alpha = 5Q/4\pi r_0^5$.

(*b*) To find $E$ inside the sphere at distance $r$ from its center, we apply Gauss's law to an imaginary sphere of radius $r$ which will enclose a charge

$$Q_{\text{encl}} = \int_0^r \rho_E \, dV = \int_0^r (\alpha r^2)\, 4\pi r^2 \, dr = \int_0^r \left(\frac{5Q}{4\pi r_0^5} r^2\right) 4\pi r^2 \, dr = Q \frac{r^5}{r_0^5}.$$

By *symmetry*, $E$ will be the same at all points on the surface of a sphere of radius $r$, so Gauss's law gives

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \frac{Q_{\text{encl}}}{\epsilon_0}, \qquad \text{so} \qquad (E)(4\pi r^2) = Q \frac{r^5}{\epsilon_0 r_0^5},$$

giving

$$E = \frac{Qr^3}{4\pi\epsilon_0 r_0^5}.$$

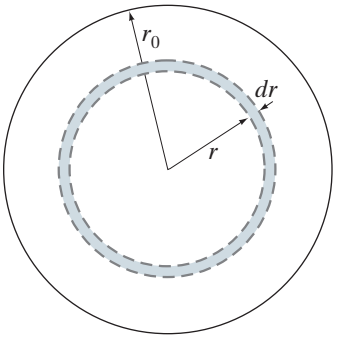


**FIGURE 22–14** Example 22–5.

**EXAMPLE 22–6** **Long uniform line of charge.** A very long straight wire possesses a uniform positive charge per unit length, $\lambda$. Calculate the electric field at points near (but outside) the wire, far from the ends.

**APPROACH** Because of the *symmetry*, we expect the field to be directed radially outward and to depend only on the perpendicular distance, $R$, from the wire. Because of the cylindrical symmetry, the field will be the same at all points on an imaginary gaussian surface that is a dashed green cylinder with the wire along its axis, Fig. 22–15. $\vec{\mathbf{E}}$ is perpendicular to the curved surface at all points. For Gauss's law, we need a closed surface, so we include the flat ends of the cylinder. Since $\vec{\mathbf{E}}$ is parallel to the ends, there is no flux through the ends (the cosine of the angle between $\vec{\mathbf{E}}$ and $d\vec{\mathbf{A}}$ on the ends is $\cos 90° = 0$).

**SOLUTION** For our chosen gaussian surface Gauss's law gives

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = E(2\pi R\ell) = \frac{Q_{\text{encl}}}{\epsilon_0} = \frac{\lambda\ell}{\epsilon_0},$$

where $\ell$ is the length of our chosen gaussian surface ($\ell \ll$ length of wire), and $2\pi R$ is its circumference. Hence

$$E = \frac{1}{2\pi\epsilon_0} \frac{\lambda}{R}.$$

**NOTE** This is the same result we found in Example 21–12 using Coulomb's law (we used $x$ there instead of $R$), but here it took much less effort. Again we see the great power of Gauss's law.†

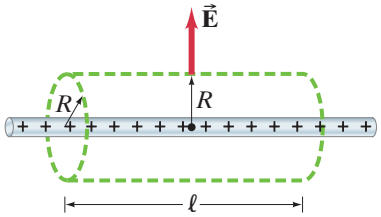

**FIGURE 22–15** Calculation of $\vec{\mathbf{E}}$ due to a very long line of charge. Example 22–6. (Note: We use $R$ for the distance from an axis—cylindrical symmetry—and $r$ for the distance from a point. See Fig. 10–2.)

†But note that the method of Example 21–12 allows calculation of $E$ also for a short line of charge by using the appropriate limits for the integral, whereas Gauss's law is not readily adapted.

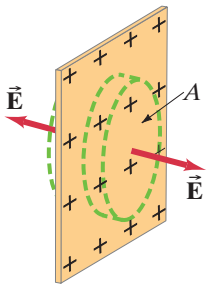

**FIGURE 22–16** Calculation of the electric field outside a large uniformly charged nonconducting plane surface. Example 22–7.

**EXAMPLE 22–7** **Infinite plane of charge.** Charge is distributed uniformly, with a surface charge density $\sigma$ ($\sigma$ = charge per unit area = $dQ/dA$), over a very large but very thin nonconducting flat plane surface. Determine the electric field at points near the plane.

**APPROACH** We choose as our imaginary gaussian surface a small closed cylinder whose axis is perpendicular to the plane and which extends through the plane as shown dashed in green in Fig. 22–16. Because of the symmetry, we expect $\vec{\mathbf{E}}$ to be directed perpendicular to the plane on both sides as shown, and to be uniform over the end caps of the cylinder, each of whose area is $A$.

**SOLUTION** Since no flux passes through the curved sides of our chosen cylindrical surface, all the flux is through the two end caps. So Gauss's law gives

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = 2EA = \frac{Q_{\text{encl}}}{\epsilon_0} = \frac{\sigma A}{\epsilon_0},$$

where $Q_{\text{encl}} = \sigma A$ is the charge enclosed by our gaussian cylinder. The electric field is then

$$E = \frac{\sigma}{2\epsilon_0}.$$

**NOTE** This is the same result we obtained much more laboriously in Chapter 21, Eq. 21–7. The field is uniform for points far from the ends of the plane, and close to its surface.

**EXAMPLE 22–8** **Electric field near any conducting surface.** Show that the magnitude of the electric field just outside the surface of a good conductor of any shape is given by

$$E = \frac{\sigma}{\epsilon_0},$$

where $\sigma$ is the surface charge density ($Q/A$) on the conductor's surface at that point.

**APPROACH** We choose as our gaussian surface a small cylindrical box (like a tiny pillbox), as we did in the previous Example. We choose the cylinder to be very small in height, so that one of its circular ends is just above the conductor (Fig. 22–17). The other end is just below the conductor's surface, and the very short sides are perpendicular to it.

**SOLUTION** The electric field is zero inside a conductor and is perpendicular to the surface just outside it (Section 21–9), so electric flux passes only through the outside end of our cylindrical box; no flux passes through the very short sides or through the inside end of our gaussian box. We choose the area $A$ (of the flat cylinder end above the conductor surface) small enough so that $E$ is essentially uniform over it. Then Gauss's law gives

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = EA = \frac{Q_{\text{encl}}}{\epsilon_0} = \frac{\sigma A}{\epsilon_0},$$

so that

$$E = \frac{\sigma}{\epsilon_0}. \qquad \text{[at surface of conductor]} \quad \textbf{(22–5)}$$

**NOTE** This useful result applies for a conductor of any shape.

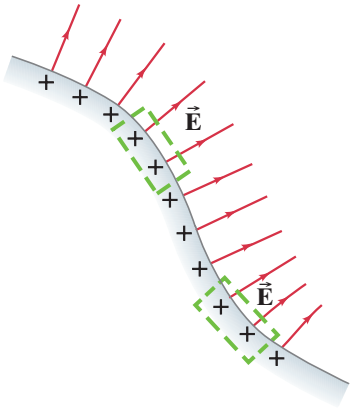

**FIGURE 22–17** Electric field near the surface of a conductor. Two small cylindrical boxes are shown dashed. Either one can serve as our gaussian surface. Example 22–8.

**CAUTION**
*When is $E = \sigma/\epsilon_0$ and when is $E = \sigma/2\epsilon_0$*

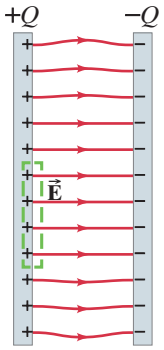
Why is it that the field outside a large plane nonconductor is $E = \sigma/2\epsilon_0$ (Example 22–7) whereas outside a conductor (Example 22–8) it is $E = \sigma/\epsilon_0$? The reason for the factor of 2 comes from how we *define* charge per unit area $\sigma$. For a thin flat nonconductor, Fig. 22–16, the charge is distributed throughout the volume (not only on the surface, as for a conductor). Perhaps more simply, we see in Fig. 22–16 that the electric field appears on *both* sides of the thin nonconductor. But for a conductor, the field appears on only one side, Fig. 22–17 (being zero inside the conductor).

Example 22–8 gives us, in a simple way, the field between the two parallel plates we discussed in Fig. 21–32, Example 21–14. If the plates are large compared to their separation, the field lines are perpendicular to the plates and, except near the edges, they are parallel to each other. Therefore the electric field (see Fig. 22–18, which shows a similar very thin gaussian surface as Fig. 22–17) is also

$$E = \frac{\sigma}{\epsilon_0} \qquad \left[\begin{array}{l}\text{between two closely spaced,}\\ \text{oppositely charged, parallel plates}\end{array}\right]$$

which is Eq. 21–8, pages 625 and 626.

We saw in Section 21–9 that the static electric field inside any conductor must be zero, even if it has a net charge. (Otherwise, the free charges in the conductor would move—until the net force on each charge, and hence $\vec{\mathbf{E}}$, were zero.) We also mentioned that any net electric charge on a conductor must all reside on its outer surface. This is readily shown using Gauss's law. Consider a conductor of any shape, carrying a net charge $Q$, such as that shown in Fig. 22–19. We choose the gaussian surface (dashed) so that it all lies just below the surface of the conductor and encloses the whole volume of the conductor, but still *inside* the conductor. The electric field is zero at all points on this gaussian surface because it is inside the conductor. From Gauss's law, Eq. 22–4, the net charge within the surface must be zero. Thus *there can be no net charge within the conductor, and any net charge must lie on the surface.*



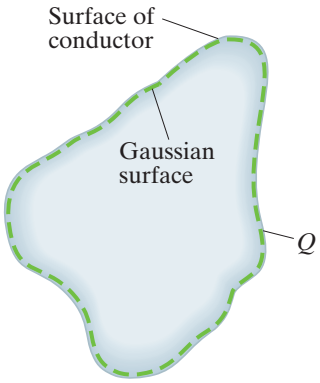


**FIGURE 22–18** The electric field between two closely spaced parallel plates is uniform and equal to $E = \sigma/\epsilon_0$.

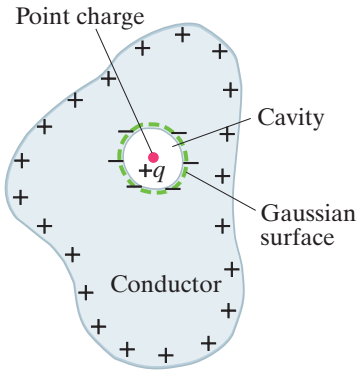

**FIGURE 22–19** An insulated charged conductor of arbitrary shape, showing a gaussian surface (dashed) just below the surface of the conductor.

**CONCEPTUAL EXAMPLE 22–9** **Conductor with charge inside a cavity.** Suppose a conductor carries a net charge $+Q$ and contains a cavity. (*a*) Inside the cavity resides a point charge $+q$. What can you say about the charges on the inner and outer surfaces of the conductor? (*b*) What if $q = 0$ (cavity empty)?

**RESPONSE** (*a*) As shown in Fig. 22–20, a gaussian surface (dashed, green) just inside the conductor surrounding the cavity must contain zero net charge ($E = 0$ in a conductor). Thus a net charge of $-q$ must exist on the cavity surface. The conductor itself carries a net charge $+Q$, so the outer surface of the conductor must carry a total charge equal to $Q + q$. These results apply to a cavity of any shape. (*b*) If the cavity is empty, $q = 0$, there is no net charge at the surface of the cavity, and the outer surface of the conductor carries charge $Q$.

**FIGURE 22–20** Example 22–9.

**EXERCISE E** Which of the following statements about Gauss's law is correct? (*a*) If we know the charge enclosed by a surface, we always know the electric field everywhere at the surface. (*b*) When finding the electric field with Gauss's law, we always use a sphere for the gaussian surface. (*c*) If we know the total flux through a surface, we also know the total charge inside the surface. (*d*) We can only use Gauss's law if the electric field is constant in space.

PROBLEM SOLVING

## Gauss's Law for Symmetric Charge Distributions

1. First identify the **symmetry** of the charge distribution: spherical, cylindrical, planar. This identification should suggest a gaussian surface for which $\vec{\mathbf{E}}$ will be constant and/or zero on all or on parts of the surface: a sphere for spherical symmetry, a cylinder for cylindrical symmetry and a small cylinder or "pillbox" for planar symmetry.
2. Draw the appropriate gaussian surface making sure it passes through the point where you want to know the electric field.
3. Use the symmetry of the charge distribution to determine the direction of $\vec{\mathbf{E}}$ at points on the gaussian surface.
4. Evaluate the flux, $\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}}$. With an appropriate gaussian surface, the dot product $\vec{\mathbf{E}} \cdot d\vec{\mathbf{A}}$ should be zero or equal to $\pm E\, dA$, with the magnitude of $E$ being constant over all or parts of the surface.
5. Determine the charge *enclosed* by the gaussian surface. Remember, it is the enclosed charge that matters. Ignore all the charge outside the gaussian surface.
6. Equate the flux to the enclosed charge and solve for $E$.

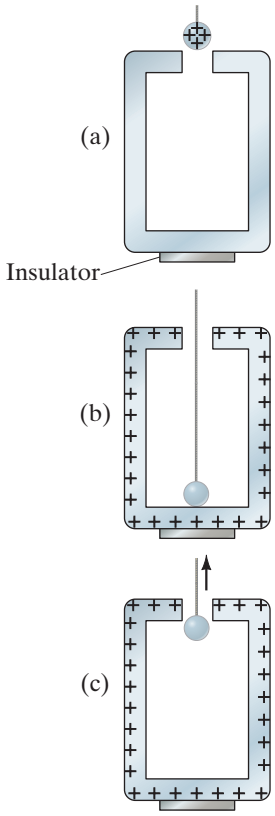

**FIGURE 22–21** (a) A charged conductor (metal ball) is lowered into an insulated metal can (a good conductor) carrying zero net charge. (b) The charged ball is touched to the can and all of its charge quickly flows to the outer surface of the can. (c) When the ball is then removed, it is found to carry zero net charge.

## *22–4 Experimental Basis of Gauss's and Coulomb's Laws

Gauss's law predicts that any net charge on a conductor must lie only on its surface. But is this true in real life? Let us see how it can be verified experimentally. And in confirming this prediction of Gauss's law, Coulomb's law is also confirmed since the latter follows from Gauss's law, as we saw in Section 22–2. Indeed, the earliest observation that charge resides only on the outside of a conductor was recorded by Benjamin Franklin some 30 years before Coulomb stated his law.

A simple experiment is illustrated in Fig. 22–21. A metal can with a small opening at the top rests on an insulator. The can, a conductor, is initially uncharged (Fig. 22–21a). A charged metal ball (also a conductor) is lowered by an insulating thread into the metal can, and is allowed to touch the can (Fig. 22–21b). The ball and metal can now form a single conductor. Gauss's law, as discussed above, predicts that all the charge will flow to the outer surface of the can. (The flow of charge in such situations does not occur instantaneously, but the time involved is usually negligible.) These predictions are confirmed in experiments by (1) connecting an electroscope to the can, which will show that the can is charged, and (2) connecting an electroscope to the ball after it has been withdrawn from the can (Fig. 22–21c), which will show that the ball carries zero charge.

The precision with which Coulomb's and Gauss's laws hold can be stated quantitatively by writing Coulomb's law as

$$F = k\frac{Q_1 Q_2}{r^{2+\delta}}.$$

For a perfect inverse-square law, $\delta = 0$. The most recent and precise experiments give $\delta = (1.0 \pm 1.2) \times 10^{-16}$. Thus Coulomb's and Gauss's laws are found to be valid to an extremely high precision!

## Summary

The **electric flux** passing through a flat area $A$ for a uniform electric field $\vec{\mathbf{E}}$ is

$$\Phi_E = \vec{\mathbf{E}} \cdot \vec{\mathbf{A}}. \qquad \textbf{(22–1b)}$$

If the field is not uniform, the flux is determined by integrating over the area:

$$\Phi_E = \int \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}}. \qquad \textbf{(22–2)}$$

The direction of the vector $\vec{\mathbf{A}}$ or $d\vec{\mathbf{A}}$ is chosen to be perpendicular to the surface whose area is $A$ or $dA$, and points outward from an enclosed surface. The flux through a surface is proportional to the number of field lines passing through it.

**Gauss's law** states that the net flux passing through any closed surface is equal to the net charge $Q_{\text{encl}}$ enclosed by the surface divided by $\epsilon_0$:

$$\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = \frac{Q_{\text{encl}}}{\epsilon_0}. \qquad \textbf{(22–4)}$$

Gauss's law can in principle be used to determine the electric field due to a given charge distribution, but its usefulness is mainly limited to a small number of cases, usually where the charge distribution displays much symmetry. The real importance of Gauss's law is that it is a more general and elegant statement (than Coulomb's law) for the relation between electric charge and electric field. It is one of the basic equations of electromagnetism.

# Questions

1. If the electric flux through a closed surface is zero, is the electric field necessarily zero at all points on the surface? Explain. What about the converse: If $\vec{\mathbf{E}} = 0$ at all points on the surface is the flux through the surface zero?
2. Is the electric field $\vec{\mathbf{E}}$ in Gauss's law, $\oint \vec{\mathbf{E}} \cdot d\vec{\mathbf{A}} = Q_{\text{encl}}/\epsilon_0$, created only by the charge $Q_{\text{encl}}$?
3. What can you say about the flux through a closed surface that encloses an electric dipole?
4. The electric field $\vec{\mathbf{E}}$ is zero at all points on a closed surface; is there necessarily no net charge within the surface? If a surface encloses zero net charge, is the electric field necessarily zero at all points on the surface?
5. Define gravitational flux in analogy to electric flux. Are there "sources" and "sinks" for the gravitational field as there are for the electric field? Discuss.
6. Would Gauss's law be helpful in determining the electric field due to an electric dipole?
7. A spherical basketball (a nonconductor) is given a charge $Q$ distributed uniformly over its surface. What can you say about the electric field inside the ball? A person now steps on the ball, collapsing it, and forcing most of the air out without altering the charge. What can you say about the field inside now?
8. In Example 22–6, it may seem that the electric field calculated is due only to the charge on the wire that is enclosed by the cylinder chosen as our gaussian surface. In fact, the entire charge along the whole length of the wire contributes to the field. Explain how the charge outside the cylindrical gaussian surface of Fig. 22–15 contributes to $E$ at the gaussian surface. [*Hint*: Compare to what the field would be due to a short wire.]
9. Suppose the line of charge in Example 22–6 extended only a short way beyond the ends of the cylinder shown in Fig. 22–15. How would the result of Example 22–6 be altered?
10. A point charge $Q$ is surrounded by a spherical surface of radius $r_0$, whose center is at C. Later, the charge is moved to the right a distance $\frac{1}{2}r_0$, but the sphere remains where it was, Fig. 22–22. Is the electric flux $\Phi_E$ through the sphere changed? Is the electric field at the surface of the sphere changed? For each "yes" answer, describe the change.

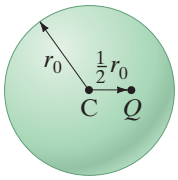

**FIGURE 22–22** Question 10.

11. A solid conductor carries a net positive charge $Q$. There is a hollow cavity within the conductor, at whose center is a negative point charge $-q$ (Fig. 22–23). What is the charge on (*a*) the outer surface of the conductor and (*b*) the inner surface of the conductor's cavity?

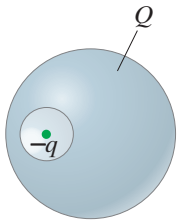

**FIGURE 22–23** Question 11.

12. A point charge $q$ is placed at the center of the cavity of a thin metal shell which is neutral. Will a charge $Q$ placed outside the shell feel an electric force? Explain.
13. A small charged ball is inserted into a balloon. The balloon is then blown up slowly. Describe how the flux through the balloon's surface changes as the balloon is blown up. Consider both the total flux and the flux per unit surface area of the balloon.

# MisConceptual Questions

1. A point charge is surrounded by a spherical gaussian surface of radius $r$. If the sphere is replaced by a cube of side $r$, $\Phi_E$ will be
   (*a*) larger.
   (*b*) smaller.
   (*c*) the same.
2. A charge $Q$ is placed on a hollow metal ball. We saw in Chapter 21 that the charge is all on the surface of the ball because metal is a conductor. How does the charge distribute itself on the ball?
   (*a*) Half on the inside surface and half on the outside surface.
   (*b*) Part on each surface in inverse proportion to the two radii.
   (*c*) Part on each surface but with a more complicated dependence on the radii than in answer (*b*).
   (*d*) All on the inside surface.
   (*e*) All on the outside surface.
3. Which statement below is correct for using Gauss's law to find the electric field at any point on the surface of the non-conducting object shown in Fig. 22–24 below?
   (*a*) Gauss's law doesn't hold for this object as there is insufficient symmetry.
   (*b*) Gauss's law is true but not useful for this situation.
   (*c*) Gauss's law is useful in this situation; just draw an imaginary gaussian sphere just inside the shape.
   (*d*) Gauss's law is useful in this situation; just draw an imaginary gaussian sphere just outside the shape.

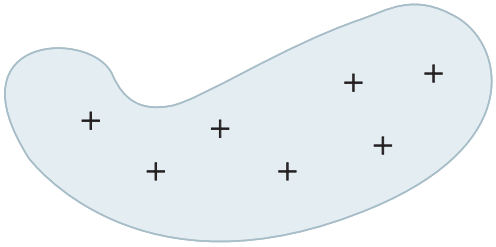

**FIGURE 22–24** MisConceptual Question 3.

**4.** If the Earth has a large charge $+Q$ uniformly distributed over its surface, it generates an electric field of strength $E$ at its surface. If this same charge were uniformly distributed over the Moon, what electric field strength would exist at the Moon's surface? The Moon's radius is about one-quarter that of the Earth.
(*a*) $16E$. (*b*) $4E$. (*c*) $E$.
(*d*) $\frac{1}{4}E$. (*e*) $\frac{1}{16}E$.

**5.** A $+Q$ point charge is located at the center of a hollow metal sphere. The sphere is also charged, carrying an equal but opposite total charge of $-Q$. Consider the region between the point charge and the inside of the spherical shell. Which statement is true?
(*a*) The electric field is only due to the point charge ($E = kQ/r^2$ pointing out).
(*b*) The electric field is zero.
(*c*) The electric field is twice that due to the point charge.
(*d*) The electric field is larger than for the point charge, but not twice as large.

**6.** For the situation described in MisConceptual Question 5, consider the region outside the spherical metal shell. Which statement is true?
(*a*) The electric field is just that due to the point charge ($E = kQ/r^2$ pointing out).
(*b*) The electric field is $kQ/r^2$ pointing in.
(*c*) The electric field points in, but is not $kQ/r^2$.
(*d*) The electric field is zero.
(*e*) The electric field points out, but is not $kQ/r^2$.

**7.** Two charged flies are buzzing around inside a sealed uncharged paper bag. The total electric flux exiting the bag is zero. Which statement is true?
(*a*) The total flux cannot be zero since the flies are charged.
(*b*) The electric field at the surface of the bag is zero.
(*c*) The flies have equal and opposite charges.
(*d*) The induced charge on the bag itself cancels out the charge on the flies to give zero flux.

**8.** A point charge, $+Q$, is at the center of a metal cubical box of side $S$. The metal box carries a net charge $-3Q$. Why can't you use Gauss's law to show that the electric field at all points just outside the box is given by $E = -2Q/(S^2\epsilon_0)$?
(*a*) Gauss's law only applies to spherical and cylindrical surfaces.
(*b*) The answer is really $E = -2Q/(6S^2\epsilon_0)$.
(*c*) The enclosed charge is $4Q$.
(*d*) The electric field is not uniform across a side of the box.
(*e*) $E = -2Q/(4\pi S^2\epsilon_0)$.

**9.** What charge would you put in Gauss's law in order to calculate the electric field at point A in Fig. 22–25? The outer conducting shell has a total charge of +2 C. The middle layer of the sphere is an insulator, and the innermost sphere is hollow with a charge of −3 C at the center.
(*a*) 0 C. (*b*) 2 C.
(*c*) −3 C. (*d*) −1 C.
(*e*) Gauss's law won't work for this situation.

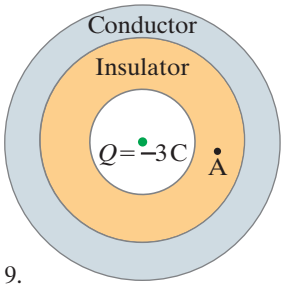

**FIGURE 22–25**
MisConceptual Question 9.

**10.** A nonconducting sphere of radius $r_0$ contains a net charge $+Q$, distributed uniformly. Which statements are not true regarding the electric field due to the charge on this sphere?
(*a*) The electric field above the surface of the sphere is uniform, nonzero, and points outward.
(*b*) The electric field outside the sphere is constant since the charge enclosed by a gaussian sphere concentric with the charged sphere is constant for any $r > r_0$.
(*c*) The electric field is 0 at the center of the sphere.
(*d*) The electric field is constant inside the sphere because for concentric gaussian spheres inside the charged sphere, the surface area and volume enclosed both increase with $r$.
(*e*) At $r = r_0/2$, the electric field has half the value of the electric field on the surface of the sphere.

# Problems

## 22–1 Electric Flux

**1.** (I) A uniform electric field of magnitude $6.4 \times 10^2$ N/C passes through a circle of radius 13 cm. What is the electric flux through the circle when its face is (*a*) perpendicular to the field lines, (*b*) at 45° to the field lines, and (*c*) parallel to the field lines?

**2.** (I) The Earth possesses an electric field of (average) magnitude 150 N/C near its surface. The field points radially inward. Calculate the net electric flux outward through a spherical surface surrounding, and just beyond, the Earth's surface.

**3.** (II) A cube of side $\ell$ is placed in a uniform field $E_0$ with edges parallel to the field lines. (*a*) What is the net flux through the cube? (*b*) What is the flux through each of its six faces?

**4.** (II) A uniform field $\vec{\mathbf{E}}$ is parallel to the axis of a hollow hemisphere of radius $r$, Fig. 22–26. (*a*) What is the electric flux through the hemispherical surface? (*b*) What is the result if $\vec{\mathbf{E}}$ is instead vertical, perpendicular to the axis and still uniform?

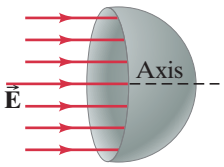

**FIGURE 22–26** Problem 4.

## 22–2 Gauss's Law

**5.** (I) The total electric flux out from a cubical box of side 21.0 cm is $1.85 \times 10^3$ N·m²/C. What charge is enclosed by the box?

**6.** (I) Figure 22–27 shows five closed surfaces that surround various charges in a plane, as indicated. Determine the electric flux through each surface, $S_1$, $S_2$, $S_3$, $S_4$, and $S_5$. The surfaces are flat "pillbox" surfaces that extend only slightly above and below the plane in which the charges lie.

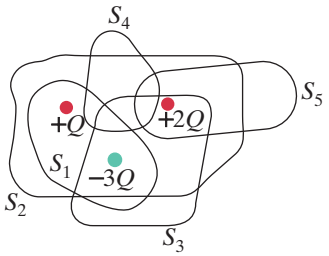

**FIGURE 22–27** Problem 6.

7. (II) In Fig. 22–28, two objects, $O_1$ and $O_2$, have charges $+1.0\,\mu C$ and $-2.0\,\mu C$, respectively, and a third object, $O_3$, is electrically neutral. (*a*) What is the electric flux through the surface $A_1$ that encloses all the three objects? (*b*) What is the electric flux through the surface $A_2$ that encloses the third object only?

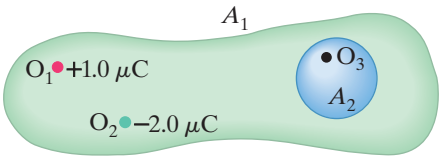

**FIGURE 22–28** Problem 7.

8. (II) A thin circular ring of charge with uniform linear charge density (as in Fig. 21–29) is completely enclosed by an imaginary hollow donut shape. An exact copy of the ring is completely enclosed by an imaginary hollow sphere. What is the ratio of the flux out of the donut shape to that out of the sphere?

9. (II) In a certain region of space, the electric field is constant in direction (say horizontal, in the $x$ direction), but its magnitude decreases from $E = 650\,N/C$ at $x = 0$ to $E = 370\,N/C$ at $x = 25\,m$. Determine the charge within a cubical box of side $\ell = 25\,m$, where the box is oriented so that four of its sides are parallel to the field lines (Fig. 22–29).

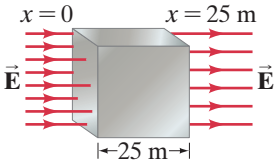

**FIGURE 22–29** Problem 9.

10. (II) A point charge $Q$ is placed at the center of a cube of side $\ell$. What is the flux through one face of the cube?

11. (II) A 25.0-cm-long uniformly charged plastic rod is sealed inside a plastic bag. The total electric flux leaving the bag is $7.3 \times 10^5\,N \cdot m^2/C$. What is the linear charge density on the rod?

## 22–3 Applications of Gauss's Law

12. (I) Draw the electric field lines around a negatively charged metal egg.

13. (I) The field just outside a 3.50-cm-radius metal sphere is $5.85 \times 10^2\,N/C$ and points toward the sphere. What charge resides on the sphere?

14. (I) Starting from the result of Example 22–3, show that the electric field just outside a uniformly charged spherical conductor is $E = \sigma/\epsilon_0$, consistent with Example 22–8.

15. (I) A long thin wire, hundreds of meters long, carries a uniformly distributed charge of $-8.4\,\mu C$ per meter of length. Estimate the magnitude and direction of the electric field at points (*a*) 5.0 m, and (*b*) 1.5 m, perpendicular from the center of the wire.

16. (I) A metal globe of the Earth has 1.50 mC of charge put on it at the north pole. Then $-3.00$ mC of charge is applied to the south pole. Draw the field lines for this system after it has come to equilibrium.

17. (II) A point charge $Q$ rests at the center of an uncharged thin spherical conducting shell. (See Fig. 22–30.) What is the electric field $E$ as a function of $r$ (*a*) for $r$ less than the inner radius of the shell, (*b*) inside the shell, and (*c*) beyond the shell? (*d*) How does the shell affect the field due to $Q$ alone? (*e*) How does the charge $Q$ affect the shell?

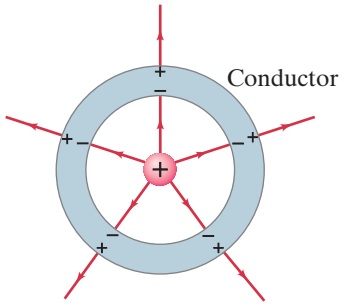

**FIGURE 22–30** Problem 17.

18. (II) A solid metal sphere of radius 3.00 m carries a total charge of $-4.80\,\mu C$. What is the magnitude of the electric field at a distance from the sphere's center of (*a*) 0.250 m, (*b*) 2.90 m, (*c*) 3.10 m, and (*d*) 8.00 m? How would the answers differ if the sphere were (*e*) a thin shell, or (*f*) a solid nonconductor uniformly charged throughout?

19. (II) A 15.0-cm-diameter nonconducting sphere carries a total charge of $3.25\,\mu C$ distributed uniformly throughout its volume. Graph the electric field $E$ as a function of the distance $r$ from the center of the sphere from $r = 0$ to $r = 30.0$ cm.

20. (II) A flat square sheet of thin aluminum foil, 25 cm on a side, carries a uniformly distributed 245 nC charge. What, approximately, is the electric field (*a*) 1.0 cm above the center of the sheet and (*b*) 15 m above the center of the sheet?

21. (II) A spherical cavity of radius 4.50 cm is at the center of a metal sphere of radius 18.0 cm. A point charge $Q = 6.50\,\mu C$ rests at the very center of the cavity, whereas the metal conductor carries no net charge. Determine the electric field at a point (*a*) 3.00 cm from the center of the cavity, (*b*) 6.00 cm from the center of the cavity, (*c*) 30.0 cm from the center.

22. (II) A solid nonconducting sphere of radius 12.0 cm is made of two layers. The innermost section has a radius of 6.0 cm and a uniform charge density of $-4.0\,C/m^3$. The outer layer has a uniform charge density of $+9.0\,C/m^3$. Determine the electric field for (*a*) $0 < r < 6.0$ cm, (*b*) $6.0\text{ cm} < r < 12.0$ cm, and (*c*) $12.0\text{ cm} < r < 50.0$ cm. (*d*) Plot the magnitude of the electric field for $0 < r < 50.0$ cm. Is the field continuous at the edges of the layers?

23. (II) A solid metal cube has a spherical cavity right at its center. At the center of the cavity there is a point charge $Q = +8.00\,\mu C$. The metal cube carries a net charge $q = -6.40\,\mu C$ (not including $Q$). Determine (*a*) the total charge on the surface of the spherical cavity and (*b*) the total charge on the outer surface of the cube.

**24.** (II) Two large, flat metal plates are separated by a distance that is very small compared to their height and width. The conductors are given equal but opposite uniform surface charge densities $\pm\sigma$. Ignore edge effects and use Gauss's law to show (*a*) that for points far from the edges, the electric field between the plates is $E = \sigma/\epsilon_0$ and (*b*) that outside the plates on either side the field is zero. (*c*) How would your results be altered if the two plates were nonconductors? (See Fig. 22–31).

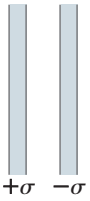

**FIGURE 22–31**
Problems 24, 25, and 26.

**25.** (II) Suppose the two conducting plates in Problem 24 have the *same* sign and magnitude of charge. What then will be the electric field (*a*) between them and (*b*) outside them on either side? (*c*) What if the plates are nonconducting?

**26.** (II) The electric field between two parallel square metal plates is 130 N/C. The plates are 0.65 m on a side and are separated by 3.0 cm. What is the charge on each plate (assume equal and opposite)? Neglect edge effects.

**27.** (II) Two thin concentric spherical shells of radii $r_1$ and $r_2$ $(r_1 < r_2)$ contain uniform surface charge densities $\sigma_1$ and $\sigma_2$, respectively (see Fig. 22–32). Determine the electric field for (*a*) $0 < r < r_1$, (*b*) $r_1 < r < r_2$, and (*c*) $r > r_2$. (*d*) Under what conditions will $E = 0$ for $r > r_2$? (*e*) Under what conditions will $E = 0$ for $r_1 < r < r_2$? Neglect the thickness of the shells.

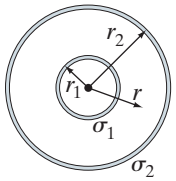

**FIGURE 22–32** Two spherical shells (Problem 27).

**28.** (II) A spherical rubber balloon carries a total charge $Q$ uniformly distributed on its surface. At $t = 0$ the nonconducting balloon has radius $r_0$ and the balloon is then slowly blown up so that $r$ increases linearly to $2r_0$ in a time $T$. Determine the electric field as a function of time (*a*) just outside the balloon surface and (*b*) at $r = 3.2r_0$.

**29.** (II) Suppose the nonconducting sphere of Example 22–4 has a spherical cavity of radius $r_1$ centered at the sphere's center (Fig. 22–33). Assuming the charge $Q$ is distributed uniformly in the "shell" (between $r = r_1$ and $r = r_0$), determine the electric field as a function of $r$ for (*a*) $0 < r < r_1$, (*b*) $r_1 < r < r_0$, and (*c*) $r > r_0$.

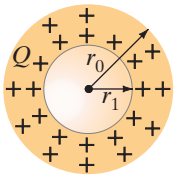

**FIGURE 22–33**
Problems 29, 30, 31, and 44.

**30.** (II) Suppose in Fig. 22–33, Problem 29, there is also a charge $-q$ at the center of the cavity. Determine the electric field for (*a*) $0 < r < r_1$, (*b*) $r_1 < r < r_0$, and (*c*) $r > r_0$.

**31.** (II) Suppose the thick spherical shell of Problem 29 is a conductor. It carries a total net charge $Q$ and at its center there is a point charge $+q$. What total charge is found on (*a*) the inner surface of the shell and (*b*) the outer surface of the shell? Determine the electric field for (*c*) $0 < r < r_1$, (*d*) $r_1 < r < r_0$, and (*e*) $r > r_0$.

**32.** (II) Suppose that at the center of the cavity inside the shell (charge $Q$) of Fig. 22–11 (and Example 22–3), there is a point charge $q$ $(\neq \pm Q)$. Determine the electric field for (*a*) $0 < r < r_0$ and for (*b*) $r > r_0$. What are your answers if (*c*) $q = Q$ and (*d*) $q = -Q$?

**33.** (II) A long cylindrical shell of radius $R_0$ and length $\ell$ $(R_0 \ll \ell)$ possesses a uniform surface charge density (charge per unit area) $\sigma$ (Fig. 22–34). Determine the electric field at points $R$: (*a*) outside the cylinder $(R > R_0)$ and (*b*) inside the cylinder $(0 < R < R_0)$; assume the points are far from the ends and not too far from the shell $(R \ll \ell)$. (*c*) Compare to the result for a long line of charge, Example 22–6. Neglect the thickness of shell.

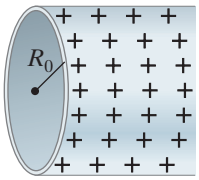

**FIGURE 22–34**
Problem 33.

**34.** (II) A very long solid nonconducting cylinder of radius $R_0$ and length $\ell$ $(R_0 \ll \ell)$ possesses a uniform volume charge density $\rho_E\,(\mathrm{C/m^3})$, Fig. 22–35. Determine the electric field at points (*a*) outside the cylinder $(R > R_0)$ and (*b*) inside the cylinder $(R < R_0)$. Do only for points far from the ends and for which $R \ll \ell$.

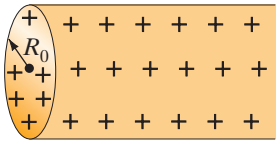

**FIGURE 22–35**
Problem 34.

**35.** (II) A thin cylindrical shell of radius $R_1$ is surrounded by a second concentric cylindrical shell of radius $R_2$ (Fig. 22–36). The inner shell has a total charge $+Q$ and the outer shell $-Q$. Assuming the length $\ell$ of the shells is much greater than $R_1$ or $R_2$, determine the electric field as a function of $R$ (the perpendicular distance from the common axis of the cylinders) for (*a*) $0 < R < R_1$, (*b*) $R_1 < R < R_2$, and (*c*) $R > R_2$. (*d*) What is the kinetic energy of an electron if it moves between (and concentric with) the shells in a circular orbit of radius $(R_1 + R_2)/2$? Neglect thickness of shells.

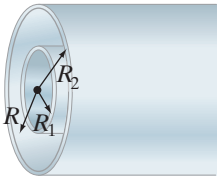

**FIGURE 22–36**
Problems 35, 36, and 37.

**36.** (II) A thin cylindrical shell of radius $R_1 = 4.5$ cm is surrounded by a second cylindrical shell of radius $R_2 = 9.0$ cm, as in Fig. 22–36. Both cylinders are 5.0 m long and the inner one carries a total charge $Q_1 = -0.88$ nC and the outer one $Q_2 = +1.56$ nC. For points far from the ends of the cylinders, determine the electric field at a radial distance $R$ from the central axis of (*a*) 3.0 cm, (*b*) 7.0 cm, and (*c*) 12.0 cm.

**37.** (II) (*a*) If an electron $(m = 9.1 \times 10^{-31}\,\mathrm{kg})$ escaped from the surface of the inner cylinder in Problem 36 (Fig. 22–36) with negligible speed, what would be its speed when it reached the outer cylinder? (*b*) If a proton $(m = 1.67 \times 10^{-27}\,\mathrm{kg})$ revolves in a circular orbit of radius $R = 7.0$ cm about the axis (i.e., between the cylinders), what must be its speed?

**38.** (II) A nonconducting sphere of radius $r_0$ is uniformly charged with volume charge density $\rho_E$. It is surrounded by a concentric metal (conducting) spherical shell of inner radius $r_1$ and outer radius $r_2$, which carries a net charge $+Q$. Determine the resulting electric field in the regions (*a*) $0 < r < r_0$, (*b*) $r_0 < r < r_1$, (*c*) $r_1 < r < r_2$, and (*d*) $r > r_2$ where the radial distance $r$ is measured from the center of the nonconducting sphere.

**39.** (II) A very long solid nonconducting cylinder of radius $R_1$ is uniformly charged with a volume charge density $\rho_E$. It is surrounded by a concentric cylindrical tube of inner radius $R_2$ and outer radius $R_3$ as shown in Fig. 22–37, and it too carries a uniform charge density $\rho_E$. Determine the electric field as a function of the distance $R$ from the center of the cylinders for (*a*) $0 < R < R_1$, (*b*) $R_1 < R < R_2$, (*c*) $R_2 < R < R_3$, and (*d*) $R > R_3$. (*e*) If $\rho_E = 15\,\mu C/m^3$ and $R_1 = \frac{1}{2}R_2 = \frac{1}{3}R_3 = 5.0$ cm, plot $E$ as a function of $R$ from $R = 0$ to $R = 20.0$ cm. Assume the cylinders are very long compared to $R_3$.

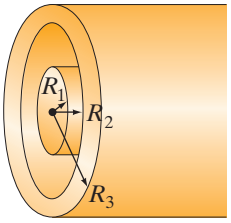

**FIGURE 22–37**
Problem 39.

**40.** (II) A very long solid nonconducting cylinder of radius $R_1$ is uniformly charged with charge density $\rho_E$. It is surrounded by a cylindrical metal (conducting) tube of inner radius $R_2$ and outer radius $R_3$, which has no net charge (cross-sectional view shown in Fig. 22–38). If the axes of the two cylinders are parallel, but displaced from each other by a distance $d$, determine the resulting electric field in the region $R > R_3$, where the radial distance $R$ is measured from the metal cylinder's axis. Assume $d < (R_2 - R_1)$.

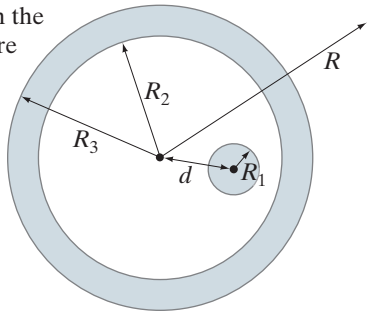

**FIGURE 22–38**
Problem 40.

**41.** (II) A flat disk-like ring (inner radius $R_0$, outer radius $4R_0$) is uniformly charged. In terms of the total charge $Q$, determine the electric field on the axis at points (*a*) $0.25R_0$ and (*b*) $75R_0$ from the center of the ring. [*Hint*: The ring can be replaced with two oppositely charged superposed disks.]

**42.** (II) An uncharged solid conducting sphere of radius $r_0$ contains two spherical cavities of radii $r_1$ and $r_2$, respectively. Point charge $Q_1$ is then placed within the cavity of radius $r_1$ and point charge $Q_2$ is placed within the cavity of radius $r_2$ (Fig. 22–39). Determine the resulting electric field (magnitude and direction) at locations outside the solid sphere ($r > r_0$), where $r$ is the distance from its center.

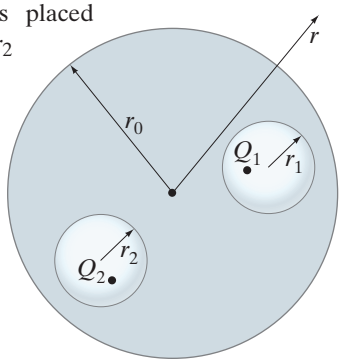

**FIGURE 22–39**
Problem 42.

**43.** (III) A very large (i.e., assume infinite) flat slab of nonconducting material has thickness $d$ and a uniform volume charge density $+\rho_E$. (*a*) Show that a uniform electric field exists outside of this slab. Determine its magnitude $E$ and its direction (relative to the slab's surface). (*b*) As shown in Fig. 22–40, the slab is now aligned so that one of its surfaces lies on the line $y = x$. At time $t = 0$, a pointlike particle (mass $m$, charge $+q$) is located at position $\vec{\mathbf{r}} = +y_0\,\hat{\mathbf{j}}$ and has velocity $\vec{\mathbf{v}} = v_0\,\hat{\mathbf{i}}$. Show that the particle will collide with the slab if $v_0 \geq \sqrt{\sqrt{2}qy_0\rho_E d/\epsilon_0 m}$. Ignore gravity.

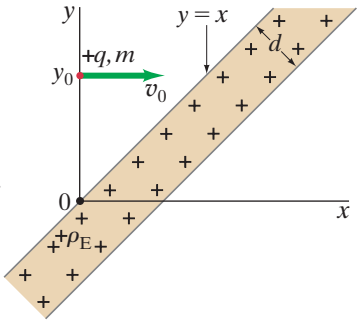

**FIGURE 22–40**
Problem 43.
Cross-section of slab.

**44.** (III) Suppose the density of charge between $r_1$ and $r_0$ of the hollow sphere of Problem 29 (Fig. 22–33) varies as a function of $r$ as $\rho_E = \rho_0 r_1/r$. Determine the electric field as a function of $r$ for (*a*) $0 < r < r_1$, (*b*) $r_1 < r < r_0$, and (*c*) $r > r_0$. (*d*) Plot $E$ versus $r$ from $r = 0$ to $r = 2r_0$, assuming $r_1 = 0.50\,r_0$.

**45.** (III) Suppose two thin flat nonconducting plates measure $1.0\text{ m} \times 1.0\text{ m}$ and are separated by 5.0 mm. They are oppositely charged with $\pm 25\,\mu C$. (*a*) Estimate the total force exerted by one plate on the other (ignore edge effects). (*b*) How much work would be required to move the plates from 5.0 mm apart to 1.00 cm apart?

**46.** (III) A flat slab of nonconducting material (Fig. 22–41) carries a uniform charge per unit volume, $\rho_E$. The slab has thickness $d$ which is small compared to the height and breadth of the slab. Determine the electric field as a function of $x$ (*a*) inside the slab and (*b*) outside the slab (at distances much less than the slab's height or breadth). Take the origin at the center of the slab.

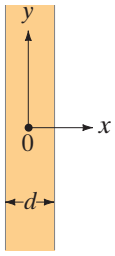

**FIGURE 22–41**
Problem 46.

**47.** (III) A flat slab of nonconducting material has thickness $2d$, which is small compared to its height and breadth. Define the $x$ axis to be along the direction of the slab's thickness with the origin at the center of the slab (Fig. 22–42). If the slab carries a volume charge density $\rho_E(x) = -\rho_0$ in the region $-d \leq x < 0$, and $\rho_E(x) = +\rho_0$ in the region $0 < x \leq +d$, determine the electric field $\vec{\mathbf{E}}$ as a function of $x$ in the regions (*a*) outside the slab, (*b*) $0 < x \leq +d$, and (*c*) $-d \leq x < 0$. Let $\rho_0$ be a positive constant.

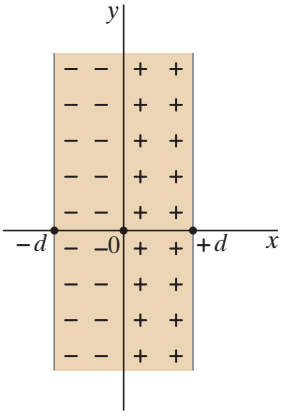

**FIGURE 22–42**
Problem 47.

**48.** (III) An extremely long, solid nonconducting cylinder has a radius $R_0$. The charge density within the cylinder is a function of the distance $R$ from the axis, given by $\rho_E(R) = \rho_0(R/R_0)^2$. What is the electric field everywhere inside and outside the cylinder (far away from the ends) in terms of $\rho_0$ and $R_0$?

**49.** (III) Charge is distributed within a solid sphere of radius $r_0$ in such a way that the charge density is a function of the radial position within the sphere of the form: $\rho_E(r) = \rho_0(r/r_0)$. If the total charge within the sphere is $Q$ (and positive), what is the electric field everywhere within the sphere in terms of $Q$, $r_0$, and the radial position $r$?

# General Problems

**50.** A point charge produces an electric flux of $+235\,\text{N}\cdot\text{m}^2/\text{C}$ through a gaussian sphere of radius 45.0 cm centered on the charge. (*a*) What is the flux through a gaussian sphere with a radius 32.5 cm? (*b*) What is the magnitude and sign of the charge?

**51.** A point charge of 8.20 nC is located at the origin and a second charge of $-5.00$ nC is located on the $x$ axis at $x = 2.75$ cm. Calculate the electric flux through a sphere centered at the origin with radius 1.00 m. Repeat the calculation for a sphere of radius 2.00 m.

**52.** The Earth is surrounded by an electric field, pointing inward at every point, of magnitude $E \approx 150\,\text{N/C}$ near the Earth's surface. (*a*) What is the net charge on the Earth? (*b*) How many excess electrons per square meter on the Earth's surface does this correspond to?

**53.** Write Gauss's law for the gravitational field $\vec{\mathbf{g}}$ (see Section 6–8).

**54.** A solid nonconducting sphere of radius $r_0$ has a total charge $Q$ which is distributed according to $\rho_E = br$, where $\rho_E$ is the charge per unit volume, or charge density $(\text{C/m}^3)$, and $b$ is a constant. Determine (*a*) $b$ in terms of $Q$, (*b*) the electric field at points inside the sphere, and (*c*) the electric field at points outside the sphere.

**55.** A cube of side $\ell$ has one corner at the origin of coordinates, and extends along the positive $x$, $y$, and $z$ axes. Suppose the electric field in this region is given by $\vec{\mathbf{E}} = (ay + b)\hat{\mathbf{j}}$. Determine the charge inside the cube.

**56.** Three large but thin charged sheets are parallel to each other as shown in Fig. 22–43. Sheet I has a total surface charge density of $7.5\,\text{nC/m}^2$, sheet II has a charge density of $-3.0\,\text{nC/m}^2$, and sheet III has a charge density of $6.0\,\text{nC/m}^2$. Estimate the force per unit area on each sheet, in $\text{N/m}^2$.

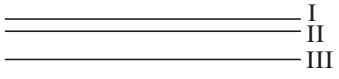

**FIGURE 22–43** Problem 56.

**57.** A point charge $Q$ is placed a distance $r_0/2$ above the surface of an imaginary spherical surface of radius $r_0$ (Fig. 22–44). (*a*) What is the total electric flux through the sphere? (*b*) What range of values does $E$ have at the surface of the sphere? (*c*) Is $\vec{\mathbf{E}}$ perpendicular to the sphere at all points? (*d*) Is Gauss's law useful for obtaining $E$ at the surface of the sphere?

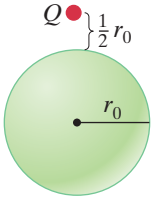

**FIGURE 22–44** Problem 57.

**58.** A point charge $Q$ is on the axis of a short cylinder at its center. The diameter of the cylinder is equal to its length $\ell$ (Fig. 22–45). What is the total flux through the curved sides of the cylinder? [*Hint*: First calculate the flux through the ends.]

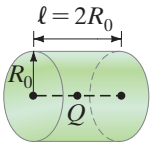

**FIGURE 22–45** Problem 58.

**59.** The neutral hydrogen atom can be modeled as a positive point charge $+1.6 \times 10^{-19}$ C surrounded by a distribution of negative charge with volume density given by $\rho_E(r) = -Ae^{-2r/a_0}$ where $a_0 = 0.53 \times 10^{-10}$ m is called the *Bohr radius*, and $e = 2.718\cdots$ is the base of the natural log. (*a*) Determine the constant $A$ so that the total amount of negative charge is $-1.6 \times 10^{-19}$ C. (*b*) What is the net charge inside a sphere of radius $a_0$? (*c*) What is the strength of the electric field at a distance $a_0$ from the nucleus? [*Hint*: Do not confuse the exponential number $e$ with the elementary charge $e$ which uses the same symbol but has a completely different meaning and value $(e = 1.6 \times 10^{-19}\,\text{C})$.]

**60.** A very large thin plane has uniform surface charge density $\sigma$. Touching it on the right (Fig. 22–46) is a long wide slab of thickness $d$ with uniform volume charge density $\rho_E$. Determine the electric field (*a*) to the left of the plane, (*b*) to the right of the slab, and (*c*) everywhere inside the slab.

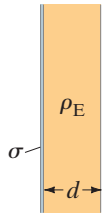

**FIGURE 22–46** Problem 60.

**61.** A sphere of radius $r_0$ carries a uniform volume charge density $\rho_E$ (Fig. 22–47). A spherical cavity of radius $r_0/2$ is then scooped out and left empty, as shown. (*a*) What is the magnitude and direction of the electric field at point A? (*b*) What is the direction and magnitude of the electric field at point B? Points A and C are at the centers of the respective spheres. [*Hint*: use the principle of superposition; subtract one sphere from the other.]

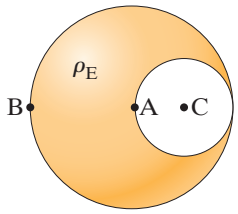

**FIGURE 22–47** Problem 61.

**62.** Dry air will break down and generate a spark if the electric field exceeds about $3 \times 10^6\,\text{N/C}$. How much charge could be packed onto the surface of a green pea (diameter 0.75 cm) before the pea spontaneously discharges?

**63.** Three very large sheets are separated by equal distances of 15.0 cm (Fig. 22–48). The first and third sheets are very thin and nonconducting and have charge per unit area $\sigma$ of $+5.00\,\mu\text{C/m}^2$ and $-5.00\,\mu\text{C/m}^2$ respectively. The middle sheet is conducting but has no net charge. (*a*) What is the electric field inside the middle sheet? What is the electric field (*b*) between the left and middle sheets, and (*c*) between the middle and right sheets? (*d*) What is the charge density on the surface of the middle sheet facing the left sheet, and (*e*) on the surface facing the right sheet?

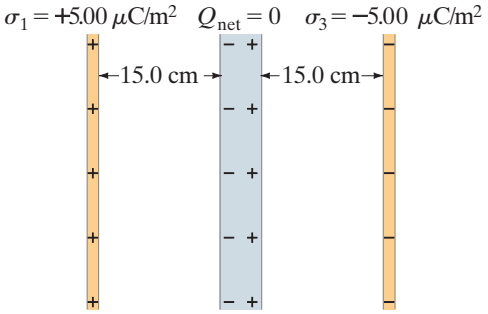

**FIGURE 22–48** Problem 63.

**64.** In a cubical volume, 0.50 m on a side, the electric field is

$$\vec{\mathbf{E}} = E_0\left(1 + \frac{z}{a}\right)\hat{\mathbf{i}} + E_0\left(\frac{z}{a}\right)\hat{\mathbf{j}}$$

where $E_0 = 0.125\,\text{N/C}$ and $a = 0.50\,\text{m}$. The cube has its sides parallel to the coordinate axes, Fig. 22–49. Determine the net charge within the cube.

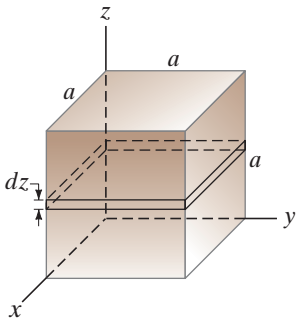

**FIGURE 22–49**
Problem 64.

**65.** A conducting spherical shell (Fig. 22–50) has inner radius = 10.0 cm, outer radius = 15.0 cm, and has a $+3.0\,\mu\text{C}$ point charge at the center. A charge of $-3.0\,\mu\text{C}$ is put on the conductor. (*a*) Where on the conductor does the $-3.0\,\mu\text{C}$ end up? (*b*) What is the electric field both inside and outside the shell?

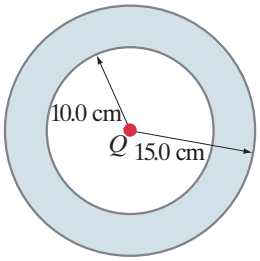

**FIGURE 22–50** Problem 65.

**66.** A hemisphere of radius $R$ is placed in a charge-free region of space where a uniform electric field exists of magnitude $E$ directed perpendicular to the hemisphere's circular base (Fig. 22–51). (*a*) Using the definition of $\Phi_E$ through an "open" surface, calculate (via explicit integration) the electric flux through the hemisphere. [*Hint*: In Fig. 22–51 you can see that, on the surface of a sphere, the infinitesimal area located between the angles $\theta$ and $\theta + d\theta$ is $dA = (2\pi R\sin\theta)(R\,d\theta) = 2\pi R^2\sin\theta\,d\theta$.] (*b*) Choose an appropriate gaussian surface and use Gauss's law to much more easily obtain the same result for the electric flux through the hemisphere.

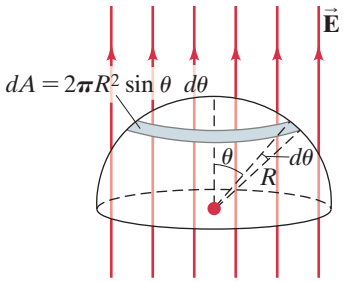

**FIGURE 22–51** Problem 66.

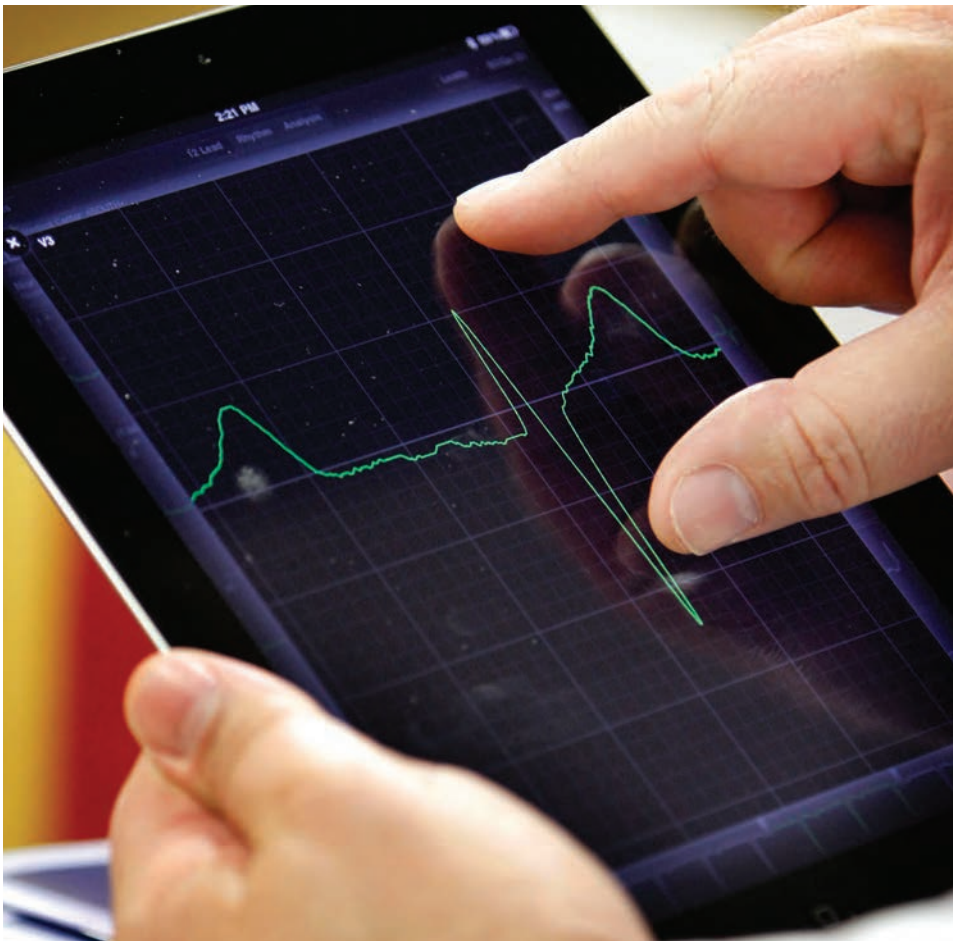

## ANSWERS TO EXERCISES

**A:** (*d*).
**B:** (*a*).
**C:** (*d*).
**D:** (*c*).
**E:** (*c*).

We are used to voltage in our lives—a 12-volt car battery, 110 V or 220 V at home, 1.5-volt flashlight batteries, and so on. Here we see displayed the voltage produced across a human heart, known as an electrocardiogram (ECG).

Voltage is the same as electric potential difference between two points. Electric potential is defined as the potential energy per unit charge.

We discuss voltage and its relation to electric field, as well as the electric potential due to point charges and charge distributions. Also discussed are digital voltages, binary numbers and digital electronics, TV and computer monitors, and digital TV.

*23–11 Electrocardiogram (ECG or EKG)

**CHAPTER-OPENING QUESTION—Guess now!**

When two positively charged small spheres are pushed toward each other, what happens to their electric potential energy?

**(a)** It remains unchanged.
**(b)** It decreases.
**(c)** It increases.
**(d)** There is no potential energy in this situation.

We saw in Chapters 7 and 8 that the concept of energy was extremely valuable in dealing with the subject of mechanics. For one thing, energy is found to be a conserved quantity and is thus an important tool for understanding nature. We also saw that many Problems could be solved using energy even when a knowledge of the forces involved was not possible, or when using Newton's laws would have been too difficult.

The energy perspective is useful also in the study of electric forces and electricity. It not only extends the law of conservation of energy, but it gives us another way to view electrical phenomena. The energy concept is also a tool in solving Problems more easily in many cases than by using forces and electric fields.

# 23–1 Electric Potential Energy and Potential Difference

## Electric Potential Energy

To apply conservation of energy to electric phenomena, we need to define electric potential energy as we did for other types of potential energy. We saw in Chapter 8 that potential energy can be defined only for a conservative force. The work done by a conservative force in moving an object between any two positions is independent of the path taken. The electrostatic force between any two charges (Eq. 21–1, $F = kQ_1 Q_2/r^2$) is conservative because the dependence on position is just like the gravitational force, $1/r^2$, which we saw in Section 8–7 is conservative. Hence we can define potential energy $U$ for the electrostatic force.

We saw in Chapter 8 that the change in potential energy between any two points, a and b, equals the negative of the work done by the conservative force on an object as it moves from point a to point b: $\Delta U = -W$.

Thus we define the change in electric potential energy, $U_b - U_a$, when a point charge $q$ moves from some point a to another point b, as the negative of the work done by the electric force on the charge as it moves from point a to point b. For example, consider the electric field between two equally but oppositely charged parallel plates; we assume their separation is small compared to their width and height, so the field $\vec{\mathbf{E}}$ will be uniform over most of the region, Fig. 23–1. Now consider a tiny positive point charge $q$ placed at the point "a" very near the positive plate as shown. The magnitude of this charge $q$ is so small that it has no effect on $\vec{\mathbf{E}}$. If this charge $q$ at point a is released, the electric force will do work on the charge and accelerate it toward the negative plate. The work $W$ done by the electric field $E$ to move the charge a distance $d$ is (using Eq. 21–5, $F = qE$)

$$W = Fd = qEd \qquad [\text{uniform } \vec{\mathbf{E}}]$$

The change in electric potential energy equals the negative of the work done by the electric force:

$$U_b - U_a = -W = -qEd \qquad [\text{uniform } \vec{\mathbf{E}}] \quad \textbf{(23–1)}$$

for this case of uniform electric field $\vec{\mathbf{E}}$. In the case illustrated, the potential energy decreases ($\Delta U$ is negative); and as the charged particle accelerates from point a to point b in Fig. 23–1, the particle's kinetic energy $K$ increases—by an equal amount. In accord with the conservation of energy, electric potential energy is transformed into kinetic energy, and the total energy is conserved. Note that the positive charge $q$ has its greatest potential energy at point a, near the positive plate.[†] The reverse is true for a negative charge: its potential energy is greatest near the negative plate.

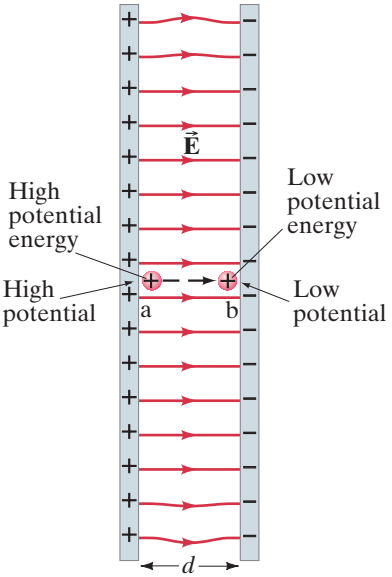

**FIGURE 23–1** Work is done by the electric field $\vec{\mathbf{E}}$ in moving the positive charge from position a to position b.

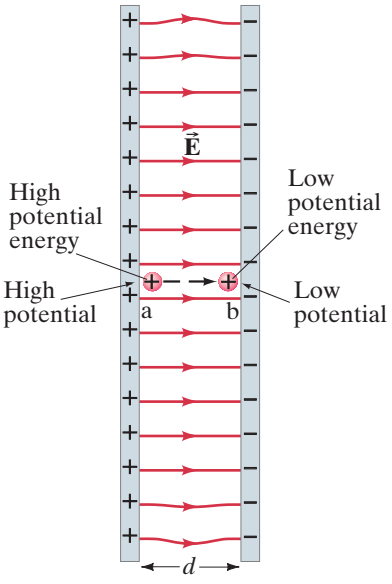
## Electric Potential and Potential Difference

In Chapter 21, we defined the electric field as the force per unit charge. Similarly, it is useful to define the **electric potential** (or simply the **potential** when "electric" is understood) as the *electric potential energy per unit charge*. Electric potential is given the symbol $V$. If we put a tiny positive test charge $q$ in an electric field, it will have electric potential energy $U_a$ at some arbitrary point a (relative to some zero potential energy); then the electric potential $V_a$ at this point is defined as

$$V_a = \frac{U_a}{q}. \qquad \textbf{(23–2a)}$$

As we discussed in Chapter 8, only differences in potential energy are physically meaningful. Hence only the **difference in potential**, or the **potential difference**, between two points a and b (such as in Fig. 23–1) is measurable. When the electric force does positive work on a charge, the kinetic energy increases and the potential energy decreases.

[†]At point a, the positive charge $q$ has its greatest ability to do work (on some other object or system).



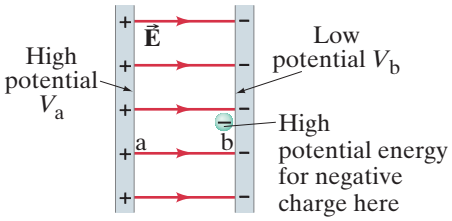


**FIGURE 23–1** (Repeated.) Work is done by the electric field $\vec{\mathbf{E}}$ in moving the positive charge from position a to position b.

**FIGURE 23–2** Central part of Fig. 23–1, showing a negative point charge near the negative plate, where its potential energy is high (but the potential $V = V_b$ is low). Example 23–1.

**⚠ CAUTION**

*A negative charge has high potential energy when potential V is low*

The difference in potential energy, $U_b - U_a$, is equal to the negative of the work, $W_{ba}$, done by the electric field to move the charge from a to b; so the potential difference $V_{ba}$ is

$$V_{ba} = \Delta V = V_b - V_a = \frac{U_b - U_a}{q} = -\frac{W_{ba}}{q}. \qquad \textbf{(23–2b)}$$

Note that electric potential, like electric field, does not depend on our test charge $q$. $V$ depends on the other charges that create the field, not on the test charge $q$; $q$ acquires potential energy by being in the potential $V$ due to the other charges.

We can see from our definition that the positive plate in Fig. 23–1 is at a higher potential than the negative plate. Thus a positively charged object moves naturally from a high potential to a low potential.

The unit of electric potential, and of potential difference, is joules/coulomb and is given a special name, the **volt**, in honor of Alessandro Volta (1745–1827) who is best known for inventing the electric battery. The volt is abbreviated V, so 1 V = 1 J/C. Potential difference, since it is measured in volts, is often referred to as **voltage**. (Be careful not to confuse V for volts with italic $V$ for voltage.)

If we wish to speak of the potential $V_a$ at some point a, we must be aware that $V_a$ depends on where the potential is chosen to be zero, just as in mechanics (Section 8–2). The zero for electric potential in a given situation can be chosen arbitrarily, as for any potential energy, because only differences in potential energy can be measured. Often the ground, or a conductor connected directly to the ground (the Earth), is taken as zero potential, and other potentials are given with respect to ground. (Thus, at a point where the voltage is 50 V, the difference of potential between it and ground is 50 V.) In other cases, we sometimes choose the potential to be zero at an infinite distance $(r = \infty)$.

**CONCEPTUAL EXAMPLE 23–1** **A negative charge.** Suppose a negative charge, such as an electron, is placed near the negative plate in Fig. 23–1, at point b, shown here in Fig. 23–2. If the electron is free to move, will its electric potential energy increase or decrease?

**RESPONSE** An electron released at point b will be attracted to the positive plate. As the electron accelerates toward the positive plate, its kinetic energy increases, so its potential energy *decreases*: $U_a < U_b$ and $\Delta U = U_a - U_b < 0$. But note that the electron moves from point b at low potential to point a at higher potential: $V_{ab} = V_a - V_b > 0$. (Potentials $V_a$ and $V_b$ are due to the charges on the plates, not due to the electron.) The signs of $\Delta U$ and $\Delta V$ are opposite because of the negative charge of the electron.

**NOTE** A positive charge placed next to the negative plate at b would stay there, with no acceleration. A positive charge tends to move from high potential to low, whereas a negative charge moves from low to high potential.

Because the electric potential difference is defined as the potential energy difference per unit charge, then the change in *potential energy* of a charge $q$ when it moves from point a to point b is

$$\Delta U = U_b - U_a = q(V_b - V_a) = qV_{ba}. \qquad \textbf{(23–3)}$$

That is, if an object with charge $q$ moves through a potential difference $V_{ba}$, its potential energy changes by an amount $qV_{ba}$. For example, if the potential difference between the two plates in Fig. 23–1 is 6 V, then a +1 C charge moved from point b to point a will gain (1 C)(6 V) = 6 J of electric potential energy. (And it will lose 6 J of electric potential energy if it moves from a to b.) Similarly, a +2 C charge will gain $\Delta U = (2\text{ C})(6\text{ V}) = 12\text{ J}$, and so on. Thus, electric potential difference is a measure of how much energy an electric charge can acquire in a given situation. And, since energy is the ability to do work, the electric potential difference is also a measure of how much *work* a given charge can do. The exact amount of energy or work depends *both* on the potential difference and on the charge.

To better understand electric potential, let's make a comparison to the gravitational case when a rock falls from the top of a cliff. The greater the height, $h$, of a cliff, the more potential energy $(=mgh)$ the rock has at the top of the cliff, relative to the bottom, and the more kinetic energy it will have when it reaches the bottom. The actual amount of kinetic energy it will acquire, and the amount of work it can do, depends both on the height of the cliff and the mass $m$ of the rock. A large rock and a small rock can be at the same height $h$ (Fig. 23–3a) and thus have the same "gravitational potential," but the larger rock has the greater potential energy (it has more mass). The electrical case is similar (Fig. 23–3b): the potential energy change, or the work that can be done, depends both on the potential difference (corresponding to the height of the cliff) and on the charge (corresponding to mass), Eq. 23–3. But note a significant difference: electric charge comes in two types, + and −, whereas gravitational mass is always +.

Sources of electrical energy such as batteries and electric generators are meant to maintain a potential difference. The actual amount of energy transformed by such a device depends on how much charge flows, as well as the potential difference (Eq. 23–3). For example, consider an automobile headlight connected to a 12.0-V battery. The amount of energy transformed (into light and thermal energy) is proportional to how much charge flows, which in turn depends on how long the light is on. If over a given period of time 5.0 C of charge flows through the light, the total energy transformed is $(5.0\,\text{C})(12.0\,\text{V}) = 60\,\text{J}$. If the headlight is left on twice as long, 10.0 C of charge will flow and the energy transformed is $(10.0\,\text{C})(12.0\,\text{V}) = 120\,\text{J}$. Table 23–1 presents some typical voltages.

**EXAMPLE 23–2** **Electron in a vacuum tube.** Suppose an electron is accelerated from rest through a potential difference $V_b - V_a = V_{ba} = +5000\,\text{V}$ (Fig. 23–4). (*a*) What is the change in electric potential energy of the electron? What is (*b*) the kinetic energy, and (*c*) the speed of the electron $(m = 9.1 \times 10^{-31}\,\text{kg})$ as a result of this acceleration?

**APPROACH** The electron, accelerated toward the positive plate, will change in potential energy by an amount $\Delta U = qV_{ba}$ (Eq. 23–3). The loss in potential energy will equal its gain in kinetic energy (energy conservation).

**SOLUTION** (*a*) The charge on an electron is $q = -e = -1.6 \times 10^{-19}\,\text{C}$. Therefore its change in potential energy is

$$\Delta U = qV_{ba} = (-1.6 \times 10^{-19}\,\text{C})(+5000\,\text{V}) = -8.0 \times 10^{-16}\,\text{J}.$$

The minus sign indicates that the potential energy decreases. The potential difference, $V_{ba}$, has a positive sign because the final potential $V_b$ is higher than the initial potential $V_a$. Negative electrons are attracted toward a positive electrode (or plate) and repelled away from a negative electrode.

(*b*) The potential energy lost by the electron becomes kinetic energy $K$. From conservation of energy (Eq. 8–9a), $\Delta K + \Delta U = 0$, so

$$\begin{aligned} \Delta K &= -\Delta U \\ \tfrac{1}{2}mv^2 - 0 &= -q(V_b - V_a) = -qV_{ba}, \end{aligned}$$

where the initial kinetic energy is zero since we are given that the electron started from rest. So the final kinetic energy $K = -qV_{ba} = 8.0 \times 10^{-16}\,\text{J}$.

(*c*) In the equation just above we solve for $v$:

$$v = \sqrt{-\frac{2qV_{ba}}{m}} = \sqrt{-\frac{2(-1.6 \times 10^{-19}\,\text{C})(5000\,\text{V})}{9.1 \times 10^{-31}\,\text{kg}}} = 4.2 \times 10^{7}\,\text{m/s}.$$

**NOTE** The electric potential energy does not depend on the mass, only on the charge and voltage. The speed *does* depend on $m$.

**EXERCISE A** Instead of the electron in Example 23–2, suppose a proton $(m = 1.67 \times 10^{-27}\,\text{kg})$ was accelerated from rest by a potential difference $V_{ba} = -5000\,\text{V}$. What would be the proton's (*a*) change in potential energy, and (*b*) final speed?

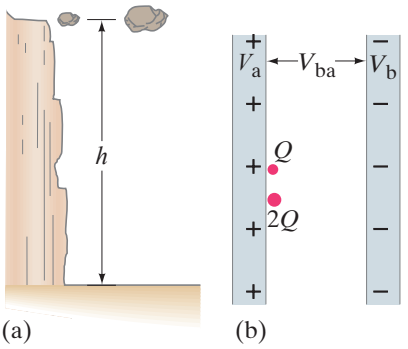

**FIGURE 23–3** (a) Two rocks are at the same height. The larger rock has more potential energy. (b) Two positive charges have the same electric potential. The $2Q$ charge has more potential energy.

**TABLE 23–1 Some Typical Potential Differences (Voltages)**

| Source | Voltage (approx.) |
|---|---|
| Thundercloud to ground | $10^8$ V |
| High-voltage power line | $10^5$–$10^6$ V |
| Automobile ignition | $10^4$ V |
| Household outlet | $10^2$ V |
| Automobile battery | 12 V |
| Flashlight battery (AA, AAA, C, D) | 1.5 V |
| Resting potential across nerve membrane | $10^{-1}$ V |
| Potential changes on skin (ECG and EEG) | $10^{-4}$ V |

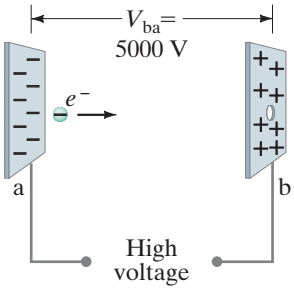

**FIGURE 23–4** Electron accelerated, Example 23–2.

# 23–2 Relation between Electric Potential and Electric Field

The effects of any charge distribution can be described either in terms of electric field or in terms of electric potential. Electric potential is often easier to use because it is a scalar, whereas electric field is a vector. There is a direct connection between the electric potential produced by a given arrangement of charges and the electric field due to those charges, which we now examine.

We start by recalling the relation between a conservative force $\vec{\mathbf{F}}$ and the potential energy $U$ associated with that force. As discussed in Section 8–2, the difference in potential energy between any two points in space, a and b, is given by Eq. 8–4:

$$U_b - U_a = -\int_a^b \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}},$$

where $d\vec{\boldsymbol{\ell}}$ is an infinitesimal increment of displacement, and the integral is taken along any path in space from point a to point b. (We call this a "line integral", as mentioned already in Section 7–3.) For the electrical case, we are more interested in the potential difference, given by Eq. 23–2b, $V_{ba} = V_b - V_a = (U_b - U_a)/q$, rather than in the potential energy itself. Also, the electric field $\vec{\mathbf{E}}$ at any point in space is defined as the force per unit charge (Eq. 21–3): $\vec{\mathbf{E}} = \vec{\mathbf{F}}/q$. Putting these two relations in the above equation gives us

$$V_{ba} = V_b - V_a = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}. \qquad \textbf{(23–4a)}$$

This is the general relation between electric field and potential difference. See Fig. 23–5. If we are given the electric field due to some arrangement of electric charge, we can use Eq. 23–4a to determine $V_{ba}$.

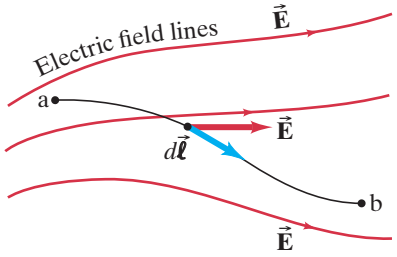

**FIGURE 23–5** To find $V_{ba}$ in a nonuniform electric field $\vec{\mathbf{E}}$, we integrate $\vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$ from point a to point b.

A simple special case is a uniform field. In Fig. 23–1, for example, a path parallel to the electric field lines from point a at the positive plate to point b at the negative plate gives (since $\vec{\mathbf{E}}$ and $d\vec{\boldsymbol{\ell}}$ are in the same direction at each point),

$$V_{ba} = V_b - V_a = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = -E\int_a^b d\ell = -Ed$$

or

$$V_{ba} = -Ed \qquad \text{[only if } E \text{ is uniform]} \qquad \textbf{(23–4b)}$$

where $d$ is the distance, parallel to the field lines, between points a and b. Be careful not to use Eq. 23–4b unless you are sure the electric field is uniform.

From either of Eqs. 23–4 we can see that the units for electric field can be written as volts per meter (V/m) as well as newtons per coulomb (N/C). These are equivalent because $1\,\text{N/C} = 1\,\text{N}\cdot\text{m/C}\cdot\text{m} = 1\,\text{J/C}\cdot\text{m} = 1\,\text{V/m}$. The minus sign in Eq. 23–4b tells us that $\vec{\mathbf{E}}$ points in the direction of decreasing potential $V$.

**EXAMPLE 23–3** **Electric field obtained from voltage.** Two parallel plates are charged to produce a potential difference of 50 V. If the separation between the plates is 0.050 m, determine the magnitude of the electric field in the space between the plates (Fig. 23–6).

**APPROACH** We can apply Eq. 23–4b to obtain the magnitude of $E$, if we assume $E$ is uniform.

**SOLUTION** The electric field magnitude is $E = V_{ba}/d = (50\,\text{V}/0.050\,\text{m}) = 1000\,\text{V/m}$.

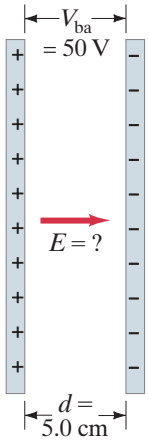

**FIGURE 23–6** Example 23–3.

**EXAMPLE 23–4** **Charged conducting sphere.** Determine the potential at a distance $r$ from the center of a charged conducting sphere of radius $r_0$ for (*a*) $r > r_0$, (*b*) $r = r_0$, (*c*) $r < r_0$. The total charge on the sphere is $Q$.

**APPROACH** The charge $Q$ is distributed over the surface of the sphere since it is a conductor. We saw in Example 22–3 that the electric field outside a conducting sphere is

$$E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2} \qquad [r > r_0]$$

and points radially outward (inward if $Q < 0$). Since we know $\vec{\mathbf{E}}$, we can start by using Eq. 23–4a.

**SOLUTION** (*a*) We use Eq. 23–4a and integrate along a radial line with $d\vec{\ell}$ parallel to $\vec{\mathbf{E}}$ (Fig. 23–7) between two points which are distances $r_a$ and $r_b$ from the sphere's center, and we set $d\ell = dr$:

$$V_b - V_a = -\int_{r_a}^{r_b}\vec{\mathbf{E}}\cdot d\vec{\ell} = -\frac{Q}{4\pi\epsilon_0}\int_{r_a}^{r_b}\frac{dr}{r^2}$$

$$= \frac{Q}{4\pi\epsilon_0}\left(\frac{1}{r_b} - \frac{1}{r_a}\right).$$

If we let $V = 0$ for $r = \infty$ (let's choose $V_b = 0$ at $r_b = \infty$), then at any other point $r$ (for $r > r_0$) we have

$$V = \frac{1}{4\pi\epsilon_0}\frac{Q}{r}. \qquad [r > r_0]$$

We will see in the next Section that this same equation applies for the potential a distance $r$ from a single point charge. (In fact we already have that result here if we let $r_0 \to 0$ in Fig. 23–7.) Thus the electric potential outside a spherical conductor with a uniformly distributed charge is the same as if all the charge were at its center.

(*b*) As $r$ approaches $r_0$, we see that

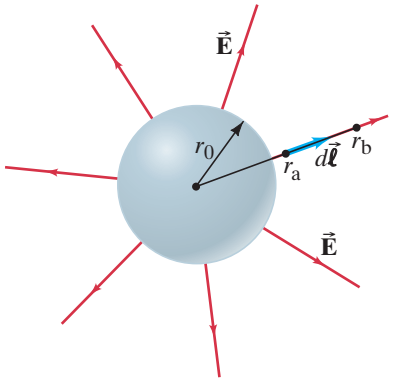
$$V = \frac{1}{4\pi\epsilon_0}\frac{Q}{r_0} \qquad [r = r_0]$$

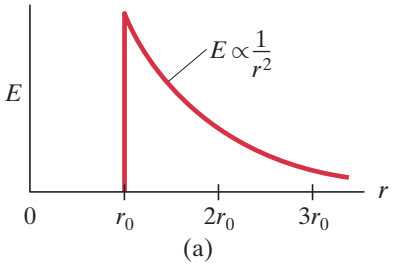
at the surface of the conductor.

(*c*) For points within the conductor, $E = 0$. Thus the integral, $\int\vec{\mathbf{E}}\cdot d\vec{\ell}$, between $r = r_0$ and any point within the conductor gives zero change in $V$. Hence $V$ is constant within the conductor:

$$V = \frac{1}{4\pi\epsilon_0}\frac{Q}{r_0}. \qquad [r \le r_0]$$

The whole conductor, not just its surface, is at this same potential. Plots of both $E$ and $V$ as a function of $r$ are shown in Fig. 23–8 for a positively charged conducting sphere.





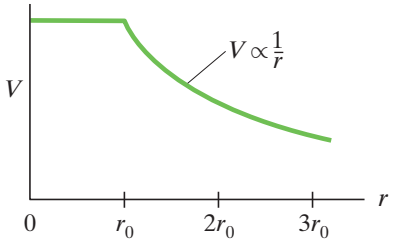


**FIGURE 23–7** Example 23–4. Integrating $\vec{\mathbf{E}}\cdot d\vec{\ell}$ for the field outside a spherical conductor.

**FIGURE 23–8** (a) $E$ versus $r$, and (b) $V$ versus $r$, for a positively charged solid conducting sphere of radius $r_0$ (the charge distributes itself evenly on the surface); $r$ is the distance from the center of the sphere. Example 23–4.

(a)

(b)

**EXAMPLE 23–5** **Breakdown voltage.** When very high voltages are present, air can become ionized due to the high electric fields. Any free electrons in the air (produced by cosmic rays, for example) can be accelerated to sufficient kinetic energy to knock electrons out of $O_2$ and $N_2$ molecules of the air. The air then becomes conducting and the high voltage cannot be maintained as charge flows. This **breakdown** of air occurs when the electric field exceeds about $E_{BD} = 3 \times 10^6\,\text{V/m}$ (*a*) Show that the breakdown voltage $V_{BD}$ for a spherical conductor in air is proportional to the radius of the sphere, and (*b*) estimate the breakdown voltage in air for a sphere of diameter 1.0 cm.

**APPROACH** The electric potential at the surface of a spherical conductor of radius $r_0$ (Example 23–4), and the electric field just outside its surface, are

$$V = \frac{1}{4\pi\epsilon_0}\frac{Q}{r_0} \quad \text{and} \quad E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r_0^2}.$$

**SOLUTION** (*a*) We combine these two equations and obtain

$$V_{BD} = r_0 E_{BD}. \quad \text{[at surface of spherical conductor]} \quad \textbf{(23–4c)}$$

(*b*) For $r_0 = 5 \times 10^{-3}\,\text{m}$, the breakdown voltage in air is

$$V_{BD} = (5 \times 10^{-3}\,\text{m})(3 \times 10^6\,\text{V/m}) \approx 15{,}000\,\text{V}.$$

**CAUTION**
*Breakdown voltage is smaller at sharp points because $V \propto r_0$.*

When high voltages are present, a glow known as a **corona discharge** may be seen around sharp points due to the high electric fields at these points with small $r_0$ (Eq. 23–4c), which can ionize air molecules. When electrons recombine with their molecules, light is emitted. Such breakdown of air is the source of lightning, the spark of a car's spark plug, and even short sparks between your fingers and a doorknob after you walk across a synthetic rug, or slide across a car seat (which can result in a significant transfer of charge to you). **Lightning rods**, with their sharp tips, are intended to ionize the surrounding air when a storm cloud is near, and to provide a conduction path to the ground in order to discharge a dangerous high-voltage cloud slowly, over a period of time. Thus lightning rods, connected to the ground, are intended to draw electric charge off threatening clouds before a large buildup of charge results in a swift destructive lightning bolt.

**EXERCISE B** On a dry day, a person can become electrically charged by rubbing against rugs and other ordinary objects. Suppose you feel a small shock as you reach for a metal doorknob, noting that the shock occurs along with a tiny spark when your hand is about 3.0 mm from the doorknob. As a rough estimate, use Eq. 23–4b to estimate the potential difference between your hand and the doorknob. (*a*) 9 V; (*b*) 90 V; (*c*) 900 V; (*d*) 9000 V.

# 23–3 Electric Potential Due to Point Charges

The electric potential at a distance $r$ from a single point charge $Q$ can be derived directly from Eq. 23–4a, $V_b - V_a = -\int \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$. The electric field due to a single point charge has magnitude (Eq. 21–4)

$$E = \frac{1}{4\pi\epsilon_0}\frac{Q}{r^2} \quad \text{or} \quad E = k\frac{Q}{r^2}$$

(where $k = 1/4\pi\epsilon_0 = 8.99 \times 10^9\,\text{N} \cdot \text{m}^2/\text{C}^2$), and is directed radially outward from a positive charge (inward if $Q < 0$). We take the integral in Eq. 23–4a along a (straight) field line (Fig. 23–9) from point a, a distance $r_a$ from $Q$, to point b, a distance $r_b$ from $Q$. Then $d\vec{\boldsymbol{\ell}}$ will be parallel to $\vec{\mathbf{E}}$ and $d\ell = dr$. Thus

$$V_b - V_a = -\int_{r_a}^{r_b} \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = -\frac{Q}{4\pi\epsilon_0}\int_{r_a}^{r_b}\frac{1}{r^2}\,dr = \frac{1}{4\pi\epsilon_0}\left(\frac{Q}{r_b} - \frac{Q}{r_a}\right).$$

As mentioned earlier, only differences in potential have physical meaning.

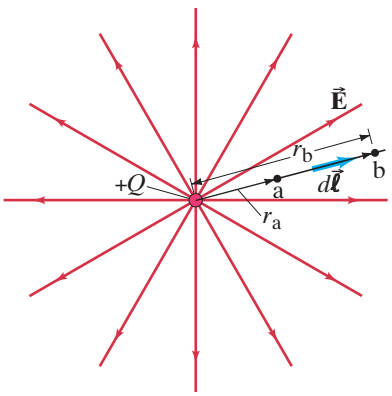

**FIGURE 23–9** We integrate Eq. 23–4a along the straight line (shown in black) from point a to point b. The line ab is parallel to a field line.

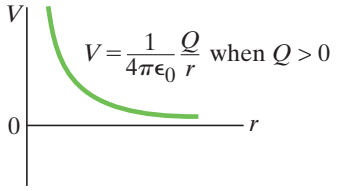
We are free, therefore, to choose the value of the potential at some one point to be whatever we please. It is common to choose the potential to be zero at infinity (let $V_b = 0$ at $r_b = \infty$). Then the electric potential $V$ at a distance $r$ from a single point charge is

$$V = \frac{1}{4\pi\epsilon_0}\frac{Q}{r} = k\frac{Q}{r}. \qquad \left[\begin{array}{c}\text{single point charge;}\\ V = 0 \text{ at } r = \infty\end{array}\right] \quad \textbf{(23–5)}$$

We can think of $V$ here as representing the absolute potential at a distance $r$ from the charge $Q$, where $V = 0$ at $r = \infty$; or we can think of $V$ as the potential difference between $r$ and infinity. Notice that the potential $V$ decreases with the first power of the distance, whereas the electric field (Eq. 21–4) decreases as the *square* of the distance. The potential near a positive charge is large, and it decreases toward zero at very large distances (Fig. 23–10). For a negative charge, the potential is negative and increases toward zero at large distances (Fig. 23–11). Equation 23–5 is sometimes called the **Coulomb potential** (it has its origin in Coulomb's law).

In Example 23–4 we found that the potential due to a uniformly charged sphere is given by the same relation, Eq. 23–5, for points outside the sphere. Thus we see that the potential outside a uniformly charged sphere is the same as if all the charge were concentrated at its center.



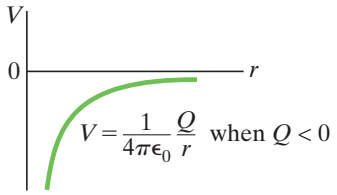


**FIGURE 23–10** Potential $V$ as a function of distance $r$ from a single point charge $Q$ when the charge is positive.

**CAUTION**

*$V \propto \frac{1}{r}$, $E \propto \frac{1}{r^2}$ for a point charge*

**FIGURE 23–11** Potential $V$ as a function of distance $r$ from a single point charge $Q$ when the charge is negative.

**EXERCISE C** What is the potential at a distance of 3.0 cm from a point charge $Q = -2.0 \times 10^{-9}$ C? (*a*) 600 V; (*b*) 60 V; (*c*) 6 V; (*d*) −600 V; (*e*) −60 V; (*f*) −6 V.

**EXAMPLE 23–6** **Work required to bring two positive charges close together.** What minimum work must be done by an external force to bring a charge $q = 3.00\,\mu$C from a great distance away (take $r = \infty$) to a point 0.500 m from a charge $Q = 20.0\,\mu$C?

**APPROACH** To find the work we cannot simply multiply the force times distance because the force is not constant (it is proportional to $1/r^2$). Instead we can set the change in potential energy equal to the (positive of the) work required of a different *external* force (Section 8–2), and Eq. 23–3: $W = \Delta U = q(V_b - V_a)$. We get the potentials $V_b$ and $V_a$ using Eq. 23–5.

**SOLUTION** The external work required is equal to the change in potential energy:

$$W = q(V_b - V_a)$$
$$= q\left(\frac{kQ}{r_b} - \frac{kQ}{r_a}\right),$$

where $r_b = 0.500$ m and $r_a = \infty$. The right-hand term within the parentheses is zero $(1/\infty = 0)$ so

$$W = (3.00 \times 10^{-6}\,\text{C})\frac{(8.99 \times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(2.00 \times 10^{-5}\,\text{C})}{(0.500\,\text{m})} = 1.08\,\text{J}.$$

**NOTE** We could not use Eq. 23–4b here because it applies *only* to uniform fields. But we did use Eq. 23–3 because it is always valid.

**CAUTION**

*We cannot use $W = Fd$ when $F$ is not constant*

**EXERCISE D** What work is required to bring a charge $q = 3.00\,\mu$C originally a distance of 1.50 m from a charge $Q = 20.0\,\mu$C until it is 0.50 m away?

To determine the electric field at points near a collection of two or more point charges requires adding up the electric fields due to each charge. Since the electric field is a vector, this can be time consuming or complicated. To find the electric potential at a point due to a collection of point charges is far easier, because the electric potential is a scalar, and you only need to add numbers (with appropriate signs) without concern for direction. This is a major advantage in using electric potential for solving Problems.

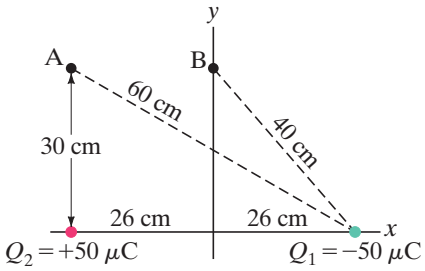

**FIGURE 23–12** Example 23–7. (See also Example 21–9, Fig. 21–28.)

**CAUTION**
*Potential is a scalar and has no components*

**EXAMPLE 23–7** **Potential above two charges.** Calculate the electric potential (*a*) at point A in Fig. 23–12 due to the two charges shown, and (*b*) at point B. [This is the same situation as Example 21–9, Fig. 21–28 in Chapter 21, where we calculated the electric field at these points.]

**APPROACH** The total potential at point A (or at point B) is the algebraic sum of the potentials at that point due to each of the two charges $Q_1$ and $Q_2$. The potential due to each single charge is given by Eq. 23–5. We do not have to worry about directions because electric potential is a scalar quantity. But we do have to keep track of the signs of charges.

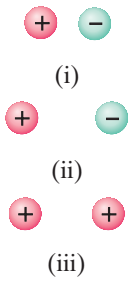
**SOLUTION** (*a*) We add the potentials at point A due to each charge $Q_1$ and $Q_2$, and we use Eq. 23–5 for each:

$$\begin{aligned} V_A &= V_{A2} + V_{A1} \\ &= k\frac{Q_2}{r_{2A}} + k\frac{Q_1}{r_{1A}} \end{aligned}$$

where $r_{1A} = 60\,\text{cm}$ and $r_{2A} = 30\,\text{cm}$. Then

$$\begin{aligned} V_A &= \frac{(9.0\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(5.0\times10^{-5}\,\text{C})}{0.30\,\text{m}} \\ &\quad + \frac{(9.0\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(-5.0\times10^{-5}\,\text{C})}{0.60\,\text{m}} \\ &= 1.50\times10^6\,\text{V} - 0.75\times10^6\,\text{V} \\ &= 7.5\times10^5\,\text{V}. \end{aligned}$$

(*b*) At point B, $r_{1B} = r_{2B} = 0.40\,\text{m}$, so



$$\begin{aligned} V_B &= V_{B2} + V_{B1} \\ &= \frac{(9.0\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(5.0\times10^{-5}\,\text{C})}{0.40\,\text{m}} \\ &\quad + \frac{(9.0\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(-5.0\times10^{-5}\,\text{C})}{0.40\,\text{m}} \\ &= 0\,\text{V}. \end{aligned}$$

**NOTE** The two terms in the sum in (*b*) cancel for any point equidistant from $Q_1$ and $Q_2$ $(r_{1B} = r_{2B})$. Thus the potential will be zero everywhere on the plane equidistant between the two opposite charges. This plane where $V$ is constant is called an "equipotential surface."

Simple summations like these can be performed for any number of point charges.

**CONCEPTUAL EXAMPLE 23–8** **Potential energies.** Consider two isolated charges, $Q_1$ and $Q_2$. This pair of charges is shown in three different configurations in Fig. 23–13. (*a*) Which set has a positive potential energy? (*b*) Which set has the most negative potential energy? (*c*) Which set requires the most work to separate the charges to infinity? Assume the charges all have the same magnitude.

**FIGURE 23–13** Example 23–8.

**RESPONSE** The potential energy equals the work required to bring the two charges near each other, starting at a great distance $(\infty)$. Assume the left $(+)$ charge $Q_1$ is already there. To bring a second charge $Q_2$ close to the first charge from a great distance away $(\infty)$ requires external work

$$W_{\text{ext}} = Q_2V = k\frac{Q_1Q_2}{r}$$

where $r$ is the final distance between them.

Thus the potential energy $U$ of the two charges is

$$U = k\frac{Q_1 Q_2}{r}.$$

(*a*) Set (iii) has a positive potential energy because the charges have the same sign. (*b*) Both (i) and (ii) have opposite signs of charge and negative potential energy. Because $r$ is smaller in (i), $U$ is most negative for (i). (*c*) Set (i) will require the most work for separation to infinity. The more negative the potential energy, the more work required to separate the charges and bring the potential energy up to zero $(r = \infty)$, as in Fig. 23–11.

**EXERCISE E** Return to the Chapter-Opening Question, page 660, and answer it again now. Try to explain why you may have answered differently the first time.

# 23–4 Potential Due to Any Charge Distribution

If we know the electric field in a region of space due to any distribution of electric charge, we can determine the difference in potential between two points in the region using Eq. 23–4a, $V_{ba} = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$. In many cases we don't know $\vec{\mathbf{E}}$ as a function of position, and it may be difficult to calculate. We can calculate the potential $V$ due to a given charge distribution in another way, using the potential due to a single point charge, Eq. 23–5:

$$V = \frac{1}{4\pi\epsilon_0}\frac{Q}{r},$$

where we choose $V = 0$ at $r = \infty$. Then we can sum over all the charges. If we have $n$ individual point charges, the potential at some point a (relative to $V = 0$ at $r = \infty$) is

$$V_a = \sum_{i=1}^{n} V_i = \frac{1}{4\pi\epsilon_0}\sum_{i=1}^{n}\frac{Q_i}{r_{ia}}, \qquad \textbf{(23–6a)}$$

where $r_{ia}$ is the distance from the $i^{\text{th}}$ charge $(Q_i)$ to the point a. (We already used this approach in Example 23–7 for two charges.) If the charge distribution can be considered continuous, then

$$V = \frac{1}{4\pi\epsilon_0}\int\frac{dq}{r}, \qquad \textbf{(23–6b)}$$

where $r$ is the distance from a tiny element of charge, $dq$, to the point where $V$ is being determined.

**EXAMPLE 23–9** **Potential due to a ring of charge.** A thin circular ring of radius $R$ has a uniformly distributed charge $Q$. Determine the electric potential at a point P on the axis of the ring a distance $x$ from its center, Fig. 23–14.

**APPROACH** We integrate over the ring using Eq. 23–6b.

**SOLUTION** Each point on the ring is equidistant from point P, and this distance is $(x^2 + R^2)^{\frac{1}{2}}$. So the potential at P is:

$$V = \frac{1}{4\pi\epsilon_0}\int\frac{dq}{r} = \frac{1}{4\pi\epsilon_0}\frac{1}{(x^2 + R^2)^{\frac{1}{2}}}\int dq = \frac{1}{4\pi\epsilon_0}\frac{Q}{(x^2 + R^2)^{\frac{1}{2}}}.$$

**NOTE** For points very far away from the ring, $x \gg R$, this result reduces to $(1/4\pi\epsilon_0)(Q/x)$, the potential of a point charge, as we should expect. This sort of check does not prove our result is correct, but it does give us very high confidence that we did not make a blunder.

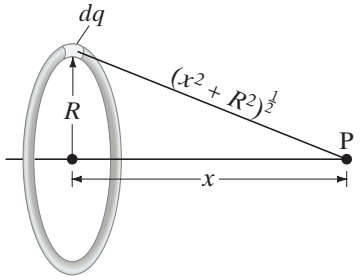


**FIGURE 23–14** Example 23–9. Calculating the potential at point P, a distance $x$ from the center of a uniform ring of charge.

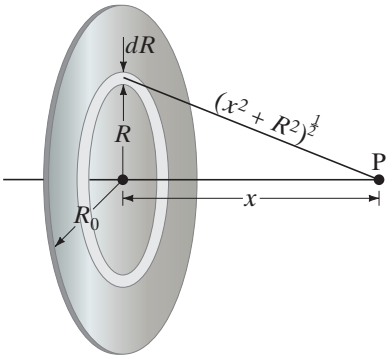

**FIGURE 23–15** Example 23–10. Calculating the electric potential at point P on the axis of a uniformly charged thin disk.

**EXAMPLE 23–10** **Potential due to a charged disk.** A thin flat disk, of radius $R_0$, has a uniformly distributed charge $Q$, Fig. 23–15. Determine the potential at a point P on the axis of the disk, a distance $x$ from its center.

**APPROACH** We divide the disk into thin rings of radius $R$ and thickness $dR$ and use the result of Example 23–9 to sum over the disk.

**SOLUTION** The charge $Q$ is distributed uniformly, so the charge contained in each concentric ring is proportional to its area. The disk has area $A = \pi R_0^2$ and each thin ring has area $dA = (2\pi R)(dR)$. Hence

$$\frac{dq}{Q} = \frac{dA}{A} = \frac{2\pi R\, dR}{\pi R_0^2}$$

so

$$dq = Q\frac{(2\pi R)(dR)}{\pi R_0^2} = \frac{2QR\, dR}{R_0^2}.$$

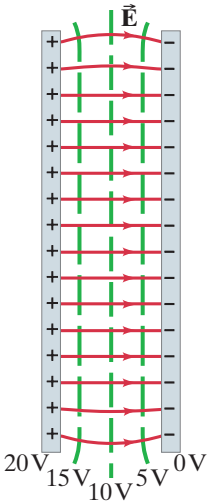
Then the potential at P, using Eq. 23–6b in which $r$ is replaced by $(x^2 + R^2)^{\frac{1}{2}}$, is

$$V = \frac{1}{4\pi\epsilon_0}\int \frac{dq}{(x^2+R^2)^{\frac{1}{2}}} = \frac{2Q}{4\pi\epsilon_0 R_0^2}\int_0^{R_0} \frac{R\, dR}{(x^2+R^2)^{\frac{1}{2}}} = \frac{Q}{2\pi\epsilon_0 R_0^2}\left(x^2+R^2\right)^{\frac{1}{2}}\Big|_{R=0}^{R=R_0}$$

$$= \frac{Q}{2\pi\epsilon_0 R_0^2}\left[(x^2+R_0^2)^{\frac{1}{2}} - x\right] = \frac{Qx}{2\pi\epsilon_0 R_0^2}\left[\left(1+\frac{R_0^2}{x^2}\right)^{\frac{1}{2}} - 1\right]$$

**NOTE** To check our result, consider $x \gg R_0$. Our formula reduces to (we use the binomial expansion—Appendix A):

$$V \approx \frac{Qx}{2\pi\epsilon_0 R_0^2}\left[\left(1 + \frac{1}{2}\frac{R_0^2}{x^2}\right) - 1\right] = \frac{Q}{4\pi\epsilon_0 x}.$$



This is the formula for a point charge, as we expect.

# 23–5 Equipotential Lines and Surfaces

The electric potential can be represented by drawing **equipotential lines** or, in three dimensions, **equipotential surfaces**. An equipotential surface is one on which all points are at the same potential. That is, the potential difference between any two points on the surface is zero, so no work is required to move a charge from one point on the surface to another. An *equipotential surface must be perpendicular to the electric field* at any point. If this were not so—that is, if there were a component of $\vec{\mathbf{E}}$ parallel to the surface—it would require work to move the charge along the surface against this component of $\vec{\mathbf{E}}$; and this would contradict the idea that it is an *equi*potential surface. This can also be seen from Eq. 23–4a, $\Delta V = -\int \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$. On a surface where $V$ is constant, $\Delta V = 0$, so we must have either $\vec{\mathbf{E}} = 0$, $d\vec{\boldsymbol{\ell}} = 0$, or $\cos\theta = 0$ where $\theta$ is the angle between $\vec{\mathbf{E}}$ and $d\vec{\boldsymbol{\ell}}$. Thus in a region where $\vec{\mathbf{E}}$ is not zero, the path $d\vec{\boldsymbol{\ell}}$ along an equipotential must have $\cos\theta = 0$, meaning $\theta = 90°$ and $\vec{\mathbf{E}}$ is perpendicular to the equipotential.

The fact that the electric field lines and equipotential surfaces are mutually perpendicular helps us locate the equipotentials when the electric field lines are known. In a normal two-dimensional drawing, we show equipotential *lines*, which are the intersections of equipotential surfaces with the plane of the drawing. In Fig. 23–16, a few of the equipotential lines are drawn (dashed green lines) for the electric field (red lines) between two parallel plates at a potential difference of 20 V. The negative plate is arbitrarily chosen to be zero volts and the potential of each equipotential line is indicated. Note that $\vec{\mathbf{E}}$ points toward lower values of $V$.

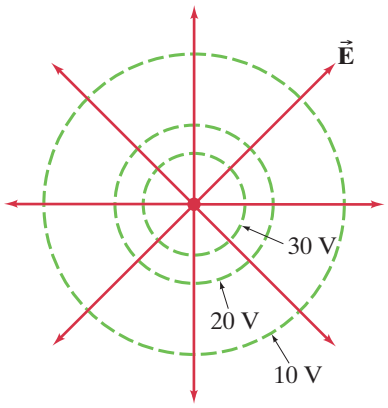
**FIGURE 23–16** Equipotential lines (the green dashed lines) between oppositely charged parallel plates are always perpendicular to the electric field lines (solid red lines).

**EXAMPLE 23–11** **Point charge equipotential surfaces.** For a single point charge with $Q = 4.0 \times 10^{-9}\,\text{C}$, sketch the equipotential surfaces (or lines in a plane containing the charge) corresponding to $V_1 = 10\,\text{V}$, $V_2 = 20\,\text{V}$, and $V_3 = 30\,\text{V}$.

**APPROACH** The electric potential $V$ depends on the distance $r$ from the charge (Eq. 23–5).

**SOLUTION** The electric field for a positive point charge is directed radially outward. Since the equipotential surfaces must be perpendicular to the lines of electric field, they will be spherical in shape, centered on the point charge, Fig. 23–17. From Eq. 23–5 we have $r = (1/4\pi\epsilon_0)(Q/V)$, so that for $V_1 = 10\,\text{V}$, $r_1 = (9.0 \times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(4.0 \times 10^{-9}\,\text{C})/(10\,\text{V}) = 3.6\,\text{m}$, for $V_2 = 20\,\text{V}$, $r_2 = 1.8\,\text{m}$, and for $V_3 = 30\,\text{V}$, $r_3 = 1.2\,\text{m}$, as shown.

**NOTE** The equipotential surface with the largest potential is closest to the positive charge. How would this change if $Q$ were negative?



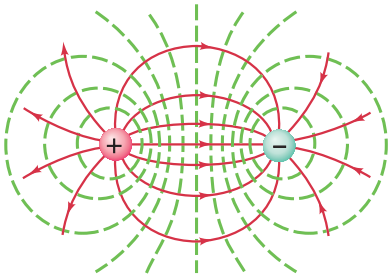


**FIGURE 23–17** Example 23–11. Electric field lines and equipotential surfaces for a point charge.

The equipotential lines for the case of two equal but oppositely charged particles are shown in Fig. 23–18 as green dashed lines. (This combination of equal + and − charges is called an "electric dipole," as we saw in Section 21–11).

Unlike electric field lines, which start and end on electric charges, equipotential lines and surfaces are always continuous and never end, and so continue beyond the borders of Figs. 23–16 and 23–18. A useful analogy for equipotential lines is a topographic map: the contour lines are essentially gravitational equipotential lines (Fig. 23–19).

**FIGURE 23–18** Equipotential lines (green, dashed) are always perpendicular to the electric field lines (solid red) shown here for two equal but oppositely charged particles (an electric dipole).

We saw in Section 21–9 that there can be no electric field within a conductor in the static case, for otherwise the free electrons would feel a force and would move, and thus not be static. Indeed, the *entire volume of a conductor must be at the same potential in the static case*. The surface of a conductor is then an equipotential surface. (If it weren't, the free electrons at the surface would move, since whenever there is a potential difference between two points, free charges will move.) This is fully consistent with our result in Section 21–9 that the electric field at the surface of a conductor must be perpendicular to the surface.

**FIGURE 23–19** A topographic map (here, a portion of the Sierra Nevada in California) shows continuous contour lines, each of which is at a fixed height above sea level. Here they are at 80 ft (25 m) intervals. The contour lines of constant elevation are gravitational equipotential lines. If you walk along one contour line, you neither climb nor descend. If you cross lines, and especially if you climb perpendicular to the lines, you will be changing your gravitational potential (rapidly, if the lines are close together, meaning steep uphill).

## 23–6 Potential Due to Electric Dipole; Dipole Moment

Two equal point charges $Q$, of opposite sign, separated by a distance $\ell$, are called an **electric dipole**. The electric field lines and equipotential surfaces for a dipole were shown in Fig. 23–18. Because electric dipoles occur often in physics, as well as in other disciplines such as molecular biology, it is useful to examine them more closely.

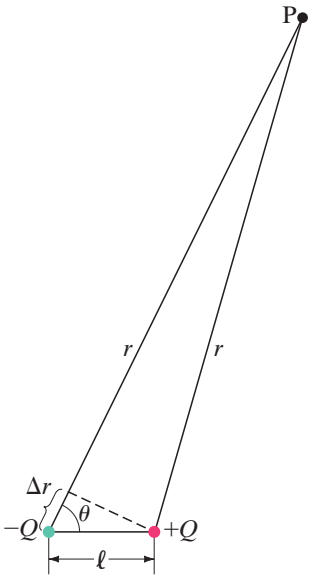

**FIGURE 23–20** Electric dipole. Calculation of potential $V$ at point P.

**PHYSICS APPLIED**
*Dipoles in molecular biology*

**TABLE 23–2 Dipole Moments of Selected Molecules**

| Molecule | Dipole Moment (C · m) |
|---|---|
| $H_2^{(+)}O^{(-)}$ | $6.1 \times 10^{-30}$ |
| $H^{(+)}Cl^{(-)}$ | $3.4 \times 10^{-30}$ |
| $N^{(-)}H_3^{(+)}$ | $5.0 \times 10^{-30}$ |
| $>N^{(-)}—H^{(+)}$ | $\approx 3.0^{\dagger} \times 10^{-30}$ |
| $>C^{(+)}=O^{(-)}$ | $\approx 8.0^{\dagger} \times 10^{-30}$ |

†These last two groups often appear on larger molecules; hence the value for the dipole moment will vary somewhat, depending on the rest of the molecule.

The electric potential at an arbitrary point P due to a dipole, Fig. 23–20, is the sum of the potentials due to each of the two charges (we take $V = 0$ at $r = \infty$):

$$V = \frac{1}{4\pi\epsilon_0}\frac{Q}{r} + \frac{1}{4\pi\epsilon_0}\frac{(-Q)}{(r+\Delta r)} = \frac{1}{4\pi\epsilon_0}Q\left(\frac{1}{r} - \frac{1}{r+\Delta r}\right) = \frac{Q}{4\pi\epsilon_0}\frac{\Delta r}{r(r+\Delta r)},$$

where $r$ is the distance from P to the positive charge and $r + \Delta r$ is the distance to the negative charge. This equation becomes simpler if we consider points P whose distance from the dipole is much larger than the separation of the two charges—that is, for $r \gg \ell$. From Fig. 23–20 we see that $\Delta r \approx \ell \cos\theta$. Thus for $r \gg \Delta r = \ell \cos\theta$, in the equation above we can neglect $\Delta r$ in the denominator as compared to $r$. Therefore, we obtain

$$V = \frac{1}{4\pi\epsilon_0}\frac{Q\ell\cos\theta}{r^2} = \frac{1}{4\pi\epsilon_0}\frac{p\cos\theta}{r^2}, \quad [\text{dipole; } r \gg \ell] \quad \textbf{(23–7)}$$

where quantity $p = Q\ell$ is called the **dipole moment**. We see that the potential decreases as the *square* of the distance from the dipole, whereas for a single point charge the potential decreases with the first power of the distance (Eq. 23–5). It is not surprising that the potential should fall off faster for a dipole; when you are far from a dipole, the two equal but opposite charges appear so close together as to tend to neutralize each other.

In many molecules, even though they are electrically neutral, the electrons spend more time in the vicinity of one atom than another, which results in a separation of charge. Such molecules have a dipole moment and are called **polar molecules**. We already saw that water (Fig. 21–4) is a polar molecule, and we have encountered others in our discussion of molecular biology (Section 21–12).

Table 23–2 gives the dipole moments for several molecules. The + and − signs indicate on which atoms these charges lie. The last two entries are a part of many organic molecules and play an important role in molecular biology. A dipole moment has units of coulomb-meters (C · m), although for molecules a smaller unit called a *debye* is sometimes used: 1 debye $= 3.33 \times 10^{-30}$ C · m.

## 23–7 $\vec{\mathbf{E}}$ Determined from $V$

We can use Eq. 23–4a, $V_b - V_a = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$, to determine the difference in potential between two points if the electric field is known in the region between those two points. By inverting Eq. 23–4a, we can write the electric field in terms of the potential. Then the electric field can be determined from a knowledge of $V$. Let us see how to do this.

We write Eq. 23–4a in differential form as

$$dV = -\vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = -E_\ell\, d\ell,$$

where $dV$ is the infinitesimal difference in potential between two points a distance $d\ell$ apart, and $E_\ell$ is the component of the electric field in the direction of the infinitesimal displacement $d\vec{\boldsymbol{\ell}}$. We can then write

$$E_\ell = -\frac{dV}{d\ell}. \quad \textbf{(23–8)}$$

Thus *the component of the electric field in any direction is equal to the negative of the rate of change of the electric potential with distance in that direction*. The quantity $dV/d\ell$ is called the **gradient** of $V$ in a particular direction. If the direction is not specified, the term *gradient* refers to that direction in which $V$ changes most rapidly; this would be the direction of $\vec{\mathbf{E}}$ at that point,† so we can write

$$E = -\frac{dV}{d\ell}. \quad [\text{if } d\vec{\boldsymbol{\ell}} \text{ is parallel to } \vec{\mathbf{E}}]$$

†A component of a vector has magnitude less than, or at most equal to, the magnitude of the vector: $E_\ell \le E$. Thus $|dV/d\ell|$ has its maximum value when $E_\ell$ in Eq. 23-8 equals $E$.

If $\vec{\mathbf{E}}$ is written as a function of $x$, $y$, and $z$, and we let $\ell$ refer to the $x$, $y$, and $z$ axes, then Eq. 23–8 becomes

$$E_x = -\frac{\partial V}{\partial x}, \qquad E_y = -\frac{\partial V}{\partial y}, \qquad E_z = -\frac{\partial V}{\partial z}. \tag{23–9}$$

Here, $\partial V/\partial x$ is the "partial derivative" of $V$ with respect to $x$, with $y$ and $z$ held constant.[†] For example, if $V(x, y, z) = (2\,\text{V/m}^2)x^2 + (8\,\text{V/m}^3)y^2z + (2\,\text{V/m}^2)z^2$, then

$$E_x = -\partial V/\partial x = -(4\,\text{V/m}^2)\,x,$$
$$E_y = -\partial V/\partial y = -(16\,\text{V/m}^3)yz,$$

and

$$E_z = -\partial V/\partial z = -(8\,\text{V/m}^3)y^2 - (4\,\text{V/m}^2)z.$$

**EXAMPLE 23–12** **$\vec{\mathbf{E}}$ for ring and disk.** Use electric potential to determine the electric field at point P on the axis of (*a*) a circular ring of charge (Fig. 23–14) and (*b*) a uniformly charged disk (Fig. 23–15).

**APPROACH** We obtained $V$ as a function of $x$ in Examples 23–9 and 23–10, so we find $E$ by taking derivatives (Eqs. 23–9).

**SOLUTION** (*a*) From Example 23–9, the potential $V$ along the axis of the circle is

$$V = \frac{1}{4\pi\epsilon_0}\frac{Q}{(x^2 + R^2)^{\frac{1}{2}}}.$$

Then

$$E_x = -\frac{\partial V}{\partial x} = \frac{1}{4\pi\epsilon_0}\frac{Qx}{(x^2 + R^2)^{\frac{3}{2}}}.$$

This is the same result we obtained in Chapter 21, Example 21–10. ($E_y = E_z = 0$ by symmetry, but also because $V$ does not depend on $y$ or $z$ so $\partial V/\partial y = \partial V/\partial z = 0$.)

(*b*) From Example 23–10,

$$V = \frac{Q}{2\pi\epsilon_0 R_0^2}\left[(x^2 + R_0^2)^{\frac{1}{2}} - x\right],$$

so

$$E_x = -\frac{\partial V}{\partial x} = \frac{Q}{2\pi\epsilon_0 R_0^2}\left[1 - \frac{x}{(x^2 + R_0^2)^{\frac{1}{2}}}\right].$$

(Again $E_y = E_z = 0$ by symmetry.) For points very close to the disk, $x \ll R_0$, the electric field can be approximated by

$$E \approx \frac{Q}{2\pi\epsilon_0 R_0^2} = \frac{\sigma}{2\epsilon_0}$$

where $\sigma = Q/\pi R_0^2$ is the surface charge density. The direction of $\vec{\mathbf{E}}$ is perpendicular to the disk. We also obtained these results in Chapter 21, Example 21–13 and Eq. 21–7.

If we compare this last Example with Examples 21–10 and 21–13, we see that here, as for many charge distributions, it is easier to calculate $V$ first, and then $\vec{\mathbf{E}}$ from Eq. 23–9, rather than to calculate $\vec{\mathbf{E}}$ due to each charge from Coulomb's law. This is because $V$ due to many charges is a scalar sum, whereas $\vec{\mathbf{E}}$ is a vector sum.

[†]Equation 23–9 can be written as a vector equation,

$$\vec{\mathbf{E}} = -\text{grad}\,V = -\vec{\boldsymbol{\nabla}}V = -\left(\hat{\mathbf{i}}\frac{\partial}{\partial x} + \hat{\mathbf{j}}\frac{\partial}{\partial y} + \hat{\mathbf{k}}\frac{\partial}{\partial z}\right)V$$

where the symbol $\vec{\boldsymbol{\nabla}}$ is called the *del operator* or *gradient operator*: $\vec{\boldsymbol{\nabla}} = \hat{\mathbf{i}}\frac{\partial}{\partial x} + \hat{\mathbf{j}}\frac{\partial}{\partial y} + \hat{\mathbf{k}}\frac{\partial}{\partial z}$.

# 23–8 Electrostatic Potential Energy; the Electron Volt

Suppose a point charge $q$ is moved between two points in space, a and b, where the electric potential due to other charges is $V_a$ and $V_b$, respectively. The change in electrostatic potential energy of $q$ in the field of these other charges is, according to Eq. 23–2b,

$$\Delta U = U_b - U_a = q(V_b - V_a).$$

Now suppose we have a system of several point charges. What is the electrostatic potential energy of the system? It is most convenient to choose the electric potential energy to be zero when the charges are very far (ideally infinitely far) apart. A single point charge, $Q_1$, in isolation, has no potential energy, because if there are no other charges around, no electric force can be exerted on it. If a second point charge $Q_2$ is brought close to $Q_1$, the potential due to $Q_1$ at the position of this second charge is

$$V = \frac{1}{4\pi\epsilon_0}\frac{Q_1}{r_{12}},$$

where $r_{12}$ is the distance between $Q_1$ and $Q_2$. The potential energy of the two charges, relative to $V = 0$ at $r = \infty$, is

$$U = Q_2 V = \frac{1}{4\pi\epsilon_0}\frac{Q_1 Q_2}{r_{12}}. \qquad \textbf{(23–10)}$$

This represents the work that needs to be done by an external force to bring $Q_2$ from infinity $(V = 0)$ to a distance $r_{12}$ from $Q_1$. It is also the negative of the work needed to separate them to infinity.

If the system consists of three charges, the total potential energy will be the work needed to bring all three together. Equation 23–10 represents the work needed to bring $Q_2$ close to $Q_1$; to bring a third charge $Q_3$ so that it is a distance $r_{13}$ from $Q_1$ and $r_{23}$ from $Q_2$ requires work equal to

$$\frac{1}{4\pi\epsilon_0}\frac{Q_1 Q_3}{r_{13}} + \frac{1}{4\pi\epsilon_0}\frac{Q_2 Q_3}{r_{23}}.$$

So the potential energy of a system of three point charges is

$$U = \frac{1}{4\pi\epsilon_0}\left(\frac{Q_1 Q_2}{r_{12}} + \frac{Q_1 Q_3}{r_{13}} + \frac{Q_2 Q_3}{r_{23}}\right). \qquad [V = 0 \text{ at } r = \infty]$$

For a system of four charges, the potential energy would contain six such terms, and so on. (Caution must be used when making such sums to avoid double counting of the different pairs.)

## The Electron Volt, a Unit of Energy

The joule is a very large unit for dealing with energies of electrons, atoms, or molecules. For this reason, the unit **electron volt** (eV) is often used. One electron volt is defined as the energy acquired by a particle carrying a charge $e$, the magnitude of the charge on an electron $(q = e)$, as a result of moving through a potential difference of 1 V. The charge on an electron has magnitude $1.6022 \times 10^{-19}$ C, and the change in potential energy equals $qV$. So 1 eV is equal to $(1.6022 \times 10^{-19}\ \text{C})\ (1.00\ \text{V}) = 1.6022 \times 10^{-19}$ J:

$$1\ \text{eV} = 1.6022 \times 10^{-19}\ \text{J} \approx 1.60 \times 10^{-19}\ \text{J}.$$

An electron that accelerates through a potential difference of 1000 V will lose 1000 eV of potential energy and thus gain 1000 eV or 1 keV (kiloelectron volt)

of kinetic energy. On the other hand, if a particle with a charge equal to twice the magnitude of the charge on the electron $(=2e=3.20\times10^{-19}\,\text{C})$ moves through a potential difference of 1000 V, its kinetic energy will change by $2000\,\text{eV}=2\,\text{keV}$.

Although the electron volt is handy for *stating* the energies of molecules and elementary particles, it is not a proper SI unit. For calculations (unless other units are not involved), electron volts must be converted to joules using the conversion factor just given.

**EXERCISE F** What is the kinetic energy of a $He^{2+}$ ion released from rest and accelerated through a potential difference of 1.0 kV? (*a*) 1000 eV, (*b*) 500 eV, (*c*) 2000 eV, (*d*) 4000 eV, (*e*) 250 eV.

**EXAMPLE 23–13** **Disassembling a hydrogen atom.** Calculate the work needed to "disassemble" a hydrogen atom. Assume that the proton $(Q_1=+e)$ and electron $(Q_2=-e)$ are initially separated by a distance equal to the "average" radius of the hydrogen atom in its ground state, $0.529\times10^{-10}\,\text{m}$, and that they end up an infinite distance apart from each other.

**APPROACH** The work necessary will be equal to the total energy, kinetic plus potential, of the electron and proton as an atom, compared to their total energy when infinitely far apart.

**SOLUTION** From Eq. 23–10 we have initially

$$U = \frac{1}{4\pi\epsilon_0}\frac{Q_1Q_2}{r} = \frac{1}{4\pi\epsilon_0}\frac{(e)(-e)}{r}$$

$$= \frac{-(8.99\times10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(1.60\times10^{-19}\,\text{C})^2}{(0.529\times10^{-10}\,\text{m})}$$

$$= -27.2(1.60\times10^{-19})\,\text{J} = -27.2\,\text{eV}.$$

This represents the potential energy. The total energy must include also the kinetic energy of the electron moving in an orbit of radius $r=0.529\times10^{-10}\,\text{m}$. From $F=ma$, using Coulomb's law for $F$ and centripetal acceleration for $a$, we have

$$\frac{1}{4\pi\epsilon_0}\left(\frac{e^2}{r^2}\right) = \frac{mv^2}{r}.$$

Then

$$K = \tfrac{1}{2}mv^2 = \tfrac{1}{2}\left(\frac{1}{4\pi\epsilon_0}\right)\frac{e^2}{r}$$

which equals $-\frac{1}{2}U$ (as calculated above), so $K=+13.6\,\text{eV}$. The total energy initially is $E=K+U=13.6\,\text{eV}-27.2\,\text{eV}=-13.6\,\text{eV}$. To separate a stable hydrogen atom into a proton and an electron at rest very far apart ($U=0$ at $r=\infty$, $K=0$ because $v=0$) requires $+13.6\,\text{eV}$. This is, in fact, the measured ionization energy for hydrogen.

**NOTE** We quoted the kinetic energy as 13.6 eV. But if we wanted to determine the speed of the electron in SI units, we would have to first convert this 13.6 eV to joules (J).

**NOTE** To treat atoms properly, we need to use quantum theory (Chapters 37 to 39). But our "classical" calculation does give the correct answer here.

**EXERCISE G** The kinetic energy of a 1000-kg automobile traveling 20 m/s (70 km/h) would be about (*a*) 100 GeV, (*b*) 1000 TeV, (*c*) $10^6$ TeV, (*d*) $10^{12}$ TeV, (*e*) $10^{18}$ TeV.

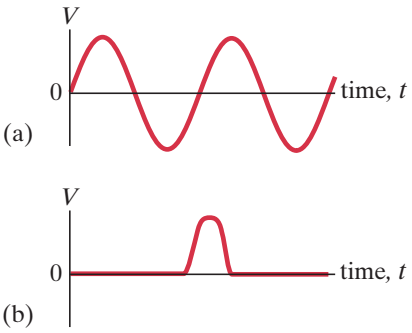

**FIGURE 23–21** Two kinds of signal voltage: (a) sinusoidal, (b) a pulse, both analog. Many other shapes are possible.

# 23–9 Digital; Binary Numbers; Signal Voltage

Batteries and a wall socket are meant to provide a steady **supply voltage** as power to operate a flashlight, lamps, electric appliances, and other electric and electronic devices.

A **signal voltage**, on the other hand, carries **information** of some sort, and is intended to affect something else. A signal voltage varies in time and can also be very brief. A sound such as a pure tone, which may be sinusoidal as we discussed in Chapters 15 and 16 (see Figs. 15–3, 16–3, and 16–13), will produce an output voltage from a high quality microphone that is also sinusoidal (Fig. 23–21a). That signal voltage is amplified and reaches a loudspeaker, making it produce the sound we hear. A signal voltage is sometimes a simple pulse (Fig. 23–21b; see also Figs. 15–2 and 15–18), and often acts to change some aspect of an electronic device.

Signal voltages are sent to cell phones ("I've got signal"), to computers from the Internet, to radios or sound systems, and to TV sets with the information about the sound and picture. Not long ago, signal voltages were mostly **analog**—the voltage varied continuously, as in Fig. 23–21. The electronics that process or amplify an analog signal (as from a microphone) are meant to give as accurate a reproduction as possible for its output (to a loudspeaker).

Today, television and computer signals are **digital**, which are more complicated. They must be encoded so that their meaning is clear, and use a binary number system to represent a numerical value, such as a voltage that gives the brightness of a TV screen pixel. In a normal number, such as 609, there are *ten* choices for each digit—from 0 to 9—and normal numbers are called **decimal** (Latin for ten). Then 609 means: $6 \times 100 + 0 \times 10 + 9 \times 1$. In a **binary** number, each digit or **bit**† has only *two* possibilities, 0 or 1 (sometimes referred to as "off" or "on").‡ In binary, 0001 means "one," 0010 means 2, 0011 means 3, and 1101 means $(1\times2^3 + 1\times2^2 + 0\times2^1 + 1\times2^0) = 8 + 4 + 0 + 1 = 13$ in decimal. See Table 23–3. Any binary value can be represented by a voltage pattern something like that shown in Fig. 23–22.

**TABLE 23–3**
**Binary to Decimal**

| Binary† number | Decimal number |
|---|---|
| 00000000 | 0 |
| 00000001 | 1 |
| 00000010 | 2 |
| 00000011 | 3 |
| 00000100 | 4 |
| 00000111 | 7 |
| 00001000 | 8 |
| 00100101 | 37 |
| 11111111 | 255 |

†Note that we start counting from right to left: the 1's digit is on the far right, then the 2's, the 4's, the 8's, the 16's, the 32's, the 64's, and the 128's.

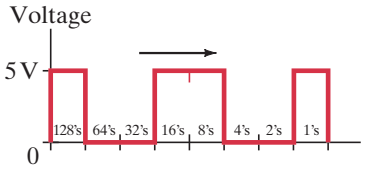

**FIGURE 23–22** A digital signal: This sequence would represent 10011001 or 153 (= 128 + 0 + 0 + 16 + 8 + 0 + 0 + 1).

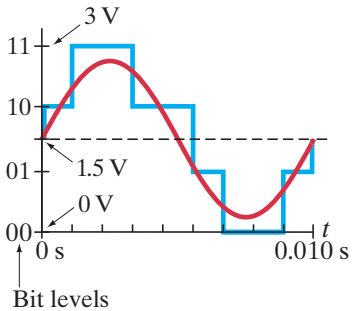
A "1" is a positive voltage such as +5 V, whereas a "0" could be represented as 0 V. For example, the brightness signal that goes to each of the millions of tiny picture elements or "subpixels" of a TV or computer screen (Fig. 23–31, Section 23–10), is contained in a **byte**. One byte is 8 bits, which means



**each byte of 8 bits allows $2^8 = 256$ possibilities**

(that is: 0, 1, 2, up to 255) or 256 shades for each of 3 colors: red, green, blue. The full color of each pixel (the three subpixel colors) has $(256)^3 = 17 \times 10^6$ possibilities.

Digital television signals, which we discuss in the next Section, are usually transmitted over the air at a **transmission rate** or **bit-rate** at about 19 Mb/s = 19 megabits per second for normal HD (high definition). So $19 \times 10^6$ bits pass a given point per second, or one bit every 53 nanoseconds. We could write this in terms of bytes as 2.4 MB/s, where for bytes we use capital B.

When an analog signal, such as the pure sine wave of Fig. 23–21a, is converted to digital (**analog-to-digital converter, ADC**), the digital signal may look like the blue squared-off curve of Fig. 23–23. The digital signal has a limited number of discrete values. The difference between the original continuous analog signal

**FIGURE 23–23** The red analog sine wave, which is at a 100-Hz frequency (1 wavelength is done in 0.010 s), has been converted to a 2-bit (4 level) digital signal (blue). (Bit depth = 2, sample rate = 900 per second.)

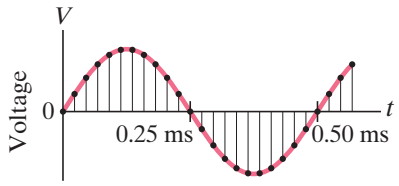
†"Bit" is a contraction of "**b**inary digi**t**", leaving out the 8 intervening letters.

‡*Morse code*, used in the telegraph for over a century (and still around) is binary: dots and dashes. The letter A is · —, an S is · · ·, and an O is — — —. The universal emergency distress signal SOS is · · · — — — · · ·, three dots and three dashes. They may be short and long *sounds*, by voice or from a loudspeaker and heard by an ear. Other possibilities are light flashes or flags.

and its digital approximation is called the **quantization error** or **quantization loss**. To minimize that loss, there are two important factors: (i) the **resolution** or **bit depth**, which is the number of bits or values for the voltage of each sample (= measurement); (ii) the **sampling rate**, which is the number of times per second the original analog voltage is measured or "sampled." (Audio CDs are sampled at 44.1 kHz with a bit depth of 16 bits per sample.)

Consider a digital approximation for the 100-Hz sine wave shown in Figure 23–23. The digital approximation uses (i) a 0 to 3-V, 2-bit depth, measuring only 4 possible voltages (00, 01, 10, 11, meaning 0, 1, 2, 3 in decimal); and (ii) a sampling rate of 9 samples in one cycle or one wavelength, which in one second becomes $(9)(100\,\text{cycles/s}) = 900\,\text{Hz}$, or 900 samples/second. This bit depth (2) and sampling rate (900 Hz) are both of very poor quality. For high quality reproduction, a greater bit depth and higher sampling rate are needed, which requires more data to be transmitted and stored.

For audio CDs, the sampling rate is 44.1 kHz (44,100 samplings every second) and 16-bit resolution, meaning each sampled voltage can have $2^{16} \approx 65{,}000$ different voltage levels between, let's say, 0 and 5 volts. See Fig. 23–24 for details. Audio *recording* often uses 24-bit $(2^{24} \approx 17 \times 10^6$ voltage levels) and 96 kHz (or 192 kHz) to get a better approximation of the original analog signal (on super-CDs, audio DVDs, Blu-ray, or solid-state memory), but must be transferred down to 44.1 kHz and 16-bit to produce ordinary CDs. But iPods and MP3 players have much lower sampling rates and much less detail, which some listeners can notice.



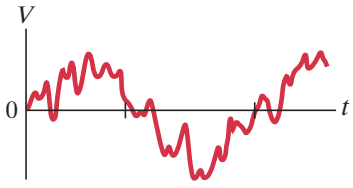


**FIGURE 23–24** The sine wave shown could represent the analog electric signal from a microphone due to a pure 2000-Hz tone. (See Chapters 15 and 16.) The analog-to-digital electronics **samples** the signal—that is, measures and records the signal's voltage at intervals, many times per second. Each black dot on the curve represents the voltage measured (sampled) at that moment in time. The sampling rate in this diagram is 44,100 each second, or 44.1 kHz, like a CD. That is, a sample is taken every $(1\,\text{s})/44{,}100 = 0.000023\,\text{s} = 0.023\,\text{ms}$. In 0.50 ms, as shown here for one wavelength, 22 samples (black dots) are taken. This is an alternate way to represent sampling compared to Fig. 23–23, and shows that we cannot see any changes that might happen between the samplings of the voltage (dots).

Figure 23–24 gives some details about a pure 2000-Hz sound sampled at 44.1 kHz. Normal musical sounds are a complex summation of many such sine waves of different frequencies and amplitudes. A simple summation was shown in Figs. 15–16 and 16–13. Another example is shown in Fig. 23–25, where we can see that the fine details may be missed by a digital conversion. Look at Fig. 23–24: if that signal was instead 20,000 Hz (highest frequency of human hearing), it would be sampled only about two times per wavelength. Both those samples might be zero volts—obviously missing the entire waveform. Over many wavelengths, it might eventually reproduce the waveform somewhat well. But many sounds may change in less than a millisecond, like the initial attack of a piano note or plucked guitar string. Many audiophiles hear the difference between an analog vinyl record and its release as a CD at 44.1 kHz, and even more difference if MP3.

**FIGURE 23–25** This type of complex signal is much more typical than the pure sine wave of Fig. 23–24. Sampling may not catch all the details, especially because the waveform is changing very fast in time.

An analog signal, such as from a microphone or analog radio, can go directly to a loudspeaker, but a digital signal cannot. Digital audio signals must be converted back to analog (**digital-to-analog converters, DAC**) before being sent to a loudspeaker or headset. Even in a TV set, the digital video signals are converted to analog voltages before addressing the color pixels (Section 23–10), although the picture itself might be said to be digital since it is made up of separate pixels.

Digital photographs are made up of millions of "pixels" to produce a sharp image that is not "pixelated" or blurry. Also important (and complicated) are the number of bits provided for colors, plus the ability of the sensors (Chapter 33) to sustain a wide range of brightnesses from dim to bright light conditions.

Digital data has some real advantages: for one, it can be **compressed**, in the sense that repeated information can be reduced so that less memory space is required—fewer bits and bytes. For example, adjacent "pixels" of a photograph that includes a blue sky may be essentially identical. If 500 almost identical pixels can be coded as identical, that takes up less memory (or "size") than to specify all the 500 pixels individually.

Compression schemes, like **jpeg** for photos, lose some information and the resulting picture is less sharp. In audio, MP3 players use about one-tenth the information that a CD does, but many listeners don't notice. Compression is one reason that more data or "information" can be transmitted digitally for a given "bandwidth". **Bandwidth** is the fixed range of frequencies allotted to each radio or TV station; or for digital transmission, it sets the upper limits for the **bit-rate**, the number of bits transmitted per second. Another advantage of digital is that data transmission rate, such as for TV, can be manipulated. For example, a TV station can use all its bandwidth for one very HD program, or instead can transmit two or three programs in lower definition. Both compression and low definition reduce quality.

Table 23–4 summarizes digital values for various audio devices. Also included are the audio of TV and DVD, but not the video which involves more complicated parameters.[†]

**TABLE 23–4 Digital Values, Audio (values typical)**

| | Bit depth | Sampling rate | Transmission rate |
|---|---|---|---|
| Cell phone | 8–18 | 8–22 kHz | <1–100 Mb/s |

| WiFi | — | — | 50–1000 Mb/s |

## *Noise, and Digital Transmission

Digital information transmission has another advantage. Any distortion or unwanted (external) electrical signal that intrudes from outside, broadly called **noise**, can badly corrupt an analog signal: Fig. 23–26a shows a time-varying analog signal, and Fig. 23–26b shows nasty outside noise interfering with it. But a digital signal would still be readable (Figs. 23–26c and d), unless the noise is very large, on the order of half the bit signal itself.

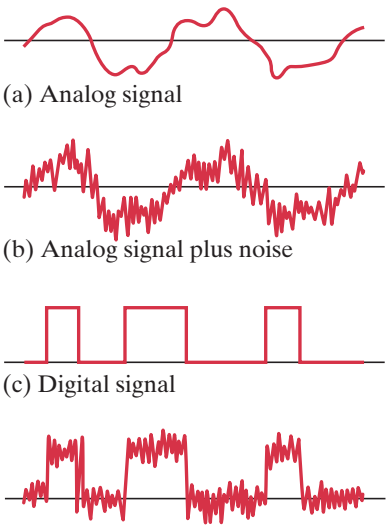

**FIGURE 23–26** (a) Original analog signal and (b) the same signal dirtied up by outside signals (= noise). A digital signal (c) is still readable (d) without error if the noise is not too great.

Electronic noise is like weeds in a carefully tended garden: an unwanted external voltage and electric field, or any unintended alteration in the original signal. Noise has a number of sources. Any electronic signal involves electric charges whose electric field can affect charges in another nearby signal (**crosstalk** or **interference**). External fields, as from high voltage wires, motors, or fluorescent lamps, can produce noise. **Thermal noise** refers to random motion of electrons, much like the "thermal motion" of the molecules in a gas (Sections 17–1 and 18–1, especially Eq. 18–4). Also important, moving electrons can encounter defects in the wire or other material in which they are moving, which can alter the signal. Cell phone reception when far from a cell tower can become seriously degraded by such noise or interference.

Noise can affect a digital transmission signal (or "data link") that is traveling in a copper wire, optical fiber, or through space as an electromagnetic wave such as WiFi, Bluetooth, and broadcast radio and TV (discussed in Chapter 31). The signal may be a continuous **data stream**, or may be a series of "packets" or "blocks" of data. Noise can cause **bit-flips** (bit changed from a 1 to a 0, or a 0 to a 1). Another type of digital error is a **bit deletion**, or **insertion** of an (unwanted) bit.[‡] A single such error can make all subsequent bits be in the wrong position, and thus fully corrupt the signal.

Digital **error detection** schemes exist. An early one was the use of a **parity** bit: for example, an extra bit was added to each byte, and this ninth bit is 1 if

[†]The specifications (Table 23–4) for cell phones, broadcast TV, and radio, are set by the government, because "airwaves are for everyone". Cable TV, satellite TV, and streaming specifications are set by each company providing service; strange, because the last two also use the airwaves (the government only specifies the carrier frequency range allowed in the electromagnetic spectrum, Chapter 31, Fig. 31–12). These forms of TV vary a lot: often they are poorer than broadcast TV (partly depending on your home network), but some companies offer higher quality picture and sound, perhaps at a high price.

[‡]One way bit deletions and insertions can occur is because the sending and receiving of a signal requires a precision clock at each end, since each bit must have a precise duration. But no two clocks can ever be perfectly in synch over long stretches of a bit stream. The slight difference in the two clocks can result in a **bit slip**, either a bit insertion or deletion.

there are an odd number of bits in that byte (such as 10110011 + 1) and a zero if the byte has an even number of bits (such as 10110010 + 0). For this code, the sum of 1's is always even. If the sum comes out odd, there is an error in that byte.

**Error correction** schemes exist, some involving added bits, but none is absolutely perfect. If an error is detected in a data packet, the electronics may send back a message requesting the corrupt packet to be resent or, when a byte is detected to be erroneous, that byte is replaced by a "good guess," such as the previous value or an "average" of the value just before and just after, called Forward Error Correction (FEC).

The quality of an analog signal may be considered reasonably good if its **signal-to-noise ratio** (S/N) is above, perhaps, about 60 dB.[†] (The decibel unit was discussed in Section 16–3 and is a type of energy comparison, Eq. 16–6.) Digital systems have S/N ratios greater than 100 dB. Digital signals are more often specified by the **bit-error-rate** (**BER**). A BER of one bit error in a trillion, or 1 in $10^9$ bits (also written as $\text{BER} = 1 \times 10^{-9}$), is considered sufficient for TV and $1 \times 10^{-13}$ ethernet transmission. Decent cell phone signals may have a BER of $10^{-3}$ (one bit error per thousand bits).

## *23–10 TV and Computer Monitors

The first television receivers used a **cathode ray tube** (**CRT**), but by 2010 they had been replaced mainly by **liquid crystal displays** (**LCD**). Nonetheless, an understanding of how a CRT works is useful in physics (see Section 27–7 on the discovery of the electron).

### *CRT

The operation of a CRT depends on **thermionic emission**, discovered by Thomas Edison (1847–1931). Consider a voltage applied to two small electrodes inside an evacuated glass "tube" as shown in Fig. 23–27: the **cathode** is negative, and the **anode** is positive. If the cathode is heated (usually by an electric current) so that it becomes hot and glowing, it is found that negative charges leave the cathode and flow to the positive anode. These negative charges are now called electrons, but originally they were called **cathode rays** because they seemed to come from the cathode (more detail in Section 27–7 on the discovery of the electron).

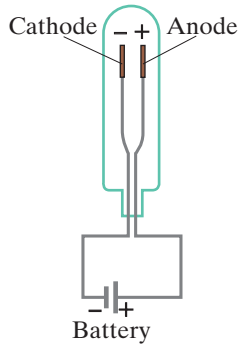

**FIGURE 23–27** If the cathode inside the evacuated glass tube is heated to glowing (by an electric current, not shown), negatively charged "cathode rays" (= electrons) are "boiled off" and flow across to the anode (+), to which they are attracted.

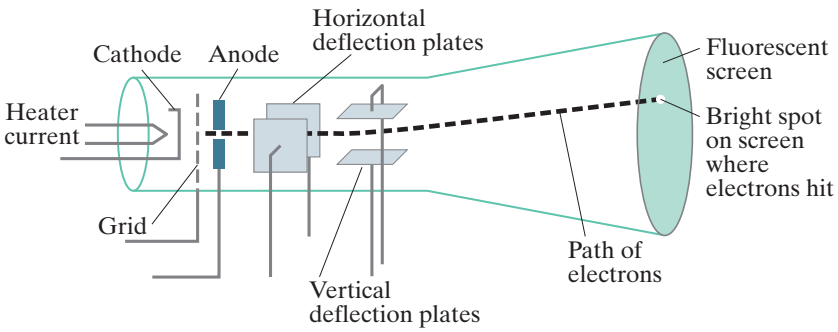
**PHYSICS APPLIED**
*CRT*

Figure 23–28 is a simplified sketch of a CRT which is contained in an evacuated glass tube. A beam of electrons, emitted by the heated cathode, is accelerated by the high-voltage anode and passes through a small hole in that anode.



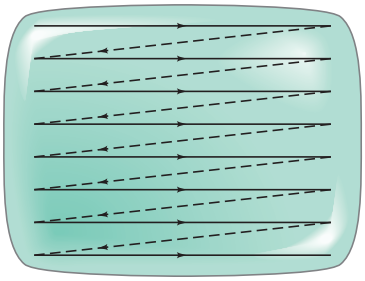


**FIGURE 23–28** A cathode-ray tube. Magnetic deflection coils are commonly used in place of the electric deflection plates shown here. The relative positions of the elements have been exaggerated for clarity.

The inside of the tube face on the right (the screen) is coated with a fluorescent material that glows at the spot where the electrons hit. Voltage applied across the horizontal and vertical deflection plates, Fig. 23–28, can be varied to deflect the electron beam to different spots on the screen.

In TV and computer monitors, the CRT electron beam sweeps over the screen in the manner ("raster") shown in Fig. 23–29 by carefully synchronized voltages applied to the deflection plates (more commonly by magnetic deflection coils—Chapter 27). During each horizontal sweep of the electron beam, the **grid** electrode (Fig. 23–28) receives a signal voltage that limits the flow of electrons at each instant during the sweep; the more negative the grid voltage is, the more electrons are repelled and fewer pass through, producing a less bright spot on the screen.

**FIGURE 23–29** Electron beam sweeps across a CRT television screen in a succession of horizontal lines, referred to as a **raster**. Each horizontal sweep is made by varying the voltage on the horizontal deflection plates (Fig. 23–28). Then the electron beam is moved down a short distance by a change in voltage on the vertical deflection plates, and the process is repeated.

[†]Vinyl records (33 rpm) and analog audio tape recordings have a background noise ("tape hiss") due to mechanical properties of vinyl grooves and magnetic tape; and the electronics can produce noise such as "hum." *Dolby noise reduction* was invented to reduce tape hiss by increasing the level (voltage) of quiet sounds above about 1 kHz during recording, and then in playback reducing their level (along with the hiss) back down.

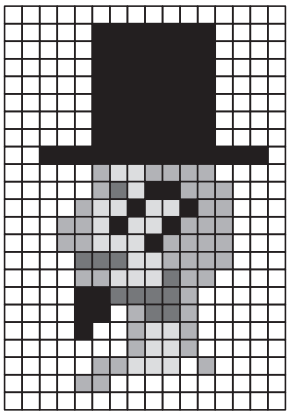

**FIGURE 23–30** Example of an image made up of many small squares or *pixels* (picture elements). This one has rather low resolution.

Thus the varying grid voltage is responsible for the brightness of each spot on the screen. At the end of each horizontal sweep of the electron beam, the horizontal deflection voltage changes dramatically to bring the beam back to the opposite side of the screen, and the vertical voltage changes slightly so the beam begins a new horizontal sweep slightly below the previous one. The difference in brightness of the spots on the screen forms the "picture", Fig. 23–30. **Color screens** have red, green, and blue phosphors which glow when struck by the electron beam. The various brightnesses of adjacent red, green, and blue phosphors (so close together we don't distinguish them) produce almost any color. Analog TV for the U.S. provided 480 visible horizontal sweeps[†] to form a complete picture every $\frac{1}{30}$ s. With 30 new frames or pictures every second (25 in countries with 50-Hz line voltage), a "moving picture" is displayed on the TV screen. (Note: commercial movies on film are 24 frames per second.)

## *Digital TV and Addressing Pixels

PHYSICS APPLIED
*How flat screens work*

Today's TV screens and computer monitors, whether flat or curved, contain millions of tiny *picture elements*, or **pixels** which are "addressed" digitally. A standard pixel consists of 3 **subpixels**, a red, a green, and a blue. A close up of a common arrangement of pixels is shown in Fig. 23–31 for an LCD screen. (How liquid crystals work in an LCD screen is described in Section 34–8.) Subpixels are small enough that at normal viewing distances we don't distinguish them and the separate red (R), green (G), and blue (B) subpixels blend to produce almost any color, depending on the relative brightnesses of the three subpixels. Liquid crystals act as filters (R, G, and B) that filter the light from a white **backlight**, usually fluorescent lamps or *light-emitting diodes* (LED, Section 40–9).[‡] The picture you see on the screen depends on the level of brightness of each subpixel (each encoded in 8 bits), as suggested in Fig. 23–30 for a simple black and white picture.

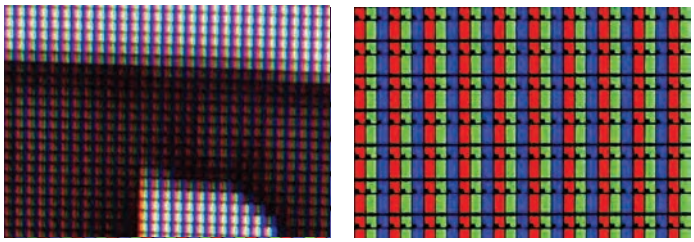

**FIGURE 23–31** Close up photographs of a tiny section of two typical LCD screens. You can even make out wires and transistors in the one on the right.

Standard "high definition" (HD) television screens have 1080 horizontal rows of pixels, each row consisting of 1920 pixels across the screen. That is, roughly 2000 pixels (2K) across by 1000 pixels high, for a total of 2 million pixels. Television in the U.S. is transmitted digitally at a rate of 60 Hz—that is, 60 frames or pictures per second (50 Hz in many countries) which makes the "moving picture." To form one frame, each subpixel must have the correct brightness. We now describe one way of doing this. Ultra high definition 4K screens (UHD) have 4 times the number of pixels, $3840 \times 2160$; their operation is the same as described below.

The brightness of each LCD subpixel (Section 34–8) depends on the voltage between its front and its back: if this voltage $\Delta V$ is zero, that subpixel is at maximum brightness; if $\Delta V$ is at its maximum (which might be +5 volts), that subpixel is dark (no color). Giving the correct voltage (to provide the correct brightness) is called **addressing** the subpixel. Typically the front of the subpixel is maintained at a positive voltage, such as +5 V. On the back of the display, the voltage at each subpixel is provided at the intersection of the 1080 horizontal wires (rows) and $1920 \times 3$ (colors) $\approx$ 6000 vertical wires (columns).

[†]525 lines in total, but only 480 form the picture; the other 45 lines contain other information such as synchronization. The sweep is **interlaced**: that is, every $\frac{1}{60}$ s every other line is traced, and in the next $\frac{1}{60}$ s, the lines in between are traced.

[‡]LEDs are discussed in Section 40–9. They *emit* light. TVs advertised as LED can be confusing. There are two meanings: an LED TV may mean an LCD screen with an LED backlight (preferable to older fluorescent backlight). Secondly, a true LED TV uses light *emitting* diodes and needs no backlight. LED pixels are somewhat large and are used in very large LED displays such as at stadiums. True LED screens for use at home must be very large because LED pixels are large (you have to view far away so you don't notice the pixels). The best home TV sets have OLED (organic LED) screens. See Section 40–9.

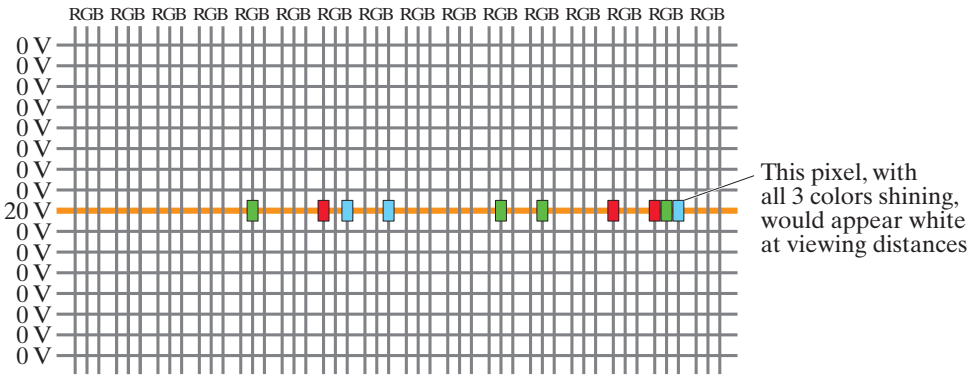

**FIGURE 23–32** Array of wires (a matrix) behind all the pixels on an LCD screen. Each intersection of two wires is at a subpixel (red, green, or blue). One horizontal wire is activated at a time (the orange one at the moment shown) meaning it is at a positive voltage (+20 V) which allows that one row of pixels to be addressed at that moment; all other horizontal wires are at 0 V. At this moment, the data stream arrives to all the vertical wires, presenting the needed voltage (between 0 and 5 V) to produce the correct brightness for each of the nearly 6000 subpixels along the activated row.

See Fig. 23–32, which shows the array, or **matrix**, of wires. Each intersection of one vertical and one horizontal wire lies behind one subpixel. Because 60 frames are shown per second (or maybe 120 in some TV sets), the signal voltages applied are brief, like a pulse (see Fig. 23–21b).

The video signal that arrives at the display **activates** only one horizontal wire at a time (the orange line in Fig. 23–32): that one horizontal wire has a voltage (let's say +20 V) whereas all the others are at 0 V. That 20 V is not applied directly to the pixels, but *allows* the vertical wires to apply briefly the proper "signal voltage" to each subpixel along that row (via a transistor, see below). These signal voltages, the **data stream**, are applied to all the vertical wires just as that one horizontal row is activated: they provide the correct brightness for each subpixel in that activated row. A few subpixels are highlighted in Fig. 23–32. Immediately afterward, the other rows are activated, one by one, until the entire frame has been completed (in $\frac{1}{60}$ s). Then a new frame is started. The addressing of subpixels for each row of each frame serves the same purpose as the sweep of the electron beam in a CRT, Fig. 23–29.

## *Active Matrix (advanced)

High-definition displays use an **active matrix**, meaning that a tiny **thin-film transistor** (**TFT**) is attached to a corner of the back of each subpixel. (Transistors are discussed in Section 40–10.) One electrode of each TFT, called the "source," is connected to the vertical wire which addresses that subpixel, Fig. 23–33, and the "drain" electrode is connected to the back of the subpixel. The horizontal "activating" wire that serves the subpixel is connected to the transistor's **gate** electrode. The gate's voltage, by attracting charge or not, functions as a switch to connect or disconnect the source voltage to the drain and to the back of the subpixel (its front is fixed at +5 V). The potential difference $\Delta V$ across a subpixel, determined by the vertical wire if the gate is "on", effects whether that subpixel will be bright in color ($\Delta V = 0$), black ($\Delta V =$ maximum), or something in between (to produce a possible range of 17 million different colors or shades of color). See Fig. 23–34. All the subpixel TFTs along the one activated horizontal wire (the orange line in Fig. 23–32) will have +20 V at the gate: the TFTs are turned "on," like a switch. That allows electric charge to flow, connecting the vertical wire signal voltage at each TFT source to its drain and to the back of the subpixel, providing the $\Delta V$ corresponding to the correct brightness or shade of the color. Thus all subpixels along one row receive the brightness they need for that line of the frame.

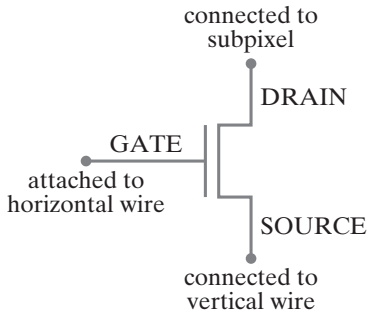

**FIGURE 23–33** Thin-film transistor. One is attached to each screen subpixel.

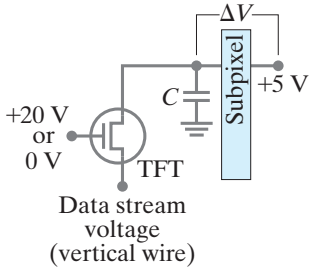

**FIGURE 23–34** Circuit diagram for one subpixel. The front of the subpixel is at +5 V. If the TFT gate is at 20 V (horizontal wire activated), the data stream voltage is applied to the back of the subpixel, and determines the brightness of that subpixel. If the gate is at 0 V (horizontal wire not activated), the TFT is "off": no charge passes through, and the capacitance helps maintain $\Delta V$ until the subpixel is updated $\frac{1}{60}$ s later.

Within a subpixel's electronics is a capacitance (which stores charge—Chapter 24) that helps maintain the $\Delta V$ until that subpixel is **updated** with a new signal for the next frame, $\frac{1}{60}$ s later ($\approx$17 ms). The row below the orange one shown in Fig. 23–32 is activated about 15 $\mu$s later $\left[=\left(\frac{1}{60}\text{ s}\right)\left(\frac{1}{1080\text{ lines}}\right)\right]$. The 6000 vertical wires **(data lines)** get their signal voltages (data stream) updated just before each row is activated in order to establish the brightness of each subpixel in that next row. All 1080 rows are activated, one-by-one, within $\frac{1}{60}$ s ($\approx$17 ms) to complete that frame. Then a new frame is started.

[Note: Digital TV in HD is transmitted at about 19 Mb/s as mentioned in Section 23–9. An HD screen has $1080 \times 1920$ pixels $\approx 2 \times 10^6$ pixels, and each pixel has 8 bits for each of the 3 colors, for a total of $24 \times 2 \times 10^6 \approx 48$ Mb (megabits); at a frame rate of 60 Hz (60 frames/s), if every pixel was addressed we would need a bit rate of $48\text{ Mb} \times 60\text{s}^{-1} \approx 3000$ Mb/s. But TV is sent at only 19 Mb/s and $3000/19 \approx 150$. So in fact, only about $1/150 \approx 1\%$ of pixels can be addressed for each frame! Huge compression is needed. In fact, if you get close to a TV screen when there is lots of movement on the screen, you will see that it is very blurry.]

The TV set or "box" that receives the digital video signal has to decode the signal in order to send analog voltages to the pixels of the screen, and at just the right time. TV stations in the U.S. are allowed to broadcast HD at $1080 \times 1920$ pixels or at $720 \times 1280$, or in standard definition (SD) of $480 \times 704$ pixels. 4K transmission is up to 57 Mb/s, only 3 times faster but with 4 times the number of pixels. 8K would quadruple pixels again; it may be that many people would not notice much difference between 4K (or 8K) and ordinary HD (2K).

When you read 1080p or 1080i for a TV, the "p" stands for "progressive," meaning an entire frame is made in $\frac{1}{60}$ s as described above. The "i" stands for "interlaced," meaning all the odd rows (half the picture) are done in $\frac{1}{60}$ s and then all the even rows are done in the next $\frac{1}{60}$ s, so a full picture is done at 30 per second or 30 Hz, thus reducing the data (or bit) rate. Analog TV (U.S.) was 480i.

**FIGURE 23–35** An electrocardiogram (ECG) trace displayed on a CRT.

### *Oscilloscopes

PHYSICS APPLIED
*Oscilloscope*

An **oscilloscope** is a device for amplifying, measuring, and visually displaying an electrical signal as a function of time on a monitor screen or computer screen. The visible "trace" on the screen, which could be an electrocardiogram of the electric signals from the heart (Fig. 23–35) or a signal from an experiment on nerve conduction, is a plot of the signal voltage (vertically) versus time (horizontally). [In a CRT, the electron beam is swept horizontally at a uniform rate in time by the horizontal deflection plates, Figs. 23–28 and 23–29. The signal to be displayed is applied (after amplification) to the vertical deflection plates.]

## *23–11 Electrocardiogram (ECG or EKG)

PHYSICS APPLIED
*Electrocardiogram*

Each time the heart beats, changes in electrical potential occur on its surface that can be detected using *electrodes* (metal contacts), which are attached to the skin. The changes in potential are small, on the order of millivolts (mV), and must be amplified. They are displayed with a chart recorder on paper, or on a monitor screen, Fig. 23–35. An **electrocardiogram** (ECG or EKG) is the record of the potential changes for a given person's heart. An example is shown in Fig. 23–36.

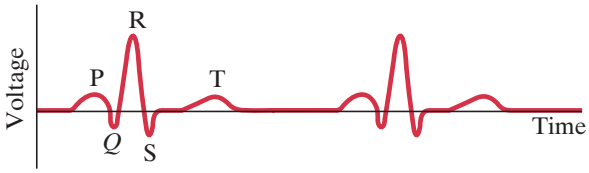

**FIGURE 23–36** Typical ECG. Two heart beats are shown.

Both muscle and nerve cells have an electric dipole layer across the cell wall. That is, in the normal situation there is a net positive charge on the exterior surface and a net negative charge on the interior surface, Fig. 23–37a. The amount of charge depends on the size of the cell, but is approximately $10^{-3}$ C/m$^2$

of surface. For a cell whose surface area is $10^{-5}\,\text{m}^2$, the total charge on each surface is thus $\approx 10^{-8}\,\text{C}$. Just before the contraction of heart muscles, changes occur in the cell wall, so that positive ions on the exterior of the cell are able to pass through the wall and neutralize charge on the inside, or even make the inside surface slightly positive compared to the exterior. This "depolarization" starts at one end of the cell and progresses toward the opposite end, as indicated by the arrow in Fig. 23–37b, until the whole muscle is depolarized; the muscle then repolarizes to its original state (Fig. 23–37a), all in less than a second. Figure 23–37c shows rough graphs of the potential $V$ as a function of time at the two points P and P′ (on either side of this cell) as the depolarization moves across the cell. The path of depolarization within the heart as a whole is more complicated than described here for one cell, and produces the complex potential difference as a function of time, Fig. 23–36.

It is standard procedure to divide a typical electrocardiogram into regions corresponding to the various deflections (or "waves"), as shown in Fig. 23–36. Each of the deflections corresponds to the activity of a particular part of the heart beat (Fig. 13–44). The P wave corresponds to contraction of the atria. The QRS group corresponds to contraction of the ventricles as the depolarization follows a very complicated path. The T wave corresponds to recovery (repolarization) of the heart in preparation for the next cycle.

The ECG is a powerful tool in identifying heart defects. For example, the right side of the heart enlarges if the right ventricle must push against an abnormally large load (as when blood vessels become hardened or clogged). This problem is readily observed on an ECG, because the S wave becomes very large (negatively). *Infarcts*, which are dead regions of the heart muscle that result from heart attacks, are also detected on an ECG because they reflect the depolarization wave.

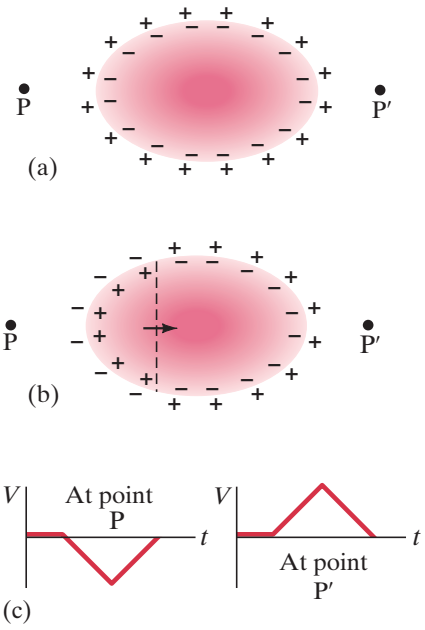

**FIGURE 23–37** A heart muscle cell showing (a) charge dipole layer in resting state; (b) depolarization of cell progressing as muscle begins to contract; and (c) potential $V$ at points P and P′ as a function of time.

# Summary

**Electric potential** is defined as electric potential energy per unit charge. That is, the **electric potential difference** between any two points in space is defined as the difference in potential energy of a test charge $q$ placed at those two points, divided by the charge $q$:

$$V_{\text{ba}} = \frac{U_{\text{b}} - U_{\text{a}}}{q}. \qquad \textbf{(23–2b)}$$

Potential difference is measured in volts $(1\,\text{V} = 1\,\text{J/C})$ and is sometimes referred to as **voltage**.

The change in potential energy of a charge $q$ when it moves through a potential difference $V_{\text{ba}}$ is

$$\Delta U = qV_{\text{ba}}. \qquad \textbf{(23–3)}$$

The potential difference $V_{\text{ba}}$ between two points, a and b, is given by the relation

$$V_{\text{ba}} = V_{\text{b}} - V_{\text{a}} = -\int_{\text{a}}^{\text{b}} \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}. \qquad \textbf{(23–4a)}$$

Thus $V_{\text{ba}}$ can be found in any region where $\vec{\mathbf{E}}$ is known. If the electric field is uniform, the integral is easy: $V_{\text{ba}} = -Ed$, where $d$ is the distance (parallel to the field lines) between the two points.

An **equipotential line** or **surface** is all at the same potential, and is perpendicular to the electric field at all points.

The electric potential due to a single point charge $Q$, relative to zero potential at infinity, is given by

$$V = \frac{1}{4\pi\epsilon_0}\frac{Q}{r}. \qquad \textbf{(23–5)}$$

The potential due to any charge distribution can be obtained by summing (or integrating) over the potentials for all the charges.

The potential due to an **electric dipole** drops off as $1/r^2$. The **dipole moment** is $p = Q\ell$, where $\ell$ is the distance between the two equal but opposite charges of magnitude $Q$.

When $V$ is known, the components of $\vec{\mathbf{E}}$ can be found from the inverse of Eq. 23–4a, namely

$$E_x = -\frac{\partial V}{\partial x}, \qquad E_y = -\frac{\partial V}{\partial y}, \qquad E_z = -\frac{\partial V}{\partial z}. \qquad \textbf{(23–9)}$$

Digital electronics converts an analog **signal voltage** into an approximate digital voltage based on a **binary code**: each **bit** has two possibilities, 1 or 0 (also "on" or "off"). The binary number 01101 equals 13. A **byte** is 8 bits and provides $2^8 = 256$ voltage levels. **Sampling rate** is the number of voltage measurements done on the analog signal per second. The **bit depth** is the number of digital voltage levels available at each sampling. CDs are 44.1 kHz, 16-bit.

[*TV and computer monitors historically used a **cathode ray tube** (CRT) which accelerates electrons by high voltage, and sweeps them across the screen using magnetic coils or electric deflection plates. **LCD flat screens** contain millions of **pixels**, each with a red, green, and blue **subpixel** whose brightness is addressed via a **matrix** of horizontal and vertical wires using a **digital** (**binary**) code.]

[*An **electrocardiogram** (ECG or EKG) records the potential changes of each heart beat as the cells depolarize and repolarize.]

# Questions

1. If two points are at the same potential, does this mean that no net work is done in moving a test charge from one point to the other? Does this imply that no force must be exerted? Explain.
2. If a negative charge is initially at rest in an electric field, will it move toward a region of higher potential or lower potential? What about a positive charge? How does the potential energy of the charge change in each instance? Explain.
3. State clearly the difference (*a*) between electric potential and electric field, (*b*) between electric potential and electric potential energy.
4. An electron is accelerated from rest by a potential difference of 0.20 V. How much greater would its final speed be if it is accelerated with four times as much voltage? Explain.
5. Is there a point along the line joining two equal positive charges where the electric field is zero? Where the electric potential is zero? Explain.
6. Can a particle ever move from a region of low electric potential to one of high potential and yet have its electric potential energy decrease? Explain.
7. If $V = 0$ at a point in space, must $\vec{\mathbf{E}} = 0$? If $\vec{\mathbf{E}} = 0$ at some point, must $V = 0$ at that point? Explain. Give examples for each.
8. Can two equipotential lines cross? Explain.
9. Draw in a few equipotential lines in Figs. 21–35b and c back in Chapter 21, as we did here in Figs. 23–16 and 23–18 for Figs. 21–35d and a.
10. Make a list of rules for and properties of equipotential surfaces or lines. You should be able to find eight distinct rules in the text.
11. When dealing with practical devices, we often take the ground (the Earth) to be 0 V. (*a*) If instead we said the ground was $-10$ V, how would this affect $V$ and $E$ at other points? (*b*) Does the fact that the Earth carries a net charge affect the choice of $V$ at its surface?
12. A satellite orbits the Earth along a gravitational equipotential line. What shape must the orbit be?
13. A conducting sphere carries a charge $Q$ and a second identical conducting sphere is neutral. The two are initially isolated, but then they are placed in contact. (*a*) What can you say about the potential of each when they are in contact? (*b*) Will charge flow from one to the other? If so, how much? (*c*) If the spheres do not have the same radius, how are your answers to parts a and b altered?
14. Suppose the charged ring of Example 23–9 was not uniformly charged, so that the density of charge was twice as great near the top as near the bottom. Assuming the total charge $Q$ is unchanged, would this affect the potential at point P on the axis (Fig. 23–14)? Would it affect the value of $\vec{\mathbf{E}}$ at that point? Is there a discrepancy here? Explain.
15. Consider a metal conductor in the shape of a football (oblong). If it carries a total charge $Q$, where would you expect the charge density $\sigma$ to be greatest, at the ends or along the flatter sides? Explain. [*Hint*: Near the surface of a conductor, $E = \sigma/\epsilon_0$.]
16. If you know $V$ at a point in space, can you calculate $\vec{\mathbf{E}}$ at that point? If you know $\vec{\mathbf{E}}$ at a point can you calculate $V$ at that point? If not, what else must be known in each case?
17. If the electric field $\vec{\mathbf{E}}$ is uniform in a region, what can you infer about the electric potential $V$? If $V$ is uniform in a region of space, what can you infer about $\vec{\mathbf{E}}$?
18. Is the electric potential energy of two isolated unlike charges positive or negative? What about two like charges? What is the significance of the sign of the potential energy in each case?
19. At a particular location, the electric field points due north. In what direction(s) will the rate of change of potential be (*a*) greatest, (*b*) least, and (*c*) zero?
20. Equipotential lines are spaced 1.00 V apart. Does the distance between the lines in different regions of space tell you anything about the relative strengths of $\vec{\mathbf{E}}$ in those regions? If so, what?

# MisConceptual Questions

1. A $+0.2\,\mu$C charge is in a uniform electric field $\vec{\mathbf{E}}$. What happens if that charge is replaced by a $-0.2\,\mu$C charge?
   (*a*) The electric potential changes sign, but the electric potential energy stays the same.
   (*b*) The electric potential stays the same, but the electric potential energy changes sign.
   (*c*) Both the electric potential and electric potential energy change sign.
   (*d*) Both the electric potential and electric potential energy stay the same.
2. Two identical positive charges are placed near each other. At the point halfway between the two charges,
   (*a*) the electric field is zero and the potential is positive.
   (*b*) the electric field is zero and the potential is zero.
   (*c*) the electric field is not zero and the potential is positive.
   (*d*) the electric field is not zero and the potential is zero.
   (*e*) None of these statements is true.
3. Four identical point charges are arranged at the corners of a square [*Hint*: Draw a figure]. The electric field $E$ and potential $V$ at the center of the square are
   (*a*) $E = 0$, $V = 0$.
   (*b*) $E = 0$, $V \neq 0$.
   (*c*) $E \neq 0$, $V \neq 0$.
   (*d*) $E \neq 0$, $V = 0$.
   (*e*) $E = V$ regardless of the value.
4. Which of the following statements is valid?
   (*a*) If the potential at a particular point is zero, the field at that point must be zero.
   (*b*) If the field at a particular point is zero, the potential at that point must be zero.
   (*c*) If the field throughout a particular region is constant, the potential throughout that region must be zero.
   (*d*) If the potential throughout a particular region is constant, the field throughout that region must be zero.

**5.** A positive charge moves in a direction opposite to that of an electric field. What happens to the energy associated with the charge?
(*a*) The electric potential energy of the charge increases, and the kinetic energy decreases.
(*b*) Both the electric potential energy and the kinetic energy of the charge increase.
(*c*) Both the electric potential energy and the kinetic energy of the charge decrease.
(*d*) The electric potential energy of the charge decreases, and the kinetic energy increases.

**6.** A uniform electric field points north. If you move south in this field, the magnitude of the electric potential
(*a*) decreases.
(*b*) increases.
(*c*) stays the same.
(*d*) cannot be determined—more information is needed.

**7.** A proton $(Q = +e)$ and an electron $(Q = -e)$ are in a constant electric field created by oppositely charged parallel plates (Fig. 23–1). You release the heavier proton from near the positive plate and the electron from near the negative plate. When they each hit the opposite plate, which has more kinetic energy?
(*a*) The proton.
(*b*) The electron.
(*c*) Both acquire the same kinetic energy.
(*d*) Neither—there is no change in kinetic energy.
(*e*) They both acquire the same kinetic energy but with opposite signs.

**8.** Figure 23–38 shows the electric potential $V$ at five different points (A, B, C, D, E) in a uniform electric field. At which point is the electric potential the largest?
(*a*) A.
(*b*) B.
(*c*) C.
(*d*) D.
(*e*) E.
(*f*) All the same.

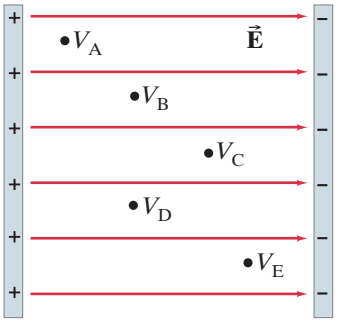

**FIGURE 23–38**
MisConceptual Question 8.

**9.** A tiny test charge $+q$ and another of charge $+2q$ are both placed a distance $r$ above a large plate holding charge $+Q$. Which of the following is true? The two test charges
(*a*) have a different potential and a different potential energy.
(*b*) have a different potential but the same potential energy.
(*c*) have the same potential but a different potential energy.
(*d*) have the same potential and the same potential energy.

**10.** If it takes an amount of work $W$ to move two $+q$ point charges initially an infinite distance apart to a distance $d$ apart from each other, then how much work should it take to move three $+q$ point charges from infinity to a distance $d$ apart from each other?
(*a*) $2W$.
(*b*) $3W$.
(*c*) $4W$.
(*d*) $6W$.

**11.** Which requires the most work—to move a positive charge at point O in a uniform electric field $\vec{\mathbf{E}}$ (Fig. 23–39), from point O to point 1, 2, 3, or 4? All points are the same distance from O.
(*a*) 1.
(*b*) 2.
(*c*) 3.
(*d*) 4.
(*e*) All would require the same amount of work.

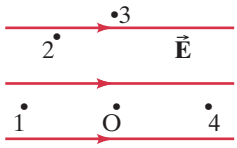

**FIGURE 23–39**
MisConceptual Question 11.

**12.** A positive charge moves in the direction of an electric field. Which of the following statements are true?
(*a*) The potential energy associated with the charge decreases.
(*b*) The potential energy associated with the charge increases.
(*c*) The electric field does positive work on the charge.
(*d*) The electric field does not do any work on the charge.
(*e*) The electric field does negative work on the charge.

**13.** Which of the following is a vector?
(*a*) Electric potential.
(*b*) Electric potential energy.
(*c*) Electric field.
(*d*) Equipotential lines.

# Problems

## 23–1 Electric Potential

**1.** (I) How much work does the electric field do in moving a $-9.7\,\mu\text{C}$ charge from ground to a point whose potential is $+65\,\text{V}$ higher?

**2.** (I) How much work does the electric field do in moving a proton from a point at a potential of $+125\,\text{V}$ to a point at $-65\,\text{V}$?

**3.** (I) What potential difference is needed to stop an electron that has an initial velocity $v = 5.2 \times 10^5\,\text{m/s}$?

**4.** (I) An electron acquires $4.65 \times 10^{-16}\,\text{J}$ of kinetic energy when it is accelerated by an electric field from plate A to plate B. What is the potential difference between the plates, and which plate is at the higher potential?

**5.** (II) (*a*) An electron accelerates from rest in a uniform electric field $E = 6.0 \times 10^3\,\text{N/C}$ to a speed of $2.0 \times 10^4\,\text{m/s}$. How far did it travel? (*b*) Through what potential difference was the electron accelerated?

**6.** (II) (*a*) A proton $(Q = +e,\ m = 1.67 \times 10^{-27}\,\text{kg})$ accelerates from rest in a uniform electric field $E = 4.5 \times 10^4\,\text{N/C}$ for 36 cm. What speed does it attain? (*b*) Through what potential difference was the proton accelerated?

**7.** (II) The work done by an external force to move a $-7.40\,\mu\text{C}$ charge from point A to point B is $15.0 \times 10^{-4}\,\text{J}$. If the charge was started from rest and had $4.82 \times 10^{-4}\,\text{J}$ of kinetic energy when it reached point B, what must be the potential difference between A and B?

## 23–2 Potential Related to Electric Field

**8.** (I) An electric field of 465 V/m is desired between two parallel plates 11.0 mm apart. How large a voltage should be applied?

**9.** (I) The electric field between two parallel plates connected to a 45-V battery is 1600 V/m. How far apart are the plates?

**10.** (I) What is the magnitude of the electric field between two parallel plates 4.0 mm apart if the potential difference between them is 85 V?

**11.** (II) What is the maximum amount of charge that a spherical conductor of radius 5.8 cm can hold in air?

**12.** (II) What minimum radius must a large conducting sphere (of an electrostatic generating machine) have if it is to be at 45,000 V without discharge into the air? How much charge will it carry?

**13.** (II) Two parallel plates, connected to a 65-V power supply, are separated by a uniform air gap. How small can the gap be if the air is not to become conducting by exceeding its breakdown value of $E = 3 \times 10^6$ V/m?

**14.** (II) The electric potential of a very large isolated flat metal plate is $V_0$. It carries a uniform distribution of charge of surface density $\sigma$ $(C/m^2)$, or $\sigma/2$ on each surface. Determine $V$ at a distance $x$ from the plate. Consider the point $x$ to be far from the edges and assume $x$ is much smaller than the plate dimensions.

**15.** (II) The Earth produces an inwardly directed electric field of magnitude 150 V/m near its surface. (*a*) What is the potential of the Earth's surface relative to $V = 0$ at $r = \infty$? (*b*) If the potential of the Earth is chosen to be zero, what is the potential at infinity? (Ignore the fact that positive charge in the ionosphere approximately cancels the Earth's net charge; then later consider how this would affect your answer.)

**16.** (II) A 32-cm-diameter conducting sphere is charged to 480 V relative to $V = 0$ at $r = \infty$. (*a*) What is the surface charge density $\sigma$? (*b*) At what distance will the potential due to the sphere be only 25 V?

**17.** (II) An insulated spherical conductor of radius $r_1$ carries a charge $Q$. A second conducting sphere of radius $r_2$ and initially uncharged is then connected to the first by a long conducting wire. (*a*) After the connection, what can you say about the electric potential of each sphere? (*b*) How much charge is transferred to the second sphere? Assume the connected spheres are far apart compared to their radii. (Why make this assumption?)

**18.** (II) Determine the difference in potential between two points that are distances $R_a$ and $R_b$ from a very long ($\gg R_a$ or $R_b$) straight wire holding a uniform charge per unit length $\lambda$.

**19.** (II) Suppose the end of your finger is charged. (*a*) Estimate the breakdown voltage in air for your finger. (*b*) About what surface charge density would have to be on your finger at this voltage?

**20.** (II) Estimate the electric field in the membrane wall of a living cell. Assume the wall is 10 nm thick and has a potential of 0.10 V across it.

**21.** (II) A uniform electric field $\vec{\mathbf{E}} = -6.30\ \text{N/C}\,\hat{\mathbf{i}}$ points in the negative $x$ direction as shown in Fig. 23–40. The $x$ and $y$ coordinates of points A, B, and C are given on the diagram (in meters). Determine the differences in potential (*a*) $V_{BA}$, (*b*) $V_{CB}$, and (*c*) $V_{CA}$.

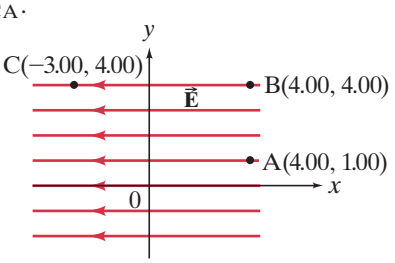

**FIGURE 23–40**
Problem 21.

**22.** (III) A hollow spherical conductor, carrying a net charge $+Q$, has inner radius $r_1$ and outer radius $r_2 = 2r_1$ (Fig. 23–41). At the center of the sphere is a point charge $+Q/2$. (*a*) Write the electric field strength $E$ in all three regions as a function of $r$. [*Hint*: Use Gauss's law.] Then determine the potential as a function of $r$, the distance from the center, for (*b*) $r > r_2$, (*c*) $r_1 < r < r_2$, and (*d*) $0 < r < r_1$. (*e*) Plot both $V$ and $E$ as a function of $r$ from $r = 0$ to $r = 2r_2$.

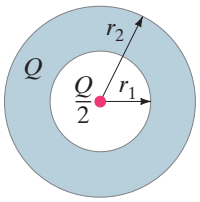

**FIGURE 23–41**
Problem 22.

**23.** (III) A very long conducting cylinder (length $\ell$) of radius $R_0$ $(R_0 \ll \ell)$ carries a uniform surface charge density $\sigma$ $(C/m^2)$. The cylinder is at an electric potential $V_0$. Determine the potential, at points far from the end, at a distance $R$ from the center of the cylinder for (*a*) $R > R_0$ and (*b*) $R < R_0$. (*c*) Is $V = 0$ at $R = \infty$ (assume $\ell = \infty$)? Explain. [*Hint*: Recall Gauss's law.]

## 23–3 Potential Due to Point Charges

[Let $V = 0$ at $x = \infty$.]

**24.** (I) What is the electric potential 15.0 cm from a 3.00 $\mu$C point charge?

**25.** (I) A point charge $Q$ creates an electric potential of +165 V at a distance of 15 cm. What is $Q$ (let $V = 0$ at $r = \infty$)?

**26.** (II) Two point charges, 3.4 $\mu$C and −2.0 $\mu$C, are placed 8.0 cm apart on the $x$ axis. At what points along the $x$ axis are (*a*) the electric field zero and (*b*) the potential zero? Let $V = 0$ at $r = \infty$.

**27.** (II) (*a*) What is the electric potential $2.5 \times 10^{-15}$ m away from a proton (charge $+e$)? (*b*) What is the electric potential energy of a system that consists of two protons $2.5 \times 10^{-15}$ m apart—as might occur inside a typical nucleus?

**28.** (II) Three point charges are arranged at the corners of a square of side $\ell$ as shown in Fig. 23–42. What is the potential at the fourth corner (point A), taking $V = 0$ at a great distance?

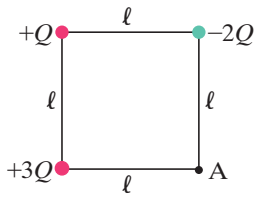

**FIGURE 23–42**
Problem 28.

**29.** (II) A +25 $\mu$C point charge is placed 6.0 cm from an identical +25 $\mu$C point charge. How much work would be required by an external force to move a +0.15 $\mu$C test charge from a point midway between them to a point 1.0 cm closer to either of the charges?

**30.** (II) Point a is 26 cm north of a $-3.8\,\mu C$ point charge, and point b is 36 cm west of the charge (Fig. 23–43). Determine (*a*) $V_b - V_a$, and (*b*) $\vec{E}_b - \vec{E}_a$ (magnitude and direction).

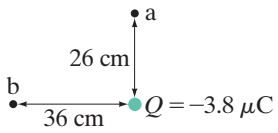

**FIGURE 23–43**
Problem 30.

**31.** (II) Two identical $+5.5\,\mu C$ point charges are initially spaced 8.5 cm from each other. If they are released at the same instant from rest, how fast will they be moving when they are very far away from each other? Assume they have identical masses of 1.0 mg.

**32.** (II) How much voltage must be used to accelerate a proton (radius $1.2 \times 10^{-15}$ m), starting from rest, so that it has sufficient energy to just "touch" a silicon nucleus? A silicon nucleus has a charge of $+14e$ and its radius is about $3.6 \times 10^{-15}$ m. Assume the potential is that for point charges.

**33.** (II) An electron starts from rest 34.5 cm from a fixed point charge with $Q = -0.125$ nC. How fast will the electron be moving when it is very far away?

**34.** (III) Two equal but opposite charges are separated by a distance $d$, as shown in Fig. 23–44. Determine a formula for $V_{BA} = V_B - V_A$ for points B and A on the line between the charges situated as shown.

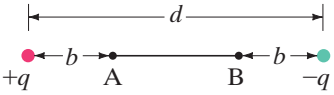

**FIGURE 23–44**
Problem 34.

## 23–4 Potential Due to Any Charge Distribution

**35.** (II) A flat ring of inner radius $R_1$ and outer radius $R_2$, Fig. 23–45, carries a uniform surface charge density $\sigma$. Determine the electric potential at points along the axis (the $x$ axis). [*Hint*: See Example 23–9.]

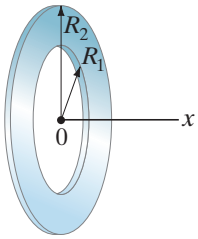

**FIGURE 23–45**
Problem 35.

**36.** (II) A total charge $Q$ is uniformly distributed on a thread of length $\ell$. The thread forms a semicircle. What is the potential at the full-circle's center? (Assume $V = 0$ at large distances.)

**37.** (II) A 12.0-cm-radius thin ring carries a uniformly distributed 15.0 $\mu$C charge. A small 7.5-g sphere with a charge of 3.6 $\mu$C is placed exactly at the center of the ring and given a very small push so it moves along the ring axis ($+x$ axis). How fast will the sphere be moving when it is 2.0 m from the center of the ring (ignore gravity)?

**38.** (II) A thin rod of length $2\ell$ is centered on the $x$ axis as shown in Fig. 23–46. The rod carries a uniformly distributed charge $Q$. Determine the potential $V$ as a function of $y$ for points along the $y$ axis. Let $V = 0$ at infinity.

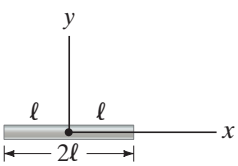

**FIGURE 23–46**
Problems 38, 39, 40, and 53.

**39.** (II) Determine the potential $V(x)$ for points along the $x$ axis outside the rod of Fig. 23–46 (Problem 38).

**40.** (III) The charge on the rod of Fig. 23–46 has a nonuniform linear charge distribution, $\lambda = ax$. Determine the potential $V$ for (*a*) points along the $y$ axis and (*b*) points along the $x$ axis outside the rod.

**41.** (III) Suppose the flat circular disk of Fig. 23–15 (Example 23–10) has a nonuniform surface charge density that depends on the distance $R$ from the center of the disk: $\sigma = aR^2$. Find the potential $V(x)$ at points along the $x$ axis, relative to $V = 0$ at $x = \infty$.

## 23–5 Equipotenial Lines and Surfaces

**42.** (I) Draw a conductor in the oblong shape of a football. This conductor carries a net negative charge, $-Q$. Sketch in a dozen or so electric field lines and equipotential lines surrounding the football.

**43.** (II) Equipotential surfaces are to be drawn 100 V apart near a very large uniformly charged metal plate carrying a surface charge density $\sigma = 0.75\,\mu C/m^2$. How far apart (in space) are the equipotential surfaces?

**44.** (II) A metal sphere of radius $r_0 = 0.35$ m carries a charge $Q = 0.50\,\mu C$. Equipotential surfaces are to be drawn for 100-V intervals outside the sphere. Determine the radius $r$ of (*a*) the first, (*b*) the tenth, and (*c*) the 100th equipotential from the surface.

## 23–6 Dipoles

**45.** (II) Calculate the electric potential due to a tiny dipole whose dipole moment is $4.8 \times 10^{-30}$ C · m at a point $4.1 \times 10^{-9}$ m away if this point is (*a*) along the axis of the dipole nearer the positive charge; (*b*) 45° above the axis but nearer the positive charge; (*c*) 45° above the axis but nearer the negative charge. Let $V = 0$ at $r = \infty$.

**46.** (III) The dipole moment, considered as a vector, points from the negative to the positive charge. The water molecule, Fig. 23–47, has a dipole moment $\vec{p}$ which can be considered as the vector sum of the two dipole moments $\vec{p}_1$ and $\vec{p}_2$ as shown. The distance between each H and the O is about $0.96 \times 10^{-10}$ m. The lines joining the center of the O atom with each H atom make an angle of 104° as shown, and the net dipole moment has been measured to be $p = 6.1 \times 10^{-30}$ C · m. (*a*) Determine the effective charge $q$ on each H atom. (*b*) Determine the electric potential, far from the molecule, due to each dipole, $\vec{p}_1$ and $\vec{p}_2$, and show that they sum to

$$V = \frac{1}{4\pi\epsilon_0}\frac{p\cos\theta}{r^2},$$

where $p$ is the magnitude of the net dipole moment, $\vec{p} = \vec{p}_1 + \vec{p}_2$, and $V$ is the total potential due to both $\vec{p}_1$ and $\vec{p}_2$. Take $V = 0$ at $r = \infty$.

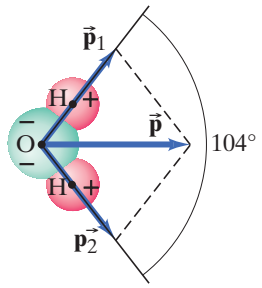

**FIGURE 23–47**
Problem 46.

## 23–7 $\vec{E}$ Determined from $V$

**47.** (I) Show that the electric field of a single point charge (Eq. 21–4) follows from Eq. 23–5, $V = (1/4\pi\epsilon_0)(Q/r)$.

**48.** (II) What is the potential gradient just outside the surface of a uranium nucleus $(Q = +92e)$ whose diameter is about $15 \times 10^{-15}$ m?

**49.** (II) The electric potential between two parallel conducting plates is given by $V(x) = (8.5\,\text{V/m})x + 4.5\,\text{V}$, with $x = 0$ taken at one of the plates and $x$ positive in the direction toward the other plate. What is the charge density on the plates?

**50.** (II) The electric potential in a region of space varies as $V = by/(a^2 + y^2)$. Determine $\vec{\mathbf{E}}$.

**51.** (II) In a certain region of space, the electric potential is given by $V = ay^2 + bxy - cxyz$. Determine the electric field vector, $\vec{\mathbf{E}}$, in this region.

**52.** (II) A dust particle with mass of 0.050 g and a charge of $2.0 \times 10^{-6}$ C is in a region of space where the potential is given by $V(x) = (2.0\,\text{V/m}^2)x^2 - (3.0\,\text{V/m}^3)x^3$. If the particle starts at $x = 2.5$ m, what is the initial acceleration of the charge?

**53.** (III) Use the results of Problems 38 and 39 to determine the electric field due to the uniformly charged rod of Fig. 23–46 for points (*a*) along the *y* axis and (*b*) along the *x* axis.

## 23–8 Electrostatic Potential Energy; Electron Volt

**54.** (I) How much work must be done to bring three electrons from a great distance apart to within $1.0 \times 10^{-10}$ m from one another (at the corners of an equilateral triangle)?

**55.** (I) What potential difference is needed to give a helium nucleus $(Q = 3.2 \times 10^{-19}\,\text{C})$ 165 keV of kinetic energy?

**56.** (I) What is the speed of (*a*) a 0.50-keV (kinetic energy) electron and (*b*) a 0.50-keV proton?

**57.** (II) Many chemical reactions release energy. Suppose that at the beginning of a reaction, an electron and a proton are separated by 0.110 nm, and their final separation is 0.100 nm. How much electric potential energy was lost in this reaction (in units of eV)?

**58.** (II) Four equal point charges, $Q$, are fixed at the corners of a square of side $b$. (*a*) What is their total electrostatic potential energy? (*b*) How much potential energy will a fifth charge, $Q$, have at the center of the square (relative to $V = 0$ at $r = \infty$)? (*c*) If constrained to remain in that plane, is the fifth charge in stable or unstable equilibrium? (*d*) If a negative $(-Q)$ charge is at the center, is it in stable equilibrium?

**59.** (II) An electron starting from rest acquires 4.8 keV of kinetic energy in moving from point A to point B. (*a*) How much kinetic energy would a proton acquire, starting from rest at B and moving to point A? (*b*) Determine the ratio of their speeds at the end of their respective trajectories.

**60.** (III) Determine the total electrostatic potential energy of a conducting sphere of radius $r_0$ that carries a total charge $Q$ distributed uniformly on its surface.

**61.** (III) Determine the total electrostatic potential energy of a nonconducting sphere of radius $r_0$ carrying a total charge $Q$ distributed uniformly throughout its volume.

## 23–9 Digital

**62.** (I) Write the decimal number 108 in binary.

**63.** (I) Write the decimal number 3597 in binary.

**64.** (I) Write the binary number 01010101 as a decimal number.

**65.** (I) Write the binary number 1010101010101010 as a decimal number.

**66.** (II) For each of the following bytes of binary data, state whether an additional parity bit should be a "0" or a "1": (*a*) 01101100, (*b*) 11011011, (*c*) 10010010.

**67.** (II) (*a*) 16-bit sampling provides how many different possible voltages? (*b*) 24-bit sampling provides how many different possible voltages? (*c*) For color TV, 3 subpixels, each 8 bits, provides a total of how many different colors?

**68.** (II) Consider a rather coarse 4-bit analog-to-digital conversion where the maximum voltage is 5.0 V. (*a*) What voltage does 1011 represent? (*b*) What is the 4-bit representation for 2.0 V?

**69.** (II) In the commonly used "ASCII" code, numbers, letters and other symbols are stored as 8-digit binary numbers. The code for the letter A is 00100001, and the next letters are just the next binary numbers. (*a*) What binary numbers are used to store C and T? (*b*) What would be the decimal numbers for ASCII B and H? (*c*) Using the format shown in Fig. 23–22, sketch the waveform of the letters that spell CAT.

**70.** (II) A few extraterrestrials arrived. They had two hands, but claimed that $3 + 2 = 11$. How many fingers did they have on their two hands? Note that our decimal system (and ten characters: 0, 1, 2, $\cdots$, 9) surely has its origin because we have ten fingers. [*Hint*: 11 is in their system. In our decimal system, the result would be written as 5.]

**71.** (III) An analog voltage signal can vary from 0 V to 5.00 V, and it is to be converted to an 8-bit binary representation. (*a*) What voltage, to the nearest 0.01 V, would have a binary representation of 01110101? (*b*) What binary number would best represent 3.47 volts?

## *23–10 TV and Computer Monitors

***72.** (II) Figure 23–48 is a photograph of a computer screen shot by a camera set at an exposure time of $\frac{1}{4}$ s. During the exposure the cursor arrow was moved around by the mouse, and we see it 15 times. (*a*) Explain why we see the cursor 15 times. (*b*) What is the refresh rate of the screen?

**FIGURE 23–48** Problem 72.

***73.** (II) For the greyscale picture in Fig. 23–30, write the line of binary numbers that gives the eleventh row of the picture. Take 000 as white and 100 as black. For the purpose of reading your answer more easily, separate each number by a semi-colon.

***74.** (II) Estimate how many gigabytes of data would be sent for 5.00 minutes of color HD TV in the U.S. if no data compression was used.

*75. (II) (*a*) Calculate the bit-rate that would be required to address all of the 6 million subpixels $(3 \times 1080 \times 1920)$ of an HD TV screen at a (refresh) rate of 60 per second. (*b*) Compare to the present-day digital fixed rate of 19 Mb/s, and explain the difference. (*c*) On average, what % of pixels get refreshed for each frame (refreshed at 60 Hz)? (*d*) If it were necessary to address every pixel for each frame, how many full scans of the screen could be done per second at 19 Mb/s?

*76. (III) (*a*) How many bits of data would it take to convey Fig. 23–30 assuming you had to specify a row number, an element number, and a 5-level greyscale for each pixel? (*b*) Describe a data compression system that would reduce the number of bits required to convey Fig. 23–30. (*c*) How many bits of data would be needed using your data compression scheme? (*d*) Would your system work for any picture with only 4 greytones? Why or why not?

# General Problems

77. If the electrons in a single raindrop, 3.5 mm in diameter, could be removed from the Earth (without removing the atomic nuclei), by how much would the potential of the Earth increase?

78. By rubbing a nonconducting material, a charge of $10^{-8}$ C can readily be produced. If this is done to a sphere of radius 15 cm, estimate the potential produced at the surface. Let $V = 0$ at $r = \infty$.

79. At each corner of a cube of side $\ell$ there is a point charge $+Q$, Fig. 23–49. (*a*) What is the potential at the center of the cube ($V = 0$ at $r = \infty$)? (*b*) What is the potential at each corner due to the other seven charges? (*c*) What is the total potential energy of this system?

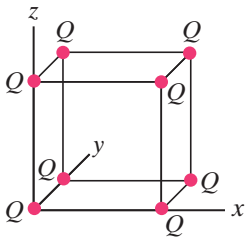

**FIGURE 23–49** Problem 79.

80. A $+38\,\mu$C point charge is placed 36 cm from an identical $+38\,\mu$C charge. Then a $-1.8\,\mu$C charge is moved from point A to point B as shown in Fig. 23–50. What is the change in potential energy?

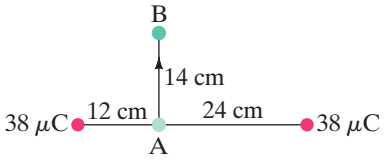

**FIGURE 23–50** Problem 80.

81. A proton $(q = +e)$ and an alpha particle $(q = +2e)$ are accelerated by the same voltage $V$. Which gains the greater kinetic energy, and by what factor?

82. In an older television tube (CRT), electrons are accelerated by thousands of volts through a vacuum. If such a television set is laid on its back, would electrons be able to move upward against the force of gravity? What potential difference, acting over a distance of 2.4 cm, would be needed to balance the downward force of gravity so that an electron would remain stationary? Assume that the electric field is uniform.

83. Two point charges are fixed 4.0 cm apart from each other. Their charges are $Q_1 = Q_2 = 6.5\,\mu$C, and their masses are $m_1 = 2.5$ mg and $m_2 = 3.5$ mg. (*a*) If $Q_1$ is released from rest, what will be its speed after a very long time? (*b*) If both charges are released from rest at the same time, what will be the speed of $Q_1$ after a very long time? Ignore the environment.

84. Two charges are placed as shown in Fig. 23–51 with $q_1 = 1.2\,\mu$C and $q_2 = -3.3\,\mu$C. Find the potential difference between points A and B.

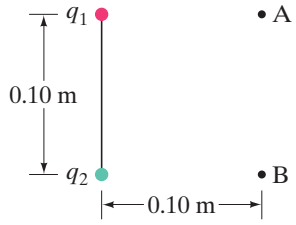

**FIGURE 23–51** Problem 84.

85. In a **photocell**, ultraviolet (UV) light provides enough energy to some electrons in barium metal to eject them from the surface at high speed. To measure the maximum energy of the electrons, another plate above the barium surface is kept at a negative enough potential that the emitted electrons are slowed down and stopped, and return to the barium surface. See Fig. 23–52. If the plate voltage is $-3.02$ V (compared to the barium) when the fastest electrons are stopped, what was the speed of these electrons when they were emitted?

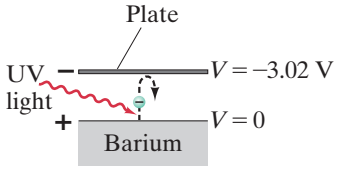

**FIGURE 23–52** Problem 85.

86. An electron is accelerated horizontally from rest by a potential difference of 3500 V. It then passes between two horizontal plates 6.5 cm long and 1.3 cm apart that have a potential difference of 250 V (Fig. 23–53). At what angle $\theta$ will the electron be traveling after it passes between the plates? Assume the electric field between the plates is uniform.

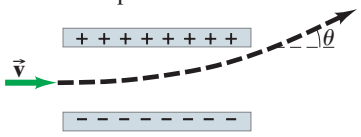

**FIGURE 23–53** Problem 86.

87. Three charges are at the corners of an equilateral triangle (side $\ell$) as shown in Fig. 23–54. Determine the potential at the midpoint of each of the sides. Let $V = 0$ at $r = \infty$.

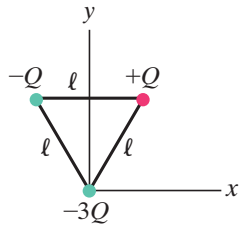

**FIGURE 23–54** Problem 87.

**88.** Near the surface of the Earth there is an electric field of about 150 V/m which points downward. Two identical balls with mass $m = 0.550\,\text{kg}$ are dropped from a height of 2.00 m, but one of the balls is positively charged with $q_1 = 650\,\mu\text{C}$, and the second is negatively charged with $q_2 = -650\,\mu\text{C}$. Use conservation of energy to determine the difference in the speeds of the two balls when they hit the ground. (Neglect air resistance.)

**89.** A lightning flash transfers 4.0 C of charge and 5.2 MJ of energy to the Earth. (*a*) Across what potential difference did it travel? (*b*) How much water could this boil and vaporize, starting from room temperature? [See also Chapter 19.]

**90.** Determine the components of the electric field, $E_x$ and $E_y$, as a function of $x$ and $y$ in the $xy$ plane due to a dipole, Fig. 23–55, starting with Eq. 23–7. Assume $r = (x^2 + y^2)^{\frac{1}{2}} \gg \ell$.

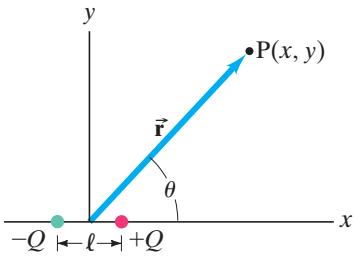

**FIGURE 23–55** Problem 90.

**91.** A nonconducting sphere of radius $r_0$ carries a total charge $Q$ distributed uniformly throughout its volume. Determine the electric potential (you may want to use Gauss's law) as a function of the distance $r$ from the center of the sphere for (*a*) $r > r_0$ and (*b*) $r < r_0$. Take $V = 0$ at $r = \infty$. (*c*) Plot $V$ versus $r$ and $E$ versus $r$.

**92.** The volume charge density $\rho_E$ within a sphere of radius $r_0$ is distributed according to the following spherically symmetric relation

$$\rho_E(r) = \rho_0\left[1 - \frac{r^2}{r_0^2}\right]$$

where $r$ is measured from the center of the sphere and $\rho_0$ is a constant. For a point P inside the sphere $(r < r_0)$, determine the electric potential $V$. Let $V = 0$ at infinity. [*Hint*: Start with Gauss's law.]

**93.** Binary numbers can be used for addition. The same basic rules apply as for decimal numbers: add in columns, and carry when the total amount in a column is greater than or equal to the value of the column. Consider the decimal numbers 14, 45, and 103. Convert these three numbers to 8-bit binary numbers, add them as binary numbers, and then change that binary sum to a decimal number. Show all of your work. Also show that you get the same result from this process as if you had just added the three numbers in decimal format.

**94.** Thunderclouds may develop a voltage difference of about $5 \times 10^7$ V. Given that an electric field of $3 \times 10^6$ V/m is required to produce an electrical spark within a volume of air, estimate the length of a thundercloud *lightning bolt*. [Can you see why, when lightning strikes from a cloud to the ground, the bolt has to propagate as a sequence of steps?]

**95.** The potential in a region of space is given by $V = B/(x^2 + R^2)^2$ where $B = 120\,\text{V}\cdot\text{m}^4$ and $R = 0.20\,\text{m}$. (*a*) Find $V$ at $x = 0.20\,\text{m}$. (*b*) Find $\vec{\mathbf{E}}$ as a function of $x$. (*c*) Find $\vec{\mathbf{E}}$ at $x = 0.20\,\text{m}$.

**96.** A charge $-q_1$ of mass $m$ rests on the $y$ axis at a distance $b$ above the $x$ axis. Two positive charges of magnitude $+q_2$ are fixed on the $x$ axis at $x = +a$ and $x = -a$, respectively (Fig. 23–56). If the $-q_1$ charge is given an initial velocity $v_0$ in the positive $y$ direction, what is the minimum value of $v_0$ such that the charge escapes to a point infinitely far away from the two positive charges?

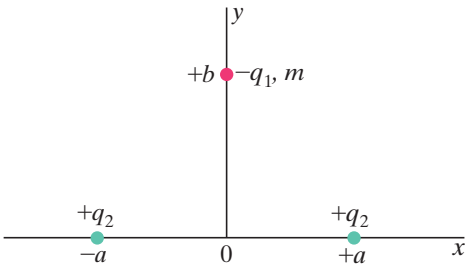

**FIGURE 23–56** Problem 96.

**97.** An electric field greater than about $3 \times 10^6$ V/m causes air to break down (electrons are removed from air atoms and then recombine, emitting light). If you shuffle along a carpet and then reach for a doorknob, a spark flies across a gap you estimate to be 1 mm between your finger and the doorknob. Estimate the voltage between your finger and the doorknob. Why is no harm done?

**98.** A **Geiger counter** is used to detect charged particles emitted by radioactive nuclei. It consists of a thin, positively charged central wire of radius $R_a$ surrounded by a concentric conducting cylinder of radius $R_b$ with an equal negative charge (Fig. 23–57). The charge per unit length on the inner wire is $\lambda$ (units C/m). The interior space between wire and cylinder is filled with low-pressure inert gas. Charged particles ionize some of these gas atoms; the resulting free electrons are attracted toward the positive central wire. If the radial electric field is strong enough, the freed electrons gain enough energy to ionize other atoms, causing an "avalanche" of electrons to strike the central wire, generating an electric "signal." (*a*) Find the expression for the electric field between the wire and the cylinder, and (*b*) show that the potential difference between $R_a$ and $R_b$ is

$$V_a - V_b = \left(\frac{\lambda}{2\pi\epsilon_0}\right)\ln\left(\frac{R_b}{R_a}\right).$$

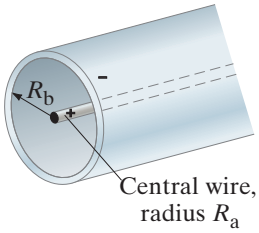

**FIGURE 23–57** Problem 98.

**99.** In the Bohr model of the hydrogen atom, an electron orbits a proton (the nucleus) in a circular orbit of radius $0.53 \times 10^{-10}$ m. (*a*) What is the electric potential at the electron's orbit due to the proton? (*b*) What is the kinetic energy of the electron? (*c*) What is the total energy of the electron in its orbit? (*d*) What is the *ionization energy*—that is, the energy required to remove the electron from the atom and take it to $r = \infty$, at rest? Express the results of parts (*b*), (*c*), and (*d*) in joules and eV.

**100.** The **liquid-drop model** of the nucleus suggests that high-energy oscillations of certain nuclei can split ("fission") a large nucleus into two unequal fragments plus a few neutrons. Using this model, consider the case of a uranium nucleus fissioning into two spherical fragments, one with a charge $q_1 = +38e$ and radius $r_1 = 5.5 \times 10^{-15}$ m, the other with $q_2 = +54e$ and $r_2 = 6.2 \times 10^{-15}$ m. Calculate the electric potential energy (MeV) of these fragments, assuming that the charge is uniformly distributed throughout the volume of each spherical nucleus and that their surfaces are initially in contact at rest. The electrons surrounding the nuclei can be neglected. This electric potential energy will then be entirely converted to kinetic energy as the fragments repel each other. How does your predicted kinetic energy of the fragments agree with the observed value associated with uranium fission (approximately 200 MeV total)? [$1\,\text{MeV} = 10^6\,\text{eV}$.]

**101.** A thin flat disk of radius $R_0$ carries a total charge $Q$ that is distributed uniformly over its surface. The electric potential at a distance $x$ on the $x$ axis is given by

$$V(x) = \frac{Q}{2\pi\epsilon_0 R_0^2}\left[(x^2 + R_0^2)^{\frac{1}{2}} - x\right].$$

(See Example 23–10.) Show that the electric field at a distance $x$ on the $x$ axis is given by

$$E(x) = \frac{Q}{2\pi\epsilon_0 R_0^2}\left(1 - \frac{x}{(x^2 + R_0^2)^{\frac{1}{2}}}\right).$$

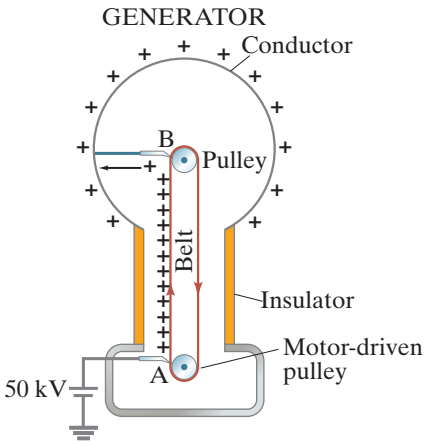
Make graphs of $V(x)$ and $E(x)$ as a function of $x/R_0$ for $x/R_0 = 0$ to 4. (Do the calculations in steps of 0.1.) Use $Q = 5.0\,\mu\text{C}$ and $R_0 = 10\,\text{cm}$ for the calculation and graphs.

**102.** A manufacturer claims that a carpet will not generate more than 6.0 kV of static electricity. What magnitude of charge would have to be transferred between a carpet and a shoe for there to be a 6.0-kV potential difference between the shoe and the carpet? Approximate the area of the shoe and assume the shoe and carpet are large sheets of charge separated by a small distance $d = 1.0\,\text{mm}$.

**103.** A nonconducting sphere of radius $r_2$ contains a concentric spherical cavity of radius $r_1$. The material between $r_1$ and $r_2$ carries a uniform charge density $\rho_E$ $(\text{C/m}^3)$. Determine the electric potential $V$, relative to $V = 0$ at $r = \infty$, as a function of the distance $r$ from the center for (*a*) $r > r_2$, (*b*) $r_1 < r < r_2$, and (*c*) $0 < r < r_1$. Is $V$ continuous at $r_1$ and $r_2$?

**104.** Figure 23–19 shows contour lines (elevations). Just for fun, assume they are equipotential lines on a flat 2-dimensional surface with the values shown being in volts. Estimate the average magnitude and the direction of the "electric field" (*a*) between Greenstone Lake and the first (lowest) Conness Lake (as you head upstream) and (*b*) on the Conness Glacier. Assume that up is $+y$, right is $+x$, and that Greenstone Lake is about 1.0 km wide at its widest.

**105.** A **Van de Graaff generator** (Fig. 23–58) can develop a very large potential difference, even millions of volts. Electrons are pulled off the belt by the high voltage pointed electrode (positive) at A, leaving the belt positively charged. (Recall Example 23–5 where we saw that near sharp points the electric field is high and ionization can occur.) The belt carries the positive charge up inside the spherical shell where electrons from the large conducting sphere are attracted over to the pointed conductor at B, leaving the outer surface of the conducting sphere positively charged. As more charge is brought up, the sphere reaches extremely high voltage. Consider a Van de Graaff generator with a sphere of radius 0.20 m. (*a*) What is the electric potential on the surface of the sphere when electrical breakdown occurs $(E = 3 \times 10^6\,\text{V/m})$? Assume $V = 0$ at $r = \infty$. (*b*) What is the charge on the sphere for the potential found in part (*a*)?



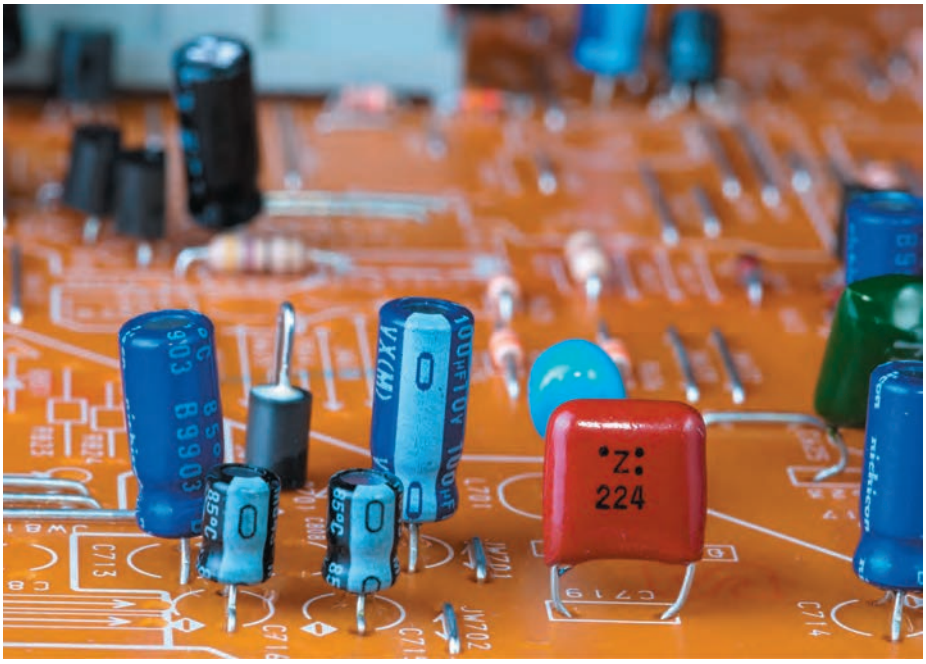


**FIGURE 23–58** Problem 105.

## ANSWERS TO EXERCISES

**A:** (*a*) $-8.0 \times 10^{-16}$ J; (*b*) $9.8 \times 10^5$ m/s.
**B:** (*d*).
**C:** (*d*).
**D:** 0.72 J.
**E:** (*c*).
**F:** (*c*).
**G:** (*d*).

Capacitors come in a wide range of sizes and shapes, only a few of which are shown here. A capacitor is basically two conductors that do not touch, and which therefore can store charge of opposite sign on its two conductors. Capacitors are used in a wide variety of circuits, for various purposes including storing of electric charge, storage of electric energy, as signal filters, and in timing circuits, as we shall see in this and later Chapters.

CHAPTER 24

# Capacitance, Dielectrics, Electric Energy Storage

CONTENTS

24–1 Capacitors
24–2 Determination of Capacitance
24–3 Capacitors in Series and Parallel
24–4 Storage of Electric Energy
24–5 Dielectrics
*24–6 Molecular Description of Dielectrics

**CHAPTER-OPENING QUESTION—Guess now!**

A fixed potential difference $V$ exists between a pair of close parallel plates carrying opposite charges $+Q$ and $-Q$. Which of the following would not increase the magnitude of charge that you could put on the plates?

**(a)** Increase the size of the plates.
**(b)** Move the plates farther apart.
**(c)** Fill the space between the plates with paper.
**(d)** Increase the fixed potential difference $V$.
**(e)** None of the above.

This Chapter will complete our study of electrostatics. It deals first of all with an important device, the capacitor, which is used in many electronic circuits. We will also discuss electric energy storage and the effects of an insulator, or dielectric, on electric fields and potential differences.

## 24–1 Capacitors

**PHYSICS APPLIED**
*Uses of capacitors*

A **capacitor** is a device that can store electric charge, and normally consists of two conducting objects (usually plates or sheets) placed near each other but not touching. Capacitors (sometimes called **condensers**) are widely used in electronic circuits. They store charge for later use, such as in a camera flash, and as energy backup in devices like computers for power failures. Capacitors also block surges of charge and energy to protect circuits. Very tiny capacitors serve as memory for the "ones" and "zeros" of the binary code in the random access memory (RAM)

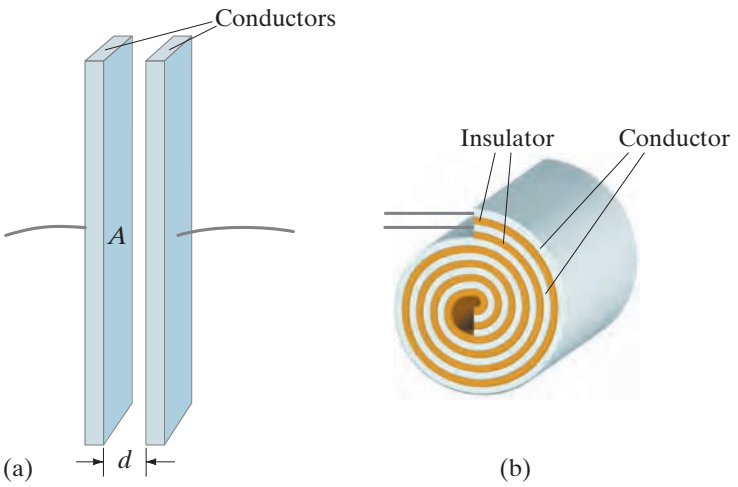

**FIGURE 24–1** Capacitors: diagrams of (a) parallel plate, (b) cylindrical (rolled up parallel plate).

of computers and other electronic devices (for example, in Fig. 23–34). Capacitors serve many other applications, some of which we will discuss.

A simple capacitor consists of a pair of parallel plates of area $A$ separated by a small distance $d$ (Fig. 24–1a). Often the two plates are rolled into the form of a cylinder with plastic, paper, or other insulator separating the plates, Fig. 24–1b. In circuit diagrams, the symbol

 or  [capacitor symbol]

represents a capacitor. A battery, which is a source of voltage, is indicated by the symbol:

 [battery symbol]

with unequal arms.

If a voltage is applied across a capacitor by connecting the capacitor to a battery with conducting wires as in Fig. 24–2, the two plates quickly become charged: one plate acquires a negative charge, the other an equal amount of positive charge. Each battery terminal and the plate of the capacitor connected to it are at the same potential; hence the full battery voltage appears across the capacitor. For a given capacitor, it is found that the amount of charge $Q$ acquired by each plate is proportional to the magnitude of the potential difference $V$ between the plates:

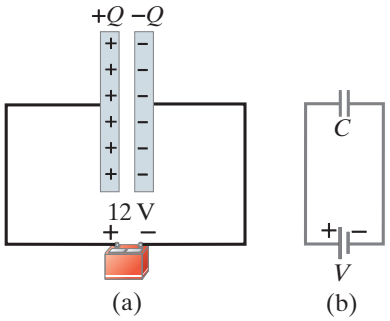
$$Q = CV. \qquad \textbf{(24–1)}$$

The constant of proportionality, $C$, in Eq. 24–1 is called the **capacitance** of the capacitor. The unit of capacitance is coulombs per volt, and this unit is called a **farad** (F). Commonly used capacitors have capacitance in the range of 1 pF $(\text{picofarad} = 10^{-12}\,\text{F})$ to $10^{3}\,\mu\text{F}$ $(\text{microfarad} = 10^{-6}\,\text{F})$. The relation, Eq. 24–1, was first suggested by Alessandro Volta (1745–1827, inventor of the electric battery as we discuss in the next Chapter). The capacitance $C$ does not in general depend on $Q$ or $V$. Its value depends only on the size, shape, and relative position of the two conductors, and also on the material that separates them.

In Eq. 24–1, and from now on, we use simply $V$ (in italics) to represent a *potential difference*, such as that produced by a battery, rather than $V_{ba}$, $\Delta V$, or $V_b - V_a$, as previously.

Also, be sure not to confuse *italic* letters $V$ and $C$ which stand for the quantities voltage and capacitance, with non-italic V and C which stand for the units volts and coulombs.

**EXERCISE A** Graphs for charge versus voltage are shown in Fig. 24–3 for three capacitors, A, B, and C. Which has the greatest capacitance?



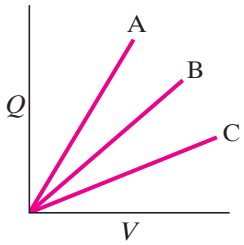


**FIGURE 24–2** (a) Parallel-plate capacitor connected to a battery. (b) Same circuit shown using symbols.

**FIGURE 24–3** Exercise A.

**CAUTION**

*V = potential difference from here on*

## 24–2 Determination of Capacitance

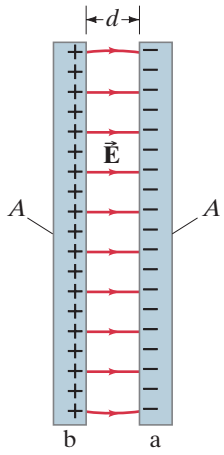

**FIGURE 24–4** Parallel-plate capacitor, each of whose plates has area $A$.

The capacitance of a given capacitor can in principle be determined experimentally directly from Eq. 24–1, by measuring the charge $Q$ on either conductor for a given potential difference $V$. But for capacitors whose geometry is simple, we can determine $C$ analytically, and in this Section we assume the conductors are separated by a vacuum or air.

First, we determine $C$ for a parallel-plate capacitor, Fig. 24–4. Each plate has area $A$ and the two plates are separated by a distance $d$. We assume $d$ is small compared to the dimensions of each plate so that the electric field $\vec{\mathbf{E}}$ is uniform between them and we ignore fringing (lines of $\vec{\mathbf{E}}$ not straight) at the edges. We saw earlier (Example 21–14) that the electric field between two closely spaced parallel plates has magnitude $E = \sigma/\epsilon_0$ and its direction is perpendicular to the plates. Since $\sigma$ is the charge per unit area, $\sigma = Q/A$, then the field between the plates is

$$E = \frac{Q}{\epsilon_0 A}.$$

The relation between electric field and electric potential, as given by Eq. 23–4a, is

$$V = V_{ba} = V_b - V_a = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}.$$

We can take the line integral along a path antiparallel to the field lines, from plate a in Fig. 24–4 to plate b; then $\theta = 180°$ and $\cos 180° = -1$, so

$$V = V_b - V_a = -\int_a^b E\, d\ell \cos 180° = +\int_a^b E\, d\ell = \frac{Q}{\epsilon_0 A}\int_a^b d\ell = \frac{Qd}{\epsilon_0 A}.$$

This relates $Q$ to $V$, and from it we can get the capacitance $C$ in terms of the geometry of the plates:

$$C = \frac{Q}{V} = \epsilon_0 \frac{A}{d}. \qquad \text{[parallel-plate capacitor]} \quad \textbf{(24–2)}$$

Note from Eq. 24–2 that the value of $C$ does not depend on $Q$ or $V$, so $Q$ is predicted to be proportional to $V$ as is found experimentally. Capacitance $C$ is always positive, never negative.

**EXAMPLE 24–1** **Capacitor calculations.** (*a*) Calculate the capacitance of a parallel-plate capacitor whose plates are $20\,\text{cm} \times 3.0\,\text{cm}$ and are separated by a 1.0-mm air gap. (*b*) What is the charge on each plate if a 12-V battery is connected across the two plates? (*c*) What is the electric field between the plates? (*d*) Estimate the area of the plates needed to achieve a capacitance of 1 F, assuming the air gap $d$ is 100 times smaller, or 10 microns (1 **micron** = $1\,\mu\text{m} = 10^{-6}\,\text{m}$).

**APPROACH** The capacitance is found by using Eq. 24–2, $C = \epsilon_0 A/d$. The charge on each plate is obtained from the definition of capacitance, Eq. 24–1, $Q = CV$. The electric field is uniform, so we can use Eq. 23–4b for the magnitude $E = V/d$. In (*d*) we use Eq. 24–2 again.

**SOLUTION** (*a*) The area $A = (20 \times 10^{-2}\,\text{m})(3.0 \times 10^{-2}\,\text{m}) = 6.0 \times 10^{-3}\,\text{m}^2$. The capacitance $C$ is then

$$C = \epsilon_0 \frac{A}{d} = (8.85 \times 10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)\frac{6.0 \times 10^{-3}\,\text{m}^2}{1.0 \times 10^{-3}\,\text{m}} = 53\,\text{pF}.$$

(*b*) The charge on each plate is

$$Q = CV = (53 \times 10^{-12}\,\text{F})(12\,\text{V}) = 6.4 \times 10^{-10}\,\text{C}.$$

(*c*) From Eq. 23–4b for a uniform electric field, the magnitude of $E$ is

$$E = \frac{V}{d} = \frac{12\,\text{V}}{1.0\times10^{-3}\,\text{m}} = 1.2\times10^{4}\,\text{V/m}.$$

(*d*) The plate separation is now $d = 10\,\mu\text{m} = 1.0\times10^{-5}\,\text{m}$ and we want $C = 1\,\text{F}$. We solve for $A$ in Eq. 24–2 and find that we need plates with an area

$$A = \frac{Cd}{\epsilon_0} \approx \frac{(1\,\text{F})(1.0\times10^{-5}\,\text{m})}{(9\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)} \approx 10^{6}\,\text{m}^2.$$

**NOTE** This is the area of a square $10^3$ m or 1 km on a side. That is inconveniently large (the size of a small town). Large-capacitance capacitors will not be simple flat parallel plates.

**EXERCISE B** Two circular plates of radius 5.0 cm are separated by a 0.10-mm air gap. What is the magnitude of the charge on each plate when connected to a 12-V battery?

**PHYSICS APPLIED**
*Very high capacitance; capacitor as power backup*

Not long ago, a capacitance greater than a few mF was unusual. Today it is possible to make capacitors that are 1 or 2 F, yet they are just a few cm on a side. Such large capacitance can be used as power backups, for example, in computer memory and electronics where the time and date can be maintained through tiny charge flow. [Capacitors are superior to rechargable batteries for this purpose because they can be recharged more than $10^5$ times with no degradation.] Such high-capacitance capacitors can be made of *activated carbon* which has very high porosity, so that the surface area is very large; one tenth of a gram of activated carbon can have a surface area of 100 $\text{m}^2$. Furthermore, the equal and opposite charges exist in an electric "double layer" about $10^{-9}$ m thick. Thus, the capacitance of 0.1 g of activated carbon, whose internal area can be $10^2\,\text{m}^2$, is equivalent to a parallel-plate capacitor with $C \approx \epsilon_0 A/d = (8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)(10^2\,\text{m}^2)/(10^{-9}\,\text{m}) \approx 1\,\text{F}$.

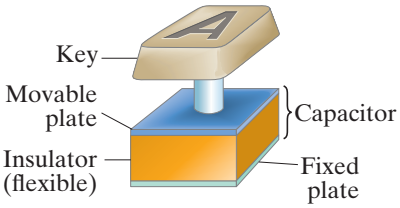

**FIGURE 24–5** Key on a computer keyboard. Pressing the key, which is fixed to the movable plate, reduces the capacitor spacing thus increasing the capacitance which can be detected electronically.

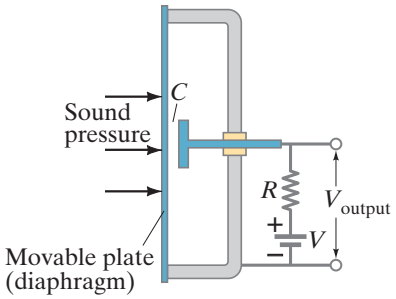
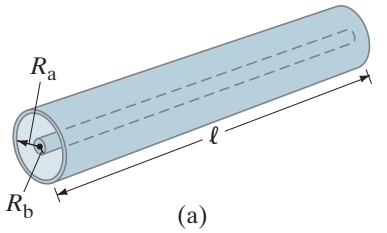
**PHYSICS APPLIED**
*Computer key*

One type of computer keyboard operates by capacitance. As shown in Fig. 24–5, each key is connected to the upper plate of a capacitor. The upper plate moves down when the key is pressed, reducing the spacing between the capacitor plates, and increasing the capacitance (Eq. 24–2: smaller $d$, larger $C$). The *change* in capacitance results in an electric signal that is detected by an electronic circuit.

**PHYSICS APPLIED**
*Condenser microphone*

One type of microphone is a **condenser**, or capacitor, **microphone**, diagrammed in Fig. 24–6. The changing air pressure in a sound wave causes one plate of the capacitor $C$ to move back and forth, and that plate is isolated so the charge on it doesn't change. Hence the voltage across the capacitor changes at the same frequency as the sound wave.





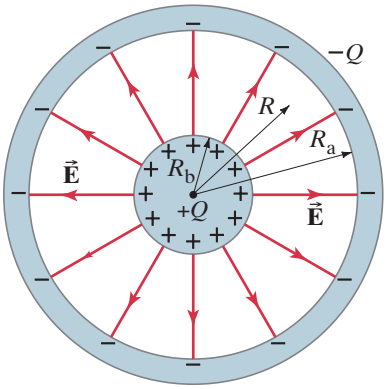


**FIGURE 24–6** Diagram of a condenser microphone.

The proportionality, $C \propto A/d$ in Eq. 24–2, is valid for a parallel-plate capacitor even if it is rolled up into a spiral cylinder, as in Fig. 24–1b. However, the constant factor, $\epsilon_0$, must be replaced if an insulator such as paper separates the plates, as is usual (discussed in Section 24–5). For a true cylindrical capacitor—consisting of two long coaxial cylinders—the result is somewhat different as the next Example shows.

(a)

(b)

**FIGURE 24–7** (a) Cylindrical capacitor consists of two coaxial cylindrical conductors. (b) The electric field lines are shown in cross-sectional view.

**PROBLEM SOLVING**
*Checking with a limiting case*

**EXAMPLE 24–2** **Cylindrical capacitor.** A cylindrical capacitor consists of a small cylinder (or wire) of radius $R_b$ surrounded by a larger coaxial cylindrical shell of inner radius $R_a$, Fig. 24–7a. Both cylinders have length $\ell$ which we assume is much greater than the separation of the cylinders, $R_a - R_b$, so we can neglect end effects. The capacitor is charged (by connecting it to a battery) so that one cylinder has a charge $+Q$ (say, the inner one) and the other one a charge $-Q$. Determine a formula for the capacitance.

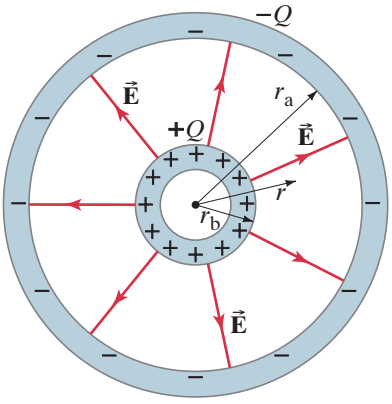
**APPROACH** To determine the capacitance $C = Q/V$, we need to determine the potential difference $V$ between the cylinders in terms of $Q$. We can use our earlier result (Example 21–12 or 22–6) that the electric field outside a long wire is directed radially outward and has magnitude $E = (1/2\pi\epsilon_0)(\lambda/R)$, where $R$ is the distance from the central axis and $\lambda$ is the charge per unit length, $Q/\ell$. Then $E = (1/2\pi\epsilon_0)(Q/\ell R)$ for points between the cylinders.

**SOLUTION** To obtain the potential difference $V$ in terms of $Q$, we insert this expression for $E$ into Eq. 23–4a, $V = V_b - V_a = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$, and write the line integral from the outer cylinder to the inner one (so $V > 0$) along a radial line ($d\vec{\boldsymbol{\ell}}$ points inward so $d\ell = -dR$ and $\cos\theta = \cos 180^\circ = -1$):

$$V = V_b - V_a = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = -\frac{Q}{2\pi\epsilon_0 \ell}\int_{R_a}^{R_b} \frac{dR}{R}$$
$$= -\frac{Q}{2\pi\epsilon_0 \ell}\ln\frac{R_b}{R_a} = \frac{Q}{2\pi\epsilon_0 \ell}\ln\frac{R_a}{R_b}.$$

$Q$ and $V$ are proportional, and the capacitance $C$ is

$$C = \frac{Q}{V} = \frac{2\pi\epsilon_0 \ell}{\ln(R_a/R_b)}. \qquad \text{[cylindrical capacitor]}$$



**NOTE** If the space between cylinders, $R_a - R_b = \Delta R$ is small, we have

$$\ln(R_a/R_b) = \ln[(R_b + \Delta R)/R_b] = \ln[1 + \Delta R/R_b] \approx \Delta R/R_b$$

(see Appendix A–3) so $C \approx 2\pi\epsilon_0 \ell R_b/\Delta R = \epsilon_0 A/\Delta R$ because the area of cylinder b is $A = 2\pi R_b \ell$. This is just Eq. 24–2 for a parallel-plate capacitor ($d = \Delta R$), as we would hope and thus a nice check.

**EXERCISE C** What is the capacitance per unit length of a cylindrical capacitor with radii $R_a = 2.5$ mm and $R_b = 0.40$ mm? (*a*) 30 pF/m; (*b*) −30 pF/m; (*c*) 56 pF/m; (*d*) −56 pF/m; (*e*) 100 pF/m; (*f*) −100 pF/m.

**FIGURE 24–8** Cross section through the center of a spherical capacitor. The thin inner shell has radius $r_b$ and the thin outer shell has radius $r_a$.

**EXAMPLE 24–3** **Spherical capacitor.** A spherical capacitor consists of two thin concentric spherical conducting shells, of radius $r_a$ and $r_b$ as shown in Fig. 24–8. The inner shell carries a uniformly distributed charge $Q$ on its surface, and the outer shell an equal but opposite charge $-Q$. Determine the capacitance of the two shells.

**APPROACH** In Example 22–3 we used Gauss's law to show that the electric field outside a uniformly charged conducting sphere is $E = Q/4\pi\epsilon_0 r^2$ as if all the charge were concentrated at the center. We then use Eq. 23–4a, $V = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$.

**SOLUTION** We integrate Eq. 23–4a along a radial line from $r_a$ to $r_b$ to obtain the potential difference between the two conducting shells:

$$V_{ba} = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = -\frac{Q}{4\pi\epsilon_0}\int_{r_a}^{r_b} \frac{1}{r^2}\,dr$$
$$= \frac{Q}{4\pi\epsilon_0}\left(\frac{1}{r_b} - \frac{1}{r_a}\right) = \frac{Q}{4\pi\epsilon_0}\left(\frac{r_a - r_b}{r_a r_b}\right).$$

Finally,

$$C = \frac{Q}{V_{ba}} = 4\pi\epsilon_0\left(\frac{r_a r_b}{r_a - r_b}\right).$$

**NOTE** If the separation $\Delta r = r_a - r_b$ is very small, then $C = 4\pi\epsilon_0 r^2/\Delta r \approx \epsilon_0 A/\Delta r$ (since $A = 4\pi r^2$), which is the parallel-plate formula, Eq. 24–2.

A single isolated conductor can also be said to have a capacitance, $C$. In this case, $C$ can still be defined as the ratio of the charge to absolute potential $V$ on the conductor (relative to $V = 0$ at $r = \infty$), so that the relation

$$Q = CV$$

remains valid. For example, the potential of a single conducting sphere of radius $r_b$ can be obtained from our results in Example 24–3 by letting $r_a$ become infinitely large. As $r_a \to \infty$, then

$$V = \frac{Q}{4\pi\epsilon_0}\left(\frac{1}{r_b} - \frac{1}{r_a}\right) = \frac{1}{4\pi\epsilon_0}\frac{Q}{r_b};$$

so its capacitance is

$$C = \frac{Q}{V} = 4\pi\epsilon_0 r_b.$$

In practical cases, a single conductor may be near other conductors or the Earth (which can be thought of as the other "plate" of a capacitor), and these will affect the value of the capacitance.

**EXAMPLE 24–4** **Capacitance of two long parallel wires.** Estimate the capacitance per unit length of two very long straight parallel wires, each of radius $R$, carrying uniform charges $+Q$ and $-Q$, and separated by a distance $d$ which is large compared to $R$ ($d \gg R$), Fig. 24–9.

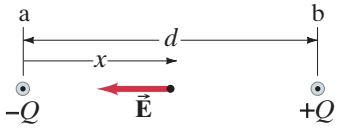


**FIGURE 24–9** Example 24–4.

**APPROACH** We calculate the potential difference between the wires by treating the electric field at any point between them as the superposition of the two fields created by each wire. (The electric field inside each wire conductor is zero.)

**SOLUTION** The electric field outside of a long straight conductor was found in Examples 21–12 and 22–6 to be radial and given by $E = \lambda/(2\pi\epsilon_0 x)$ where $\lambda$ is the charge per unit length, $\lambda = Q/\ell$. The total electric field due to both wires at distance $x$ from the left-hand wire in Fig. 24–9 has magnitude

$$E = \frac{\lambda}{2\pi\epsilon_0 x} + \frac{\lambda}{2\pi\epsilon_0(d - x)},$$

and points to the left (from + to −). Now we find the potential difference between the two wires using Eq. 23–4a and integrating along the straight line from the surface of the negative wire to the surface of the positive wire, noting that $\vec{\mathbf{E}}$ and $d\vec{\boldsymbol{\ell}}$ point in opposite directions ($\vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} < 0$):

$$V = V_b - V_a = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = \left(\frac{\lambda}{2\pi\epsilon_0}\right)\int_R^{d-R}\left[\frac{1}{x} + \frac{1}{(d - x)}\right]dx$$

$$= \left(\frac{\lambda}{2\pi\epsilon_0}\right)[\ln(x) - \ln(d - x)]\Big|_R^{d-R}$$

$$= \left(\frac{\lambda}{2\pi\epsilon_0}\right)[\ln(d - R) - \ln R - \ln R + \ln(d - R)]$$

$$= \left(\frac{\lambda}{\pi\epsilon_0}\right)[\ln(d - R) - \ln(R)] \approx \left(\frac{\lambda}{\pi\epsilon_0}\right)[\ln(d) - \ln(R)]$$

because we are given that $d \gg R$. So

$$V \approx \left(\frac{Q}{\pi\epsilon_0\ell}\right)\left[\ln\left(\frac{d}{R}\right)\right].$$

The capacitance from Eq. 24–1 is $C = Q/V \approx (\pi\epsilon_0\ell)/\ln(d/R)$, so the capacitance per unit length is given approximately by

$$\frac{C}{\ell} \approx \frac{\pi\epsilon_0}{\ln(d/R)}.$$

# 24–3 Capacitors in Series and Parallel

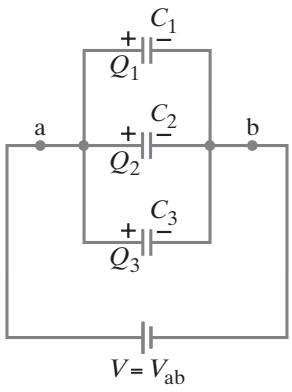

**FIGURE 24–10** Capacitors in parallel: $C_{eq} = C_1 + C_2 + C_3$.

Capacitors are found in many electric circuits. By electric circuit we mean a closed path of conductors, usually wires connecting capacitors and/or other devices, in which charge can flow and which includes a source of voltage such as a battery. The battery voltage is usually given the symbol $V$, which means that $V$ represents a *potential difference*. Capacitors can be connected together in various ways. Two common ways are in *series*, or in *parallel*, and we now discuss both.

A circuit containing three capacitors connected in **parallel** is shown in Fig. 24–10. They are in "parallel" because when a battery of voltage $V$ is connected to points a and b, this same potential difference $V = V_{ab}$ exists across each of the capacitors. That is, since the left-hand plates of all the capacitors are connected by conductors, they all reach the same potential $V_a$ when connected to the battery; and the right-hand plates each reach potential $V_b$. Each capacitor plate acquires a charge given by $Q_1 = C_1 V$, $Q_2 = C_2 V$, and $Q_3 = C_3 V$. The total charge $Q$ that must leave the battery is then

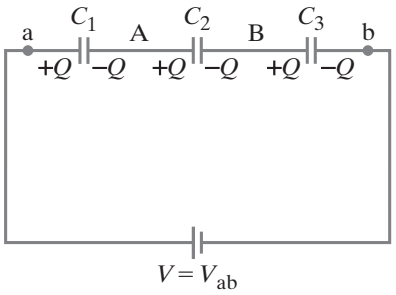
$$Q = Q_1 + Q_2 + Q_3 = C_1 V + C_2 V + C_3 V.$$

Let us try to find a single equivalent capacitor that will hold the same charge $Q$ at the same voltage $V = V_{ab}$. It will have a capacitance $C_{eq}$ given by

$$Q = C_{eq} V.$$

Combining the two previous equations, we have

$$C_{eq} V = C_1 V + C_2 V + C_3 V = (C_1 + C_2 + C_3) V$$



or

*Capacitors in parallel*

$$C_{eq} = C_1 + C_2 + C_3. \qquad \text{[parallel]} \quad \textbf{(24–3)}$$

The net effect of connecting capacitors in parallel is thus to *increase* the capacitance. This makes sense because we are essentially increasing the area of the plates where charge can accumulate (see, for example, Eq. 24–2).

**FIGURE 24–11** Capacitors in series: $\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}$.

Capacitors can also be connected in **series**: that is, end to end as shown in Fig. 24–11. A charge $+Q$ flows from the battery to one plate of $C_1$, and $-Q$ flows to one plate of $C_3$. The regions A and B between the capacitors were originally neutral, so the net charge there must still be zero. The $+Q$ on the left plate of $C_1$ attracts a charge of $-Q$ on the opposite plate. Because region A must have a zero net charge, there is $+Q$ on the left plate of $C_2$. The same applies to the other capacitors, so we see that the charge on each capacitor has the same magnitude $Q$. A single capacitor that could replace these three in series without affecting the circuit (that is, $Q$ and $V$ the same) would have a capacitance $C_{eq}$ where

$$Q = C_{eq} V.$$

Now the total voltage $V$ across the three capacitors in series must equal the sum of the voltages across each capacitor:

$$V = V_1 + V_2 + V_3.$$

We also have for each capacitor $V_1 = Q/C_1$, $V_2 = Q/C_2$, and $V_3 = Q/C_3$, since all three have the same charge $Q$. Also, $V = Q/C_{eq}$, so we substitute for $V$, $V_1$, $V_2$, and $V_3$ into $V = V_1 + V_2 + V_3$ and get

$$\frac{Q}{C_{eq}} = \frac{Q}{C_1} + \frac{Q}{C_2} + \frac{Q}{C_3} = Q\left(\frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}\right)$$

or

*Capacitors in series*

$$\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_2} + \frac{1}{C_3}. \qquad \text{[series]} \quad \textbf{(24–4)}$$

Notice that the equivalent capacitance $C_{eq}$ is *smaller* than the smallest contributing capacitance.

Other connections of capacitors can be analyzed similarly using charge conservation, and often simply in terms of series and parallel connections.

**EXAMPLE 24–5** **Equivalent capacitance.** Determine the capacitance of a single capacitor that will have the same effect as the combination shown in Fig. 24–12a. Take $C_1 = C_2 = C_3 = C$.

**APPROACH** First we find the equivalent capacitance of $C_2$ and $C_3$ in parallel, and then consider that capacitance in series with $C_1$ (Fig. 24–12b).

**SOLUTION** Capacitors $C_2$ and $C_3$ are connected in parallel, so they are equivalent to a single capacitor having capacitance

$$C_{23} = C_2 + C_3 = C + C = 2C.$$

This $C_{23}$ is in *series* with $C_1$, Fig. 24–12b, so the equivalent capacitance of the entire circuit, $C_{eq}$, is given by

$$\frac{1}{C_{eq}} = \frac{1}{C_1} + \frac{1}{C_{23}} = \frac{1}{C} + \frac{1}{2C} = \frac{3}{2C}.$$

Hence the equivalent capacitance of the entire combination is $C_{eq} = \frac{2}{3}C$, and it is smaller than any of the contributing capacitors, $C_1 = C_2 = C_3 = C$.

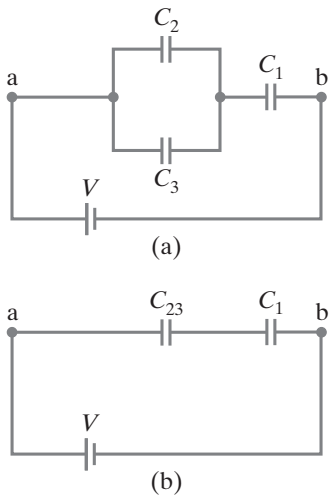


**FIGURE 24–12** Example 24–5 and Example 24–6.

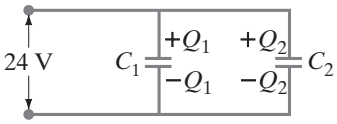
**EXAMPLE 24–6** **Charge and voltage on capacitors.** Determine the charge on each capacitor in Fig. 24–12a of Example 24–5 and the voltage across each, assuming $C = 3.0\,\mu\text{F}$ and the battery voltage is $V = 4.0\,\text{V}$.

**APPROACH** We have to work "backward" through Example 24–5. That is, we find the charge $Q$ that leaves the battery, using the equivalent capacitance. Then we find the charge on each separate capacitor and the voltage across each. Each step uses Eq. 24–1, $Q = CV$.

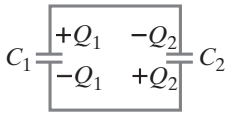
**SOLUTION** The 4.0-V battery behaves as if it is connected to a capacitance $C_{eq} = \frac{2}{3}C = \frac{2}{3}(3.0\,\mu\text{F}) = 2.0\,\mu\text{F}$. Therefore the charge $Q$ that leaves the battery, by Eq. 24–1, is

$$Q = CV = (2.0\,\mu\text{F})(4.0\,\text{V}) = 8.0\,\mu\text{C}.$$



From Fig. 24–12a, this charge arrives at the negative plate of $C_1$, so $Q_1 = 8.0\,\mu\text{C}$. The charge $Q$ that leaves the positive plate of the battery is split evenly between $C_2$ and $C_3$ (symmetry: $C_2 = C_3$) and is $Q_2 = Q_3 = \frac{1}{2}Q = 4.0\,\mu\text{C}$. Next, the voltages across $C_2$ and $C_3$ have to be the same. The voltage across each capacitor is obtained using $V = Q/C$. So

$$V_1 = Q_1/C_1 = (8.0\,\mu\text{C})/(3.0\,\mu\text{F}) = 2.7\,\text{V}$$



$$V_2 = Q_2/C_2 = (4.0\,\mu\text{C})/(3.0\,\mu\text{F}) = 1.3\,\text{V}$$

$$V_3 = Q_3/C_3 = (4.0\,\mu\text{C})/(3.0\,\mu\text{F}) = 1.3\,\text{V}.$$

**EXERCISE D** Consider two identical capacitors $C_1 = C_2 = 10\,\mu\text{F}$. What are the smallest and largest capacitances that can be obtained by connecting these in series or parallel combinations? (*a*) $0.2\,\mu\text{F}, 5\,\mu\text{F}$; (*b*) $0.2\,\mu\text{F}, 10\,\mu\text{F}$; (*c*) $0.2\,\mu\text{F}, 20\,\mu\text{F}$; (*d*) $5\,\mu\text{F}, 10\,\mu\text{F}$; (*e*) $5\,\mu\text{F}, 20\,\mu\text{F}$; (*f*) $10\,\mu\text{F}, 20\,\mu\text{F}$.

(a) Initial configuration.

(b) At the instant of reconnection only.

(c) A short time later.

**FIGURE 24–13** Example 24–7.

**EXAMPLE 24–7** **Capacitors reconnected.** Two capacitors, $C_1 = 2.2\,\mu\text{F}$ and $C_2 = 1.2\,\mu\text{F}$, are connected in parallel to a 24-V source as shown in Fig. 24–13a. After they are charged they are disconnected from the source and from each other, and then reconnected directly to each other with plates of opposite sign connected together (see Fig. 24–13b). Find the charge on each capacitor and the potential across each after equilibrium is established.

**APPROACH** We find the charge $Q = CV$ on each capacitor initially. Charge is conserved, although rearranged after the switch. The two new voltages will have to be equal.

**SOLUTION** First we calculate how much charge has been placed on each capacitor after the power source has charged them fully, using Eq. 24–1:

$$Q_1 = C_1 V = (2.2\,\mu\text{F})(24\,\text{V}) = 52.8\,\mu\text{C},$$
$$Q_2 = C_2 V = (1.2\,\mu\text{F})(24\,\text{V}) = 28.8\,\mu\text{C}.$$

Next the capacitors are connected in parallel, Fig. 24–13b, and the potential difference across each must quickly equalize. Thus, the charge cannot remain as shown in Fig. 24–13b, but the charge must rearrange itself so that the upper plates have the same sign of charge, with the lower plates having the opposite charge as shown in Fig. 24–13c. Equation 24–1 applies for each:

$$Q'_1 = C_1 V' \quad \text{and} \quad Q'_2 = C_2 V',$$

where $V'$ is the voltage across each capacitor after the charges have rearranged themselves. We don't know $Q'_1$, $Q'_2$, or $V'$, so we need a third equation. This is provided by charge conservation. The charges have rearranged themselves between Figs. 24–13b and c. The total charge on the upper plates in those two Figures must be the same, so we have

$$Q'_1 + Q'_2 = Q_1 - Q_2 = (52.8 - 28.8)\,\mu\text{C} = 24.0\,\mu\text{C}.$$

Combining the last three equations we find:

$$Q'_1 + Q'_2 = C_1 V' + C_2 V' = (C_1 + C_2)\,V'$$

or

$$V' = (Q'_1 + Q'_2)/(C_1 + C_2) = 24.0\,\mu\text{C}/3.4\,\mu\text{F} = 7.06\,\text{V} \approx 7.1\,\text{V}$$
$$Q'_1 = C_1 V' = (2.2\,\mu\text{F})(7.06\,\text{V}) = 15.5\,\mu\text{C} \approx 16\,\mu\text{C}$$
$$Q'_2 = C_2 V' = (1.2\,\mu\text{F})(7.06\,\text{V}) = 8.5\,\mu\text{C}$$

where we have kept only two significant figures in our final answers.

## 24–4 Storage of Electric Energy

A charged capacitor stores electric energy. The energy stored in a capacitor will be equal to the work done to charge it. The net effect of charging a capacitor is to remove charge from one plate and add it to the other plate. This is what a battery does when it is connected to a capacitor. A capacitor does not become charged instantly. It takes some time (Section 26–5). Initially, when the capacitor is uncharged, no work is required to move the first bit of charge over. When some charge is on each plate, it requires work to add more charge of the same sign because of the electric repulsion. The more charge already on a plate, the more work required to add additional charge. The work needed to add a small amount of charge $dq$, when a potential difference $V$ is across the plates, is $dW = V\,dq$.

Since $V = q/C$ at any moment (Eq. 24–1), where $C$ is the capacitance, the work needed to store a total charge $Q$ is

$$W = \int_0^Q V\,dq = \frac{1}{C}\int_0^Q q\,dq = \tfrac{1}{2}\frac{Q^2}{C}.$$

Thus we can say that the energy "stored" in a capacitor is

$$U = \tfrac{1}{2}\frac{Q^2}{C}$$

when the capacitor $C$ carries charges $+Q$ and $-Q$ on its two conductors. Since $Q = CV$, where $V$ is the potential difference across the capacitor, we can also write

$$U = \tfrac{1}{2}\frac{Q^2}{C} = \tfrac{1}{2}CV^2 = \tfrac{1}{2}QV. \qquad \textbf{(24–5)}$$

**EXAMPLE 24–8** **Energy stored in a capacitor.** A camera flash unit (Fig. 24–14) stores energy in a 660-$\mu$F capacitor at 330 V. (*a*) How much electric energy can be stored? (*b*) What is the power output if nearly all this energy is released in 1.0 ms as a flash of light?

PHYSICS APPLIED
*Camera flash*

**FIGURE 24–14** A camera flash unit. The 660-$\mu$F capacitor is the black cylinder.

**APPROACH** We use Eq. 24–5 in the form $U = \frac{1}{2}CV^2$ because we are given $C$ and $V$.

**SOLUTION** (*a*) The energy stored is

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}(660\times10^{-6}\,\text{F})(330\,\text{V})^2 = 36\,\text{J}.$$

(*b*) If this energy is released in $\frac{1}{1000}$ of a second, the power output is $P = U/t = (36\,\text{J})/(1.0\times10^{-3}\,\text{s}) = 36{,}000\,\text{W}$.

**CONCEPTUAL EXAMPLE 24–9** **Capacitor plate separation increased.** A parallel-plate capacitor carries charge $Q$ and is then disconnected from a battery. The two plates are initially separated by a distance $d$. Suppose the plates are pulled apart until the separation is $2d$. How has the energy stored in this capacitor changed?

**RESPONSE** If we increase the plate separation $d$, we decrease the capacitance according to Eq. 24–2, $C = \epsilon_0 A/d$, by a factor of 2. The charge $Q$ hasn't changed. So according to Eq. 24–5, where we choose the form $U = \frac{1}{2}Q^2/C$ because we know $Q$ is the same and $C$ has been halved, the reduced $C$ means the potential energy stored increases by a factor of $1/(1/2) = 2$.

**NOTE** We can see why the energy stored increases from a physical point of view: the two plates are charged equal and opposite, so they attract each other. If we pull them apart, we must do work, so we raise their potential energy.

**EXAMPLE 24–10** **Repositioning parallel capacitor plates.** The plates of a parallel-plate capacitor have area $A$, separation $x$, and are connected to a battery with voltage $V$. While connected to the battery, the plates are pulled apart until they are separated by $3x$. (*a*) What are the initial and final energies stored in the capacitor? (*b*) How much work is required to pull the plates apart (assume slow constant speed)? (*c*) How much energy is exchanged with the battery?

**APPROACH** The stored energy when the plates are separated by $x$ is given by Eq. 24–5: $U = \frac{1}{2}CV^2$, where $C = \epsilon_0 A/x$. Unlike Example 24–9, here the capacitor remains connected to the battery so $Q$ can change but $V$ stays the same. Hence charge and energy can flow to or from the battery, and we can not set the work $W = \Delta U$. Instead, the work can be calculated from Eq. 7–7, $W = \int \vec{\mathbf{F}} \cdot d\vec{\boldsymbol{\ell}}$.

**SOLUTION** (*a*) When the separation is $x$, the capacitance is $C_1 = \epsilon_0 A/x$ and the energy stored is

$$U_1 = \tfrac{1}{2} C_1 V^2 = \tfrac{1}{2}\frac{\epsilon_0 A}{x} V^2.$$

When the separation is $3x$, $C_2 = \epsilon_0 A/3x$ and

$$U_2 = \tfrac{1}{2}\frac{\epsilon_0 A}{3x} V^2.$$

Then

$$\Delta U_{\text{capacitor}} = U_2 - U_1 = \left(\frac{1}{6} - \frac{1}{2}\right)\frac{\epsilon_0 A}{x} V^2 = -\frac{\epsilon_0 A V^2}{3x}.$$

The potential energy decreases as the oppositely charged plates are pulled apart: the plates remain connected to the battery, so $V$ does not change and $C$ decreases; hence some charge leaves each plate $(Q = CV)$, going into the battery, causing $U$ to decrease.

(*b*) The work done in pulling the plates apart is $W = \int_x^{3x} F\, d\ell = \int_x^{3x} QE\, d\ell$, where $Q$ is the charge on one plate at a given moment when the plates are a distance $\ell$ apart, and $E$ is the field due to the other plate at that instant. You might think we could use $E = V/\ell$ where $\ell$ is the separation of the plates (Eq. 23–4b). But we want the force on one plate due to the electric field of the other plate only, which is half by *symmetry*; that is, we can say each plate produces half the total electric field, $E = V/2\ell$, to produce the total field $E = (V/2\ell) + (V/2\ell) = V/\ell$. Each plate carries the same charge with opposite sign. The charge $Q$ on each plate at any separation $\ell$ is given by $Q = CV = (\epsilon_0 A/\ell)V$, so $QE = (\epsilon_0 A/\ell)V(V/2\ell) = \epsilon_0 AV^2/2\ell^2$. Then

$$W = \int_{\ell=x}^{\ell=3x} QE\, d\ell = \frac{\epsilon_0 AV^2}{2}\int_x^{3x}\frac{d\ell}{\ell^2} = -\frac{\epsilon_0 AV^2}{2\ell}\Bigg|_{\ell=x}^{\ell=3x}$$
$$= \frac{\epsilon_0 AV^2}{2}\left(\frac{-1}{3x} + \frac{1}{x}\right) = \frac{\epsilon_0 AV^2}{3x}.$$

As you might expect, the work required to pull these oppositely charged plates apart is positive.

(*c*) Even though the work done is positive, the potential energy stored in the capacitor has decreased, as we saw in part (*a*), which tells us that energy must have gone into the battery (as if charging it). Conservation of energy tells us that the work $W$ done on the system must equal the change in potential energy of the capacitor plus that of the battery (kinetic energy can be assumed to be essentially zero):

$$W = \Delta U_{\text{capacitor}} + \Delta U_{\text{batt}}.$$

Thus the battery experiences a change in energy of

$$\Delta U_{\text{batt}} = W - \Delta U_{\text{capacitor}} = \frac{\epsilon_0 AV^2}{3x} + \frac{\epsilon_0 AV^2}{3x} = \frac{2\epsilon_0 AV^2}{3x}.$$

Thus charge flows back into the battery, raising *its* stored energy. In fact, the battery energy increase is double the work we do.

It is useful to think of the energy stored in a capacitor as being stored in the electric field between the plates. As an example let us calculate the energy stored in a parallel-plate capacitor in terms of the electric field.

We have seen (Fig. 23–1) that the electric field $\vec{\mathbf{E}}$ between two close parallel plates is nearly uniform and its magnitude is related to the potential difference by $V = Ed$ where $d$ is the plate separation (Eq. 23–4b). Also, Eq. 24–2 tells us $C = \epsilon_0 A/d$ for a parallel-plate capacitor. Thus

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}\left(\frac{\epsilon_0 A}{d}\right)(E^2 d^2)$$
$$= \tfrac{1}{2}\epsilon_0 E^2 A d.$$

The quantity $Ad$ is the volume between the plates in which the electric field $E$ exists. If we divide both sides of this equation by the volume, we obtain an expression for the *energy per unit volume* or **energy density**, $u$:

$$u = \text{energy density} = \frac{\text{energy}}{\text{volume}} = \tfrac{1}{2}\epsilon_0 E^2. \qquad \textbf{(24–6)}$$

The *electric energy stored per unit volume in any region of space is proportional to the square of the electric field* in that region. We derived Eq. 24–6 for the special case of a parallel-plate capacitor. But it can be shown to be true for any region of space where there is an electric field. Note that the units check: for $(\epsilon_0 E^2)$ we have $(\mathrm{C^2/N \cdot m^2})(\mathrm{N/C})^2 = \mathrm{N/m^2} = (\mathrm{N \cdot m})/\mathrm{m^3} = \mathrm{J/m^3}$.

### Health Effects

The energy stored in a large capacitance can give you a burn or a shock. One reason you are warned not to touch a circuit, or open up an electronic device, is because capacitors may still be carrying charge even if the external power is turned off.

Capacitors have medical applications. The basis of a **heart defibrillator** is a capacitor charged to a high voltage. A heart attack can be characterized by fast irregular beating of the heart, known as *ventricular* (or *cardiac*) *fibrillation*. The heart then does not pump blood to the rest of the body properly, and if the irregular rhythm lasts for long, death results. A sudden, brief jolt of charge through the heart from a defibrillator can cause complete heart stoppage, sometimes followed by a resumption of normal beating. The defibrillator capacitor is charged to a high voltage, typically a few thousand volts, and is allowed to discharge very rapidly through the heart via a pair of wide contacts known as "pads" or "paddles" that spread out the current over the chest (Fig. 24–15).

**PHYSICS APPLIED**
*Shocks, burns, defibrillators*

**FIGURE 24–15** Heart defibrillator.

## 24–5 Dielectrics

In most capacitors there is an insulating sheet of material, such as paper or plastic, called a **dielectric** between the plates (Fig. 24–1b). This serves several purposes. First, dielectrics do not break down (allowing electric charge to flow) as easily as air, so higher voltages can be applied without charge passing across the gap. Second, a dielectric allows the plates to be placed closer together without touching, thus allowing an increased capacitance because the thickness $d$ is smaller in Eq. 24–2. Third, it is found experimentally that if the dielectric fills the space between the two conductors, it increases the capacitance by a factor $K$, known as the **dielectric constant**. Thus

$$C = KC_0, \qquad \textbf{(24–7)}$$

where $C_0$ is the capacitance when the space between the two conductors of the capacitor is air (or vacuum), and $C$ is the capacitance when the space is filled with a material whose dielectric constant is $K$.

The values of the dielectric constant for various materials are given in Table 24–1. Also shown in Table 24–1 is the **dielectric strength**, the maximum electric field before breakdown (charge flow) occurs.

**TABLE 24–1**
**Dielectric Constants (at 20°C)**

| Material | Dielectric constant $K$ | Dielectric strength (V/m) |
|---|---|---|
| Vacuum | 1.0000 | |
| Air (1 atm) | 1.0006 | $3 \times 10^6$ |
| Paraffin | 2.2 | $10 \times 10^6$ |
| Polystyrene | 2.6 | $24 \times 10^6$ |
| Vinyl (plastic) | 2–4 | $50 \times 10^6$ |
| Paper | 3.7 | $15 \times 10^6$ |
| Quartz | 4.3 | $8 \times 10^6$ |
| Oil | 4 | $12 \times 10^6$ |
| Glass, Pyrex | 5 | $14 \times 10^6$ |
| Rubber, neoprene | 6.7 | $20 \times 10^6$ |
| Porcelain | 6–8 | $5 \times 10^6$ |
| Mica | 7 | $120 \times 10^6$ |
| Water (liquid) | 80 | $70 \times 10^6$ |
| Strontium titanate | 300 | $8 \times 10^6$ |

For a parallel-plate capacitor (combining Eqs. 24–2 and 24–7),

$$C = K\epsilon_0 \frac{A}{d} \qquad \text{[parallel-plate capacitor]} \quad \textbf{(24–8)}$$

when the space between the plates is completely filled with a dielectric whose dielectric constant is $K$. (The situation when the dielectric only partially fills the space will be discussed in Example 24–14.)

The quantity $K\epsilon_0$ appears so often in formulas that we define a new quantity

$$\epsilon = K\epsilon_0 \qquad \textbf{(24–9)}$$

called the **permittivity** of a material. Then the capacitance of a parallel-plate capacitor becomes in general

$$C = \epsilon \frac{A}{d}.$$

Note that $\epsilon_0$ represents the permittivity of free space (a vacuum), as in Section 21–5.

**CONCEPTUAL EXAMPLE 24–11** **Inserting a dielectric at constant $V$.** An air-filled capacitor ($C_0$) consisting of two parallel plates separated by a distance $d$ is connected to a battery of constant voltage $V = V_0$ and acquires a charge $Q_0$. While it is still connected to the battery, a slab of dielectric material with $K = 3$ is inserted to fill the space between the plates of the capacitor. Will $Q$ increase, decrease, or stay the same?

**RESPONSE** Since the capacitor remains connected to the battery, the voltage stays constant and equal to the battery voltage $V_0$. The capacitance $C$ increases from $C_0$ to $KC_0$ when the dielectric material is inserted because $K$ in Eq. 24–8 has increased. From the relation $Q = CV$, if $V$ stays constant but $C$ increases, $Q$ must increase to

$$Q = KQ_0.$$

**CONCEPTUAL EXAMPLE 24–12** **Inserting a dielectric into an isolated capacitor.** Suppose the air-filled capacitor ($C_0$) of Example 24–11 is charged (to $Q_0$) and then disconnected from the battery ($V_0$). Next that same dielectric is inserted between the plates. Will $Q$, $C$, or $V$ change?

**RESPONSE** The charge $Q_0$ remains the same—the capacitor is isolated, so there is nowhere for the charge to go. The capacitance, though, *increases* as a result of inserting the dielectric (Eq. 24–8) to $C = KC_0$. The voltage across the capacitor also changes. The voltage *decreases* because, by Eq. 24–1, $Q = Q_0 = CV$, so $V = Q_0/C = Q_0/KC_0 = V_0/K$ where $V_0 = Q_0/C_0$ is the initial voltage. So $Q$ stays constant, $C$ increases, and $V$ decreases by a factor of $K$:

$$V = \frac{V_0}{K}.$$

**EXERCISE E** Return to the Chapter-Opening Question, page 692, and answer it again now. Try to explain why you may have answered differently the first time.

The energy density stored in an electric field $E$ (Section 24–4) when a dielectric ($K$) is present becomes (see Eq. 24–6)

$$u = \tfrac{1}{2}K\epsilon_0 E^2 = \tfrac{1}{2}\epsilon E^2. \qquad [E \text{ in a dielectric}]$$

An electric field is also altered when a dielectric is inserted. When no dielectric is present, the electric field between the plates of a parallel-plate capacitor, for example, is given by Eq. 23–4b:

$$E_0 = \frac{V_0}{d},$$

where $V_0$ is the potential difference between the plates and $d$ is their separation. If the capacitor is isolated so that the charge remains fixed on the plates when a

dielectric is inserted, filling the space between the plates, the potential difference drops to $V = V_0/K$ (as we saw in Example 24–12). So the electric field inside the dielectric is

$$E = E_D = \frac{V}{d} = \frac{V_0}{Kd}$$

or

$$E_D = \frac{E_0}{K}. \qquad \text{[in a dielectric]} \quad \textbf{(24–10)}$$

The electric field in a dielectric is reduced by a factor equal to the dielectric constant. But the field in a dielectric (or insulator) is not reduced all the way to zero as in a conductor. Equation 24–10 is valid inside a dielectric even if the dielectric's thickness is smaller than the gap between the capacitor plates.

**EXAMPLE 24–13** **Dielectric removal.** A parallel-plate capacitor, filled with a dielectric with $K = 3.4$, is connected to a 100-V battery (Fig. 24–16a). After the capacitor is fully charged, the battery is disconnected. The plates have area $A = 4.0\,\text{m}^2$, and are separated by $d = 4.0\,\text{mm}$. (*a*) Find the capacitance, the charge on the capacitor, the electric field strength, and the energy stored in the capacitor. (*b*) The dielectric is then carefully removed, without changing the plate separation nor does any charge leave the capacitor (Fig. 24–16b). Find the new values of capacitance, electric field strength, voltage between the plates, and the energy stored in the capacitor.

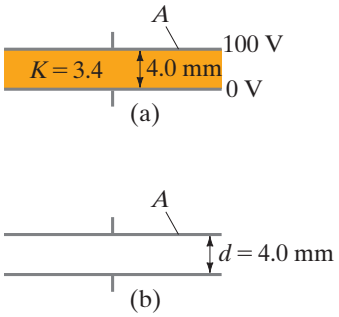


**FIGURE 24–16** Example 24–13.

**APPROACH** We use the expressions for parallel-plate capacitance and electric field with and without a dielectric.

**SOLUTION** (*a*) First we find the capacitance, with dielectric:

$$C = \frac{K\epsilon_0 A}{d} = \frac{3.4\left(8.85\times10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2\right)\left(4.0\,\text{m}^2\right)}{4.0\times10^{-3}\,\text{m}}$$
$$= 3.0\times10^{-8}\,\text{F} = 30\,\text{nF}.$$

The charge $Q$ on the plates is

$$Q = CV = \left(3.0\times10^{-8}\,\text{F}\right)(100\,\text{V}) = 3.0\times10^{-6}\,\text{C}.$$

The electric field between the plates is

$$E = \frac{V}{d} = \frac{100\,\text{V}}{4.0\times10^{-3}\,\text{m}} = 25\,\text{kV/m}.$$

Finally, the total energy stored in the capacitor is

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}\left(3.0\times10^{-8}\,\text{F}\right)(100\,\text{V})^2 = 1.5\times10^{-4}\,\text{J}.$$

(*b*) The capacitance without dielectric decreases by a factor $K = 3.4$:

$$C_0 = \frac{C}{K} = \frac{\left(3.0\times10^{-8}\,\text{F}\right)}{3.4} = 8.8\times10^{-9}\,\text{F} = 8.8\,\text{nF}.$$

Because the battery has been disconnected, the charge $Q$ cannot go anywhere; it is still $Q$. When the dielectric is removed, $V = Q/C$ increases by a factor $K = 3.4$ to 340 V, since $C$ decreases. The electric field is

$$E = \frac{V}{d} = \frac{340\,\text{V}}{4.0\times10^{-3}\,\text{m}} = 85\,\text{kV/m},$$

so is 3.4× larger than before. The energy stored is

$$U = \tfrac{1}{2}CV^2 = \tfrac{1}{2}\left(8.8\times10^{-9}\,\text{F}\right)(340\,\text{V})^2 = 5.1\times10^{-4}\,\text{J},$$

also increasing by a factor of $K = 3.4$.

**NOTE** Where did all this extra energy come from? The energy increased because work had to be done to remove the dielectric. The work required was $W = \left(5.1\times10^{-4}\,\text{J}\right) - \left(1.5\times10^{-4}\,\text{J}\right) = 3.6\times10^{-4}\,\text{J}$. (We will see in the next Section that work is required because of the force of attraction between induced charge on the dielectric and the charges on the plates, Fig. 24–17c.)

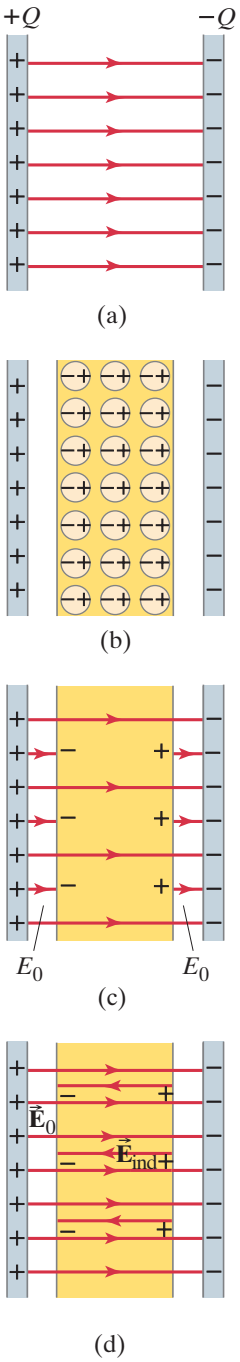

**FIGURE 24–17** Molecular view of the effects of a dielectric.

# *24–6 Molecular Description of Dielectrics

Let us examine, from the molecular point of view, why the capacitance of a capacitor should be larger when a dielectric is between the plates. A capacitor whose plates are separated by an air gap has capacitance $C_0$ and a charge $+Q$ on one plate and $-Q$ on the other (Fig. 24–17a). Assume it is isolated (not connected to a battery) so charge cannot flow to or from the plates. The potential difference between the plates, $V_0$, is given by Eq. 24–1:

$$Q = C_0 V_0,$$

where the subscripts refer to air between the plates. Now we insert a dielectric between the plates (Fig. 24–17b). Because of the electric field between the capacitor plates, the dielectric molecules will tend to become oriented as shown in Fig. 24–17b. If the dielectric molecules are *polar*, the positive end is attracted to the negative plate and vice versa. Even if the dielectric molecules are not polar, electrons within them will tend to move slightly toward the positive capacitor plate, so the effect is the same. The net effect of the aligned dipoles is a net negative charge on the outer edge of the dielectric facing the positive plate, and a net positive charge on the opposite side, as shown in Fig. 24–17c.

Some of the electric field lines, then, do not pass through the dielectric but instead end on charges induced on the surface of the dielectric as shown in Fig. 24–17c. Hence the electric field within the dielectric is less than in air. That is, the electric field in the space between the capacitor plates, assumed filled by the dielectric, has been reduced by some factor $K$. The voltage across the capacitor is reduced by the same factor $K$ because $V = Ed$ (Eq. 23–4b) and hence, by Eq. 24–1, $Q = CV$, the capacitance $C$ must increase by that same factor $K$ to keep $Q$ constant.

As shown in Fig. 24–17d, the electric field within the dielectric $E_{\text{D}}$ can be considered as the vector sum of the electric field $\vec{\mathbf{E}}_0$ due to the "free" charges on the conducting plates, and the field $\vec{\mathbf{E}}_{\text{ind}}$ due to the induced charge on the surfaces of the dielectric. Since these two fields are in opposite directions, the net field within the dielectric, $E_0 - E_{\text{ind}}$, is less than $E_0$. The precise relationship is given by Eq. 24–10, even if the dielectric does not fill the gap between the plates:

$$E_{\text{D}} = E_0 - E_{\text{ind}} = \frac{E_0}{K},$$

so

$$E_{\text{ind}} = E_0\left(1 - \frac{1}{K}\right).$$

The electric field in air between two parallel plates is related to the surface charge density, $\sigma$, by $E = \sigma/\epsilon_0$ (Example 21–14 or 22–8). Thus

$$E_0 = \sigma/\epsilon_0$$

where $\sigma = Q/A$ is the surface charge density on the conductor; $Q$ is the net charge on the conductor and is often called the **free charge** (since charge is free to move in a conductor). Similarly, we define an equivalent induced surface charge density $\sigma_{\text{ind}}$ on the dielectric; then

$$E_{\text{ind}} = \sigma_{\text{ind}}/\epsilon_0$$

where $E_{\text{ind}}$ is the electric field due to the induced charge $Q_{\text{ind}} = \sigma_{\text{ind}} A$ on the surface of the dielectric, Fig. 24–17d. $Q_{\text{ind}}$ is often called the **bound charge**, since it is on an insulator and is not free to move. Since $E_{\text{ind}} = E_0(1 - 1/K)$ as shown above, we now have

$$\sigma_{\text{ind}} = \sigma\left(1 - \frac{1}{K}\right) \qquad \textbf{(24–11a)}$$

and

$$Q_{\text{ind}} = Q\left(1 - \frac{1}{K}\right). \qquad \textbf{(24–11b)}$$

$K$ is always greater than 1, so we see that the charge induced on the dielectric is always less than the free charge on each of the capacitor plates.

**EXAMPLE 24–14** **Dielectric partially fills capacitor.** A parallel-plate capacitor has plates of area $A = 250\,\text{cm}^2$ and separation $d = 2.00\,\text{mm}$. The capacitor is charged to a potential difference $V_0 = 150\,\text{V}$. Then the battery is disconnected (the charge $Q$ on the plates then won't change), and a dielectric sheet $(K = 3.50)$ of the same area $A$ but thickness $\ell = 1.00\,\text{mm}$ is placed between the plates as shown in Fig. 24–18. Determine (*a*) the initial capacitance of the air-filled capacitor, (*b*) the charge on each plate before the dielectric is inserted, (*c*) the charge induced on each face of the dielectric after the dielectric is inserted, (*d*) the electric field in the space between each plate and the dielectric, (*e*) the electric field in the dielectric, (*f*) the potential difference between the plates after the dielectric is added, and (*g*) the capacitance after the dielectric is in place.

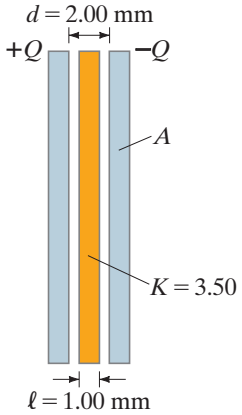

**FIGURE 24–18** Example 24–14.

**APPROACH** We use the expressions for capacitance and charge developed in this Section plus (part *e*) Eq. 23–4a, $V = -\int \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$.

**SOLUTION** (*a*) Before the dielectric is in place, the capacitance is

$$C_0 = \epsilon_0 \frac{A}{d} = (8.85 \times 10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)\left(\frac{2.50 \times 10^{-2}\,\text{m}^2}{2.00 \times 10^{-3}\,\text{m}}\right) = 111\,\text{pF}.$$

(*b*) The charge on each plate is

$$Q = C_0 V_0 = (1.11 \times 10^{-10}\,\text{F})(150\,\text{V}) = 1.66 \times 10^{-8}\,\text{C}.$$

(*c*) Now the dielectric is between the plates. Equations 24–10 and 24–11 are valid even when the dielectric does not fill the gap, so (Eq. 24–11b)

$$Q_{\text{ind}} = Q\left(1 - \frac{1}{K}\right) = (1.66 \times 10^{-8}\,\text{C})\left(1 - \frac{1}{3.50}\right) = 1.19 \times 10^{-8}\,\text{C}.$$

(*d*) The electric field in the gaps between the plates and the dielectric (see Fig. 24–17c) is the same as in the absence of the dielectric since the charge on the plates has not been altered. That is, $E_0 = \sigma/\epsilon_0$ as we just saw on the previous page (also Example 21–14). Thus

$$E_0 = \frac{\sigma}{\epsilon_0} = \frac{Q}{\epsilon_0 A} = \frac{1.66 \times 10^{-8}\,\text{C}}{(8.85 \times 10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)(2.50 \times 10^{-2}\,\text{m}^2)} = 7.50 \times 10^4\,\text{V/m}.$$

(*e*) In the dielectric the electric field is (Eq. 24–10)

$$E_{\text{D}} = \frac{E_0}{K} = \frac{7.50 \times 10^4\,\text{V/m}}{3.50} = 2.14 \times 10^4\,\text{V/m}.$$

(*f*) To obtain the potential difference in the presence of the dielectric we use Eq. 23–4a, and integrate from the surface of the negative plate a to the positive plate b along a straight line parallel to the field lines:

$$V = -\int_{\text{a}}^{\text{b}} \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = E_0(d - \ell) + E_{\text{D}}\ell,$$

which can be simplified to

$$\begin{aligned} V &= E_0\left(d - \ell + \frac{\ell}{K}\right) \\ &= (7.50 \times 10^4\,\text{V/m})\left(1.00 \times 10^{-3}\,\text{m} + \frac{1.00 \times 10^{-3}\,\text{m}}{3.50}\right) \\ &= 96.4\,\text{V}. \end{aligned}$$

**PROBLEM SOLVING**
*Voltage across plates a distance d apart with dielectric K of thickness ℓ*

(*g*) In the presence of the dielectric, the capacitance is

$$C = \frac{Q}{V} = \frac{1.66 \times 10^{-8}\,\text{C}}{96.4\,\text{V}} = 172\,\text{pF}.$$

**EXERCISE F** If the dielectric filled the space between the plates $(\ell = d)$, what would be the answers to (*f*) and (*g*)?

# Summary

A **capacitor** is a device used to store charge (and electric energy), and consists of two nontouching conductors. The two conductors generally hold equal and opposite charges of magnitude $Q$. The ratio of this charge $Q$ to the potential difference $V$ between the conductors is called the **capacitance**, $C$:

$$C = \frac{Q}{V} \quad \text{or} \quad Q = CV. \qquad \textbf{(24–1)}$$

The capacitance of a parallel-plate capacitor is proportional to the area $A$ of each plate and inversely proportional to their separation $d$:

$$C = \epsilon_0 \frac{A}{d}. \qquad \textbf{(24–2)}$$

When capacitors are connected in **parallel**, the equivalent capacitance is the sum of the individual capacitances:

$$C_{\text{eq}} = C_1 + C_2 + \cdots. \qquad \textbf{(24–3)}$$

When capacitors are connected in **series**, the reciprocal of the equivalent capacitance equals the sum of the reciprocals of the individual capacitances:

$$\frac{1}{C_{\text{eq}}} = \frac{1}{C_1} + \frac{1}{C_2} + \cdots. \qquad \textbf{(24–4)}$$

A charged capacitor stores an amount of electric energy given by

$$U = \tfrac{1}{2}QV = \tfrac{1}{2}CV^2 = \tfrac{1}{2}\frac{Q^2}{C}. \qquad \textbf{(24–5)}$$

This energy can be thought of as stored in the electric field between the plates. In any electric field $\vec{\mathbf{E}}$ in free space the **energy density** $u$ (energy per unit volume) is

$$u = \tfrac{1}{2}\epsilon_0 E^2. \qquad \textbf{(24–6)}$$

The space between the two conductors of a capacitor usually contains a nonconducting material such as air, paper, or plastic. These materials are referred to as **dielectrics**, and the capacitance is proportional to a property of dielectrics called the **dielectric constant**, $K$ (nearly equal to 1 for air). For a parallel-plate capacitor

$$C = K\epsilon_0 \frac{A}{d} = \epsilon \frac{A}{d} \qquad \textbf{(24–8)}$$

where $\epsilon = K\epsilon_0$ is called the **permittivity** of the dielectric material. When a dielectric is present, the energy density is

$$u = \tfrac{1}{2}K\epsilon_0 E^2 = \tfrac{1}{2}\epsilon E^2.$$

# Questions

1. Suppose two nearby conductors carry the same negative charge. Can there be a potential difference between them? If so, can the definition of capacitance, $C = Q/V$, be used here? Why or why not?
2. Suppose the separation of plates $d$ in a parallel-plate capacitor is not very small compared to the dimensions of the plates. Would you expect Eq. 24–2 to give an overestimate or underestimate of the true capacitance? Explain.
3. Suppose one of the plates of a parallel-plate capacitor was moved so that the area of overlap was reduced by half, but they are still parallel. How would this affect the capacitance?
4. When a battery is connected to a capacitor, why do the two plates acquire charges of the same magnitude? Will this be true if the two plates are different sizes or shapes?
5. Describe a simple method of measuring $\epsilon_0$ using a capacitor.
6. Suppose three identical capacitors are connected to a battery. Will they store more energy if connected in series or in parallel?
7. A large copper sheet of thickness $\ell$ is placed between the parallel plates of a capacitor, but does not touch the plates. How will this affect the capacitance?
8. The parallel plates of an isolated capacitor carry opposite charges, $Q$. If the separation of the plates is increased, is a force required to do so? Is the potential difference changed? What happens to the work done in the pulling process?
9. How does the energy stored in a capacitor change, as the capacitor remains connected to a battery, if the separation of the plates is doubled?
10. If the voltage across a fixed capacitor is doubled, the amount of energy it stores (*a*) doubles; (*b*) is halved; (*c*) is quadrupled; (*d*) is unaffected; (*e*) none of these. Explain.
11. An isolated charged capacitor has horizontal plates. If a thin dielectric is inserted a short way between the plates, Fig. 24–19, will it move left or right when it is released? Explain.

**FIGURE 24–19** Question 11.

12. Suppose a battery remains connected to the capacitor in Question 11. What then will happen when the dielectric is released? Explain.
13. How does the energy stored in a capacitor change when a dielectric is inserted if (*a*) the capacitor is isolated so $Q$ does not change; (*b*) the capacitor remains connected to a battery so $V$ does not change? Explain.
14. For dielectrics consisting of polar molecules, how would you expect the dielectric constant to change with temperature?
15. A dielectric is pulled out from between the plates of a capacitor which remains connected to a battery. What changes occur to (*a*) the capacitance, (*b*) the charge on the plates, (*c*) the potential difference, (*d*) the energy stored in the capacitor, and (*e*) the electric field? Explain your answers.
16. We have seen that the capacitance $C$ depends on the size and position of the two conductors, as well as on the dielectric constant $K$. What then did we mean when we said that $C$ is a constant in Eq. 24–1?
17. What value might we assign to the dielectric constant for a good conductor? Explain.

# MisConceptual Questions

**1.** Which of the following do not affect capacitance?
(*a*) Area of the plates.
(*b*) Separation of the plates.
(*c*) Material between the plates.
(*d*) Charge on the plates.
(*e*) Energy stored in the capacitor.

**2.** Two uncharged capacitors are connected in series and then to a battery. The battery transfers a charge of $-Q$ to one side of one capacitor as shown in Figure 24–20. What are the charges on the capacitor sides A and B respectively?
(*a*) $0, 0$.
(*b*) $-2Q, +Q$.
(*c*) $-Q, +Q$.
(*d*) $0, -Q$.
(*e*) $+2Q, -2Q$.
(*f*) Not enough information to tell.

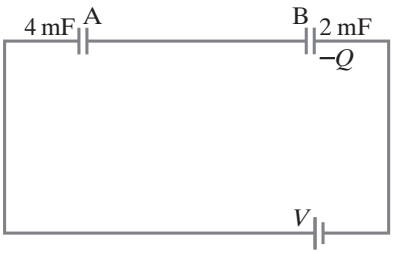

**FIGURE 24–20**
MisConceptual Question 2.

**3.** Two flat pieces of metal form a parallel-plate capacitor. The plates carry equal but opposite charges and are not connected to anything. As the plates are moved closer together,
(*a*) both the charge and voltage decrease.
(*b*) both the charge and voltage increase.
(*c*) the charge decreases while the voltage remains constant.
(*d*) the charge remains constant while the voltage decreases.
(*e*) the charge remains constant while the voltage increases.

**4.** Which of the following would decrease the capacitance of a capacitor?
(*a*) Increasing the spacing between the plates.
(*b*) Increasing the area of the plates.
(*c*) Adding a dielectric between the plates.
(*d*) Increasing the voltage applied across the capacitor.

**5.** When capacitors are connected in series, the equivalent capacitance is _____ the smallest capacitance; when capacitors are connected in parallel, the equivalent capacitance is _____ the largest capacitance.
(*a*) greater than; equal to
(*b*) greater than; less than
(*c*) less than; greater than
(*d*) equal to; less than
(*e*) equal to; equal to

**6.** Two different capacitors store the same amount of charge. Which capacitor has a larger potential difference across it?
(*a*) The one with the larger capacitance.
(*b*) The one with the smaller capacitance.
(*c*) Both have the same potential difference.
(*d*) The answer cannot be determined without knowing the actual values involved.

**7.** The plates of a parallel-plate capacitor are maintained at constant voltage as they are gradually moved closer together, without touching. How is the amount of charge on the plates affected during this process?
(*a*) It quickly becomes 0.
(*b*) It remains constant.
(*c*) It gradually increases.
(*d*) It gradually decreases.

**8.** The plates of a parallel-plate capacitor are maintained at constant voltage (by a battery) as they are gradually pulled apart. How is the strength of the electric field affected?
(*a*) It gradually increases.
(*b*) It gradually decreases.
(*c*) It becomes zero immediately.
(*d*) It increases very rapidly.
(*e*) It remains constant.

**9.** A battery establishes a voltage $V$ across a parallel-plate capacitor. After the battery is disconnected, the distance between the plates is doubled without loss of charge. Accordingly, the capacitance _____ and the voltage between the plates _____.
(*a*) increases; decreases.
(*b*) decreases; increases.
(*c*) increases; increases.
(*d*) decreases; decreases.
(*e*) stays the same; stays the same.

**10.** Adding a dielectric that fills the space between the plates of a capacitor increases all of the following except
(*a*) electric field between the plates.
(*b*) capacitance.
(*c*) charge stored for a given voltage.
(*d*) maximum voltage that can be applied between the plates.
(*e*) the energy stored in a capacitor for a given voltage.

**11.** As a result of being connected to a voltage $V$, a capacitor stores energy $U$. If the voltage is changed to $2V$,
(*a*) the energy is unchanged.
(*b*) the energy is $2U$.
(*c*) the energy is $\frac{1}{2}U$.
(*d*) the energy is $4U$.
(*e*) the energy changes, but not to one of these values.

**12.** Two unequal capacitors are connected in series and the series combination is connected to a voltage $V_0$. For this arrangement
(*a*) each capacitor carries the same charge.
(*b*) the charges are different on each capacitor but must add up to the charge supplied by the voltage source.
(*c*) each capacitor has the same voltage and it is the same as $V_0$.
(*d*) None of these statements is true.

**13.** When the distance $d$ between the two plates of an isolated charged ($Q_0$) parallel-plate capacitor is reduced to $d/2$, the energy stored
(*a*) is reduced by $\frac{1}{4}$.
(*b*) is reduced by $\frac{1}{2}$.
(*c*) stays the same.
(*d*) is increased by 2.
(*e*) is increased by 4.

# Problems

## 24–1 Capacitors

1. (I) The two plates of a capacitor hold $+3500\,\mu C$ and $-3500\,\mu C$ of charge, respectively, when the potential difference is 960 V. What is the capacitance?
2. (I) A 6500-pF capacitor holds plus and minus charges of $16.5 \times 10^{-8}$ C. What is the voltage across the capacitor?
3. (I) How much charge flows from each terminal of a 12.0-V battery when it is connected to a 7.50-$\mu$F capacitor?
4. (II) The charge on a capacitor increases by 15 $\mu$C when the voltage across it increases from 83 V to 121 V. What is the capacitance of the capacitor?
5. (II) An isolated capacitor $C_1$ carries a charge $Q_0$. Its wires are then connected to those of a second capacitor $C_2$, previously uncharged. What charge will each carry now? What will be the potential difference across each?
6. (II) A 7.7-$\mu$F capacitor is charged by a 185-V battery (Fig. 24–21a) and then is disconnected from the battery. When this capacitor $(C_1)$ is then connected (Fig. 24–21b) to a second (initially uncharged) capacitor, $C_2$, the final voltage on each capacitor is 15 V. What is the value of $C_2$? [*Hint*: Charge is conserved.]

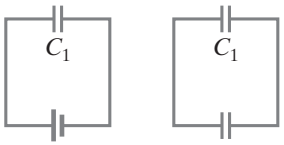

**FIGURE 24–21**
Problem 6.

7. (II) It takes 24 J of energy to move a 0.30-mC charge from one plate of a 15-$\mu$F capacitor to the other. How much charge is on each plate?
8. (II) A 2.70-$\mu$F capacitor is charged to 435 V and a 4.00-$\mu$F capacitor is charged to 525 V. (*a*) These capacitors are then disconnected from their batteries. Then the positive plates are connected to each other and the negative plates are connected to each other. What will be the potential difference across each capacitor and the charge on each? (*b*) What is the voltage and charge for each capacitor if plates of opposite sign are connected? [*Hint*: Charge is conserved.]

## 24–2 Determination of Capacitance

9. (I) To make a 0.40-$\mu$F capacitor, what area must the plates have if they are to be separated by a 3.4-mm air gap?
10. (I) What is the capacitance per unit length (F/m) of a coaxial cable whose inner conductor has a 1.0-mm diameter and the outer cylindrical sheath has a 5.0-mm diameter? Assume the space between is filled with air.
11. (I) Determine the capacitance of the Earth, assuming it to be a spherical conductor.
12. (II) If a capacitor has opposite 4.2-$\mu$C charges on the plates, and an electric field of 1.8 kV/mm is desired between the plates, what must each plate's area be?
13. (II) To get an idea how big a farad is, suppose you want to make a 1-F air-filled parallel-plate capacitor for a circuit you are building. To make it a reasonable size, suppose you limit the plate area to 1.0 $cm^2$. What would the gap have to be between the plates? Is this practically achievable?
14. (II) Use Gauss's law to show that $\vec{\mathbf{E}} = 0$ inside the inner conductor of a cylindrical capacitor (see Fig. 24–7 and Example 24–2) as well as outside the outer cylinder.
15. (II) An electric field of $8.50 \times 10^5$ V/m is desired between two parallel plates, each of area 38.0 $cm^2$ and separated by 2.45 mm of air. What charge must be on each plate?
16. (II) Dry air will break down if the electric field exceeds about $3.0 \times 10^6$ V/m. What amount of charge can be placed on an air-gap capacitor if the area of each plate is 8.2 $cm^2$?
17. (II) How strong is the electric field between the plates of a 0.80-$\mu$F air-gap capacitor if they are 2.0 mm apart and each has a charge of magnitude 84 $\mu$C?
18. (III) A large metal sheet of thickness $\ell$ is placed between, and parallel to, the plates of the parallel-plate capacitor of Fig. 24–4. It does not touch the plates, and extends beyond their edges. (*a*) What is now the net capacitance in terms of $A$, $d$, and $\ell$? (*b*) If $\ell = 0.40\,d$, by what factor does the capacitance change when the sheet is inserted?
19. (III) Small distances can be measured using a capacitor whose plate separation $x$ is variable. Consider an air-filled parallel-plate capacitor with fixed plate area $A = 25\ mm^2$ separated by a variable distance $x$. Assume this capacitor is attached to a capacitance-measuring instrument which can measure capacitance $C$ in the range 1.0 pF to 1000.0 pF with an accuracy of $\Delta C = 0.1$ pF. (*a*) If $C$ is measured while $x$ is varied, over what range $(x_{min} \le x \le x_{max})$ can the plate-separation distance (in $\mu$m) be determined by this setup? (*b*) Define $\Delta x$ to be the accuracy (magnitude) to which $x$ can be determined, and determine a formula for $\Delta x$. (*c*) Determine the percent accuracy to which $x_{min}$ and $x_{max}$ can be measured.
20. (III) In an **electrostatic air cleaner ("precipitator")**, the strong nonuniform electric field in the central region of a cylindrical capacitor (with outer and inner cylindrical radii $R_a$ and $R_b$) is used to create ionized air molecules for use in charging dust and soot particles (Fig. 24–22). Under standard atmospheric conditions, if air is subjected to an electric field magnitude that exceeds its dielectric strength $E_S \approx 3.0 \times 10^6$ N/C, air molecules will dissociate into positively charged ions and free electrons. In a precipitator, the region within which air is ionized (the *corona discharge* region) occupies a cylindrical volume of radius $R$ that is typically five times that of the inner cylinder. Assume a particular precipitator is constructed with $R_b = 0.10$ mm and $R_a = 10.0$ cm. In order to create a corona discharge region with radius $R = 5.0\,R_b$, what potential difference $V$ should be applied between the precipitator's inner and outer conducting cylinders? [Besides dissociating air, the charged inner cylinder repels the resulting positive ions from the corona discharge region, where they are put to use in charging dust particles, which are then "collected" on the negatively charged outer cylinder.]

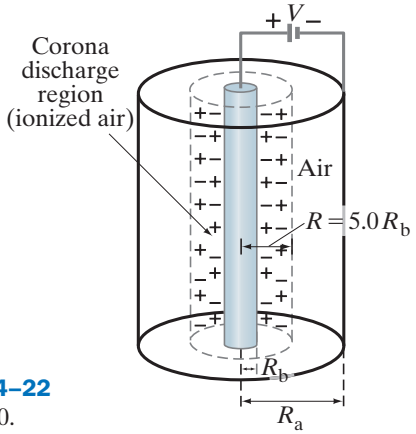

**FIGURE 24–22**
Problem 20.

## 24–3 Capacitors in Series and Parallel

**21.** (I) The capacitance of a portion of a circuit is to be reduced from 3400 pF to 1600 pF. What capacitance can be added to the circuit to produce this effect without removing existing circuit elements? Must any existing connections be broken to accomplish this?

**22.** (I) (*a*) Six 3.2-$\mu$F capacitors are connected in parallel. What is the equivalent capacitance? (*b*) What is their equivalent capacitance if connected in series?

**23.** (II) Suppose three parallel-plate capacitors, whose plates have areas $A_1$, $A_2$, and $A_3$ and separations $d_1$, $d_2$, and $d_3$, are connected in parallel. Show, using only Eq. 24–2, that Eq. 24–3 is valid.

**24.** (II) An electric circuit was accidentally constructed using a 5.0-$\mu$F capacitor instead of the required 22-$\mu$F value. Without removing the 5.0-$\mu$F capacitor, what can a technician add to correct this circuit?

**25.** (II) Three conducting plates, each of area $A$, are connected as shown in Fig. 24–23. (*a*) Are the two capacitors thus formed connected in series or in parallel? (*b*) Determine $C$ as a function of $d_1$, $d_2$, and $A$. Assume $d_1 + d_2$ is much less than the dimensions of the plates. (*c*) The middle plate can be moved (changing the values of $d_1$ and $d_2$), so as to vary the capacitance. What are the minimum and maximum values of the net capacitance?

**FIGURE 24–23**
Problem 25.

**26.** (II) Answer the same questions as for Problem 25, for the three plates connected as shown in Fig. 24–24.

**FIGURE 24–24**
Problem 26.

**27.** (II) Consider three capacitors, of capacitance 3100 pF, 5800 pF, and 0.0100 $\mu$F. What maximum and minimum capacitance can you form from these? How do you make the connection in each case?

**28.** (II) In Fig. 24–25, suppose $C_1 = C_2 = C_3 = C_4 = C$. (*a*) Determine the equivalent capacitance between points a and b. (*b*) Determine the charge on each capacitor and the potential difference across each in terms of $V$.

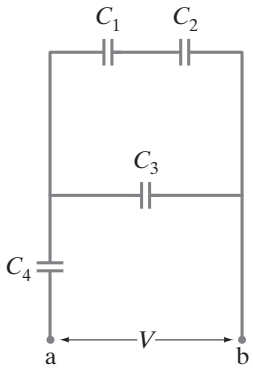

**FIGURE 24–25**
Problems 28 and 29.

**29.** (II) Suppose in Fig. 24–25 that $C_1 = C_2 = C_3 = 16.0\,\mu$F and $C_4 = 28.5\,\mu$F. If the charge on $C_2$ is $Q_2 = 14.8\,\mu$C, determine the charge on each of the other capacitors, the voltage across each capacitor, and the voltage $V_{ab}$ across the entire combination.

**30.** (II) A 0.50-$\mu$F and a 0.80-$\mu$F capacitor are connected in series to a 9.0-V battery. Calculate (*a*) the potential difference across each capacitor and (*b*) the charge on each. (*c*) Repeat parts (*a*) and (*b*) assuming the two capacitors are in parallel.

**31.** (II) The switch S in Fig. 24–26 is connected downward so that capacitor $C_2$ becomes fully charged by the battery of voltage $V_0$. If the switch is then connected upward, determine the charge on each capacitor after the switching.

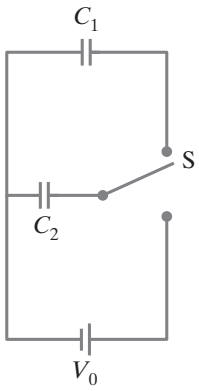

**FIGURE 24–26**
Problem 31.

**32.** (II) Given three capacitors, $C_1 = 2.0\,\mu$F, $C_2 = 1.5\,\mu$F, and $C_3 = 3.0\,\mu$F, what arrangement of parallel and series connections with a 12-V battery will give the minimum voltage drop across the 2.0-$\mu$F capacitor? What is the minimum voltage drop?

**33.** (II) A circuit contains a single 250-pF capacitor hooked across a battery. It is desired to store 5.0 times as much energy in a combination of two capacitors by adding a single capacitor to this one. How would you hook it up, and what would its value be?

**34.** (II) Suppose in Fig. 24–27 that $C_1 = C_3 = 8.0\,\mu$F, $C_2 = C_4 = 16\,\mu$F, and $Q_3 = 21\,\mu$C. Determine (*a*) the charge on each of the other capacitors, (*b*) the voltage across each capacitor, and (*c*) the voltage $V_{ba}$ across the combination.

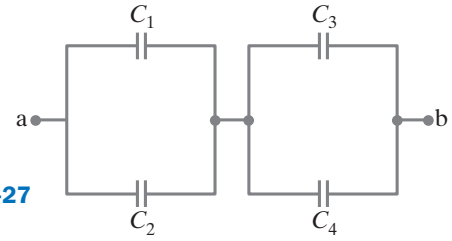

**FIGURE 24–27**
Problem 34.

**35.** (II) In the **capacitance bridge** shown in Fig. 24–28, a voltage $V_0$ is applied and the variable capacitor $C_1$ is adjusted until there is zero voltage between points a and b as measured on the voltmeter (•–Ⓥ–•). Determine the unknown capacitance $C_x$ if $C_1 = 8.9\,\mu$F and the fixed capacitors have $C_2 = 16.0\,\mu$F and $C_3 = 4.8\,\mu$F. No charge flows through the voltmeter when it reads zero.)

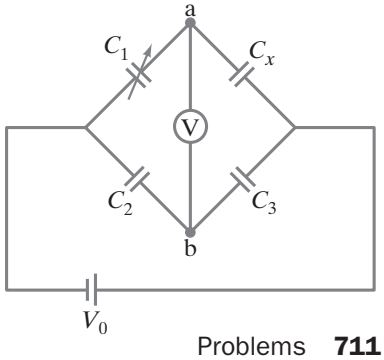

**FIGURE 24–28**
Problem 35.

**36.** (II) Two capacitors connected in parallel produce an equivalent capacitance of 32.9 $\mu$F, but when connected in series the equivalent capacitance is only 5.5 $\mu$F. What is the individual capacitance of each capacitor?

**37.** (III) Suppose one plate of a parallel-plate capacitor is tilted so it makes a small angle $\theta$ with the other plate, as shown in Fig. 24–29. Determine a formula for the capacitance $C$ in terms of $A$, $d$, and $\theta$, where $A$ is the area of each plate and $\theta$ is small. Assume the plates are square. [*Hint*: Imagine the capacitor as many infinitesimal capacitors in parallel.]

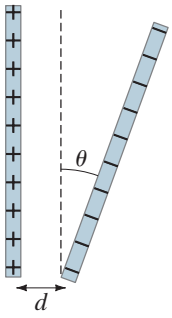

**FIGURE 24–29**
Problem 37.

## 24–4 Electric Energy Storage

**38.** (I) 720 V is applied to a 2800-pF capacitor. How much energy is stored?

**39.** (I) There is an electric field near the Earth's surface whose intensity is about 150 V/m. How much energy is stored per cubic meter in this field?

**40.** (I) A **cardiac defibrillator** is used to shock a heart that is beating erratically. A capacitor in this device is charged to 5.0 kV and stores 1200 J of energy. What is its capacitance?

**41.** (II) How much energy is stored by the electric field between two square plates, 8.0 cm on a side, separated by a 1.5-mm air gap? The charges on the plates are equal and opposite and of magnitude 420 $\mu$C.

**42.** (II) A parallel-plate capacitor has fixed charges $+Q$ and $-Q$. The separation of the plates is then halved. (*a*) By what factor does the energy stored in the electric field change? (*b*) How much work must be done to decrease the separation of the plates from $d$ to $\frac{1}{2}d$? The area of each plate is $A$.

**43.** (II) How much energy must a 24-V battery expend to charge a 0.45-$\mu$F and a 0.20-$\mu$F capacitor fully when they are placed (*a*) in parallel, (*b*) in series? (*c*) How much charge flowed from the battery in each case?

**44.** (II) (*a*) Suppose the radius $R_a$ of the outer cylinder of a cylindrical capacitor was tripled, but the charge was kept constant. By what factor would the stored energy change? Where would the energy come from? (*b*) Repeat part (*a*), assuming the voltage remains constant.

**45.** (II) A 3.70-$\mu$F capacitor is charged by a 16.0-V battery. It is disconnected from the battery and then connected to an uncharged 5.00-$\mu$F capacitor. Determine the total stored energy (*a*) before the two capacitors are connected, and (*b*) after they are connected. (*c*) What is the change in energy?

**46.** (II) How much work would be required to remove a metal sheet from between the plates of a capacitor (as in Problem 18a), assuming: (*a*) the battery remains connected so the voltage remains constant; (*b*) the battery is disconnected so the charge remains constant?

**47.** (II) When two uncharged capacitors are connected in parallel and then connected to a battery, the total stored energy is 6.0 times greater than when they are connected in series and then connected to the same battery. What is the ratio of the two capacitances?

**48.** (II) The electric field near the Earth is about 150 N/C. (*a*) What is the energy density near the Earth? (*b*) Approximately how much electric energy is stored in the Earth's electric field in the first 10 m above the Earth's surface? (*c*) Compare (by a ratio) the answer to part (*b*) with the daily output from a 2000-MW power station.

**49.** (II) (*a*) Show that each plate of a parallel-plate capacitor exerts a force

$$F = \frac{1}{2}\frac{Q^2}{\epsilon_0 A}$$

on the other, by calculating $dW/dx$ where $dW$ is the work needed to increase the separation by $dx$. (*b*) Why does using $F = QE$, with $E$ being the electric field between the plates, give the wrong answer?

**50.** (II) A cylindrical capacitor (Example 24–2) has $R_a = 3.5$ mm and $R_b = 0.50$ mm. The two conductors have a potential difference of 625 V, with the inner conductor at the higher potential. (*a*) Calculate the energy stored in a 1.0-m length of the capacitor. (*b*) What is the linear charge density (C/m) on the capacitor's conductors? (*c*) Calculate the electric field at the surface of the inner conductor.

**51.** (III) Determine the energy stored per meter of capacitor length, for the capacitor of Problem 50, by integrating the energy density from $R_b$ to $R_a$.

**52.** (III) Show that the electrostatic energy stored in the electric field outside an isolated spherical conductor of radius $r_0$ carrying a net charge $Q$ is

$$U = \frac{1}{8\pi\epsilon_0}\frac{Q^2}{r_0}.$$

Do this in three ways: (*a*) Use Eq. 24–6 for the energy density in an electric field [*Hint*: Consider spherical shells of thickness $dr$]; (*b*) use Eq. 24–5 together with the capacitance of an isolated sphere (Section 24–2); (*c*) by calculating the work needed to bring all the charge $Q$ up from infinity in infinitesimal bits $dq$.

## 24–5 Dielectrics

**53.** (I) What is the capacitance of a pair of circular plates with a radius of 5.0 cm separated by 2.3 mm of mica?

**54.** (I) What is the capacitance of two square parallel plates 4.7 cm on a side that are separated by 1.8 mm of paraffin?

**55.** (II) Suppose the capacitor in Example 24–13 remains connected to the battery as the dielectric is removed. What will be the work required to remove the dielectric in this case?

**56.** (II) How much energy would be stored in the capacitor of Problem 41 if a mica dielectric is placed between the plates? Assume the mica is 1.5 mm thick (and therefore fills the space between the plates).

**57.** (II) A 3500-pF air-gap capacitor is connected to an 18-V battery. If a piece of mica fills the space between the plates, how much charge will flow from the battery?

**58.** (II) Two different dielectrics each fill half the space between the plates of a parallel-plate capacitor as shown in Fig. 24–30. Determine a formula for the capacitance in terms of $K_1$, $K_2$, the area $A$ of the plates, and the separation $d$. [*Hint*: Can you consider this capacitor as two capacitors in series or in parallel?]

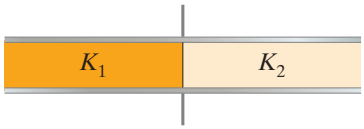

**FIGURE 24–30** Problem 58.

**59.** (II) Two different dielectrics fill the space between the plates of a parallel-plate capacitor as shown in Fig. 24–31. Determine a formula for the capacitance in terms of $K_1$, $K_2$, the area $A$ of the plates, and the separation $d_1 = d_2 = d/2$. [*Hint*: Can you consider this capacitor as two capacitors in series or in parallel?]

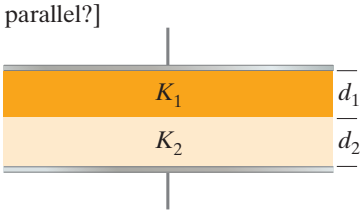

**FIGURE 24–31** Problems 59 and 60.

**60.** (II) Repeat Problem 59 (Fig. 24–31) but assume the separation $d_1 \neq d_2$.

**61.** (II) Two identical capacitors are connected in parallel and each acquires a charge $Q_0$ when connected to a source of voltage $V_0$. The voltage source is disconnected and then a dielectric $(K = 3.6)$ is inserted to fill the space between the plates of one of the capacitors. Determine (*a*) the charge now on each capacitor, and (*b*) the voltage now across each capacitor.

**62.** (II) An uncharged capacitor is connected to an 18.0-V battery until it is fully charged, after which it is disconnected from the battery. A slab of paraffin is then inserted between the plates. What will now be the voltage across the plates?

**63.** (II) The electric field between the plates of a paper-separated $(K = 3.75)$ capacitor is $8.24 \times 10^4$ V/m. The plates are 1.95 mm apart, and the charge on each is 0.765 $\mu$C. Determine the capacitance of this capacitor and the area of each plate.

**64.** (III) A slab of width $d$ and dielectric constant $K$ is inserted a distance $x$ into the space between the square parallel plates (of side $\ell$) of a capacitor as shown in Fig. 24–32. Determine, as a function of $x$, (*a*) the capacitance, (*b*) the energy stored if the potential difference is $V_0$, and (*c*) the magnitude and direction of the force exerted on the slab (assume $V_0$ is constant).

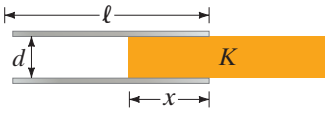

**FIGURE 24–32** Problem 64.

**65.** (III) The quantity of liquid (such as cryogenic liquid nitrogen) available in its storage tank is often monitored by a capacitive level sensor. This sensor is a vertically aligned cylindrical capacitor with outer and inner conductor radii $R_a$ and $R_b$, whose length $\ell$ spans the height of the tank. When a nonconducting liquid fills the tank to a height $h$ $(\leq \ell)$ from the tank's bottom, the dielectric in the lower and upper regions between the cylindrical conductors is the liquid $(K_{liq})$ and its vapor $(K_V)$, respectively (Fig. 24–33). (*a*) Determine a formula for the fraction $F$ of the tank filled by liquid in terms of the level-sensor capacitance $C$. [*Hint*: Consider the sensor as a combination of two capacitors.] (*b*) By connecting a capacitance-measuring instrument to the level sensor, $F$ can be monitored. Assume the sensor dimensions are $\ell = 2.0$ m, $R_a = 5.0$ mm, and $R_b = 4.5$ mm. For liquid nitrogen $(K_{liq} = 1.4,\ K_V = 1.0)$, what values of $C$ (in pF) will correspond to the tank being completely full and completely empty?

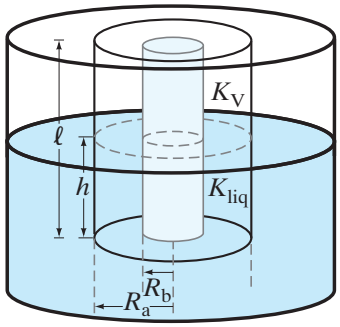

**FIGURE 24–33**
Problem 65.

## *24–6 Molecular Description of Dielectrics

***66.** (II) In Example 24–14 what percent of the stored energy is stored in the electric field in the dielectric?

***67.** (II) Show that the capacitor in Example 24–14 with dielectric inserted can be considered as equivalent to three capacitors in series, and using this assumption show that the same value for the capacitance is obtained as was obtained in part (*g*) of the Example.

***68.** (II) Repeat Example 24–14 assuming the battery remains connected when the dielectric is inserted. Also, what is the free charge on the plates after the dielectric is added (let this be part (*h*) of this Problem)?

***69.** (II) Using Example 24–14 as a model, derive a formula for the capacitance of a parallel-plate capacitor whose plates have area $A$, separation $d$, with a dielectric of dielectric constant $K$ and thickness $\ell$ $(\ell < d)$ placed between the plates.

***70.** (III) The capacitor shown in Fig. 24–34 is connected to an 80.0-V battery. Calculate (and sketch) the electric field everywhere between the capacitor plates. Find both the free charge on each capacitor plate and the induced charge on the faces of the glass dielectric plate.

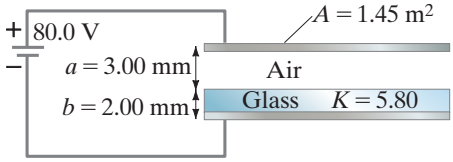

**FIGURE 24–34** Problem 70.

# General Problems

**71.** A homemade capacitor is assembled by placing two 9-in. pie pans 6 cm apart and connecting them to the opposite terminals of a 9-V battery. Estimate (*a*) the capacitance, (*b*) the charge on each plate, (*c*) the electric field halfway between the plates, and (*d*) the work done by the battery to charge them. (*e*) Which of the above values change if a dielectric is inserted?

**72.** (*a*) A general rule for estimating the capacitance $C$ of an isolated conducting sphere with radius $r$ is $C$ (in pF) $\approx r$ (in cm). That is, the numerical value of $C$ in pF is about the same as the numerical value of the sphere's radius in cm. Justify this rule. (*b*) Modeling the human body as a 1-m-radius conducting sphere, use the given rule to estimate your body's capacitance. (*c*) While walking across a carpet, you acquire an excess "static electricity" charge $Q$ and produce a 0.5-cm spark when reaching out to touch a metallic doorknob. The dielectric strength of air is 30 kV/cm. Use this information to estimate $Q$ (in $\mu$C).

**73.** A huge 4.0-F capacitor has enough stored energy to heat 2.4 kg of water from 21°C to 95°C. What is the potential difference across the plates?

**74.** How does the energy stored in an isolated capacitor change if (*a*) the potential difference is doubled, or (*b*) the separation of the plates is doubled?

**75.** By what factor does the energy stored in a capacitor change if (*a*) the potential difference is doubled, or (*b*) the charge on each plate is doubled? (*c*) What happens to the energy stored if the separation of the plates is doubled, as the capacitor remains connected to a battery?

**76.** A **coaxial cable**, Fig. 24–35, consists of an inner cylindrical conducting wire of radius $R_b$ surrounded by a dielectric insulator. Surrounding the dielectric insulator is an outer conductor of radius $R_a$, which is usually "grounded." (*a*) Determine an expression for the capacitance per unit length of a cable whose insulator has dielectric constant $K$. (*b*) For a given cable, $R_b = 2.5$ mm and $R_a = 9.0$ mm. The dielectric constant of the dielectric insulator is $K = 3.2$. Suppose that there is a potential of 1.0 kV between the inner conducting wire and the outer conducting sheath. Find the charge, and capacitance, per meter of the cable.

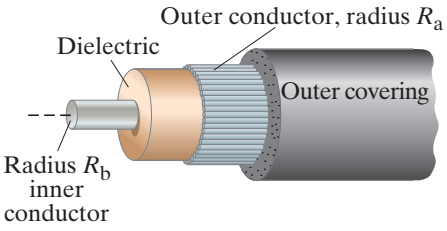

**FIGURE 24–35** Problem 76.

**77.** A 2.1-$\mu$F capacitor is fully charged by a 9.0-V battery. The battery is then disconnected. The capacitor is not ideal and the charge slowly leaks out from the plates. The next day, the capacitor has lost half its stored energy. Calculate the amount of charge lost.

**78.** A capacitor is made from two 1.1-cm-diameter coins separated by a 0.10-mm-thick piece of paper ($K = 3.7$). A 12-V battery is connected to the capacitor. How much charge is on each coin?

**79.** New compact **ultracapacitors** can have capacitance up to several thousand farads. One application is in providing power for electrical circuits when other sources (such as a battery) are turned off. To get an idea of how much charge can be stored in such a capacitor, assume a 1200-F ultracapacitor is initially charged to 12.0 V by a battery and is then disconnected from the battery. If charge is then drawn off the plates of this capacitor at a rate of 1.0 mC/s to power the backup memory of some electrical device, how long (in days) will it take for the potential difference across this capacitor to drop to 6.0 V?

**80.** A parallel-plate capacitor is isolated with a charge $\pm Q$ on each plate. If the separation of the plates is halved and a dielectric (constant $K$) is inserted in place of air, by what factor does the energy storage change? To what do you attribute the change in stored potential energy? How does the new value of the electric field between the plates compare with the original value?

**81.** A multilayer "film" capacitor has a maximum voltage rating of 100 V and a capacitance of 1.0 $\mu$F. It is made from alternating sheets of very thin metal foil connected together, separated by films of polyester dielectric. The sheets are 12.0 mm by 14.0 mm and the total thickness of the capacitor is 6.0 mm (not counting the thickness of the insulator on the outside). The metal foils are actually very thin layers of metal deposited directly on the dielectric, so most of the thickness of the capacitor is due to the dielectric. The dielectric strength of the polyester is about $30 \times 10^6$ V/m. Estimate the dielectric constant of the polyester material in the capacitor.

**82.** A 3.5-$\mu$F capacitor is charged by an 11.2-V battery and then is disconnected from the battery. When this capacitor ($C_1$) is then connected to a second (initially uncharged) capacitor, $C_2$, the voltage on the first drops to 5.9 V. What is the value of $C_2$?

**83.** The power supply for a pulsed nitrogen laser has a 0.080-$\mu$F capacitor with a maximum voltage rating of 25 kV. (*a*) Estimate how much energy could be stored in this capacitor. (*b*) If 15% of this stored electrical energy is converted to light energy in a pulse that is 4.0 $\mu$s long, what is the power of the laser pulse?

**84.** A parallel-plate capacitor has square plates 12 cm on a side separated by 0.10 mm of plastic with a dielectric constant of $K = 3.8$. The plates are connected to a battery, causing them to become oppositely charged. Since the oppositely charged plates attract each other, they exert a pressure on the dielectric. If this pressure is 40.0 Pa, what is the battery voltage?

**85.** A parallel-plate capacitor with plate area 2.0 cm$^2$ and air-gap separation 0.50 mm is connected to a 12-V battery, and fully charged. The battery is then disconnected. (*a*) What is the charge on the capacitor? (*b*) The plates are now pulled to a separation of 0.85 mm. What is the charge on the capacitor now? (*c*) What is the potential difference across the plates now? (*d*) How much work was required to pull the plates to their new separation?

**86.** A 155-pF capacitor is connected in series with an unknown capacitor, and as a series combination they are connected to a 25.0-V battery. If the 155-pF capacitor stores 125 pC of charge on its plates, what is the unknown capacitance?

**87.** The *variable capacitance* of an old radio tuner consists of four plates connected together placed alternately between four other plates, also connected together (Fig. 24–36). Each plate is separated from its neighbor by 1.6 mm of air. One set of plates can move so that the area of overlap of each plate varies from $2.0\,\text{cm}^2$ to $9.0\,\text{cm}^2$. (*a*) Are these seven capacitors connected in series or in parallel? (*b*) Determine the range of capacitance values.

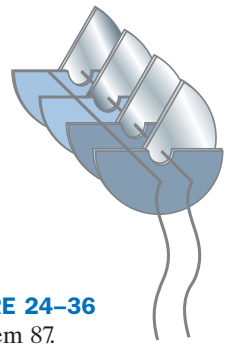

**FIGURE 24–36**
Problem 87.

**88.** The long cylindrical capacitor shown in Fig. 24–37 consists of four concentric cylinders, with respective radii $R_a$, $R_b$, $R_c$, and $R_d$. The cylinders b and c are joined by metal strips. Determine the capacitance per unit length of this arrangement. (Assume equal and opposite charges are placed on the innermost and outermost cylinders.)

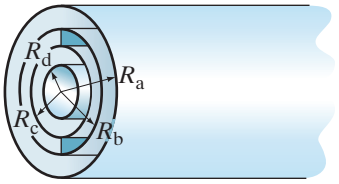

**FIGURE 24–37**
Problem 88.

**89.** A parallel-plate capacitor has plate area $A$, plate separation $x$, and has a charge $Q$ stored on its plates (Fig. 24–38). (*a*) Determine the work required to double the plate separation to $2x$, assuming the charge remains constant at $Q$. (*Hint*: See Example 24–10.) (*b*) Show that your answer is consistent with the change in energy stored by the capacitor.

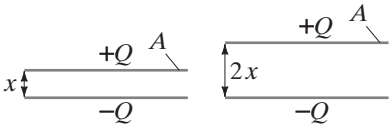

**FIGURE 24–38**
Problem 89.

**90.** Let us try to estimate the maximum "static electricity" charge that might result during each walking step across a non-metal floor. Assume the sole of a person's shoe has area $A \approx 150\,\text{cm}^2$, and when the foot is lifted from the ground during each step, the sole acquires an excess charge $Q$ from rubbing contact with the floor. (*a*) Model the sole as a plane conducting surface with $Q$ uniformly distributed across it as the foot is lifted from the ground. Given the dielectric strength of the air between the sole and floor as the foot is lifted is $E_S = 3 \times 10^6\,\text{N/C}$, determine $Q_{max}$, the maximum possible excess charge that can be transferred to the sole during each step. (*b*) Modeling a person as an isolated conducting sphere of radius $r \approx 1\,\text{m}$, estimate a person's capacitance. (*c*) After lifting the foot from the floor, assume the excess charge $Q$ quickly redistributes itself over the entire surface area of the "spherical" person. Estimate the maximum potential difference that the person can develop with respect to the floor.

**91.** A parallel-plate capacitor with plate area $A = 2.0\,\text{m}^2$ and plate separation $d = 3.0\,\text{mm}$ is connected to a 45-V battery (Fig. 24–39a). (*a*) Determine the charge on the capacitor, the electric field, the capacitance, and the energy $U_0$ stored in the capacitor. (*b*) With the capacitor still connected to the battery, a slab of plastic with dielectric constant $K = 3.2$ is placed between the plates of the capacitor, so that the gap is completely filled with the dielectric. What are the new values of charge, electric field, capacitance, and the energy $U$ stored in the capacitor?

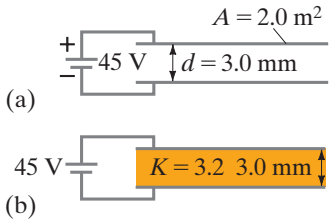

**FIGURE 24–39**
Problem 91.

**92.** Consider the use of capacitors as memory cells. A charged capacitor would represent a one and an uncharged capacitor a zero. Suppose these capacitors were fabricated on a silicon chip and each has a capacitance of 30 femto-farads $(1\,\text{fF} = 10^{-15}\,\text{F}.)$ The dielectric filling the space between the parallel plates has dielectric constant $K = 15$ and a dielectric strength of $1.0 \times 10^9\,\text{V/m}$. (*a*) If the operating voltage is 1.5 V, how many electrons would be stored on one of these capacitors when charged? (*b*) If no safety factor is allowed, how thin a dielectric layer could we use for operation at 1.5 V? (*c*) Using the layer thickness from your answer to part (*b*), what would be the area of the capacitor plates?

**93.** The potential energy stored in a capacitor can be written as either $CV^2/2$ or $Q^2/2C$. In the first case the energy is proportional to $C$; in the second case the energy is proportional to $1/C$. (*a*) Explain how both of these equations can be correct. (*b*) When might you use the first equation and when might you use the second equation? (*c*) If a paper dielectric is inserted into a parallel-plate capacitor that is attached to a battery ($V$ does not change), by what factor will the energy stored in the capacitor change? (*d*) If a quartz dielectric is inserted into a charged parallel-plate capacitor that is isolated from any battery, by what factor will the energy stored in the capacitor change?

**94.** A student wearing shoes with thin insulating soles is standing on a grounded metal floor when he puts his hand on the metal case of a high voltage supply. The voltage inside, 6.3 mm from his hand, is 25,000 V. The student's hand and the voltage supply form a capacitor, considering the student as a conductor. Another capacitor is between the floor and the student (his feet). Using reasonable numbers for hand and foot areas, estimate the student's voltage relative to the floor. Assume vinyl-soled shoes 1 cm thick.

**95.** Capacitors can be used as "electric charge counters." Consider an initially uncharged capacitor of capacitance $C$ with its bottom plate grounded and its top plate connected to a source of electrons. (*a*) If $N$ electrons flow onto the capacitor's top plate, show that the resulting potential difference $V$ across the capacitor is directly proportional to $N$. (*b*) Assume a voltage-measuring device can accurately resolve voltage changes of about 1 mV. What value of $C$ would be necessary to resolve the arrival of an individual electron? (*c*) Using semiconductor technology, a micron-size capacitor can be constructed with parallel conducting plates separated by an insulator of dielectric constant $K = 3$ and thickness $d = 100\,\text{nm}$. What side length $\ell$ should the square plates have (in $\mu$m)?

**96.** In the **dynamic random access memory (DRAM)** of a cell phone, each memory cell contains a capacitor for charge storage. Each of these cells represents a single binary-bit value of "1" when its 25-fF capacitor $(1\,\text{fF} = 10^{-15}\,\text{F})$ is charged at 0.6 V, or "0" when uncharged at 0 V. (*a*) When fully charged, how many excess electrons are on a cell capacitor's negative plate? (*b*) After charge has been placed on a cell capacitor's plate, it slowly "leaks" off at a rate of about 0.5 pA. How long does it take for the potential difference across this capacitor to decrease by 2.0% from its fully charged value? (Because of this leakage effect, the charge on a DRAM capacitor is "refreshed" many times per second.) Note: A DRAM cell is shown in Fig. 29–31.

**97.** In the DRAM computer chip of Problem 96, suppose the two parallel plates of one cell's 25-fF capacitor are separated by a 10-nm-thick insulating material with dielectric constant $K = 25$. (*a*) Determine the area $A$ $(\text{in } \mu\text{m}^2)$ of the cell capacitor's plates. (*b*) If the plate area $A$ accounts for half of the area of each cell, estimate how many megabytes of memory can be placed on a 3.0-$\text{cm}^2$ silicon wafer. (1 byte = 8 bits.)

**98.** In lightning storms, the potential difference between the Earth and the bottom of the thunderclouds can be as high as 35,000,000 V. The bottoms of thunderclouds are typically 1500 m above the Earth, and can have an area of 110 $\text{km}^2$. Modeling the Earth–cloud system as a huge capacitor, calculate (*a*) the capacitance of the Earth–cloud system, (*b*) the charge stored in the "capacitor," and (*c*) the energy stored in the "capacitor."

**99.** Suppose it takes 75 kW of power for your car to travel at a constant speed on the highway. (*a*) What is this in horsepower? (*b*) How much energy in joules would it take for your car to travel at highway speed for 4.0 hours? (*c*) Suppose this amount of energy is to be stored in the electric field of a parallel-plate capacitor. If the voltage on the capacitor is to be 850 V, what is the required capacitance? (*d*) If this capacitor were to be made from activated carbon (Section 24–2), the voltage would be limited to no more than 10 V. In this case, how many grams of activated carbon would be required? (*e*) Is this practical?

**100.** Capacitors can be recharged many thousands of times with little degradation, so consider why electric cars don't use a bank of capacitors rather than a bank of batteries. (*a*) Estimate how large a capacitance would be needed to store the energy equivalent of 10 gallons of gasoline $(\approx 10^9\,\text{J})$, assuming 12 V. (*b*) Physically how large would this capacitor be if it was a conventional parallel-plate capacitor using the best dielectric in Table 24–1? (*c*) If this capacitor was 0.1 mm thick and cut and stacked into 1 $\text{m}^2$ sheets to make it more compact, could it make a practical replacement for the battery of an electric car? (*d*) If the capacitor instead used the activated carbon capacitor material described in Section 24–2, how heavy would the capacitor be?

**101.** Paper has a dielectric constant $K = 3.7$ and a dielectric strength of $15 \times 10^6\,\text{V/m}$. Suppose that a typical sheet of paper has a thickness of 0.11 mm. You make a "homemade" capacitor by placing a sheet of 21 cm × 14 cm paper between two aluminum foil sheets (Fig. 24–40) of the same size. (*a*) What is the capacitance $C_0$ of your device? (*b*) About how much charge could you store on your capacitor before it would break down? (*c*) Show in a sketch how you could overlay sheets of paper and aluminum for a parallel combination. (*d*) Suppose you made 100 such capacitors by connecting the edges of alternate sheets of 0.016-mm-thick aluminum foil to form capacitors in parallel. How thick would this single large capacitor of capacitance 100 $C_0$ be? (*e*) What is the maximum voltage you can apply to this 100-$C_0$ capacitor without breakdown?

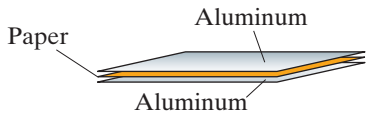

**FIGURE 24–40** Problem 101.

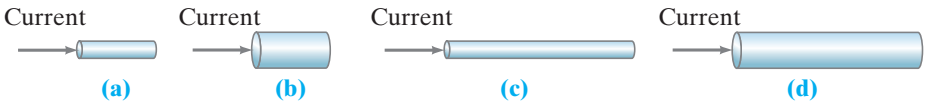
## ANSWERS TO EXERCISES

**A:** A.
**B:** $8.3 \times 10^{-9}$ C.
**C:** (*a*).
**D:** (*e*).
**E:** (*b*).
**F:** 42.9 V; 387 pF.

The glow of the wire heating element of an electric heater (in a mountain restaurant) is caused by the electric current passing through it. Electric energy is transformed to thermal energy (via collisions between moving electrons and atoms of the wire), which causes the wire's temperature to become so high that it glows.



Electric current and electric power in electric circuits are of basic importance in everyday life. We examine both dc and ac in this Chapter, and include the microscopic analysis of electric current.

CHAPTER 25

# Electric Current and Resistance

**CHAPTER-OPENING QUESTION—Guess now!**

The conductors shown below are all made of copper and are at the same temperature. Which conductor would have the greatest resistance to the flow of charge entering from the left? Which would offer the least resistance?

In the previous four Chapters we have been studying static electricity: electric charges at rest. In this Chapter we begin our study of charges in motion, and we call a flow of charge an electric current.

In everyday life we are familiar with electric currents in wires and other conductors. Most practical electrical devices depend on electric current: current through a lightbulb, current in the heating element of a stove, hair dryer, or electric heater, as well as currents in electronic devices. Electric currents can exist in conductors such as wires, but also in semiconductor devices, human cells and their membranes (Section 25–10), and in empty space.

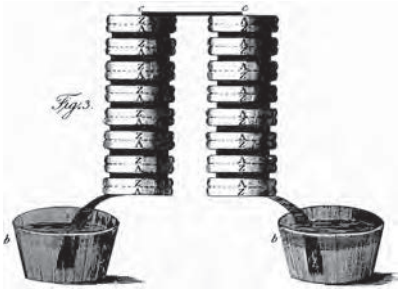
**FIGURE 25–1** Alessandro Volta. In this portrait, Volta demonstrates his battery to Napoleon in 1801.

In electrostatic situations, we saw in Sections 21–9 and 22–3 that the electric field must be zero inside a conductor (if it weren't, the charges would move). But when charges *are moving* in a conductor, an electric field is needed to set charges into motion, and to keep them in motion against resistance in any normal conductor. We can control the flow of charge using electric fields and electric potential (voltage), concepts we have just been discussing. In order to have a current in a wire, a potential difference is needed, which can be provided by a battery.

We first look at electric current from a macroscopic point of view: that is, current as measured in a laboratory. Later in this Chapter we look at currents from a microscopic (theoretical) point of view as a flow of electrons in a wire.

Until the year 1800, the technical development of electricity consisted mainly of producing a static charge by friction. It all changed in 1800 when Alessandro Volta (1745–1827; Fig. 25–1) invented the electric battery, and with it produced the first steady flow of electric charge—that is, a steady electric current.



# 25–1 The Electric Battery

The events that led to the discovery of the battery are interesting. Not only was this an important discovery, but it also gave rise to a famous scientific debate.

In the 1780s, Luigi Galvani (1737–1798), professor at the University of Bologna, carried out a series of experiments on the contraction of a frog's leg muscle by using static electricity. Galvani found that the muscle also contracted when dissimilar metals were inserted into the frog. Galvani believed that the source of the electric charge was in the frog muscle or nerve itself, and that the metal merely transmitted the charge to the proper points. When he published his work in 1791, he termed this charge "animal electricity." Many wondered, including Galvani himself, if he had discovered the long-sought "life-force."

Volta, at the University of Pavia 200 km away, was skeptical of Galvani's results, and came to believe that the source of the electricity was not in the animal itself, but rather in the *contact between the dissimilar metals*. Volta realized that a moist conductor, such as a frog muscle or moisture at the contact point of two dissimilar metals, was necessary in the circuit if it was to be effective. He also saw that the contracting frog muscle was a sensitive instrument for detecting electric "tension" or "electromotive force" (his words for what we now call potential), in fact more sensitive than the best available electroscopes (Section 21–4) that he and others had developed.[†]

**FIGURE 25–2** A voltaic battery, from Volta's original publication.

Volta's research found that certain combinations of metals produced a greater effect than others, and, using his measurements, he listed them in order of effectiveness. (This "electrochemical series" is still used by chemists today.) He also found that carbon could be used in place of one of the metals.

Volta then conceived his greatest contribution to science. Between a disc of zinc and one of silver, he placed a piece of cloth or paper soaked in salt solution or dilute acid and piled a battery of such couplings, one on top of another, as shown in Fig. 25–2. This "pile" or "battery" produced a much increased potential difference. Indeed, when strips of metal connected to the two ends of the pile were brought close, a spark was produced. Volta had designed and built the first **electric battery**. He published his discovery in 1800.

## Electric Cells and Batteries

A battery produces electricity by transforming chemical energy into electrical energy. Today a great variety of electric cells and batteries are available, from flashlight batteries to the starter batteries of gasoline cars, from those used in cell phones to those for energy storage in electric vehicles.

The simplest batteries contain two plates or rods made of dissimilar metals (one can be carbon) called **electrodes**. The electrodes are immersed in a solution or paste, such as a dilute acid, called the **electrolyte**. Such a device is properly called an **electric cell**, and

[†]Volta's most sensitive electroscope (Section 21–4) measured about 40 V per degree (angle of leaf separation). Nonetheless, he was able to estimate the potential differences produced by combinations of dissimilar metals in contact. For a silver–zinc contact he got about 0.7 V, remarkably close to today's value of 0.78 V.

several cells connected together is a **battery**, although today even a single cell is called a battery. The chemical reactions involved in most electric cells are quite complicated. Here we describe how one very simple cell works, emphasizing the physical aspects.

The cell shown in Fig. 25–3 uses dilute sulfuric acid as the electrolyte. One of the electrodes is made of carbon, the other of zinc. The part of each electrode outside the solution is called the **terminal**, and connections to wires and circuits are made here. The acid tends to dissolve the zinc electrode. Each zinc atom leaves two electrons behind on the electrode and enters the solution as a positive ion. The zinc electrode thus acquires a negative charge. The electrolyte becomes positively charged, and can pull electrons off the carbon electrode. Thus the carbon electrode becomes positively charged. Because there is an opposite charge on the two electrodes, there is a potential difference between the two terminals. The positive electrode is called the **anode**, the negative one the **cathode**.

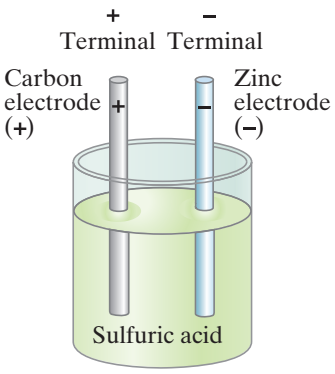


**FIGURE 25–3** Simple electric cell.

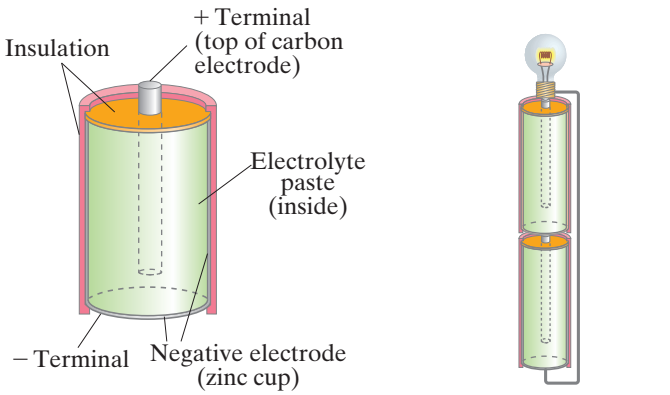
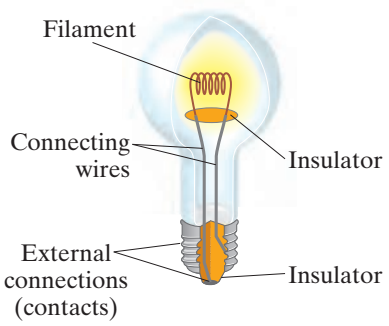


In a cell whose terminals are not connected, only a small amount of the zinc is dissolved, for as the zinc electrode becomes increasingly negative, any new positive zinc ions produced are attracted back to the electrode. Thus, a particular potential difference (or voltage) is maintained between the two terminals. If charge is allowed to flow between the terminals, say, through a wire (or a toaster heating element), then more zinc can be dissolved. After a time, one or the other electrode is used up and the cell becomes "dead."

The voltage that exists between the terminals of a battery depends on what the electrodes are made of and their relative ability to be dissolved or give up electrons.

When two or more cells are connected so that the positive terminal of one is connected to the negative terminal of the next, they are said to be connected in *series* and their voltages add up. Thus, the voltage between the ends of two 1.5-V AA flashlight batteries connected in series is 3.0 V, whereas the six 2-V cells of an ordinary car battery give 12 V. Figure 25–4a shows a diagram of a common "dry cell" or "flashlight battery" used in flashlights and many portable electronic devices, and Fig. 25–4b shows two batteries (AA or AAA) connected in series to a flashlight bulb.



The simple incandescent lightbulb in Fig. 25–4b consists of a thin, coiled wire (filament) inside an evacuated glass bulb, as shown in Fig. 25–5. When charge passes through the filament, it gets very hot ($\approx 2700\,\text{K}$) and glows. Halogen bulbs are incandescent with the filament enclosed in a capsule containing a halogen such as bromine or iodine; they last longer and can glow at 2900 K giving better efficiency. [Halogens, via chemical reactions, restore many of the tungsten atoms that were evaporated from the hot filament, allowing longer life. The higher temperature (typically 2900 K) gives whiter light, closer to what the Sun produces, around 6000 K. Color vs. temperature is discussed in Section 37–1 on blackbody radiation.] Other bulb types, such as fluorescent (Chapter 39) and LED (Chapter 40) work in a more complicated way.

**FIGURE 25–4** (a) Diagram of an ordinary dry cell (like a D-cell or AA). The cylindrical zinc cup is covered on the sides by an insulator (pink here); its flat bottom is the negative terminal. (b) Two dry cells (AA type) connected in series. Note that the positive terminal of one cell pushes against the negative terminal of the other.

(a) One D-cell (b) Two AA batteries

**FIGURE 25–5** A plain incandescent lightbulb: the fine wire of the filament becomes so hot that it glows. Incandescent *halogen* bulbs enclose the filament in a small quartz tube filled with a halogen gas (bromine or iodine) which allows longer filament life and higher filament temperature for greater efficiency and whiteness.

## Electric Cars

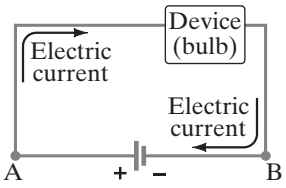
**PHYSICS APPLIED**
*Electric cars*

Considerable research is being done to improve batteries for electric cars and for hybrids (which use both a gasoline internal combustion engine and an electric motor). One type of battery is lithium-ion, in which the anode contains lithium and the cathode is carbon. Electric cars need no gear changes and can develop full torque starting from rest, and so can accelerate quickly and smoothly. The distance an electric car can go between charges of the battery (its "range") is an important parameter because each recharging of an electric car battery may take hours, not minutes like a gas fill-up. Because charging an electric car can draw a large current over a period of several hours, electric power companies need upgraded power grids so they won't fail when many electric cars are being charged at the same time in any given urban area.

# 25–2 Electric Current

The purpose of a battery is to produce a potential difference, which can then make charges move. When a continuous conducting path, such as a wire and some electrical device, is connected between the terminals of a battery, we have an electric **circuit**, Fig. 25–6a. On any diagram of a circuit, as in Fig. 25–6b, we use the symbol

or [battery symbol]



to represent a battery. A device connected to the battery could be a lightbulb, a heater, a radio, or some other device. When such a circuit is formed, charge can move (or flow) through the wires of the circuit, from one terminal of the battery to the other, as long as the conducting path is continuous. Any flow of charge such as this is called an **electric current**.

**FIGURE 25–6** (a) A simple electric circuit. (b) Schematic drawing of the same circuit, consisting of a battery, connecting wires (thick gray lines), and a lightbulb or other device.

(a)

(b)

More precisely, the electric current in a wire is defined as the net amount of charge that passes through the wire's full cross section at any point per unit time. Thus, the average current $\bar{I}$ is defined as

$$\bar{I} = \frac{\Delta Q}{\Delta t}, \qquad \textbf{(25–1a)}$$

where $\Delta Q$ is the amount of charge that passes through the conductor at any location during the time interval $\Delta t$. The instantaneous current is defined by the derivative limit

$$I = \frac{dQ}{dt}. \qquad \textbf{(25–1b)}$$

Electric current is measured in coulombs per second; this is given a special name, the **ampere** (abbreviated amp or A), after the French physicist André Ampère (1775–1836). Thus, $1\ \text{A} = 1\ \text{C/s}$. Smaller units of current are often used, such as the milliampere $(1\ \text{mA} = 10^{-3}\ \text{A})$ and microampere $(1\ \mu\text{A} = 10^{-6}\ \text{A})$.

A current can flow in a circuit only if there is a *continuous* conducting path. We then have a **complete circuit**. If there is a break in the circuit, say, a cut wire, we call it an **open circuit** and no current flows. In any single circuit, with only a single path for current to follow such as in Fig. 25–6b, a steady current at any instant is the same at one point (say, point A) as at any other point (such as B). This follows from the conservation of electric charge: charge doesn't disappear. A battery does not create (or destroy) any net charge, nor does a lightbulb absorb or destroy charge.

**CAUTION**
*A battery does not create charge; a lightbulb does not destroy charge*

**EXAMPLE 25–1** **Current is flow of charge.** A steady current of 2.5 A exists in a wire for 4.0 min. (*a*) How much total charge passes by a given point in the circuit during those 4.0 min? (*b*) How many electrons would this be?

**APPROACH** (*a*) Current is flow of charge per unit time, Eqs. 25–1, so the amount of charge passing a point is the product of the current and the time interval. (*b*) To get the number of electrons, we divide the total charge by the charge on one electron.

**SOLUTION** (*a*) Since the current was 2.5 A, or 2.5 C/s, then in 4.0 min $(= 240\ \text{s})$ the total charge that flowed past a given point in the wire was, from Eq. 25–1a,

$$\Delta Q = I\,\Delta t = (2.5\ \text{C/s})(240\ \text{s}) = 600\ \text{C}.$$

(*b*) The charge on one electron is $1.60 \times 10^{-19}\ \text{C}$, so 600 C would consist of

$$\frac{600\ \text{C}}{1.6 \times 10^{-19}\ \text{C/electron}} = 3.8 \times 10^{21}\ \text{electrons}.$$

**EXERCISE A** If 1 million electrons per second pass a point in a wire, what is the current?

**CONCEPTUAL EXAMPLE 25–2** **How to connect a battery.** What is wrong with each of the schemes shown in Fig. 25–7 for lighting a flashlight bulb with a flashlight battery and a single wire?

**RESPONSE** (*a*) There is no closed path for charge to flow around. Charges might briefly start to flow from the battery toward the lightbulb, but there they run into a "dead end," and the flow would immediately come to a stop.

(*b*) Now there is a closed path passing to and from the lightbulb; but the wire touches only one battery terminal, so there is no potential difference in the circuit to make the charge move. Neither here, nor in (*a*), does the bulb light up.

(*c*) Nothing is wrong here. This is a complete circuit: charge can flow out from one terminal of the battery, through the wire and the bulb, and into the other terminal. This scheme will light the bulb.

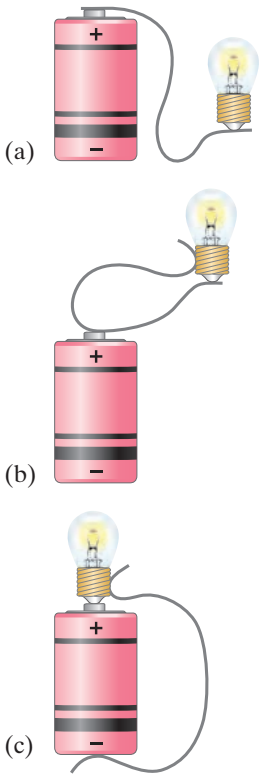


**FIGURE 25–7** Example 25–2.

In many real circuits, wires are connected to a common conductor that provides continuity. This common conductor is called **ground**, usually represented as ⏚ or ⏚, and really is connected to the ground for a building or house. In a car, one terminal of the battery is called "ground," but is not connected to the earth itself—it is connected to the frame of the car, as is one connection to each lightbulb and other devices. Thus the car frame is a conductor in each circuit, ensuring a continuous path for charge flow, and is called "ground" for the car's circuits. (The car frame is well insulated from the earth by the rubber tires.)

We saw in Chapter 21 that conductors contain many free electrons. Thus, if a continuous conducting wire is connected to the terminals of a battery, negatively charged electrons flow in the wire. When the wire is first connected, the potential difference between the terminals of the battery sets up an electric field inside the wire[†] and parallel to it. Free electrons at one end of the wire are attracted into the positive terminal, and at the same time other electrons enter the other end of the wire at the negative terminal of the battery. There is a continuous flow of electrons throughout the wire that begins as soon as the wire is connected to *both* terminals.

When the conventions of positive and negative charge were invented two centuries ago, however, it was assumed that positive charge flowed in a wire. For nearly all purposes, positive charge flowing in one direction is exactly equivalent to negative charge flowing in the opposite direction,[‡] as shown in Fig. 25–8.

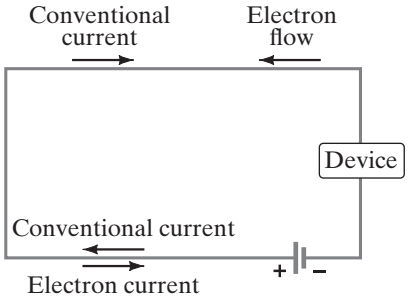

**FIGURE 25–8** Conventional current from + to − is equivalent to a negative electron flow from − to +.

Today, we still use the historical convention of positive charge flow when discussing the direction of a current. So when we speak of the current direction in a circuit, we mean the direction *positive* charge would flow. This is sometimes referred to as **conventional current**. When we want to speak of the direction of electron flow, we will specifically state it is the electron current. In liquids and gases, both positive and negative charges (ions) can move.

**CAUTION**
*Distinguish conventional current from electron flow*

In practical life, such as rating the total charge available (positive or negative) in a car battery, you may see the unit **ampere-hour** (A · h): from Eq. 25–1a, $\Delta Q = I\,\Delta t$.

**EXERCISE B** How many coulombs is 1.00 A · h?

[†]This does not contradict what was said in Section 21–9 that in the *static* case, there can be no electric field within a conductor since otherwise the charges would move. Indeed, when there is an electric field in a conductor, charges do move, and we get an electric current.

[‡]An exception is discussed in Section 27–8, the Hall effect.

## 25–3 Ohm's Law: Resistance and Resistors

To produce an electric current in a circuit, a difference in potential is required. One way of producing a potential difference along a wire is to connect its ends to the opposite terminals of a battery. It was Georg Simon Ohm (1787–1854) who established experimentally that the current in a metal wire is proportional to the potential difference $V$ applied to its two ends:

$$I \propto V.$$

If, for example, we connect a wire to the two terminals of a 6-V battery, the current in the wire will be twice what it would be if the wire were connected to a 3-V battery. It is also found that reversing the sign of the voltage does not affect the magnitude of the current.

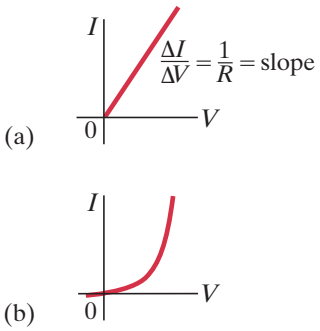
Exactly how large the current is in a wire depends not only on the voltage between its ends, but also on the resistance the wire offers to the flow of electrons. We can think of electron flow as being impeded partly because of collisions with the atoms of the wire.[†] We define electrical **resistance** $R$ as the proportionality factor between the voltage $V$ (between the ends of the wire) and the current $I$ (passing through the wire):

*OHM'S "LAW"*

$$V = IR. \qquad \textbf{(25–2)}$$

Ohm found experimentally that in metal conductors $R$ is a constant independent of $V$, a result known as **Ohm's law**. Equation 25–2, $V = IR$, is itself sometimes called Ohm's law, but only when referring to materials or devices for which $R$ is a constant independent of $V$. But $R$ is not a constant for many substances other than metals, nor for devices such as diodes, vacuum tubes, transistors, and so on. Even for metals, $R$ is not constant if the temperature changes much: for an incandescent lightbulb filament the measured resistance is low for small currents, but is much higher at the filament's normal large operating current that puts it at the high temperature needed to make it glow ($\approx 3000$ K). Thus Ohm's "law" is not a fundamental law of nature, but rather a description of a certain class of materials: metal conductors, whose temperature does not change much. Such materials are said to be "ohmic." Materials or devices that do not follow Ohm's law are said to be *nonohmic*. See Fig. 25–9.

The unit for resistance is called the **ohm** and is abbreviated Ω (Greek capital letter omega). Because $R = V/I$, we see that 1.0 Ω is equivalent to 1.0 V/A.



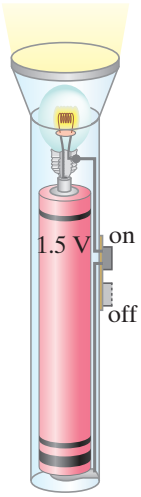


**FIGURE 25–9** Graphs of current vs. voltage (a) for a metal conductor which obeys Ohm's law, and (b) for a nonohmic device, in this case a semiconductor diode.

**FIGURE 25–10** Flashlight (Example 25–3). Note how the circuit is completed along the side strip. The on-off switch is shown in 2 positions. When "on" it connects the 2 wire contacts.

**EXAMPLE 25–3** **Flashlight bulb resistance.** A small flashlight bulb (Fig. 25–10) draws 300 mA from its 1.5-V battery. (*a*) What is the resistance of the bulb? (*b*) If the battery becomes weak and the voltage drops to 1.2 V, how would the current change? Assume the bulb is approximately ohmic.

**APPROACH** We apply Ohm's law to the bulb, where the voltage applied across it is the battery voltage.

**SOLUTION** (*a*) We change 300 mA to 0.30 A and use Eq. 25–2:

$$R = \frac{V}{I} = \frac{1.5\,\text{V}}{0.30\,\text{A}} = 5.0\,\Omega.$$

(*b*) If the resistance stays the same, the current would be

$$I = \frac{V}{R} = \frac{1.2\,\text{V}}{5.0\,\Omega} = 0.24\,\text{A} = 240\,\text{mA},$$

or a decrease of 60 mA.

**NOTE** With the smaller current in part (*b*), the bulb filament's temperature would be lower and the bulb less bright. Also, resistance *does* depend on temperature (Section 25–4), so our calculation is only a rough approximation.

[†]A useful analogy compares the flow of electric charge in a wire to the flow of water in a river, or in a pipe, acted on by gravity. If the river (or pipe) is nearly level, the flow rate is small. But if one end is somewhat higher than the other, the water flow rate—or current—is greater. The greater the difference in height, the greater the current. We saw in Chapter 23 that electric potential is analogous to the height of a cliff for gravity. Just as an increase in height can cause a greater flow of water, so a greater electric potential difference, or voltage, causes a greater electric current. Resistance in a wire is analogous to rocks in a river that retard water flow.

**EXERCISE C** What resistance should be connected across a 9.0-V battery to make a 10-mA current? (*a*) 9 Ω, (*b*) 0.9 Ω, (*c*) 900 Ω, (*d*) 1.1 Ω, (*e*) 0.11 Ω.

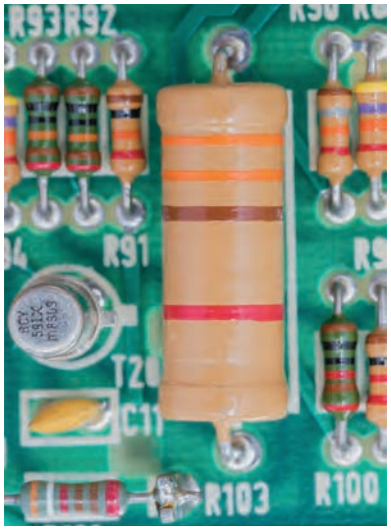
All electric devices, from heaters to lightbulbs to ovens and electronic devices, offer resistance to the flow of current. The filaments of incandescent lightbulbs (Fig. 25–5), toasters, stove burners (Fig. 25–16), and electric heaters are special types of wires whose resistance results in their becoming very hot. Generally, the connecting wires have very low resistance in comparison to the resistance of the wire filaments or coils, so the connecting wires usually have a minimal effect on the magnitude of the current.

In many circuits, particularly in electronic devices, **resistors** are used to control the amount of current. Resistors have resistances ranging from less than an ohm to millions of ohms (see Figs. 25–11 and 25–12). The main types are "wire-wound" resistors which consist of a coil of fine wire, "composition" resistors which are usually made of carbon, resistors made of thin carbon or metal films, and (on tiny integrated circuit "chips") undoped semiconductors.

When we draw a diagram of a circuit, we use the symbol

[resistor symbol]

to indicate a resistance. Wires whose resistance is negligible, however, are shown simply as straight lines. Figure 25–12 and its Table show one way to specify the resistance of a resistor.



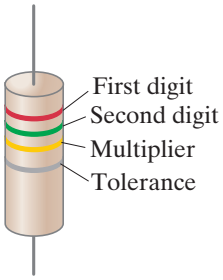


**FIGURE 25–11** Photo of resistors with color-coded stripes representing resistance and tolerances. Most are $\frac{1}{4}$ watt (maximum $P = I^2R$ without damage). The large one can handle more current and power, perhaps 4 or 5 W.

**Resistor Color Code**

| Color | Number | Multiplier | Tolerance |
|---|---|---|---|
| Black | 0 | 1 | |
| Brown | 1 | $10^1$ | 1%† |
| Red | 2 | $10^2$ | 2%† |
| Orange | 3 | $10^3$ | |
| Yellow | 4 | $10^4$ | |
| Green | 5 | $10^5$ | |
| Blue | 6 | $10^6$ | |
| Violet | 7 | $10^7$ | |
| Gray | 8 | $10^8$ | |
| White | 9 | $10^9$ | |
| Gold | | $10^{-1}$ | 5% |
| Silver | | $10^{-2}$ | 10% |
| No color | | | 20% |

†Used on 5-line precision resistors.

**FIGURE 25–12** The resistance value of a given resistor is written on the exterior, or may be given as a color code as shown below and in the Table to the left: for a 4-line code, the first two colors represent the first two digits in the value of the resistance, the third color represents the power of ten that it must be multiplied by, and the fourth is the manufactured tolerance. For example, a resistor whose four colors are red, green, yellow, and silver has a resistance of $25 \times 10^4\ \Omega = 250{,}000\ \Omega = 250\ \text{k}\Omega$, plus or minus 10%. [An alternative code is a number such as 104, which means $R = 1.0 \times 10^4\ \Omega$.] A 5 or 6 line color code is a precision resistor with an accuracy of 1% or 2% or even better. For these, the third line is the third significant figure, the fourth line is the multiplier, such as $452 \times 10^4\ \Omega$, and the fifth line is the tolerance. A sixth line represents temperature dependence of its $R$.

**CONCEPTUAL EXAMPLE 25–4** **Current and potential.** Current $I$ enters a resistor $R$ as shown in Fig. 25–13. (*a*) Is the potential higher at point A or at point B? (*b*) Is the current greater at point A or at point B?

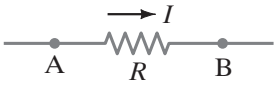

**FIGURE 25–13** Example 25–4.

**RESPONSE** (*a*) Positive charge always flows from + to −, from high potential to low potential. So if current $I$ is conventional (positive) current, point A is at a higher potential than point B.

(*b*) Conservation of charge requires that whatever charge flows into the resistor at point A, an equal amount of charge emerges at point B. Charge or current does not get "used up" by a resistor. So the current is the same at A and B.

An electric potential decrease, as from point A to point B in Example 25–4, is often called a **potential drop** or a **voltage drop**.

## Some Helpful Clarifications

Here we briefly summarize some possible misunderstandings and clarifications. Batteries do not put out a constant current. Instead, batteries are intended to maintain a constant potential difference, or very nearly so. (Details in the next Chapter.) Thus a battery should be considered a source of voltage. The voltage is applied *across* a wire or device.

**CAUTION**
*Voltage is applied* across *a device; current passes* through *a device*

Electric current passes *through* a wire or device (connected to a battery), and its magnitude depends on that device's resistance. The resistance is a *property* of the wire or device. The voltage, on the other hand, is external to the wire or device, and is applied across the two ends of the wire or device. The current through the device might be called the "response": the current increases if the voltage increases or the resistance decreases, as $I = V/R$.

In a thin wire, the direction of the current is always parallel to the wire at each point, no matter how the wire curves, just like water in a pipe. The direction of conventional (positive) current is from high potential $(+)$ toward lower potential $(-)$.

**CAUTION**
*Current is not consumed*

Current and charge do not increase or decrease or get "used up" when going through a wire or other device. The amount of charge that goes in at one end comes out at the other end.

# 25–4 Resistivity

It is found experimentally that the resistance $R$ of any wire is directly proportional to its length $\ell$ and inversely proportional to its cross-sectional area $A$. That is,

$$R = \rho \frac{\ell}{A}, \tag{25–3}$$

where $\rho$, the constant of proportionality, is called the **resistivity** and depends on the material used. Typical values of $\rho$, whose units are $\Omega \cdot \text{m}$ (see Eq. 25–3), are given for various materials in the middle column of Table 25–1, which is divided into the categories *conductors*, *insulators*, and *semiconductors* (Section 21–3). The values depend somewhat on purity, heat treatment, temperature, and other factors. Notice that silver has the lowest resistivity and is thus the best conductor (although it is expensive). Copper is close, and much less expensive, which is why most wires are made of copper. Aluminum, although it has a higher resistivity, is much less dense than copper; it is thus preferable to copper in some situations, such as for transmission lines, because its resistance for the same weight is less than that for copper.

**TABLE 25–1 Resistivity and Temperature Coefficients (at 20°C)**

| Material | Resistivity, $\rho$ ($\Omega \cdot \text{m}$) | Temperature Coefficient, $\alpha$ $(\text{C}°)^{-1}$ |
|---|---|---|
| *Conductors* | | |
| Silver | $1.59 \times 10^{-8}$ | 0.0061 |
| Copper | $1.68 \times 10^{-8}$ | 0.0068 |
| Gold | $2.21 \times 10^{-8}$ | 0.0034 |
| Aluminum | $2.65 \times 10^{-8}$ | 0.00429 |
| Tungsten | $5.28 \times 10^{-8}$ | 0.0045 |
| Iron | $9.61 \times 10^{-8}$ | 0.00651 |
| Platinum | $10.5 \times 10^{-8}$ | 0.003927 |
| Mercury | $96.1 \times 10^{-8}$ | 0.0009 |
| Nichrome (Ni, Fe, Cr alloy) | $100 \times 10^{-8}$ | 0.0004 |
| *Semiconductors*† | | |
| Carbon (graphite) | $(3–60) \times 10^{-5}$ | −0.0005 |
| Germanium | $(1–500) \times 10^{-3}$ | −0.05 |
| Silicon | 0.1–60 | −0.07 |
| *Insulators* | | |
| Glass | $10^{9}$–$10^{12}$ | |
| Hard rubber | $10^{13}$–$10^{15}$ | |

†Values depend strongly on the presence of even slight amounts of impurities.

The reciprocal of the resistivity, called the **conductivity** $\sigma$, is

$$\sigma = \frac{1}{\rho} \tag{25–4}$$

and has units of $(\Omega \cdot \text{m})^{-1}$.

**EXERCISE D** Return to the Chapter-Opening Question, page 717, and answer it again now. Try to explain why you may have answered differently the first time.

**EXERCISE E** A copper wire has a resistance of 10 Ω. What would its resistance be if it had the same diameter but was only half as long? (*a*) 20 Ω, (*b*) 10 Ω, (*c*) 5 Ω, (*d*) 1 Ω, (*e*) none of these.

**EXAMPLE 25–5** **Speaker wires.** Suppose you want to connect your home theater or stereo system to remote speakers (Fig. 25–14). (*a*) If each wire must be 20 m long, what diameter copper wire should you use to keep the resistance less than 0.10 Ω per wire? (*b*) If the current to each speaker is 4.0 A, what is the potential difference, or voltage drop, across each wire?

**APPROACH** We solve Eq. 25–3 to get the area $A$, from which we can calculate the wire's radius using $A = \pi r^2$. The diameter is $2r$. In (*b*) we can use Ohm's law, $V = IR$.

**SOLUTION** (*a*) We solve Eq. 25–3 for the area $A$ and find $\rho$ for copper in Table 25–1:

$$A = \rho \frac{\ell}{R} = \frac{(1.68 \times 10^{-8}\ \Omega \cdot \text{m})(20\ \text{m})}{(0.10\ \Omega)} = 3.4 \times 10^{-6}\ \text{m}^2.$$

The cross-sectional area $A$ of a circular wire is $A = \pi r^2$. The radius must then be at least

$$r = \sqrt{\frac{A}{\pi}} = 1.04 \times 10^{-3}\ \text{m} = 1.04\ \text{mm}.$$

The diameter is twice the radius and so must be at least $2r = 2.1$ mm.

(*b*) From $V = IR$ we find that the voltage drop across each wire is

$$V = IR = (4.0\ \text{A})(0.10\ \Omega) = 0.40\ \text{V}.$$

**NOTE** The voltage drop across the wires reduces the voltage that reaches the speakers from the stereo amplifier, thus reducing the sound level a bit.

**FIGURE 25–14** Example 25–5.

**CONCEPTUAL EXAMPLE 25–6** **Stretching changes resistance.** Suppose a wire of resistance $R$ could be stretched uniformly until it was twice its original length. What would happen to its resistance? Make the reasonable assumption that the amount of material, and its volume, doesn't change.

**RESPONSE** If the length $\ell$ doubles, then the cross-sectional area $A$ is halved, because the volume $(V = A\ell)$ of the wire remains the same. From Eq. 25–3 we see that the resistance would increase by a factor of four $\left(2/\frac{1}{2} = 4\right)$.

**EXERCISE F** Copper wires in houses typically have a diameter of about 1.5 mm. How long a wire would have a 1.0-Ω resistance?

## Temperature Dependence of Resistivity

The resistivity of a material depends somewhat on temperature. The resistance of metals generally increases with temperature. This is not surprising, because at higher temperatures, the atoms are moving more rapidly and are arranged in a less orderly fashion. So they might be expected to interfere more with the flow of electrons.

If the temperature change is not too great, the resistivity of metals usually increases nearly linearly with temperature. That is,

$$\rho_T = \rho_0[1 + \alpha(T - T_0)] \qquad \textbf{(25–5a)}$$

where $\rho_0$ is the resistivity at some reference temperature $T_0$ (such as 0°C or 20°C), $\rho_T$ is the resistivity at a higher temperature $T$, and $\alpha$ is the **temperature coefficient of resistivity**. Values for $\alpha$ are given in Table 25–1. Note that the temperature coefficient for semiconductors can be negative. Why? At higher temperatures, some of the electrons that are normally not free in a semiconductor can become free and contribute to the current. Thus, the resistance of a semiconductor can decrease with an increase in temperature.

PHYSICS APPLIED
*Resistance thermometer*

**EXAMPLE 25–7** **Resistance thermometer.** The variation in electrical resistance with temperature can be used to make precise temperature measurements. Platinum is commonly used since it is relatively free from corrosive effects and has a high melting point. Suppose at 20.0°C the resistance of a platinum resistance thermometer is 164.2 Ω. When placed in a particular solution, the resistance is 187.4 Ω. What is the temperature of this solution?

**APPROACH** Since the resistance $R$ is directly proportional to the resistivity $\rho$, we can combine Eq. 25–3 with Eq. 25–5a to find $R$ as a function of temperature $T$, and then solve that equation for $T$.

**SOLUTION** Equation 25–3 tells us $R = \rho\ell/A$, so we multiply Eq. 25–5a by $(\ell/A)$ to obtain

$$R = R_0[1 + \alpha(T - T_0)]. \qquad \textbf{(25–5b)}$$

Here $R_0 = \rho_0\ell/A$ is the resistance of the wire at $T_0 = 20.0°C$. We solve this equation for $T$ and find (see Table 25–1 for $\alpha$)

$$T = T_0 + \frac{R - R_0}{\alpha R_0} = 20.0°C + \frac{187.4\ \Omega - 164.2\ \Omega}{(3.927 \times 10^{-3}(C°)^{-1})(164.2\ \Omega)} = 56.0°C.$$

**NOTE** Resistance thermometers have the advantage that they can be used at very high or low temperatures where gas or liquid thermometers would be useless.

**NOTE** More convenient for some applications is a **thermistor** (Fig. 25–15), which consists of a metal oxide or semiconductor whose resistance also varies in a repeatable way with temperature. Thermistors can be made quite small and respond very quickly to temperature changes.

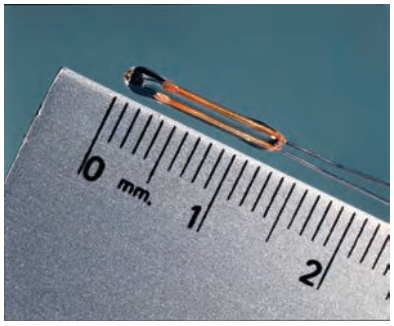

**FIGURE 25–15** A thermistor only 13 mm long, shown next to a millimeter ruler for scale.

**EXERCISE G** The resistance of the tungsten filament of a common incandescent lightbulb is how many times greater at its operating temperature of 2800 K than its resistance at room temperature? (*a*) Less than 1% greater; (*b*) roughly 10% greater; (*c*) about 2 times greater; (*d*) roughly 10 times greater; (*e*) more than 100 times greater.

The value of $\alpha$ in Eqs. 25–5 can itself depend on temperature, so it is important to check the temperature range of validity of any value (say, in a handbook of physical data). If the temperature range is wide, Eq. 25–5a or b is not adequate and terms proportional to the square and cube of the temperature are needed, but these terms are generally very small except when $T - T_0$ is large.

## 25–5 Electric Power

Electric energy is useful to us because it can be easily transformed into other forms of energy. Motors transform electric energy into mechanical energy, and are examined in Chapter 27.

In other devices such as electric heaters, stoves, toasters, and hair dryers, electric energy is transformed into thermal energy in a wire resistance known as a "heating element." Heating elements (Fig. 25–16) in household appliances have resistances typically of a few ohms to a few hundred ohms.

(a)

(b)

**FIGURE 25–16** (a) Hot electric stove burner, and (b) the hot heating element of a toaster, glow because of energy transformed by electric current.

Electric energy is transformed into thermal energy (and light) in such devices, and there are many collisions between the moving electrons and the atoms of the wire. In each collision, part of the electron's kinetic energy is transferred to the atom with which it collides. As a result, the kinetic energy of the wire's atoms increases and hence the temperature of the wire element increases (Section 18–1). The increased thermal energy can be transferred as heat by conduction and convection to the air in a heater or to food in a pan, by radiation to bread in a toaster and to people under an outside restaurant heater in cold weather (big photo page 717), or radiated as light.

To find the power transformed by an electric device, recall that the energy transformed when an infinitesimal charge $dq$ moves through a potential difference $V$ is $dU = V\,dq$ (Eq. 23–3). Let $dt$ be the time required for an amount of charge $dq$ to move through a potential difference $V$. Then the power $P$, which is the rate energy is transformed, is

$$P = \frac{dU}{dt} = \frac{dq}{dt}V.$$

The charge that flows per second, $dq/dt$, is the electric current $I$. Thus we have

$$P = IV. \qquad \textbf{(25–6)}$$

This general relation gives us the power transformed by any device, where $I$ is the current passing through it and $V$ is the potential difference across it. It also gives the power delivered by a source such as a battery. The SI unit of electric power is the same as for any kind of power, the **watt** $(1\,\text{W} = 1\,\text{J/s})$.

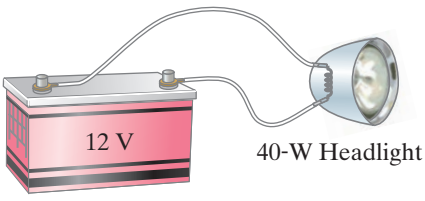
The rate of energy transformation in a resistance $R$ can be written in two other ways, starting with the general relation $P = IV$ and substituting in $V = IR$:

$$P = IV = I(IR) = I^2R \qquad \textbf{(25–7a)}$$

$$P = IV = \left(\frac{V}{R}\right)V = \frac{V^2}{R}. \qquad \textbf{(25–7b)}$$

Equations 25–7a and b apply only to resistors, whereas Eq. 25–6, $P = IV$, is more general and applies to any device.

**EXAMPLE 25–8** **Headlights.** Calculate the resistance of a 40-W automobile headlight designed for 12 V (Fig. 25–17).



**APPROACH** We solve for $R$ in Eq. 25–7b which has the given variables.

**SOLUTION** From Eq. 25–7b,

$$R = \frac{V^2}{P} = \frac{(12\,\text{V})^2}{(40\,\text{W})} = 3.6\,\Omega.$$

**NOTE** This is the resistance when the bulb is burning brightly at 40 W. When the bulb is cold, the resistance is much lower, as we saw in Eq. 25–5b (also Exercise G). Since the current is high when the resistance is low, lightbulbs burn out most often when first turned on.

**FIGURE 25–17** Example 25–8.

**PHYSICS APPLIED**

*Why lightbulbs burn out when first turned on*

**CAUTION**
*You pay for energy, which is power × time, not for power*

It is energy, not power, that you pay for on your electric bill. Since power is the *rate* energy is transformed, the total energy used by any device is simply its power consumption multiplied by the time it is on. If the power is in watts and the time is in seconds, the energy will be in joules since $1\,\text{W} = 1\,\text{J/s}$. Electric companies usually specify the energy with a much larger unit, the **kilowatt-hour** (kWh). One kWh $= (1000\,\text{W})(3600\,\text{s}) = 3.60 \times 10^6\,\text{J}$.

**EXAMPLE 25–9** **Electric heater.** An electric heater draws a steady 15.0 A on a 120-V line. How much power does it require and how much does it cost per month (30 days) if it operates 3.0 h per day and the electric company charges 12 cents per kWh?

**APPROACH** We use Eq. 25–6, $P = IV$, to find the power. We multiply the power (in kW) by the time (h) used in a month and by the cost per energy unit, \$0.12 per kWh, to get the cost per month.

**SOLUTION** The power is

$$P = IV = (15.0\,\text{A})(120\,\text{V}) = 1800\,\text{W} = 1.80\,\text{kW}.$$

The time (in hours) the heater is used per month is $(3.0\,\text{h/d})(30\,\text{d}) = 90\,\text{h}$, which at \$ 0.12/kWh would cost $(1.80\,\text{kW})(90\,\text{h})(\$0.12/\text{kWh}) \approx \$19$ just for this heater.

**NOTE** Household current is actually alternating (ac), but our solution is still valid assuming the given values for $V$ and $I$ are the proper averages (rms) as we discuss in Section 25–7.

**PHYSICS APPLIED**
*Lightning*

**EXAMPLE 25–10** **ESTIMATE** **Lightning bolt.** Lightning is a spectacular example of electric current in a natural phenomenon (Fig. 25–18). There is much variability to lightning bolts, but a typical event might transfer $10^9\,\text{J}$ of energy across a potential difference of perhaps $5 \times 10^7\,\text{V}$ during a time interval of about 0.2 s. Use this information to estimate (*a*) the total amount of charge transferred between cloud and ground, (*b*) the current in the lightning bolt, and (*c*) the average power delivered over the 0.2 s.

**FIGURE 25–18** Example 25–10. A lightning bolt.

**APPROACH** We estimate the charge $Q$, recalling that potential energy change equals the potential difference $\Delta V$ times the charge $Q$, Eq. 23–3. We equate $\Delta U$ with the energy transferred, $\Delta U \approx 10^9\,\text{J}$. Next, the current $I$ is $Q/t$ (Eq. 25–1a) and the power $P$ is energy/time.

**SOLUTION** (*a*) From Eq. 23–3, the energy transformed is $\Delta U = Q\,\Delta V$. We solve for $Q$:

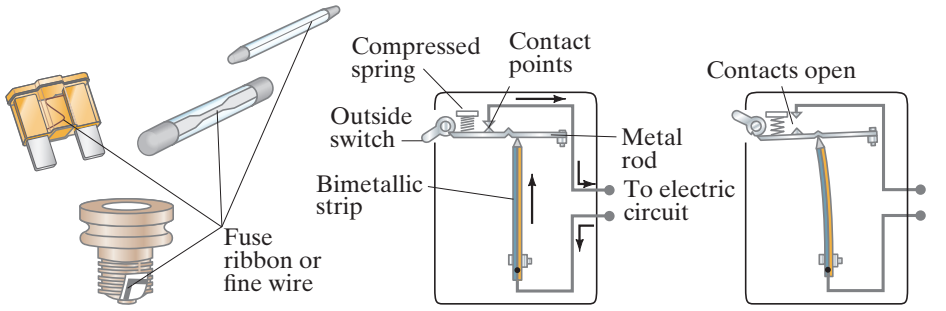
$$Q = \frac{\Delta U}{\Delta V} \approx \frac{10^9\,\text{J}}{5 \times 10^7\,\text{V}} = 20\,\text{coulombs}.$$

(*b*) The current during the 0.2 s is about

$$I = \frac{Q}{t} \approx \frac{20\,\text{C}}{0.2\,\text{s}} = 100\,\text{A}.$$

(*c*) The average power delivered is

$$P = \frac{\text{energy}}{\text{time}} = \frac{10^9\,\text{J}}{0.2\,\text{s}} = 5 \times 10^9\,\text{W} = 5\,\text{GW}.$$



We can also use Eq. 25–6:

$$P = IV = (100\,\text{A})(5 \times 10^7\,\text{V}) = 5\,\text{GW}.$$

**NOTE** Since most lightning bolts consist of several stages, it is possible that individual parts could carry currents much higher than the 100 A calculated above.

# 25–6 Power in Household Circuits

The electric wires that carry electricity to lights and other electric appliances have some resistance, although usually it is quite small. Nonetheless, if the current is large enough, the wires will heat up and produce thermal energy at a rate equal to $I^2R$, where $R$ is the wire's resistance. One possible hazard is that the current-carrying wires in the wall of a building may become so hot as to start a fire. Thicker wires have less resistance (see Eq. 25–3) and thus can carry more current without becoming too hot. When a wire carries more current than is safe, it is said to be "overloaded." To prevent overloading, **fuses** or **circuit breakers** are installed in circuits.

(a) Types of fuses (b) Circuit breaker (closed) (c) Circuit breaker (open)

**FIGURE 25–19** (a) Fuses. When the current exceeds a certain value, the metallic ribbon or wire inside melts and the circuit opens. Then the fuse must be replaced. (b) One type of circuit breaker. The electric current passes through a bimetallic strip. When the current exceeds a safe level, the heating of the bimetallic strip causes the strip to bend so far to the left that the notch in the spring-loaded metal rod drops down over the end of the bimetallic strip (c) and the circuit opens at the contact points (one is attached to the rod) and the outside switch is also flipped. When the bimetallic strip cools, it can be reset using the outside switch. Better magnetic-type circuit breakers are discussed in Chapters 28 and 29.

**PHYSICS APPLIED**
*Safety—wires getting hot*

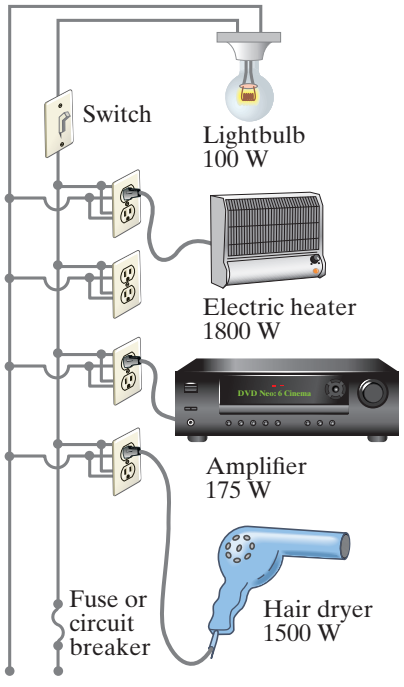
They are basically switches (Fig. 25–19) that open the circuit when the current exceeds a safe value. A 20-A fuse or circuit breaker, for example, opens when the current passing through it exceeds 20 A. If a circuit repeatedly burns out a fuse or opens a circuit breaker, and no connected device requires more than 20 A, there are two possibilities: there may be too many devices drawing current in that circuit; or there is a fault somewhere, such as a "short." A short, or "short circuit," means that two wires have touched that should not have (perhaps because the insulation has worn through) so the path of the current is shortened through a path of very low resistance. With reduced resistance, the current becomes very large and can make a wire hot enough to start a fire. Short circuits should be remedied immediately.

Household circuits are designed with the various devices connected so that each receives the standard voltage (usually 120 V in the United States) from the electric company (Fig. 25–20). Circuits with the devices arranged as in Fig. 25–20 are called *parallel circuits*, just as for capacitors, Section 24–3, and as we discuss for resistors in the next Chapter. When a fuse blows or circuit breaker opens, it is important to check the total current being drawn on that circuit, which is the sum of the currents through each device.

**EXAMPLE 25–11** **Will a fuse blow?** Determine the total current drawn by all the devices in the circuit of Fig. 25–20.

**APPROACH** Each device has the same 120-V voltage across it. The current each draws from the source is found from $I = P/V$, Eq. 25–6.

**SOLUTION** The circuit in Fig. 25–20 draws the following currents: the lightbulb draws $I = P/V = 100\text{ W}/120\text{ V} = 0.8\text{ A}$; the heater draws $1800\text{ W}/120\text{ V} = 15.0\text{ A}$; the stereo or home theater amplifier draws a maximum of $175\text{ W}/120\text{ V} = 1.5\text{ A}$; and the hair dryer draws $1500\text{ W}/120\text{ V} = 12.5\text{ A}$. The total current drawn, if all devices are used at the same time, is



$$0.8\text{ A} + 15.0\text{ A} + 1.5\text{ A} + 12.5\text{ A} = 29.8\text{ A}.$$

**NOTE** The heater draws as much current as 18 100-W lightbulbs. For safety, the heater should probably be on a circuit by itself.

If the circuit in Fig. 25–20 is designed for a 20-A fuse, the fuse should blow, and we hope it will, to prevent overloaded wires from getting hot enough to start a fire.

**PHYSICS APPLIED**
*Fuses and circuit breakers, and shorts*

**FIGURE 25–20** Connection of household appliances.

Something will have to be turned off to get this circuit below 20 A. (Houses and apartments usually have several circuits, each with its own fuse or circuit breaker; try moving one of the devices to another circuit.) If the circuit in Fig. 25–20 is designed with heavier wire and a 30-A fuse, the fuse shouldn't blow—if it does, a short may be the problem. (The most likely place for a short is in the cord of one of the devices.) Proper fuse size is selected according to the wire used to supply the current. A properly rated fuse should *never* be replaced by a higher-rated one, even in a car. A fuse blowing or a circuit breaker opening is acting like a switch, making an "open circuit." By an open circuit, we mean that there is no longer a complete conducting path, so no current can flow; it is as if $R = \infty$.

**PHYSICS APPLIED**
*Proper fuses and shorts*

**PHYSICS APPLIED**
*Extension cords and possible danger*

**CONCEPTUAL EXAMPLE 25–12** **A dangerous extension cord.** Your 1800-W portable electric heater is too far from your desk to warm your feet. Its cord is too short, so you plug it into an extension cord rated at 11 A. Why is this dangerous?

**RESPONSE** 1800 W at 120 V draws a 15-A current. The wires in the extension cord rated at 11 A could become hot enough to melt the insulation and cause a fire.

**EXERCISE H** How many 60-W 120-V lightbulbs can operate on a 20-A line? (*a*) 2; (*b*) 3; (*c*) 6; (*d*) 20; (*e*) 40.

Resistors used in electronic circuits, like those shown in Figs. 25–11 and 25–12, can also be overheated and destroyed if too much current passes through them. The upper limit is sometimes written on the resistor, but frequently it is not. The physical size of the resistor is a clue that engineers keep track of. The common small ones shown in Fig. 25–11 are probably $\frac{1}{4}$ W.

## 25–7 Alternating Current

When a battery is connected to a circuit, the current moves steadily in one direction. This is called a **direct current**, or **dc**. Electric generators at electric power plants, however, produce **alternating current**, or **ac**. (Sometimes capital letters are used, **DC** and **AC**.) An alternating current reverses direction many times per second and is commonly sinusoidal, Fig. 25–21. The electrons in a wire first move in one direction and then in the other. The current supplied to homes and businesses by electric companies is ac throughout virtually the entire world. We will discuss and analyze ac circuits in detail in Chapter 30. But because ac circuits are so common in real life, we will discuss some of their basic aspects here.

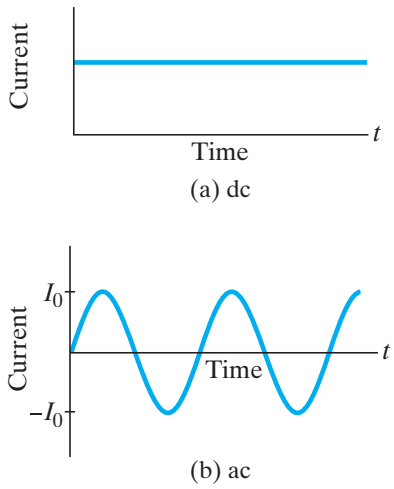


**FIGURE 25–21** (a) Direct current, and (b) alternating current, as functions of time.

The voltage produced by an ac electric generator is sinusoidal, as we shall see later. The current it produces is thus sinusoidal (Fig. 25–21b). We can write the voltage as a function of time as

$$V = V_0 \sin 2\pi f t = V_0 \sin \omega t, \qquad \textbf{(25–8a)}$$

where $\omega = 2\pi f$. The potential $V$ oscillates between $+V_0$ and $-V_0$, and $V_0$ is referred to as the **peak voltage**. The frequency $f$ is the number of complete oscillations made per second, and $\omega = 2\pi f$. In most areas of the United States and Canada, $f$ is 60 Hz (the unit "hertz," as we saw in Chapters 10 and 14, means cycles per second). In many countries, 50 Hz is used.

Equation 25–2, $V = IR$, works also for ac: if a voltage $V$ exists across a resistance $R$, then the current $I$ through the resistance is

$$I = \frac{V}{R} = \frac{V_0}{R} \sin \omega t = I_0 \sin \omega t. \qquad \textbf{(25–8b)}$$

The quantity $I_0 = V_0/R$ is the **peak current**. The current is considered positive when the electrons flow in one direction and negative when they flow in the opposite direction. It is clear from Fig. 25–21b that an alternating current is as often positive as it is negative. Thus, the average current is zero. This does not mean, however, that no power is needed or that no heat is produced in a resistor. Electrons

do move back and forth, and do produce heat. Indeed, the power transformed in a resistance $R$ at any instant is (Eq. 25–8b)

$$P = I^2R = I_0^2 R \sin^2 \omega t.$$

Because the current is squared, we see that the power is always positive, as graphed in Fig. 25–22. The quantity $\sin^2 \omega t$ varies between 0 and 1; and it is not too difficult to show[†] that its average value is $\frac{1}{2}$, as indicated in Fig. 25–22. Thus, the *average power* transformed, $\overline{P}$, is

$$\overline{P} = \tfrac{1}{2} I_0^2 R.$$

Since power can also be written $P = V^2/R = (V_0^2/R)\sin^2 \omega t$, we also have that the average power is

$$\overline{P} = \tfrac{1}{2}\frac{V_0^2}{R}.$$

The average or mean value of the *square* of the current or voltage is thus what is important for calculating average power: $\overline{I^2} = \frac{1}{2} I_0^2$ and $\overline{V^2} = \frac{1}{2} V_0^2$. The square root of each of these is the **rms** (root-mean-square) value of the current or voltage:

$$I_{\text{rms}} = \sqrt{\overline{I^2}} = \frac{I_0}{\sqrt{2}} = 0.707 I_0, \qquad \textbf{(25–9a)}$$

$$V_{\text{rms}} = \sqrt{\overline{V^2}} = \frac{V_0}{\sqrt{2}} = 0.707 V_0. \qquad \textbf{(25–9b)}$$

The rms values of $V$ and $I$ are sometimes called the *effective values*, as well as rms values. They are useful because they can be substituted directly into the power formulas, Eqs. 25–6 and 25–7, to get the average power:

$$\overline{P} = I_{\text{rms}} V_{\text{rms}} \qquad \textbf{(25–10a)}$$

$$\overline{P} = \tfrac{1}{2} I_0^2 R = I_{\text{rms}}^2 R \qquad \textbf{(25–10b)}$$

$$\overline{P} = \tfrac{1}{2}\frac{V_0^2}{R} = \frac{V_{\text{rms}}^2}{R}. \qquad \textbf{(25–10c)}$$

Thus, a direct current whose values of $I$ and $V$ equal the rms values of $I$ and $V$ for an alternating current will produce the same power. Hence it is usually the rms value of current and voltage that is specified or measured. For example, in the United States and Canada, standard line voltage is 120-V ac. The 120 V is $V_{\text{rms}}$; the peak voltage $V_0$ is

$$V_0 = \sqrt{2}\, V_{\text{rms}} = 170 \text{ V}.$$

In much of the world (Europe, Australia, Asia) the rms voltage is 240 V, so the peak voltage is 340 V. The line voltage can vary, depending on the total load (resistance); the frequency of 60 Hz or 50 Hz, however, remains extremely steady.

The power specified by any device or appliance is the average power $\overline{P}$. The instantaneous power varies from zero to $2\overline{P}$ as we saw in Fig. 25–22. The glow of an electric heating element looks steady because the changes are fast, 60 Hz or 50 Hz; the heating element cannot cool much during these brief moments when $P$ drops to zero and we don't even see the brightness flicker at these frequencies (at 4 or 5 Hz we might).

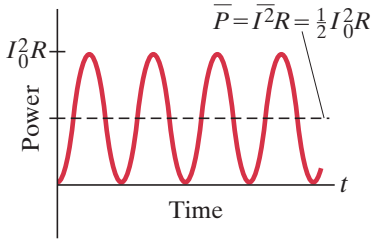

**FIGURE 25–22** Power transformed in a resistor in an ac circuit is always positive.

[†]A graph of $\cos^2 \omega t$ versus $t$ is identical to that for $\sin^2 \omega t$ in Fig. 25–22, except that the points are shifted (by $\frac{1}{4}$ cycle) on the time axis. Hence the average value of $\sin^2$ and $\cos^2$, averaged over one or more full cycles, will be the same. From the trigonometric identity $\sin^2\theta + \cos^2\theta = 1$, we can write

$$\overline{(\sin^2 \omega t)} + \overline{(\cos^2 \omega t)} = 2\overline{(\sin^2 \omega t)} = 1.$$

Hence the average value of $\sin^2 \omega t$ is $\frac{1}{2}$.

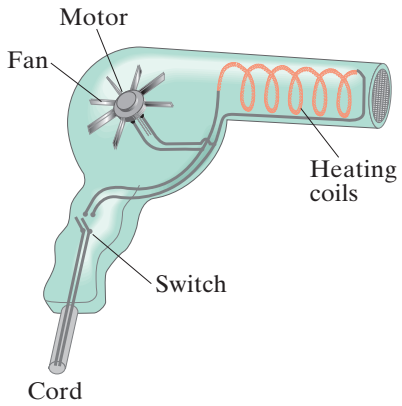

**FIGURE 25–23** A hair dryer. Most of the current goes through the heating coils, a pure resistance; a small part goes to the motor to turn the fan. Example 25–13.

**EXAMPLE 25–13** **Hair dryer.** (*a*) Calculate the resistance and the peak current in an 1875-W hair dryer (Fig. 25–23) connected to a 120-V ac line. (*b*) What happens if it is connected to a 240-V ac line in Britain?

**APPROACH** We are given $\overline{P}$ and $V_{\text{rms}}$, so $I_{\text{rms}} = \overline{P}/V_{\text{rms}}$ (Eq. 25–10a or 25–6), and $I_0 = \sqrt{2}\, I_{\text{rms}}$. Then we find $R$ from $V = IR$.

**SOLUTION** (*a*) We solve Eq. 25–10a for the rms current:

$$I_{\text{rms}} = \frac{\overline{P}}{V_{\text{rms}}} = \frac{1875\ \text{W}}{120\ \text{V}} = 15.6\ \text{A}.$$

Then

$$I_0 = \sqrt{2}\, I_{\text{rms}} = 22.1\ \text{A}.$$

The resistance is

$$R = \frac{V_{\text{rms}}}{I_{\text{rms}}} = \frac{120\ \text{V}}{15.6\ \text{A}} = 7.7\ \Omega.$$

The resistance could equally well be calculated using peak values:

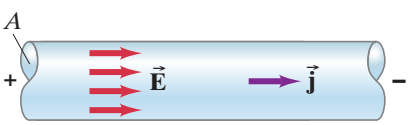
$$R = \frac{V_0}{I_0} = \frac{170\ \text{V}}{22.1\ \text{A}} = 7.7\ \Omega.$$

(*b*) When connected to a 240-V line, more current would flow and the resistance would change with the increased temperature (Section 25–4). But let us make an estimate of the power transformed based on the same 7.7-Ω resistance. The average power would be

$$\overline{P} = \frac{V_{\text{rms}}^2}{R} = \frac{(240\ \text{V})^2}{(7.7\ \Omega)} = 7500\ \text{W}.$$

This is four times the hair dryer's power rating and would undoubtedly melt the heating element or the wire coils of the motor.

**EXERCISE I** A home sound system sends an average audio power output of 100 W into an 8-Ω loudspeaker (see Fig. 25–14). What are the rms voltage and the rms current fed to the speaker (*a*) at the highest rated power of 100 W, and (*b*) at 1.0 W when the volume is turned down?



This Section has given a brief introduction to the basic aspects of alternating currents. We will discuss ac circuits in more detail in Chapter 30. In the next chapter, Chapter 26, we will deal with the details of dc circuits only.

## 25–8 Microscopic View of Electric Current

Up to now in this Chapter we have dealt mainly with a macroscopic view of electric current. We saw, however, that according to atomic theory, the electric current in metal wires is carried by negatively charged electrons, and that in liquid solutions current can also be carried by positive and/or negative ions. Let us now look at this microscopic picture in more detail.

When a potential difference is applied to the two ends of a wire of uniform cross section, the direction of the electric field $\vec{\mathbf{E}}$ is parallel to the walls of the wire (Fig. 25–24). The existence of $\vec{\mathbf{E}}$ within the conducting wire does not contradict our earlier result that $\vec{\mathbf{E}} = 0$ inside a conductor in the electrostatic case, as we are no longer dealing with the static case. Charges are free to move in a conductor, and hence can move under the action of the electric field. If all the charges are at rest, then $\vec{\mathbf{E}}$ must be zero (electrostatics).

**FIGURE 25–24** Electric field $\vec{\mathbf{E}}$ in a uniform wire of cross-sectional area $A$ carrying a current $I$. The current density $j = I/A$.

## Current Density and Drift Speed

We now define a new microscopic quantity, the **current density**, $\vec{\mathbf{j}}$. It is defined as the *electric current per unit cross-sectional area* at any point in space. If the current density $\vec{\mathbf{j}}$ in a wire of cross-sectional area $A$ is uniform over the cross section, then $j$ is related to the electric current by

$$j = \frac{I}{A} \qquad \text{or} \qquad I = jA. \tag{25–11}$$

If the current density is not uniform, then the general relation is

$$I = \int \vec{\mathbf{j}} \cdot d\vec{\mathbf{A}}, \tag{25–12}$$

where $I$ is the current through the whole surface and $d\vec{\mathbf{A}}$ is an element of surface area over which the integration is taken. The direction of the current density at any point is the direction that a positive charge would move when placed at that point—that is, the direction of $\vec{\mathbf{j}}$ at any point is generally the same as the direction of $\vec{\mathbf{E}}$, Fig. 25–24. The current density exists for any *point* in space. The current $I$, on the other hand, refers to a conductor as a whole, and hence is a macroscopic quantity.

The direction of $\vec{\mathbf{j}}$ is chosen to represent the direction of net flow of positive charge. In a metal, it is negatively charged electrons that move, so they move in the direction of $-\vec{\mathbf{j}}$, or $-\vec{\mathbf{E}}$ (to the left in Fig. 25–24). We can imagine the free electrons as moving about randomly at high speeds, bouncing off the metal atoms of the wire (somewhat like the molecules of a gas—Chapter 18). When an electric field exists in the wire, Fig. 25–25, the electrons feel a force and initially begin to accelerate. But they soon reach a more or less steady average speed, known as their **drift speed**, $v_d$ (collisions with atoms in the wire keep them from accelerating further). The drift speed is normally very much smaller than the electrons' average random speed inside the metal wire.

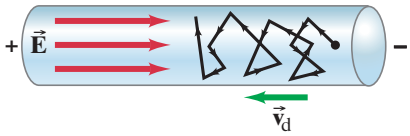


**FIGURE 25–25** Black zagged line represents the motion of an electron in a metal wire due to an electric field. The field $\vec{\mathbf{E}}$ gives electrons in random motion a net drift speed $v_d$. Its direction (the net charge flow) is $\vec{\mathbf{v}}_d$ and is in the opposite direction of $\vec{\mathbf{E}}$ because electrons have a negative charge ($\vec{\mathbf{F}} = q\vec{\mathbf{E}}$).

We can relate the electron drift speed $v_d$ to the macroscopic current $I$ in the wire. In a time $\Delta t$, the electrons will travel a distance $\ell = v_d\,\Delta t$ on average. Suppose the wire has cross-sectional area $A$. Then in time $\Delta t$, electrons in a volume $V = A\ell = Av_d\,\Delta t$ will pass through the cross section $A$ of wire, as shown in Fig. 25–26. If there are $n$ free electrons (each of charge $-e$) per unit volume, then the total number of electrons is $N = nV$ ($V$ is volume, not voltage) and the total charge $\Delta Q$ that passes through the area $A$ in a time $\Delta t$ is

$$\begin{aligned}\Delta Q &= (\text{number of charges, } N) \times (\text{charge per particle}) \\ &= (nV)(-e) = -(nAv_d\,\Delta t)(e).\end{aligned}$$

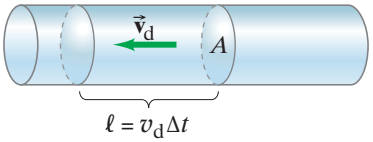

**FIGURE 25–26** Electrons in the volume $A\ell$ will all pass through the cross section indicated in a time $\Delta t$, where $\ell = v_d\,\Delta t$.

The current $I$ in the wire is thus

$$I = \frac{\Delta Q}{\Delta t} = -neAv_d. \tag{25–13}$$

The current density, $j = I/A$, is

$$j = -nev_d, \tag{25–14}$$

where the minus sign indicates that the direction of (positive) current flow is opposite to the drift speed of electrons.

We can generalize Eq. 25–14 to any type of charge flow, such as flow of ions in an electrolyte (as on page 719). If there are several types of ions (which can include free electrons), each of density $n_i$ (number per unit volume), charge $q_i$ ($q_i = -e$ for electrons) and drift speed $v_{di}$, then the net current density at any point is

$$j = \sum_i n_i q_i v_{di}. \tag{25–15}$$

The total current $I$ passing through an area $A$ perpendicular to the direction of a uniform $j$ is then

$$I = \sum_i n_i q_i v_{di} A.$$

**EXAMPLE 25–14** **Electron speeds in a wire.** A copper wire 3.2 mm in diameter carries a 5.0-A current. Determine (*a*) the current density in the wire (assumed uniform), and (*b*) the drift speed of the free electrons. (*c*) Estimate the rms speed of electrons assuming they behave like an ideal gas at 20°C. Assume that one electron per Cu atom is free to move (the others remain bound to the atom).

**APPROACH** For (*a*) $j = I/A = I/\pi r^2$. For (*b*) we can apply Eq. 25–14 to find $v_d$ if we can determine the number $n$ of free electrons per unit volume. Since we assume there is one free electron per atom, the density of free electrons, $n$, is the same as the number of Cu atoms per unit volume. The atomic mass of Cu is 63.5 u (see Periodic Table inside the back cover), so 63.5 g of Cu contains one mole or $6.02 \times 10^{23}$ free electrons. To find the volume $V$ of this amount of copper, and then $n = N/V$, we use the mass density of copper (Table 13–1), $\rho_D = 8.9 \times 10^3\ \text{kg/m}^3$, where $\rho_D = m/V$. (We use $\rho_D$ to distinguish it here from $\rho$ for resistivity.) In (*c*) we use $K = \frac{3}{2}kT$, Eq. 18–4. (Do not confuse $V$ for volume with $V$ for voltage.)

**SOLUTION** (*a*) The radius of the wire is $r = \frac{1}{2}(3.2\ \text{mm}) = 1.6 \times 10^{-3}\ \text{m}$, so the current density is (if we assume it is uniform):

$$j = \frac{I}{A} = \frac{I}{\pi r^2} = \frac{5.0\ \text{A}}{\pi(1.6 \times 10^{-3}\ \text{m})^2} = 6.2 \times 10^5\ \text{A/m}^2.$$

(*b*) The number of free electrons per unit volume, $n = N/V$ (where $V = \text{volume} = m/\rho_D$), is

$$n = \frac{N}{V} = \frac{N}{m/\rho_D} = \frac{N(1\ \text{mole})}{m(1\ \text{mole})}\rho_D$$

$$n = \left(\frac{6.02 \times 10^{23}\ \text{electrons}}{63.5 \times 10^{-3}\ \text{kg}}\right)(8.9 \times 10^3\ \text{kg/m}^3) = 8.4 \times 10^{28}\ \text{m}^{-3}.$$

Then, by Eq. 25–14, the drift speed has magnitude

$$v_d = \frac{j}{ne} = \frac{6.2 \times 10^5\ \text{A/m}^2}{(8.4 \times 10^{28}\ \text{m}^{-3})(1.6 \times 10^{-19}\ \text{C})}$$

$$= 4.6 \times 10^{-5}\ \text{m/s} \approx 0.05\ \text{mm/s}.$$

(*c*) If we model the free electrons as an ideal gas (a rather rough approximation), we use Eq. 18–5 to estimate the random rms speed of an electron as it darts around at 20°C = 293 K:

$$v_{\text{rms}} = \sqrt{\frac{3kT}{m}} = \sqrt{\frac{3(1.38 \times 10^{-23}\ \text{J/K})(293\ \text{K})}{9.11 \times 10^{-31}\ \text{kg}}} = 1.2 \times 10^5\ \text{m/s}.$$

The drift speed (average speed in the direction of the current) is very much less than the rms thermal speed of the electrons, by a factor of about $10^9$.

**NOTE** The result in (*c*) is an underestimate. Quantum theory calculations, and experiments, give the rms speed in copper to be about $1.6 \times 10^6\ \text{m/s}$.

The drift speed of electrons in a wire is very slow, only about 0.05 mm/s (Example 25–14 above), which means it takes an electron $20 \times 10^3$ s, or $5\frac{1}{2}$ h, to travel only 1 m. This is not how fast "electricity travels": when you flip a light switch, the light—even if many meters away—goes on nearly instantaneously. Why? Because electric fields travel essentially at the speed of light $(3 \times 10^8\ \text{m/s})$. We can think of electrons in a wire as being like a pipe full of water: when a little water enters one end of the pipe, some water comes out at the other end almost immediately.

### Electric Field Inside a Wire

Equation 25–2, $V = IR$ where $V$ = voltage (not volume), can be written in terms of microscopic quantities as follows. We write the resistance $R$ in terms of the resistivity $\rho$, Eq. 25–3:

$$R = \rho \frac{\ell}{A}.$$

Then we write $V$ and $I$ as

$$I = jA \qquad \text{and} \qquad V = E\ell.$$

These relations follow from Eqs. 25–11 and 23–4, where we assume the electric field is uniform within the wire and $\ell$ is the length of the wire (or a portion of the wire) between whose ends the potential difference is $V$. Thus, from $V = IR$, we have

$$V = IR$$

$$E\ell = (jA)\left(\rho \frac{\ell}{A}\right) = j\rho\ell$$

so

$$j = \frac{1}{\rho} E = \sigma E, \tag{25–16}$$

where $\sigma = 1/\rho$ is the *conductivity* (Eq. 25–4). For a metal conductor, $\rho$ and $\sigma$ do not depend on $V$ (and hence not on $E$). Therefore the current density $\vec{\mathbf{j}}$ is proportional to the electrical field $\vec{\mathbf{E}}$ in the conductor. This is the "microscopic" statement of Ohm's law. Equation 25–16, which can be written in vector form as

$$\vec{\mathbf{j}} = \sigma\vec{\mathbf{E}} = \frac{1}{\rho}\vec{\mathbf{E}},$$

is sometimes taken as the definition of conductivity $\sigma$ and resistivity $\rho$.

**EXAMPLE 25–15** **Electric field inside a wire.** What is the electric field inside the wire of Example 25–14?

**APPROACH** We use Eq. 25–16 and $\rho = 1.68 \times 10^{-8}\ \Omega \cdot \text{m}$ for copper.

**SOLUTION** Example 25–14 gives $j = 6.2 \times 10^5\ \text{A/m}^2$, so

$$E = \rho j = (1.68 \times 10^{-8}\ \Omega \cdot \text{m})(6.2 \times 10^5\ \text{A/m}^2) = 1.0 \times 10^{-2}\ \text{V/m}.$$

**NOTE** For comparison, the electric field between the plates of a capacitor is often much larger; in Example 24–1, for example, $E$ is on the order of $10^4\ \text{V/m}$. Thus we see that only a modest electric field is needed for current flow in practical cases.

## *25–9 Superconductivity

At very low temperatures, well below 0°C, the resistivity (Section 25–4) of certain metals and certain compounds or alloys becomes zero as measured by the highest-precision techniques. Materials in such a state are said to be **superconducting**. This phenomenon was first observed by H. K. Onnes (1853–1926) in 1911 when he cooled mercury below 4.2 K (−269°C) and found that the resistance of mercury suddenly dropped to zero. In general, superconductors become superconducting only below a certain **transition temperature** or **critical temperature**, $T_C$, which until recently was always within a few degrees of absolute zero. Electric current in a ring-shaped superconducting material has been observed to flow for years in the absence of a potential difference, with no measurable decrease. Measurements show that the resistivity $\rho$ of superconductors is less than $4 \times 10^{-25}\ \Omega \cdot \text{m}$, which is over $10^{16}$ times smaller than that for copper, and is considered to be zero in practice. See Fig. 25–27.

Before 1986 the highest temperature at which a material was found to superconduct was 23 K, which required liquid helium to keep the material cold enough to be superconducting. In 1987, a compound of yttrium, barium, copper, and oxygen (YBCO) was developed that can be superconducting at 90 K.

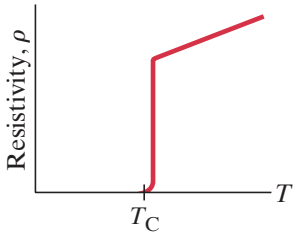

**FIGURE 25–27** A superconducting material has zero resistivity when its temperature is below $T_C$, its "critical temperature." At temperatures above $T_C$, the resistivity has a "normal" nonzero value and increases with temperature as normal metals do (Eq. 25–5 and Table 25–1).

Since this is above the boiling temperature of liquid nitrogen, 77 K, liquid nitrogen is sufficiently cold to keep the material superconducting. This was an important breakthrough because liquid nitrogen is much more easily and cheaply obtained ($N_2$ is 80% of the air around us) than is the much rarer (and colder) liquid helium needed for earlier superconductors. Superconductivity at "high" temperatures, such as 160 K, has been reported, and perhaps also at $-23°C$ (250 K), though in fragile compounds and under very high pressure.

To develop high-temperature superconductors (HTS–above 77 K) for use as wires, such as for wires in "superconducting electromagnets" (Section 28–9), is challenging because HTS materials are ceramic; they are very brittle and do not form into flexible wires. The first generation HTS "wires" made use of bismuth-strontium-calcium-copper oxide (BSCCO), which was embedded as tiny filaments or powders into a metal alloy base, which is not resistanceless but has resistance much less than a conventional copper cable. Second-generation HTS apply superconducting powders or a very thin film of YBCO (other rare earths like neodymium also work) onto specially prepared metal tapes; they can be wound into cables, and carry hundreds of amperes. More recently, a compound of magnesium and boron has been made into wires; even though they superconduct at a lower temperature, they are much cheaper to produce.

## *25–10 Electrical Conduction in the Human Nervous System

The flow of electric charge in the human nervous system provides us the means for being aware of the world, for communication within the body, and for controlling the body's muscles. Indeed, we could not exist without electricity in our bodies. Although the detailed functioning of the nervous system is complex and still not well understood, we do have a reasonable understanding of how messages are transmitted within the nervous system: they are electrical signals passing along the basic element of the nervous system, the **neuron**.

Neurons are living cells of unusual shape (Fig. 25–28). Attached to the main cell body are several small appendages known as *dendrites* and a long tail called the *axon*. Signals are received by the dendrites and are propagated along the axon. When a signal reaches the nerve endings, it is transmitted to the next neuron or to a muscle at a connection called a **synapse**.

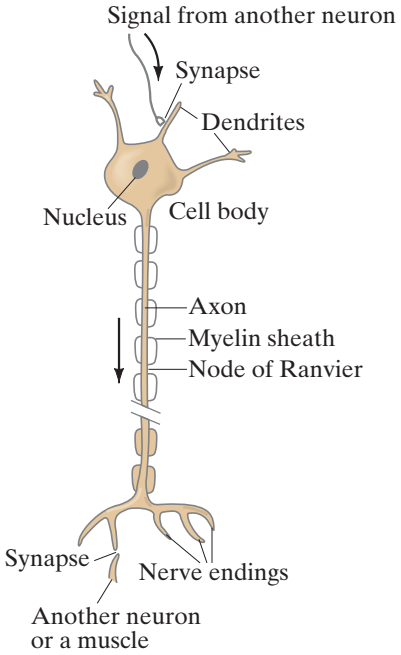

**FIGURE 25–28** A simplified sketch of a typical neuron.

A neuron, before transmitting an electrical signal, is in the so-called "resting state." Like nearly all living cells, neurons have a net positive charge on the outer surface of the cell membrane and a negative charge on the inner surface. This difference in charge, or **dipole layer**, means that a potential difference exists across the cell membrane. When a neuron is not transmitting a signal, this **resting potential**, normally stated as

$$V_{\text{inside}} - V_{\text{outside}},$$

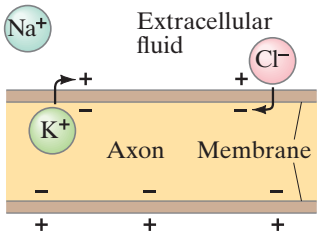
is typically $-60$ mV to $-90$ mV, depending on the type of organism. The most common ions in a cell are $K^+$, $Na^+$, and $Cl^-$. There are large differences in the concentrations of these ions inside and outside an axon, as indicated by the typical values given in Table 25–2. Other ions are also present, so the fluids both inside and outside the axon are electrically neutral. Because of the differences in concentration, there is a tendency for ions to diffuse across the membrane (see Section 18–7 on diffusion). However, in the resting state the cell membrane prevents any net flow of $Na^+$ through a mechanism of active transport† of $Na^+$ ions out of the cell by a particular protein to which $Na^+$ attach; energy needed comes from ATP.‡ But a cell membrane does allow the flow of $Cl^-$ ions, and less so of $K^+$ ions, and it is these two ions that produce the dipole charge layer on the membrane. Because there is a greater concentration of $K^+$ inside the cell than outside, more $K^+$ ions tend to diffuse outward across the membrane than diffuse inward.

**TABLE 25–2**
**Concentrations of Ions Inside and Outside a Typical Axon**

| | Concentration inside axon ($mol/m^3$) | Concentration outside axon ($mol/m^3$) |
|---|---|---|
| $K^+$ | 140 | 5 |
| $Na^+$ | 15 | 140 |
| $Cl^-$ | 9 | 125 |

†This transport mechanism is sometimes referred to as the **sodium pump**.

‡ATP = adenosine triphosphate. How it works to store energy is discussed in Section 40–2.



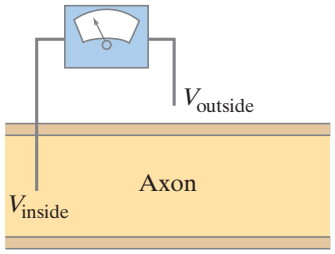


**FIGURE 25–29** How a dipole layer of charge forms on a cell membrane.

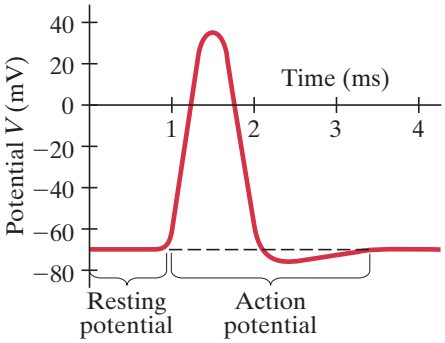

**FIGURE 25–30** Measuring the potential difference between the inside and outside of a nerve cell.

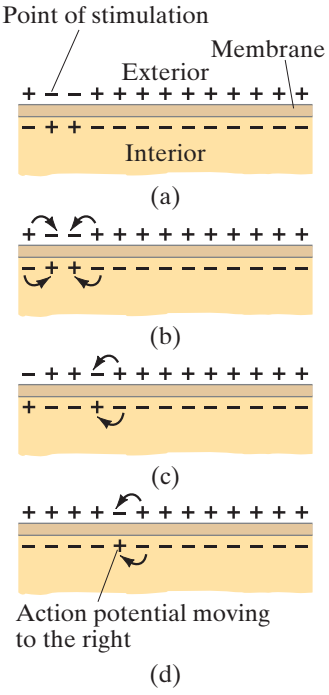
A $K^+$ ion that passes through the membrane becomes attached to the outer surface of the membrane, and leaves behind an equal negative charge that lies on the inner surface of the membrane (Fig. 25–29). The fluids themselves remain neutral. What keeps the ions on the membrane is their attraction for each other across the membrane. Independently, $Cl^-$ ions tend to diffuse *into* the cell since their concentration outside is higher. Both $K^+$ and $Cl^-$ diffusion tends to charge the interior surface of the membrane negative and the outside positive. As charge accumulates on the membrane surface, it becomes increasingly difficult for more ions to diffuse: $K^+$ ions trying to move outward, for example, are repelled by the positive charge already there. Equilibrium is reached when the tendency to diffuse because of the concentration difference is just balanced by the electrical potential difference across the membrane. The greater the concentration difference, the greater the potential difference across the membrane ($-60$ mV to $-90$ mV).



The most important aspect of a neuron is not that it has a resting potential (most cells do), but rather that it can respond to a stimulus and conduct an electrical signal along its length. The stimulus could be thermal (when you touch a hot stove) or chemical (as in taste buds); it could be pressure (as on the skin or at the eardrum), or light (as in the eye); or it could be the electric stimulus of a signal coming from the brain or another neuron. In the laboratory, the stimulus is usually electrical and is applied by a tiny probe at some point on the neuron. If the stimulus exceeds some threshold, a voltage pulse will travel down the axon. This voltage pulse can be detected at a point on the axon using a voltmeter or an oscilloscope connected as in Fig. 25–30. This voltage pulse has the shape shown in Fig. 25–31, and is called an **action potential**. As can be seen, the potential increases from a resting potential of about $-70$ mV and becomes a positive 30 mV or 40 mV. The action potential lasts for about 1 ms and travels down an axon with a speed of 30 m/s to 150 m/s. When an action potential is stimulated, the nerve is said to have "fired."

**FIGURE 25–31** Action potential.

What causes the action potential? At the point where the stimulus occurs, the membrane suddenly alters its permeability, becoming much more permeable to $Na^+$ than to $K^+$ and $Cl^-$ ions. Thus, $Na^+$ ions rush into the cell and the inner surface of the wall becomes positively charged, and the potential difference quickly swings positive ($\approx +30$ mV in Fig. 25–31). Just as suddenly, the membrane returns to its original characteristics; it becomes impermeable to $Na^+$ and in fact pumps out $Na^+$ ions. The diffusion of $Cl^-$ and $K^+$ ions again predominates and the original resting potential is restored ($-70$ mV in Fig. 25–31).

**FIGURE 25–32** Propagation of an action potential along an axon membrane.

What causes the action potential to travel along the axon? The action potential occurs at the point of stimulation, as shown in Fig. 25–32a. The membrane momentarily is positive on the inside and negative on the outside at this point. Nearby charges are attracted toward this region, as shown in Fig. 25–32b. The potential in these adjacent regions then flips, causing an action potential there. Thus, as the membrane returns to normal at the original point, nearby it experiences an action potential, so the action potential moves down the axon (Figs. 25–32c and d).

You may wonder if the number of ions that pass through the membrane would significantly alter the concentrations. The answer is no; and we can show why by treating the axon as a capacitor in the following Example.

**EXAMPLE 25–16 ESTIMATE** **Capacitance of an axon.** (*a*) Do an order-of-magnitude estimate for the capacitance of an axon 10 cm long of radius 10 $\mu$m. The thickness of the membrane is about $10^{-8}$ m, and the dielectric constant is about 3. (*b*) By what factor does the concentration (number of ions per volume) of $Na^+$ ions in the cell change as a result of one action potential?

**APPROACH** We model the membrane of an axon as a cylindrically shaped parallel-plate capacitor, with opposite charges on each side. The separation of the "plates" is the thickness of the membrane, $d \approx 10^{-8}$ m. We first calculate the area of the cylinder and then can use Eq. 24–8, $C = K\epsilon_0 A/d$, to find the capacitance. In (*b*), we use the voltage change during one action potential to find the amount of charge moved across the membrane.

**SOLUTION** (*a*) The area $A$ is the area of a cylinder of radius $r$ and length $\ell$:

$$A = 2\pi r\ell \approx (6.28)(10^{-5}\,\text{m})(0.1\,\text{m}) \approx 6 \times 10^{-6}\,\text{m}^2.$$

From Eq. 24–8, we have

$$C = K\epsilon_0 \frac{A}{d} \approx (3)(8.85 \times 10^{-12}\,\text{C}^2/\text{N}\cdot\text{m}^2)\frac{6 \times 10^{-6}\,\text{m}^2}{10^{-8}\,\text{m}} \approx 10^{-8}\,\text{F}.$$

(*b*) Since the voltage changes from $-70$ mV to about $+30$ mV, the total change is about 100 mV. The amount of charge that moves is then

$$Q = CV \approx (10^{-8}\,\text{F})(0.1\,\text{V}) = 10^{-9}\,\text{C}.$$

Each ion carries a charge $e = 1.6 \times 10^{-19}$ C, so the number of ions that flow per action potential is $Q/e = (10^{-9}\,\text{C})/(1.6 \times 10^{-19}\,\text{C}) \approx 10^{10}$. The volume of our cylindrical axon is

$$V = \pi r^2\ell \approx (3)(10^{-5}\,\text{m})^2(0.1\,\text{m}) = 3 \times 10^{-11}\,\text{m}^3,$$

and the concentration of $Na^+$ ions inside the cell (Table 25–2) is $15\,\text{mol/m}^3 = 15 \times 6.02 \times 10^{23}\,\text{ions/m}^3 \approx 10^{25}\,\text{ions/m}^3$. Thus, the cell contains $(10^{25}\,\text{ions/m}^3) \times (3 \times 10^{-11}\,\text{m}^3) \approx 3 \times 10^{14}$ $Na^+$ ions. One action potential, then, will change the concentration of $Na^+$ ions by about $10^{10}/(3 \times 10^{14}) = \frac{1}{3} \times 10^{-4}$, or 1 part in 30,000. This tiny change would not be measurable.

Thus, even 1000 action potentials will not alter the concentration significantly. The sodium pump does not, therefore, have to remove $Na^+$ ions quickly after an action potential, but can operate slowly over time to maintain a relatively constant concentration.

# Summary

An electric **battery** serves as a source of nearly constant potential difference by transforming chemical energy into electric energy. A simple battery consists of two electrodes made of different metals immersed in a solution or paste known as an **electrolyte**.

**Electric current**, $I$, refers to the rate of flow of electric charge and is measured in **amperes** (A): 1 A equals a flow of 1 C/s past a given point.

The direction of **conventional current** is that of positive charge flow. In a wire, it is actually negatively charged electrons that move, so they flow in a direction opposite to what we call conventional current. A positive charge flow in one direction is almost always equivalent to a negative charge flow in the opposite direction. Positive conventional current always flows from a high potential to a low potential.

The **resistance** $R$ of a device is defined by the relation

$$V = IR, \qquad \textbf{(25–2)}$$

where $I$ is the current in the device when a potential difference $V$ is applied across it. For materials such as metals, $R$ is a constant independent of $V$ (thus $I \propto V$), a result known as **Ohm's law**. Thus, the current $I$ coming from a battery of voltage $V$ depends on the resistance $R$ of the circuit connected to it.

Voltage is applied *across* a device or between the ends of a wire. Current passes *through* a wire or device. Resistance is a property *of* the wire or device.

The unit of resistance is the **ohm** ($\Omega$), where $1\ \Omega = 1\ \text{V/A}$. See Table 25–3.

**TABLE 25–3 Summary of Units**

| | |
|---|---|
| Current | $1\ \text{A} = 1\ \text{C/s}$ |
| Potential difference | $1\ \text{V} = 1\ \text{J/C}$ |
| Power | $1\ \text{W} = 1\ \text{J/s}$ |
| Resistance | $1\ \Omega = 1\ \text{V/A}$ |

The resistance $R$ of a wire is inversely proportional to its cross-sectional area $A$, and directly proportional to its length $\ell$ and to a property of the material called its resistivity $\rho$:

$$R = \rho\frac{\ell}{A}. \qquad \textbf{(25–3)}$$

The **resistivity**, $\rho$, increases with temperature for metals, but for semiconductors it may decrease.

The rate at which energy is transformed in a resistance $R$ from electric to other forms of energy (such as heat and light) is equal to the product of current and voltage. That is, the **power** transformed, measured in watts, is given by

$$P = IV, \qquad \textbf{(25–6)}$$

which for resistors can be written as

$$P = I^2R = \frac{V^2}{R}. \qquad \textbf{(25–7)}$$

The SI unit of power is the **watt** $(1\ \text{W} = 1\ \text{J/s})$.

The total electric energy transformed in any device equals the product of the power and the time during which the device is operated. In SI units, energy is given in joules $(1\ \text{J} = 1\ \text{W}\cdot\text{s})$, but electric companies use a larger unit, the **kilowatt-hour** $(1\ \text{kWh} = 3.6\times10^6\ \text{J})$.

Electric current can be **direct current** (**dc**), in which the current is steady in one direction; or it can be **alternating current** (**ac**), in which the current reverses direction at a particular frequency $f$, typically 60 Hz. Alternating currents are typically sinusoidal in time,

$$I = I_0\sin\omega t, \qquad \textbf{(25–8)}$$

where $\omega = 2\pi f$, and are produced by an alternating voltage.

The **rms** values of sinusoidally alternating currents and voltages are given by

$$I_{\text{rms}} = \frac{I_0}{\sqrt{2}} \quad \text{and} \quad V_{\text{rms}} = \frac{V_0}{\sqrt{2}}, \qquad \textbf{(25–9)}$$

respectively, where $I_0$ and $V_0$ are the **peak** values. The power relationship, $P = IV = I^2R = V^2/R$, is valid for the average power in alternating currents when the rms values of $V$ and $I$ are used.

**Current density** $\vec{\mathbf{j}}$ is the current per cross-sectional area. From a microscopic point of view, the current density is related to the number of charge carriers per unit volume, $n$, their charge, $q$, and their **drift speed**, $v_{\text{d}}$ by

$$j = nqv_{\text{d}} \qquad \textbf{(25–15)}$$

The electric field within a wire is related to $\vec{\mathbf{j}}$ by $\vec{\mathbf{j}} = \sigma\vec{\mathbf{E}}$ where $\sigma = 1/\rho$ is the **conductivity**.

[*At very low temperatures certain materials become **superconducting**, which means their electrical resistance becomes zero.]

[*The human nervous system operates via electrical conduction: when a nerve "fires," an electrical signal travels as a voltage pulse known as an **action potential**.]

# Questions

1. When an electric cell is connected to a circuit, electrons flow away from the negative terminal in the circuit. But within the cell, electrons flow *to* the negative terminal. Explain.
2. When a flashlight is operated, what is being used up: battery current, battery voltage, battery energy, battery power, or battery resistance? Explain.
3. What quantity is measured by a battery rating given in ampere-hours $(\text{A}\cdot\text{h})$? Explain.
4. Can a copper wire and an aluminum wire of the same length have the same resistance? Explain.
5. One terminal of a car battery is said to be connected to "ground." Since it is not really connected to the ground, what is meant by this expression?
6. When you turn on a water faucet, the water usually flows immediately. You don't have to wait for water to flow from the faucet valve to the spout. Why not? Is the same thing true when you connect a wire to the terminals of a battery?
7. The equation $P = V^2/R$ indicates that the power dissipated in a resistor decreases if the resistance is increased, whereas the equation $P = I^2R$ implies the opposite. Is there a contradiction here? Explain.
8. What happens when a lightbulb burns out?
9. If the resistance of a small immersion heater (to heat water for tea or soup, Fig. 25–33) was increased, would it speed up or slow down the heating process? Explain.

**FIGURE 25–33** Question 9.

10. If a rectangular solid made of carbon has sides of lengths $a$, $2a$, and $3a$, to which faces would you connect the wires from a battery so as to obtain (*a*) the least resistance, (*b*) the greatest resistance?

**11.** Explain why lightbulbs almost always burn out just as they are turned on and not after they have been on for some time.

**12.** Which draws more current at 110 V, an 18-W lightbulb or a 12-W lightbulb? Which has the higher resistance?

**13.** Electric power is transferred over large distances at very high voltages. Explain how the high voltage reduces power losses in the transmission lines.

**14.** A 15-A fuse blows repeatedly. Why is it dangerous to replace this fuse with a 25-A fuse?

**15.** When electric lights are operated on low-frequency ac (say, 5 Hz), they flicker noticeably. Why?

**16.** Driven by ac power, the same electrons pass back and forth through your reading lamp over and over again. Explain why the light stays lit instead of going out after the first pass of electrons.

**17.** The heating element in a toaster is made of Nichrome wire. Immediately after the toaster is turned on, is the current magnitude $(I_{\text{rms}})$ in the wire increasing, decreasing, or staying constant? Explain.

**18.** Is current used up in a resistor? Explain.

**19.** Why is it more dangerous to turn on an electric appliance when you are standing outside in bare feet than when you are inside wearing shoes with thick soles?

**20.** Compare the drift speeds and electric currents in two wires that are geometrically identical and the density of atoms is similar, but the number of free electrons per atom in the material of one wire is twice that in the other.

**21.** A voltage $V$ is connected across a wire of length $\ell$ and radius $r$. How is the electron drift speed affected if (*a*) $\ell$ is doubled, (*b*) $r$ is doubled, (*c*) $V$ is doubled, assuming in each case that other quantities stay the same?

## MisConceptual Questions

**1.** When connected to a battery, a lightbulb glows brightly. If the battery is reversed and reconnected to the bulb, the bulb will glow
(*a*) brighter.
(*b*) dimmer.
(*c*) with the same brightness.
(*d*) not at all.

**2.** When a battery is connected to a lightbulb, current flows through the lightbulb and makes it glow. How much current flows through the battery compared with the lightbulb?
(*a*) More.
(*b*) Less.
(*c*) The same amount.
(*d*) No current flows through the battery.

**3.** Which of the following statements about Ohm's law is true?
(*a*) Ohm's law relates the current through a wire to the voltage across the wire.
(*b*) Ohm's law holds for all materials.
(*c*) Any material that obeys Ohm's law does so independently of temperature.
(*d*) Ohm's law is a fundamental law of physics.
(*e*) Ohm's law is valid for superconductors.

**4.** Electrons move as a current from a battery to a lightbulb. What happens to the electrons when they reach the lightbulb?
(*a*) The electrons are used up.
(*b*) The electrons stay in the lightbulb.
(*c*) The electrons are emitted as light.
(*d*) Fewer electrons leave the bulb than enter it.
(*e*) None of the above.

**5.** Where in the circuit of Fig. 25–34 is the current the largest, (*a*), (*b*), (*c*), or (*d*)? Or (*e*) it is the same at all points?

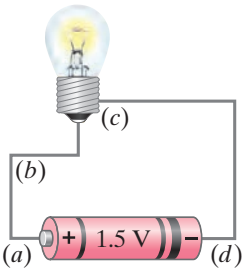


**FIGURE 25–34**
MisConceptual Question 5.

**6.** When you double the *voltage* across a certain material or device, you observe that the *current* increases by a factor of 3. What can you conclude?
(*a*) Ohm's law is obeyed, because the current increases when $V$ increases.
(*b*) Ohm's law is not obeyed in this case.
(*c*) Ohm's law is OK if the temperature is over 100°C.

**7.** When current flows through a resistor,
(*a*) some of the charge is used up by the resistor.
(*b*) some of the current is used up by the resistor.
(*c*) Both (*a*) and (*b*) are true.
(*d*) Neither (*a*) nor (*b*) is true.

**8.** The unit kilowatt-hour is a measure of
(*a*) the rate at which energy is transformed.
(*b*) power.
(*c*) an amount of energy.
(*d*) the amount of power used per second.

**9.** Why might a circuit breaker open if you plug too many electrical devices into a single circuit?
(*a*) The voltage becomes too high.
(*b*) The current becomes too high.
(*c*) The resistance becomes too high.
(*d*) A circuit breaker will not "trip" no matter how many electrical devices you plug into the circuit.

**10.** Nothing happens when birds land on a power line, yet we are warned not to touch a power line with a ladder. What is the difference?
(*a*) Birds have extremely high internal resistance compared to humans.
(*b*) There is little to no voltage drop between a bird's two feet, but there is a significant voltage drop between the top of a ladder touching a power line and the bottom of the ladder on the ground.
(*c*) Dangerous current comes from the ground only.
(*d*) Most birds don't understand the situation.

**11.** When a light switch is turned on, the light comes on immediately because
(*a*) the electrons coming from the power source move through the initially empty wires very fast.
(*b*) the electrons already in the wire are instantly "pushed" by a voltage difference.
(*c*) the lightbulb may be old with low resistance. It would take longer if the bulb were new and had high resistance.
(*d*) the electricity bill is paid. The electric company can make it take longer when the bill is unpaid.

**12.** A constant voltage is applied across a circuit. If the resistance in the circuit is doubled, what is the effect on the power dissipated by the circuit?
(*a*) The power dissipated remains constant.
(*b*) The power dissipated is doubled.
(*c*) The power dissipated is reduced by a factor of 4.
(*d*) The power dissipated is reduced by a factor of 2.
(*e*) The power dissipated is quadrupled.

**13.** Which of the following is not true about alternating current?
(*a*) Alternating current cannot deliver power because the average current and voltage are each zero.
(*b*) $V_0/V_{\text{rms}} = I_0/I_{\text{rms}}$.
(*c*) $V = IR$ holds for voltage across a resistor.
(*d*) rms values are sometimes called effective values.

**14.** Which of the following is true about the microscopic view of current in a metal?
(*a*) Drift speed is proportional to the current density.
(*b*) For a given voltage and length and thickness of wire, current density is independent of the type of wire.
(*c*) Electrons drift at nearly the speed of light.
(*d*) Electrons drift in a straight line down a wire.
(*e*) Drift speed in a wire is on the order of magnitude of mm/s.

# Problems

## 25–2 and 25–3 Electric Current, Resistance, Ohm's Law

(*Note*: The charge on one electron is $1.60 \times 10^{-19}$ C.)

**1.** (I) What voltage will produce 0.25 A of current through a 5400-Ω resistor?

**2.** (I) What is the resistance of a toaster if 120 V produces a current of 4.2 A?

**3.** (I) A current of 1.75 A flows in a wire. How many electrons are flowing past any point in the wire per second?

**4.** (I) How many positive coulombs are stored in a fully-charged 95 ampere-hour car battery?

**5.** (II) What is the current in amperes if 1200 $Na^+$ ions flow across a cell membrane in 2.8 μs? The charge on the sodium is the same as on an electron, but positive.

**6.** (II) A bird stands on a dc electric transmission line carrying 3800 A (Fig. 25–35). The line has $2.5 \times 10^{-5}$ Ω resistance per meter, and the bird's feet are 4.0 cm apart. What is the potential difference between the bird's feet?

**FIGURE 25–35** Problem 6.

**7.** (II) (*a*) What is the current in the 13-Ω heating element of a 240-V clothes dryer? (*b*) How much charge passes through the element in 15 min? (Assume direct current.)

**8.** (II) A 12-V battery causes a current of 0.50 A through a resistor. (*a*) What is its resistance, and (*b*) how many joules of energy does the battery lose in a minute?

**9.** (II) A hair dryer draws 13.5 A when plugged into a 120-V line. (*a*) What is its resistance? (*b*) How much charge passes through it in 8.0 min? (Assume direct current.)

**10.** (II) A 4.5-V battery is connected to a bulb whose resistance is 2.3 Ω. How many electrons leave the battery per minute?

**11.** (II) An electric device draws 5.25 A at 240 V. (*a*) If the power company reduces the voltage by 15% because of a "brown out," what will be the current, assuming nothing else changes? (*b*) If the resistance of the device were reduced by 7.5%, what current would be drawn at the lower voltage?

## 25–4 Resistivity

**12.** (I) What is the diameter of a 1.00-m length of tungsten wire whose resistance is 0.38 Ω?

**13.** (I) What is the resistance of a 5.1-m length of copper wire 1.5 mm in diameter?

**14.** (II) Calculate the ratio of the resistance of 10.0 m of aluminum wire 2.2 mm in diameter, to 27.0 m of copper wire 1.8 mm in diameter.

**15.** (II) Can a 1.8-mm-diameter copper wire have the same resistance as a tungsten wire of the same length? Give numerical details.

**16.** (II) A certain copper wire has a resistance of 18.5 Ω. At what point along its length must the wire be cut so that the resistance of one piece is 4.0 times the resistance of the other? What is the resistance of each piece?

**17.** (II) How much would you have to raise the temperature of a copper wire (originally at 20°C) to increase its resistance by 16%?

**18.** (II) Two aluminum wires have the same resistance. If one has twice the length of the other, what is the ratio of the diameter of the longer wire to the diameter of the shorter wire?

**19.** (II) A 100-W halogen incandescent lightbulb may have a resistance of about 12 Ω when cold (20°C). What is its resistance when "on", at 2900 K? Assume an average temperature coefficient of resistivity $\alpha = 0.0045\ (\text{C}^\circ)^{-1}$.

**20.** (II) Compute the voltage drop along an 18-m length of household no. 14 copper wire (used in 15-A circuits). The wire has diameter 1.628 mm and carries a 12-A current.

**21.** (II) A rectangular solid made of carbon has sides of lengths 1.0 cm, 2.0 cm, and 4.0 cm, lying along the $x$, $y$, and $z$ axes, respectively (Fig. 25–36). Determine the resistance for current that passes through the solid in (*a*) the $x$ direction, (*b*) the $y$ direction, and (*c*) the $z$ direction. Assume the resistivity is $\rho = 3.0 \times 10^{-5}\ \Omega \cdot \text{m}$.

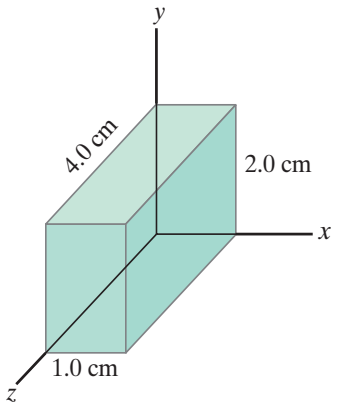

**FIGURE 25–36** Problem 21.

**22.** (II) A length of wire is cut in half and the two lengths are wrapped together side by side to make a thicker wire. How does the resistance of this new combination compare to the resistance of the original wire?

**23.** (II) A length of aluminum wire is connected to a precision 10.00-V power supply, and a current of 0.4212 A is precisely measured at 23.5°C. The wire is placed in a new environment of unknown temperature where the measured current is 0.3646 A. What is the unknown temperature?

**24.** (III) For some applications, it is important that the value of a resistance not change with temperature. For example, suppose you made a 3.60-kΩ resistor from a carbon resistor and a Nichrome wire-wound resistor connected together so the total resistance is the sum of their separate resistances. What value should each of these resistors have (at 0°C) so that the combination is temperature independent?

**25.** (III) Determine a formula for the total resistance of a spherical shell made of material whose conductivity is $\sigma$ and whose inner and outer radii are $r_1$ and $r_2$. Assume the current flows radially outward.

**26.** (III) The filament of an incandescent lightbulb has a resistance of 12 Ω at 20°C and 140 Ω when hot. (*a*) Calculate the temperature of the filament when it is hot, and take into account the change in length and area of the filament due to thermal expansion (assume tungsten for which the thermal expansion coefficient is $\approx 5.5 \times 10^{-6}\ \text{C}^{\circ -1}$). (*b*) In this temperature range, what is the percentage change in resistance due to thermal expansion, and what is the percentage change in resistance due solely to the change in $\rho$? Use Eq. 25–5.

**27.** (III) A hollow cylindrical resistor with inner radius $r_1$ and outer radius $r_2$, and length $\ell$, is made of a material whose resistivity is $\rho$ (Fig. 25–37). (*a*) Show that the resistance is given by

$$R = \frac{\rho}{2\pi\ell} \ln \frac{r_2}{r_1}$$

for current that flows radially outward. [*Hint*: Divide the resistor into concentric cylindrical shells and integrate.] (*b*) Evaluate the resistance $R$ for such a resistor made of carbon whose inner and outer radii are 1.0 mm and 1.8 mm and whose length is 2.4 cm. (Choose $\rho = 15 \times 10^{-5}\ \Omega \cdot \text{m}$.) (*c*) What is the resistance in part (*b*) for current flowing *parallel* to the axis?

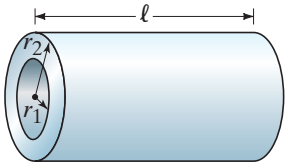

**FIGURE 25–37** Problem 27.

## 25–5 and 25–6 Electric Power

**28.** (I) What is the maximum power consumption of a 3.0-V portable electronic device that draws a maximum of 240 mA of current?

**29.** (I) The heating element of an electric oven is designed to produce 3.1 kW of heat when connected to a 240-V source. What must be the resistance of the element?

**30.** (I) What is the maximum current that can pass through a 4.2-kΩ resistor rated at $\frac{1}{4}$ watt? What happens if the current is greater than this?

**31.** (I) An electric car uses a 45-kW (160-hp) motor. If the battery pack is designed for 340 V, what current would the motor need to draw from the battery? Neglect any energy losses in getting energy from the battery to the motor.

**32.** (II) An electric car has a battery that can hold 16 kWh of energy (approximately $6 \times 10^7$ J). If the battery is designed to operate at 340 V, how many coulombs of charge would need to leave the battery at 340 V and return at 0 V to equal the stored energy of the battery?

**33.** (II) A 120-V hair dryer has two settings: 1250 W and 1875 W. (*a*) At which setting do you guess the resistance to be higher? After making a guess, determine the resistance at (*b*) the lower setting, and (*c*) the higher setting.

**34.** (II) A 110-V fish-tank heater is rated at 130 W. Calculate (*a*) the current through the heater when it is operating, and (*b*) its resistance.

**35.** (II) You buy a 75-W lightbulb in Europe, where electricity is delivered at 240 V. If you use the bulb in the United States at 120 V (assume its resistance does not change), how bright will it be relative to 75-W 120-V bulbs? [*Hint*: Assume roughly that brightness is proportional to power consumed.]

**36.** (II) How many kWh of energy does a 650-W toaster use in the morning if it is in operation for a total of 5.0 min? At a cost of 13 euro cents/kWh, estimate how much this would add to your monthly electric energy bill while you were in Europe if you made toast four mornings per week.

**37.** (II) At $0.12/kWh, what does it cost to leave a 25-W porch light on day and night for a year?

**38.** (II) What is the total amount of energy stored in a 12-V, 85 A · h car battery when it is fully charged? Give result in J and kWh.

**39.** (II) A flashlight uses two AA 1.5-V batteries connected in series to provide 3.0 V across the bulb, as in Fig. 25–4b. The bulb draws 135 mA when turned on. (*a*) Calculate the resistance of the bulb and the power dissipated. (*b*) By what factor would the power increase if four AA batteries in series (total 6.0 V) were used with the same bulb? (Neglect heating effects of the filament.) Why shouldn't you try this?

**40.** (II) An extension cord made of two wires of diameter 0.129 cm (no. 16 copper wire) and of length 2.7 m (9 ft) is connected to an electric heater which draws 16.0 A on a 120-V line. How much power is dissipated in the cord?

**41.** (II) A power station delivers 750 kW of power at 12,000 V to a factory through wires with total resistance 3.0 Ω. How much less power is wasted if the electricity is delivered at 50,000 V rather than 12,000 V?

**42.** (II) You want to design a portable electric blanket that runs on a 1.5-V battery. If you use a 0.50-mm-diameter copper wire as the heating element, how long should the wire be if you want to generate 18 W of heating power? What happens if you accidentally connect the blanket to a 9.0-V battery?

**43.** (II) A traditional incandescent lamp filament may have been lit to a temperature of 2700 K. A contemporary halogen incandescent lamp filament may be at around 2900 K. (*a*) Estimate the percent increase in efficiency of the halogen bulb over the traditional one. [*Hint*: See Section 19–10.] (*b*) To produce the same amount of light as a traditional 100-W bulb, estimate what wattage a halogen bulb should use.

**44.** (III) A small immersion heater can be used in a car to heat a cup of water for coffee or tea. If the heater can heat 120 mL of water from 25°C to 95°C in 7.0 min, (*a*) approximately how much current does it draw from the car's 12-V battery, and (*b*) what is its resistance? Assume the manufacturer's claim of 85% efficiency.

**45.** (III) A 1.0-m-long round tungsten wire is to reach a temperature of 3100 K when a current of 18.0 A flows through it. What diameter should the wire be? Assume the wire loses energy only by radiation (emissivity $\epsilon = 1.0$, Section 19–10) and the surrounding temperature is 20°C.

## 25–7 Alternating Current

**46.** (I) Calculate the peak current in a 2.5-kΩ resistor connected to a 220-V rms ac source.

**47.** (I) An ac voltage, whose peak value is 180 V, is across a 350-Ω resistor. What are the rms and peak currents in the resistor?

**48.** (II) Estimate the resistance of the 120-$V_{rms}$ circuits in your house as seen by the power company, when (*a*) everything electrical is unplugged, and (*b*) a 1500-W heater is on.

**49.** (II) The peak value of an alternating current in a 1750-W device is 6.1 A. What is the rms voltage across it?

**50.** (II) An 1800-W arc welder is connected to a 660-$V_{rms}$ ac line. Calculate (*a*) the peak voltage and (*b*) the peak current.

**51.** (II) An average power output of 150 W is sent into a 4-Ω loudspeaker (see Fig. 25–14). What are the rms voltage and the rms current fed to the speaker (*a*) at the highest rated power of 150 W, and (*b*) at 1.0 W when the volume is turned down?

**52.** (II) Determine (*a*) the maximum instantaneous power transformed by a 2.7-hp pump connected to a 240-$V_{rms}$ ac power source, and (*b*) the maximum current passing through the pump.

**53.** (II) For a time-dependent voltage $V(t)$, which is periodic with period $T$, the rms voltage is defined to be $V_{rms} = \left[\frac{1}{T}\int_0^T V^2\,dt\right]^{\frac{1}{2}}$. Use this definition to determine $V_{rms}$ (in terms of the peak voltage $V_0$) for (*a*) a sinusoidal voltage, i.e., $V(t) = V_0 \sin(2\pi t/T)$ for $0 \le t \le T$; and (*b*) a positive square-wave voltage, i.e.,

$$V(t) = \begin{cases} V_0 & 0 \le t \le \dfrac{T}{2} \\ 0 & \dfrac{T}{2} \le t \le T. \end{cases}$$

**54.** (II) A heater coil connected to a 240-$V_{rms}$ ac line has a resistance of 32 Ω. (*a*) What is the average power used? (*b*) What are the maximum and minimum values of the instantaneous power?

## 25–8 Microscopic View of Electric Current

**55.** (II) A 0.65-mm-diameter copper wire carries a tiny current of 3.2 μA. Estimate (*a*) the electron drift speed, (*b*) the current density, and (*c*) the electric field in the wire.

**56.** (II) A 5.30-m length of 2.0-mm-diameter wire carries a 750-mA current when 22.0 mV is applied to its ends. If the drift speed is $1.7 \times 10^{-5}$ m/s, determine (*a*) the resistance $R$ of the wire, (*b*) the resistivity $\rho$, (*c*) the current density $j$, (*d*) the electric field inside the wire, and (*e*) the number $n$ of free electrons per unit volume.

**57.** (II) At a point high in the Earth's atmosphere, $He^{2+}$ ions in a concentration of $2.8 \times 10^{12}/m^3$ are moving due north at a speed of $2.0 \times 10^6$ m/s. Also, a $7.0 \times 10^{11}/m^3$ concentration of $O_2^-$ ions is moving due south at a speed of $6.2 \times 10^6$ m/s. Determine the magnitude and direction of the current density $\vec{\mathbf{j}}$ at this point.

## *25–10 Nerve Conduction

***58.** (I) What is the magnitude of the electric field across an axon membrane $1.0 \times 10^{-8}$ m thick if the resting potential is −70 mV?

***59.** (II) A neuron is stimulated with an electric pulse. The action potential is detected at a point 3.40 cm down the axon 0.0052 s later. When the action potential is detected 7.20 cm from the point of stimulation, the time required is 0.0063 s. What is the speed of the electric pulse along the axon? (Why are two measurements needed instead of only one?)

***60.** (III) During an action potential, $Na^+$ ions move into the cell at a rate of about $3 \times 10^{-7}$ mol/m² · s. How much power must be produced by the "active $Na^+$ pumping" system to produce this flow against a +30-mV potential difference? Assume that the axon is 10 cm long and 20 μm in diameter.

# General Problems

**61.** A person accidentally leaves a car with the lights on. If each of the two headlights uses 55 W and each of the two taillights 6 W, for a total of 122 W, how long will a fresh 12-V battery last if it is rated at 75 A · h? Assume the full 12 V appears across each bulb.

**62.** What is the average current drawn by a 1.0-hp 120-V motor? (1 hp = 746 W.)

**63.** The **conductance** $G$ of an object is defined as the reciprocal of the resistance $R$; that is, $G = 1/R$. The unit of conductance is a *mho* $(= \text{ohm}^{-1})$, which is also called the *siemens* (S). What is the conductance (in siemens) of an object that draws 380 mA of current at 3.0 V?

**64.** The heating element of a 110-V, 1500-W heater is 4.2 m long. If it is made of iron, what must its diameter be?

**65.** (*a*) A particular household uses a 2.2-kW heater 2.0 h/day ("on" time), four 100-W lightbulbs 6.0 h/day, a 3.0-kW electric stove element for a total of 1.0 h/day, and miscellaneous power amounting to 2.0 kWh/day. If electricity costs \$0.115 per kWh, what will be their monthly bill (30 d)? (*b*) How much coal (which produces 7500 kcal/kg) must be burned by a 35%-efficient power plant to provide the yearly needs of this household?

**66.** A tungsten filament used in a flashlight bulb operates at 0.20 A and 3.0 V. If its resistance at 20°C is 1.5 Ω, what is the temperature of the filament when the flashlight is on?

**67.** The current in an electromagnet connected to a 240-V line is 21.5 A. At what rate must cooling water pass over the coils for the water temperature to rise no more than 5.50 C°?

**68.** A sequence of potential differences $V$ is applied across a wire (diameter = 0.32 mm, length = 11 cm) and the resulting currents $I$ are measured as follows:

| $V$ (V) | 0.100 | 0.200 | 0.300 | 0.400 | 0.500 |
|---|---|---|---|---|---|
| $I$ (mA) | 72 | 142 | 218 | 290 | 357 |

(*a*) If this wire obeys Ohm's law, graphing $I$ vs. $V$ will result in a straight-line plot. Explain why this is so and determine the theoretical predictions for the straight line's slope and $y$-intercept. (*b*) Plot $I$ vs. $V$. Based on this plot, can you conclude that the wire obeys Ohm's law (i.e., did you obtain a straight line with the expected $y$-intercept, within the values of the significant figures)? If so, determine the wire's resistance $R$. (*c*) Calculate the wire's resistivity and use Table 25–1 to identify the solid material from which it is composed.

**69.** For the wire in Fig. 25–38, whose diameter varies uniformly from $a$ to $b$ as shown, suppose a current $I = 2.5$ A enters at $a$. If $a = 2.5$ mm and $b = 4.0$ mm, what is the current density (assume uniform) at each end?

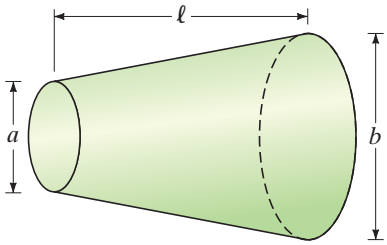

**FIGURE 25–38** Problems 69 and 70.

**70.** The cross section of a portion of wire increases uniformly as shown in Fig. 25–38 so it has the shape of a truncated cone. The diameter at one end is $a$ and at the other it is $b$, and the total length along the axis is $\ell$. If the material has resistivity $\rho$, determine the resistance $R$ between the two ends in terms of $a$, $b$, $\ell$, and $\rho$. Assume that the current flows uniformly through each section, and that the taper is small, i.e., $(b - a) \ll \ell$.

**71.** Since $1\,\text{kWh} = 3.6 \times 10^6\,\text{J}$, how much mass must be lifted against gravity through 1.0 meter to do the equivalent amount of work?

**72.** An 1875-W hair dryer is designed for 117 V. (*a*) What will be the percentage change in power output if the voltage drops to 105 V? Assume no change in resistance. (*b*) How would the actual change in resistivity with temperature affect your answer?

**73.** The wiring in a house must be thick enough so it does not become so hot as to start a fire. What diameter must a copper wire be if it is to carry a maximum current of 35 A and produce no more than 1.5 W of heat per meter of length?

**74.** A microwave oven running at 72% efficiency delivers 950 W to the interior. Find (*a*) the power drawn from the source, and (*b*) the current drawn. Assume a source voltage of 120 V.

**75.** A 1.00-Ω wire is stretched uniformly to 1.25 times its original length. What is its resistance now?

**76.** 220 V is applied to two different conductors made of the same material. One conductor is twice as long and twice the diameter of the second. What is the ratio of the power transformed in the first relative to the second?

**77.** An electric power plant can produce electricity at a fixed power $P$, but the plant operator is free to choose the voltage $V$ at which it is produced. This electricity is carried as an electric current $I$ through a transmission line (resistance $R$) from the plant to the user, where it provides the user with electric power $P'$. (*a*) Show that the reduction in power $\Delta P = P - P'$ due to transmission losses is given by $\Delta P = P^2R/V^2$. (*b*) In order to reduce power losses during transmission, should the operator choose $V$ to be as large or as small as possible?

**78.** A 2800-W oven is connected to a 240-V source. (*a*) What is the resistance of the oven's heating elements? (*b*) How long will it take to bring 150 mL of 15°C water to 100°C assuming 65% efficiency? (*c*) How much will this cost at 11 cents/kWh?

**79.** A proposed electric vehicle makes use of storage batteries as its source of energy. It is powered by 24 batteries, each 12 V, 95 A · h. Assume that the car is driven on level roads at an average speed of 45 km/h, and the average friction force is 440 N. Assume 100% efficiency and neglect energy used for acceleration. No energy is consumed when the vehicle is stopped, since the engine doesn't need to idle. (*a*) Determine the horsepower required. (*b*) After approximately how many kilometers must the batteries be recharged?

**80.** Determine the resistance of the tungsten filament in a 75-W 120-V incandescent lightbulb (*a*) at its operating temperature of about 2800 K, (*b*) at room temperature.

**81.** Suppose a current is given by the equation $I = 1.40 \sin 210t$, where $I$ is in amperes and $t$ in seconds. (*a*) What is the frequency? (*b*) What is the rms value of the current? (*c*) If this is the current through a 21.5-Ω resistor, write the equation that describes the voltage as a function of time.

**82.** A 100-W, 120-V incandescent lightbulb has a resistance of 12 Ω when cold (20°C) and 150 Ω when on (hot). Calculate its power consumption (*a*) at the instant it is turned on, and (*b*) after a few moments when it is hot.

**83.** A small city requires about 15 MW of power. Suppose that instead of using high-voltage lines to supply the power from a power plant 45 km away, the power is delivered at 120 V. Assuming a two-wire line of 0.50-cm-diameter copper wire, estimate the cost of the energy lost to heat per hour. Assume the cost of electricity is about 12 cents per kWh.

**84.** In an automobile, the system voltage varies from about 12 V when the car is off to about 13.8 V when the car is on and the car's generator (or "alternator") is in operation, a difference of 15%. By what percentage does the power delivered to the headlights vary as the voltage changes from 12 V to 13.8 V? Assume the headlight resistance remains constant.

**85.** An air conditioner draws 18 A at 220-V ac. The connecting cord is copper wire with a diameter of 1.62 mm. (*a*) How much total power does the air conditioner draw? (*b*) If the length of the cord (containing two wires) is 3.5 m, how much power is dissipated in the wiring? (*c*) If wire with a diameter of 2.05 mm was used instead, how much power would be dissipated in the wiring? (*d*) Assuming that the air conditioner is run 12 h per day, how much money per month (30 days) would be saved by using the thicker wire? Assume that the cost of electricity is 12 cents per kWh.

**86.** Lightbulb A is rated at 120 V and 40 W for household applications. Lightbulb B is rated at 12 V and 40 W for automotive applications. (*a*) What is the current through each bulb? (*b*) What is the resistance of each bulb? (*c*) In one hour, how much charge passes through each bulb? (*d*) In one hour, how much energy does each bulb use? (*e*) Which bulb requires larger diameter wires to connect its power source and the bulb?

**87.** If a wire of resistance $R$ is stretched uniformly so that its length doubles, by what factor does the power dissipated in the wire change, assuming it remains hooked up to the same voltage source? Assume the wire's volume and density remain constant.

**88.** An electric wheelchair is designed to run on a single 12-V battery rated to provide 85 ampere-hours (85 A · h). (*a*) How much energy is stored in this battery? (*b*) If the wheelchair experiences an average total retarding force (mainly friction) of 260 N, how far can the wheelchair travel on one charge?

**89.** Battery-powered electricity is very expensive compared with that available from a wall receptacle. Estimate the cost per kWh of (*a*) an alkaline D-cell (cost $1.70) and (*b*) an alkaline AA-cell (cost $1.25). These batteries can provide a continuous current of 25 mA for 820 h and 120 h, respectively, at 1.5 V. (*c*) Compare to the cost of a normal 120-V ac house source at $0.11/kWh.

**90.** Copper wire of diameter 0.259 cm is used to connect a set of appliances at 120 V, which draw 1250 W of power total. (*a*) What power is wasted in 25.0 m of this wire? (*b*) What is your answer if wire of diameter 0.412 cm is used?

**91.** A copper pipe has an inside diameter of 3.00 cm and an outside diameter of 5.00 cm (Fig. 25–39). What is the resistance to a dc current of a 12.0-m length of this pipe?

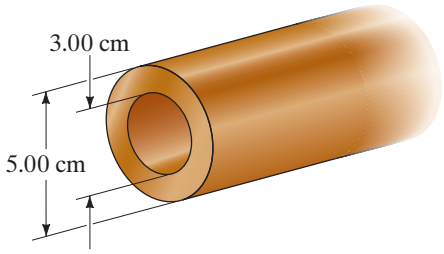

**FIGURE 25–39** Problem 91.

***92.** The level of liquid helium (temperature ≈ 4 K) in its storage tank can be monitored using a vertically aligned niobium–titanium (NbTi) wire, whose length $\ell$ spans the height of the tank. In this level-sensing setup, an electronic circuit maintains a constant electrical current $I$ at all times in the NbTi wire and a voltmeter monitors the voltage $V$ across this wire. The NbTi wire is superconducting ($R = 0$) if below its transition temperature of 10 K, so the portion of the wire immersed in the liquid helium is in the superconducting state, while the portion above the liquid (in helium vapor with temperature above 10 K) is in the normal state. Define $f = x/\ell$ to be the fraction of the tank filled with liquid helium (Fig. 25–40) and $V_0$ to be the value of the voltage $V$ when the tank is empty ($f = 0$). Determine the relation between $f$ and $V$ (in terms of $V_0$).

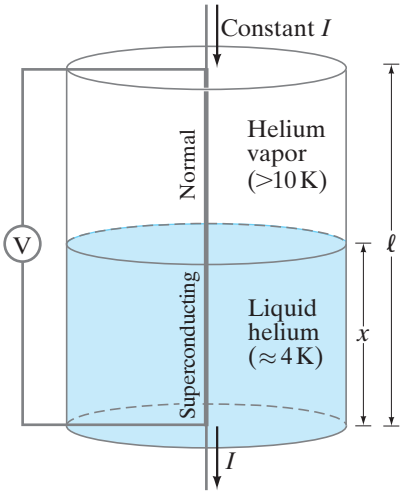

**FIGURE 25–40** Problem 92.

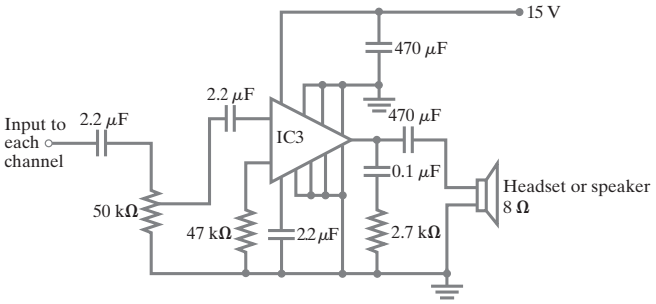
**93.** An electric heater is used to heat a room of volume 65 $m^3$. Air is brought into the room at 5°C and is completely replaced twice per hour. Heat loss through the walls amounts to approximately 750 kcal/h. If the air is to be maintained at 22°C, what minimum wattage must the heater have? (The specific heat of air is about 0.17 kcal/kg · C°.)

**94.** You find a small cylindrical resistor that measures 9.00 mm in length and 2.15 mm in diameter, and it has a color code of red, yellow, brown, and gold. What is the resistor made of primarily?

**95.** Household wiring has sometimes used aluminium instead of copper. (*a*) Using Table 25–1, find the ratio of the resistance of a copper wire to that of an aluminum wire of the same length and diameter. (*b*) Typical copper wire used for home wiring in the U.S. has a diameter of 1.63 mm. What is the resistance of 125 m of this wire? (*c*) What would be the resistance of the same wire if it were made of aluminum? (*d*) How much power would be dissipated in each wire if it carried 18 A of current? (*e*) What should be the diameter of the aluminum wire for it to have the same resistance as the copper wire? (*f*) In Section 25–4, a statement is made about the resistance of copper and aluminum wires of the same weight. Using Table 13–1 for the densities of copper and aluminum, find the resistance of an aluminum wire of the same mass and length as the copper wire in part (*b*). Is the statement true?

**96.** The LHC accelerator at CERN (Switzerland) is designed to carry a 0.58-A beam of protons $\left(q = 1.6 \times 10^{-19}\,\text{C}\right)$ traveling at very nearly the speed of light $\left(3.0 \times 10^{8}\,\text{m/s}\right)$ around a ring 27 km in circumference. How many protons are in the beam?

**97.** Estimate how far can an average electron move along one of the connecting wires of a 750-W toaster during an alternating current cycle? The power cord has copper wires of diameter 1.7 mm and is plugged into a 60-Hz 120-V ac outlet. [*Hint*: For sinusoidal motion, Chapter 14, we saw that the maximum distance traveled from equilibrium (amplitude $A$) is proportional to the maximum (drift) speed (Eq. 14–9a). This maximum drift speed is related to the maximum current (Section 25–8), which is calculated as the first step here; see Chapter 14.]

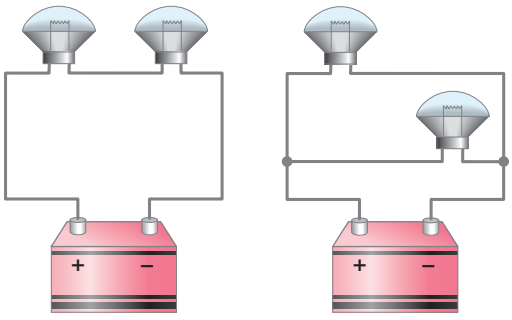


**98.** Small changes in the length of an object can be measured using a **strain gauge** sensor, which is a wire that when undeformed has length $\ell_0$, cross-sectional area $A_0$, and resistance $R_0$. This sensor is rigidly affixed to the object's surface, aligning its length in the direction in which length changes are to be measured. As the object deforms, the length of the wire sensor changes by $\Delta\ell$, and the resulting change $\Delta R$ in the sensor's resistance is measured. Assuming that as the solid wire is deformed to a length $\ell$, its density and volume remain constant (only approximately valid), show that the strain $\left(= \Delta\ell/\ell_0\right)$ of the wire sensor, and thus of the object to which it is attached, is approximately $\Delta R/2R_0$.

## ANSWERS TO EXERCISES

**A:** $1.6 \times 10^{-13}$ A.
**B:** 3600 C.
**C:** (*c*).
**D:** (*c*), (*b*).
**E:** (*c*).
**F:** 105 m.
**G:** (*d*).
**H:** (*e*) 40.
**I:** (*a*) 28 V, 3.5 A; (*b*) 2.8 V, 0.35 A.

This cell phone has an attachment that measures a person's blood sugar level, and plots it over a period of days. All electronic devices contain circuits that are dc, at least in part. The circuit diagram (below right) shows a possible amplifier circuit for an audio output (cell phone ear piece). We have already met two of the circuit elements shown: resistors and capacitors, and we discuss them in circuits in this Chapter. (The large triangle is an amplifier chip containing transistors.) We also discuss how voltmeters and ammeters work, and how measurements affect the quantity being measured.



CHAPTER 26

# DC Circuits

**CHAPTER-OPENING QUESTION—Guess now!**

The automobile headlight bulbs shown in the circuits here are identical. The battery connection which produces more light is

**(a)** circuit 1.
**(b)** circuit 2.
**(c)** both the same.
**(d)** not enough information.

26–7 Ammeters and Voltmeters—Measurement Affects Quantity Measured

Electric circuits are basic parts of all electronic devices from cell phones and TV sets to computers and automobiles. Scientific measurements—whether in physics, biology, or medicine—make use of electric circuits. In Chapter 25 we discussed the basic principles of electric current. Now we apply these principles to analyze dc circuits involving combinations of batteries, resistors, and capacitors. We also study the operation of some useful instruments.†

When we draw a diagram for a circuit, we represent batteries, capacitors, and resistors by the symbols shown in Table 26–1. Wires whose resistance is negligible compared with other resistance in the circuit are drawn as straight lines. A ground symbol (⏚ or ⏚) may mean a real connection to the ground, perhaps via a metal pipe, or it may mean a common connection, such as the frame of a car.

For the most part in this Chapter, except in Section 26–5 on *RC* circuits, we will be interested in circuits operating in their steady state. We won't be looking at a circuit at the moment a change is made in it, such as when a battery or resistor is connected or disconnected, but only when the currents have reached their steady values.

†AC circuits that contain only a voltage source and resistors can be analyzed like the dc circuits in this Chapter. However, ac circuits that contain capacitors and other circuit elements are more complicated, and we discuss them in Chapter 30.

| ⁄\/\⁄ | Resistor |
| —— | Wire with negligible resistance |
| —/— | Switch |
| ⏚ or ⏚ | Ground |

# 26–1 EMF and Terminal Voltage

To have current in an electric circuit, we need a device such as a battery or an electric generator that transforms one type of energy (chemical, mechanical, or light, for example) into electric energy. Such a device is called a **source** of **electromotive force**[†] or of **emf**. The *potential difference* between the terminals of such a source, when no current flows to an external circuit, is called the **emf** of the source. The symbol $\mathscr{E}$ is usually used for emf (don't confuse $\mathscr{E}$ with $E$ for electric field), and its unit is volts.

**⚠ CAUTION**

*Why battery voltage isn't perfectly constant*

A battery is not a source of constant current—the current out of a battery varies according to the resistance in the circuit. A battery *is*, however, a nearly constant voltage source, but not perfectly constant as we now discuss. For example, if you start a car with the headlights on, you may notice the headlights dim. This happens because the starter draws a large current, and the battery voltage drops below its rated emf as a result. The voltage drop occurs because the chemical reactions in a battery (Section 25–1) cannot supply charge fast enough to maintain the full emf. For one thing, charge must move (within the electrolyte) between the electrodes inside the battery, and there is always some hindrance to completely free flow. Thus, a battery itself has some resistance, which is called its **internal resistance**; it is usually designated $r$.

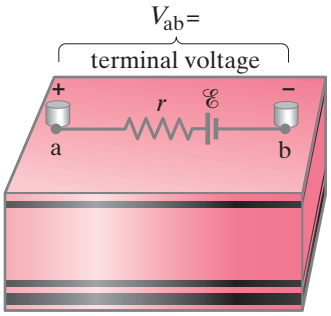

**FIGURE 26–1** Diagram for an electric cell or battery.

A real battery is modeled as if it were a perfect emf $\mathscr{E}$ in series with a resistor $r$, as shown in Fig. 26–1. Since this resistance $r$ is inside the battery, we can never separate it from the battery. The two points a and b in Fig. 26–1 represent the two terminals of the battery. What we measure is the **terminal voltage** $V_{ab} = V_a - V_b$. When no current is drawn from the battery, the terminal voltage equals the emf, which is determined by the chemical reactions in the battery: $V_{ab} = \mathscr{E}$. However, when a current $I$ flows from the battery there is an internal drop in voltage equal to $Ir$. Thus the terminal voltage (the actual voltage applied to a circuit) is[‡]

$$V_{ab} = \mathscr{E} - Ir. \qquad \text{[current } I \text{ flows from battery]} \quad \textbf{(26–1)}$$

For example, if a 12-V battery has an internal resistance of 0.1 Ω, then when 10 A flows from the battery, the terminal voltage is $12\text{ V} - (10\text{ A})(0.1\ \Omega) = 11\text{ V}$. The internal resistance of a battery is usually small. For example, an ordinary flashlight battery when fresh may have an internal resistance of perhaps 0.20 Ω. (However, as it ages and the electrolyte dries out, the internal resistance increases to many ohms.) Good car batteries have even lower internal resistance.

**EXAMPLE 26–1** **Battery with internal resistance.** A 65.0-Ω resistor is connected to the terminals of a battery whose emf is 12.0 V and whose internal resistance is 0.5 Ω, Fig. 26–2. Calculate (*a*) the current in the circuit, (*b*) the terminal voltage of the battery, $V_{ab}$, and (*c*) the power dissipated in the resistor $R$ and in the battery's internal resistance $r$.

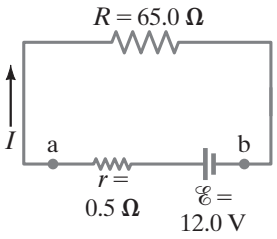

**FIGURE 26–2** Example 26–1.

**APPROACH** We first consider the battery as a whole, which is shown in Fig. 26–2 as an emf $\mathscr{E}$ and internal resistance $r$ between points a and b. Then we apply $V = IR$ to the circuit itself.

[†]The term "electromotive force" is a misnomer—it does not refer to a "force," which is measured in newtons. To avoid confusion, we use the abbreviation, emf.

[‡]When a battery is being charged, a current is forced to pass through it; we then have to write

$$V_{ab} = \mathscr{E} + Ir.$$

See Section 26–4 or Problem 27 and Fig. 26–51.

**SOLUTION** (*a*) From Eq. 26–1, we have $V_{ab} = \mathcal{E} - Ir$. We apply Ohm's law (Eq. 25–2) to this battery and the resistance $R$ of the circuit: $V_{ab} = IR$. Hence

$$\mathcal{E} - Ir = IR$$

or

$$\mathcal{E} = I(R + r).$$

So

$$I = \frac{\mathcal{E}}{R + r} = \frac{12.0\,\text{V}}{65.0\,\Omega + 0.5\,\Omega} = \frac{12.0\,\text{V}}{65.5\,\Omega} = 0.183\,\text{A}.$$

(*b*) The terminal voltage is

$$V_{ab} = \mathcal{E} - Ir = 12.0\,\text{V} - (0.183\,\text{A})(0.5\,\Omega) = 11.9\,\text{V}.$$

(*c*) The power dissipated in $R$ (Eq. 25–7) is

$$P_R = I^2R = (0.183\,\text{A})^2(65.0\,\Omega) = 2.18\,\text{W},$$

and in the battery's resistance $r$ it is

$$P_r = I^2r = (0.183\,\text{A})^2(0.5\,\Omega) = 0.02\,\text{W}.$$

Unless stated otherwise, we assume the battery's internal resistance is negligible, and the battery voltage given is its terminal voltage, which we will usually write as $V$ rather than $V_{ab}$. Do not confuse $V$ (italic) for voltage, with V (not italic) for the volt unit.

## 26–2 Resistors in Series and in Parallel

When two or more resistors are connected end to end along a single path as shown in Fig. 26–3a, they are said to be connected in **series**. The resistors could be simple resistors as were pictured in Fig. 25–11, or they could be lightbulbs (Fig. 26–3b), or heating elements, or other resistive devices. Any charge that passes through $R_1$ in Fig. 26–3a will also pass through $R_2$ and then $R_3$. Hence the same current $I$ passes through each resistor. (If it did not, this would imply either that charge was not conserved, or that charge was accumulating at some point in the circuit, which does not happen in the steady state.)

We let $V$ represent the potential difference (voltage) across all three resistors in Fig. 26–3a. We assume all other resistance in the circuit can be ignored, so $V$ equals the terminal voltage supplied by the battery. We let $V_1$, $V_2$, and $V_3$ be the potential differences across each of the resistors, $R_1$, $R_2$, and $R_3$, respectively. From Ohm's law, $V = IR$, we can write $V_1 = IR_1$, $V_2 = IR_2$, and $V_3 = IR_3$. Because the resistors are connected end to end, energy conservation tells us that the total voltage $V$ is equal to the sum of the voltages[†] across each resistor:

$$V = V_1 + V_2 + V_3 = IR_1 + IR_2 + IR_3. \qquad \text{[series]} \quad \textbf{(26–2)}$$

Now let us determine the equivalent single resistance $R_{eq}$ that would draw the same current $I$ as our combination of three resistors in series; see Fig. 26–3c. Such a single resistance $R_{eq}$ would be related to $V$ by

$$V = IR_{eq}.$$

We equate this expression with Eq. 26–2, $V = I(R_1 + R_2 + R_3)$, and find

$$R_{eq} = R_1 + R_2 + R_3. \qquad \text{[series]} \quad \textbf{(26–3)}$$

When we put several resistances in series, the total or equivalent resistance is the sum of the separate resistances. Sometimes we call it "net resistance." This sum applies to any number of resistances in series.

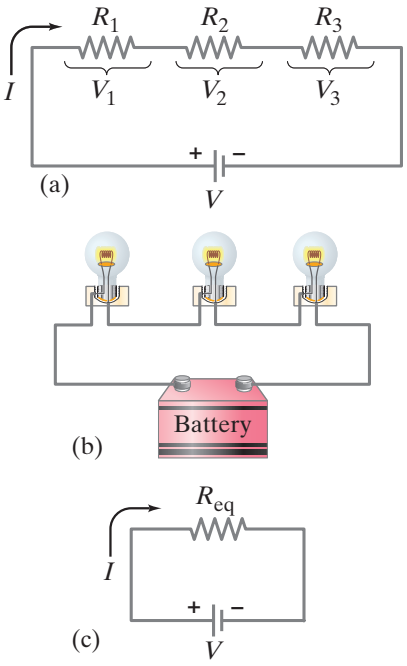

**FIGURE 26–3** (a) Resistances connected in series. (b) Resistances could be lightbulbs, or any other type of resistance. (c) Equivalent single resistance $R_{eq}$ that draws the same current: $R_{eq} = R_1 + R_2 + R_3$.

[†]To see in more detail why this is true, note that an electric charge $q$ passing through $R_1$ loses an amount of potential energy equal to $qV_1$. In passing through $R_2$ and $R_3$, the potential energy $U$ decreases by $qV_2$ and $qV_3$, for a total $\Delta U = qV_1 + qV_2 + qV_3$; this sum must equal the energy given to $q$ by the battery, $qV$, so that energy is conserved. Hence $qV = q(V_1 + V_2 + V_3)$, and so $V = V_1 + V_2 + V_3$, which is Eq. 26–2.

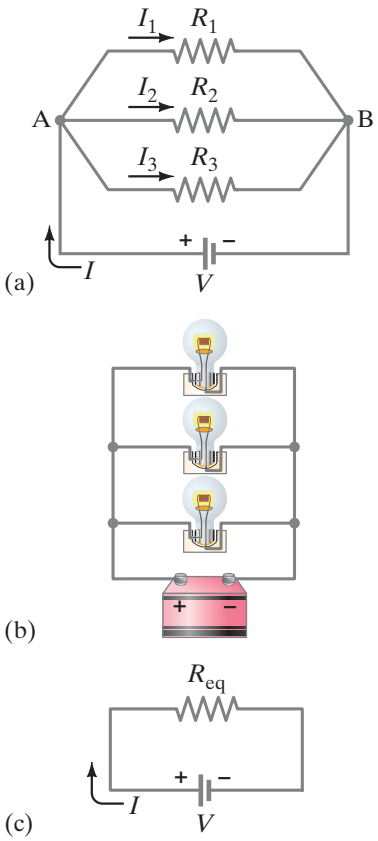

**FIGURE 26–4** (a) Resistances connected in parallel. (b) Resistances could be lightbulbs. (c) The equivalent circuit with $R_{eq}$ obtained from Eq. 26–4:

$$\frac{1}{R_{eq}} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}.$$

Note that when you add more resistance to the circuit, the current through the circuit will decrease. For example, if a 12-V battery is connected to a 4-Ω resistor, the current will be 3 A. But if the 12-V battery is connected to three 4-Ω resistors in series, the total resistance is 12 Ω and the current through the entire circuit will be only 1 A.

Another way to connect resistors is in **parallel**, so that the current from the source splits into separate branches or paths (Fig. 26–4a and b). Wiring in houses and buildings is arranged so all electric devices are in parallel, as we saw in Chapter 25, Fig. 25–20. With parallel wiring, if you disconnect one device (say, $R_1$ in Fig. 26–4a), the current to the other devices is not interrupted. Compare to a series circuit, where if one device (say, $R_1$ in Fig. 26–3a) is disconnected, the current *is* stopped to all the others (for example light bulbs).

In all of our analyses of circuits, we often make use of the fact that any two points in a circuit connected by a wire of negligible resistance are at the same potential.

In a parallel circuit, Fig. 26–4a, the total current $I$ that leaves the battery splits into three separate paths. We let $I_1$, $I_2$, and $I_3$ be the currents through each of the resistors, $R_1$, $R_2$, and $R_3$, respectively. Because *electric charge is conserved*, the current $I$ flowing into junction A (where the different wires or conductors meet in Fig. 26–4a) must equal the current flowing out of the junction. Thus

$$I = I_1 + I_2 + I_3. \qquad \text{[parallel]}$$

When resistors are connected in parallel, each has the same voltage across it. Hence the full voltage of the battery is applied to each resistor in Fig. 26–4a. Applying Ohm's law to each resistor, we have

$$I_1 = \frac{V}{R_1}, \quad I_2 = \frac{V}{R_2}, \quad \text{and} \quad I_3 = \frac{V}{R_3}.$$

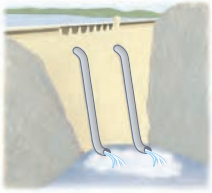
Let us now determine what single resistor $R_{eq}$ (Fig. 26–4c) will draw the same current $I$ as these three resistances in parallel. This equivalent resistance $R_{eq}$ must satisfy Ohm's law too:

$$I = \frac{V}{R_{eq}}.$$

We now combine the equations above:

$$I = I_1 + I_2 + I_3,$$

$$\frac{V}{R_{eq}} = \frac{V}{R_1} + \frac{V}{R_2} + \frac{V}{R_3}.$$



When we divide out the $V$ from each term, we have

$$\frac{1}{R_{eq}} = \frac{1}{R_1} + \frac{1}{R_2} + \frac{1}{R_3}. \qquad \text{[parallel]} \quad \textbf{(26–4)}$$

For example, suppose you connect two 4-Ω loudspeakers in parallel to a single set of output terminals of an audio amplifier. The equivalent resistance of the two 4-Ω "resistors" in parallel is

$$\frac{1}{R_{eq}} = \frac{1}{4\,\Omega} + \frac{1}{4\,\Omega} = \frac{2}{4\,\Omega} = \frac{1}{2\,\Omega},$$

and so $R_{eq} = 2\,\Omega$. Thus the net (or equivalent) resistance is *less* than each single resistance. This may at first seem surprising. But remember that when you connect resistors in parallel, you are giving the electric current additional paths to follow. Hence the net resistance will be less.[†] (If you have $n$ identical resistors in parallel, $R_{eq} = R/n$.)

[†]An analogy may help. Consider two identical pipes taking in water near the top of a dam and releasing it below as shown in the figure to the left. If both pipes are open, rather than only one, twice as much water will flow through. That is, the net resistance to the flow of water will be reduced by half with two equal pipes open, just as for electrical resistors in parallel. If both pipes are closed, the dam offers infinite resistance to the flow of water, which corresponds in the electrical case to an open circuit—when the path is not continuous and no current flows—so the electrical resistance is infinite.

Equations 26–3 and 26–4 make good sense. Recalling Eq. 25–3 for resistivity, $R = \rho\ell/A$, we see that placing resistors in series effectively increases the length and therefore the resistance; putting resistors in parallel increases the area through which current flows, thus reducing the overall resistance.

Note that whenever a group of resistors is replaced by the equivalent resistance, current and voltage and power in the rest of the circuit are unaffected.

**EXERCISE A** You have a 10-Ω and a 15-Ω resistor. What is the smallest and largest equivalent resistance that you can make with these two resistors?

**CONCEPTUAL EXAMPLE 26–2** **Series or parallel?** (*a*) The lightbulbs in Fig. 26–5 are identical. Which configuration produces more light? (*b*) Which way do you think the headlights of a car are wired? Ignore change of filament resistance $R$ with current.

**RESPONSE** (*a*) The equivalent resistance of the parallel circuit is found from Eq. 26–4, $1/R_{eq} = 1/R + 1/R = 2/R$. Thus $R_{eq} = R/2$. The parallel combination then has lower resistance $(= R/2)$ than the series combination $(R_{eq} = R + R = 2R)$. There will be more total current in the parallel configuration (2), since $I = V/R_{eq}$ and $V$ is the same for both circuits. The total power transformed, which is related to the light produced, is $P = IV$, so the greater current in (2) means more light is produced. Another simple way to see this result is that the full 12 V is across each bulb in parallel, but only half (6 V) across each bulb in series.

(*b*) Headlights are wired in parallel (2), because if one bulb goes out, the other bulb can stay lit. If they were in series (1), if one bulb burned out, the circuit would be open and no current would flow, so neither bulb would light.

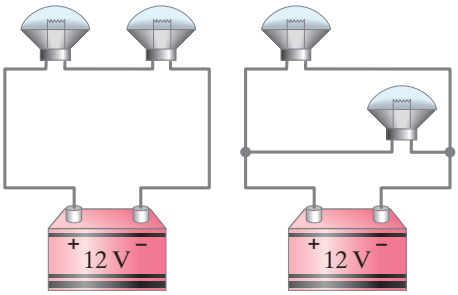


**FIGURE 26–5** Example 26–2.

**EXERCISE B** Return to the Chapter-Opening Question, page 747, and answer it again now. Try to explain why you may have answered differently the first time.

**EXAMPLE 26–3** **Circuit with series and parallel resistors.** How much current is drawn from the battery shown in Fig. 26–6a?

**APPROACH** The current $I$ that flows out of the battery all passes through the 400-Ω resistor, but then it splits into $I_1$ and $I_2$ passing through the 500-Ω and 700-Ω resistors. The latter two resistors are in parallel with each other. We look for something that we already know how to treat. So let's start by finding the equivalent resistance, $R_P$, of the parallel resistors, 500 Ω and 700 Ω. Then we can consider this $R_P$ to be in series with the 400-Ω resistor.

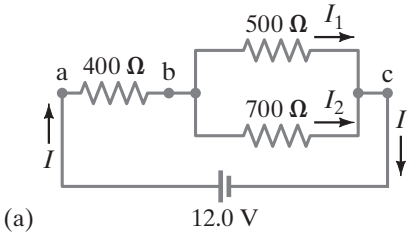
**SOLUTION** The equivalent resistance, $R_P$, of the 500-Ω and 700-Ω resistors in parallel is

$$\frac{1}{R_P} = \frac{1}{500\ \Omega} + \frac{1}{700\ \Omega} = 0.0020\ \Omega^{-1} + 0.0014\ \Omega^{-1} = 0.0034\ \Omega^{-1}.$$

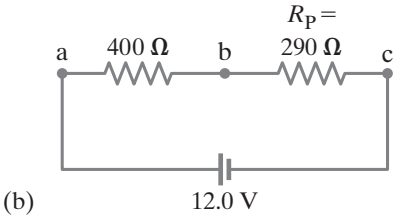
This is $1/R_P$, so we take the reciprocal to find $R_P$. It is a common mistake to forget to take this reciprocal. The units of reciprocal ohms, $\Omega^{-1}$, are a reminder. Thus

$$R_P = \frac{1}{0.0034\ \Omega^{-1}} = 290\ \Omega.$$

This 290 Ω is the equivalent resistance of the two parallel resistors, and is in series with the 400-Ω resistor (see equivalent circuit, Fig. 26–6b). The total equivalent resistance $R_{eq}$ is the sum of the 400-Ω and 290-Ω resistances, which are in series:



$$R_{eq} = 400\ \Omega + 290\ \Omega = 690\ \Omega.$$



The total current flowing from the battery is then

$$I = \frac{V}{R_{eq}} = \frac{12.0\ \text{V}}{690\ \Omega} = 0.0174\ \text{A} \approx 17\ \text{mA}.$$

**NOTE** This $I$ is also the current flowing through the 400-Ω resistor, but not through the 500-Ω and 700-Ω resistors (both currents are less—see the next Example).

**FIGURE 26–6** (a) Circuit for Example 26–3. (b) Equivalent circuit, showing the equivalent resistance of 290 Ω for the two parallel resistors in (a).

**CAUTION**
*Remember to take the reciprocal*

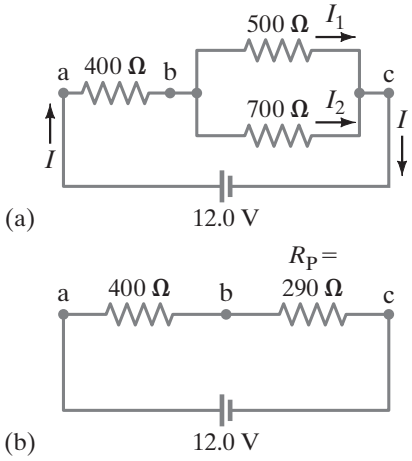


**FIGURE 26–6** (Repeated.) (a) Circuit for Examples 26–3 and 26–4. (b) Equivalent circuit, showing the equivalent resistance of 290 Ω for the two parallel resistors in (a).

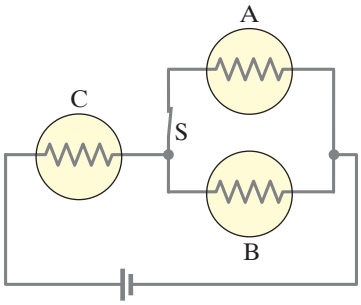
**EXAMPLE 26–4** **Current in one branch.** What is the current $I_1$ through the 500-Ω resistor in Fig. 26–6a?

**APPROACH** We need the voltage across the 500-Ω resistor, which is the voltage between points b and c in Fig. 26–6a, and we call it $V_{bc}$. Once $V_{bc}$ is known, we can apply Ohm's law, $V = IR$, to get the current. First we find the voltage across the 400-Ω resistor, $V_{ab}$, since we know that 17.4 mA passes through it (Example 26–3).

**SOLUTION** $V_{ab}$ can be found using $V = IR$:

$$V_{ab} = (0.0174\,\text{A})(400\,\Omega) = 7.0\,\text{V}.$$

The total voltage across the network of resistors is $V_{ac} = 12.0\,\text{V}$, so $V_{bc}$ must be $12.0\,\text{V} - 7.0\,\text{V} = 5.0\,\text{V}$. Ohm's law gives the current $I_1$ through the 500-Ω resistor:



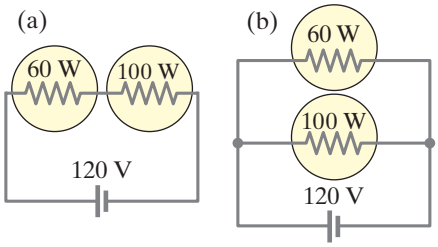
$$I_1 = \frac{5.0\,\text{V}}{500\,\Omega} = 1.0 \times 10^{-2}\,\text{A} = 10\,\text{mA}.$$

This is the answer we wanted. We can also calculate the current $I_2$ through the 700-Ω resistor since the voltage across it is also 5.0 V:

$$I_2 = \frac{5.0\,\text{V}}{700\,\Omega} = 7\,\text{mA}.$$

**NOTE** When $I_1$ combines with $I_2$ to form the total current $I$ (at point c in Fig. 26–6a), their sum is $10\,\text{mA} + 7\,\text{mA} = 17\,\text{mA}$. This equals the total current $I$ as calculated in Example 26–3, as it should.

**FIGURE 26–7** Example 26–5, three identical lightbulbs. Each yellow circle with ⁓ inside represents a lightbulb and its resistance.



**CONCEPTUAL EXAMPLE 26–5** **Bulb brightness in a circuit.** The circuit in Fig. 26–7 has three identical lightbulbs, each of resistance $R$. (*a*) When switch S is closed, how will the brightness of bulbs A and B compare with that of bulb C? (*b*) What happens when switch S is opened? Use a minimum of mathematics.

**RESPONSE** (*a*) With switch S closed, the current that passes through bulb C must split into two equal parts when it reaches the junction leading to bulbs A and B (the resistance of bulb A equals that of B). Thus, A and B each receive half of C's current; A and B will be equally bright, but less bright than C ($P = I^2R$).

(*b*) When the switch S is open, no current can flow through bulb A, so it will be dark. Now, the same current passes through bulbs B and C, so B and C will be equally bright. The equivalent resistance of this circuit ($= R + R$) is greater than that of the circuit with the switch closed, so the current leaving the battery is reduced. Thus, bulb C will be dimmer when we open the switch, but bulb B will be brighter because it gets more current when the switch is open (you may want to use some mathematics here).

**FIGURE 26–8** Exercise C.

**EXERCISE C** A 100-W, 120-V lightbulb and a 60-W, 120-V lightbulb are connected in two different ways as shown in Fig. 26–8. In each case, which bulb glows more brightly? Ignore change of filament resistance with current (and temperature).

**EXAMPLE 26–6** **ESTIMATE** **A two-speed fan.** One way a multiple-speed ventilation fan for a car can be designed is to put resistors in series with the fan motor. The resistors reduce the current through the motor and make it run more slowly. Suppose the current in the motor is 5.0 A when it is connected directly across a 12-V battery. (*a*) What series resistor should be used to reduce the current to 2.0 A for low-speed operation? (*b*) What power rating should the resistor have?

**APPROACH** An electric motor in series with a resistor can be treated as two resistors in series. The power comes from $P = IV$.

**SOLUTION** (*a*) When the motor is connected to 12 V and drawing 5.0 A, its resistance is $R = V/I = (12\text{ V})/(5.0\text{ A}) = 2.4\ \Omega$. We will assume that this is the motor's resistance for all speeds (this is only an approximation). Then, when a current of 2.0 A is flowing, the voltage across the motor is $(2.0\text{ A})(2.4\ \Omega) = 4.8\text{ V}$. The remaining $12.0\text{ V} - 4.8\text{ V} = 7.2\text{ V}$ must appear across the series resistor. When 2.0 A flows through the resistor, its resistance must be $R = (7.2\text{ V})/(2.0\text{ A}) = 3.6\ \Omega$.

(*b*) The power dissipated by the resistor is $P = (7.2\text{ V})(2.0\text{ A}) = 14.4\text{ W}$. To be safe, a power rating of 20 W would be appropriate.

**EXAMPLE 26–7** **Analyzing a circuit.** A 9.0-V battery whose internal resistance $r$ is 0.50 Ω is connected in the circuit shown in Fig. 26–9a. (*a*) How much current is drawn from the battery? (*b*) What is the terminal voltage of the battery? (*c*) What is the current in the 6.0-Ω resistor?

**APPROACH** To find the current out of the battery, we first need to determine the equivalent resistance $R_{eq}$ of the entire circuit, including $r$, which we do by identifying and isolating simple series or parallel combinations of resistors. Once we find $I$ from Ohm's law, $I = \mathscr{E}/R_{eq}$, we get the terminal voltage using $V_{ab} = \mathscr{E} - Ir$. For (*c*) we apply Ohm's law to the 6.0-Ω resistor.

**SOLUTION** (*a*) We want to determine the equivalent resistance of the circuit. But where do we start? We note that the 4.0-Ω and 8.0-Ω resistors are in parallel, and so have an equivalent resistance $R_{eq1}$ given by

$$\frac{1}{R_{eq1}} = \frac{1}{8.0\ \Omega} + \frac{1}{4.0\ \Omega} = \frac{3}{8.0\ \Omega};$$

taking the reciprocal, $R_{eq1} = 8.0\ \Omega/3 = 2.7\ \Omega$. This 2.7 Ω is in series with the 6.0-Ω resistor, as shown in the equivalent circuit of Fig. 26–9b. The net resistance of the lower arm of the circuit is then

$$R_{eq2} = 6.0\ \Omega + 2.7\ \Omega = 8.7\ \Omega,$$

as shown in Fig. 26–9c. The equivalent resistance $R_{eq3}$ of the 8.7-Ω and 10.0-Ω resistances in parallel is given by

$$\frac{1}{R_{eq3}} = \frac{1}{10.0\ \Omega} + \frac{1}{8.7\ \Omega} = 0.21\ \Omega^{-1},$$

so $R_{eq3} = (1/0.21\ \Omega^{-1}) = 4.8\ \Omega$. This 4.8 Ω is in series with the 5.0-Ω resistor and the 0.50-Ω internal resistance of the battery (Fig. 26–9d), so the total equivalent resistance $R_{eq}$ of the circuit is $R_{eq} = 4.8\ \Omega + 5.0\ \Omega + 0.50\ \Omega = 10.3\ \Omega$. Hence the current drawn is

$$I = \frac{\mathscr{E}}{R_{eq}} = \frac{9.0\text{ V}}{10.3\ \Omega} = 0.87\text{ A}.$$

(*b*) The terminal voltage of the battery is

$$V_{ab} = \mathscr{E} - Ir = 9.0\text{ V} - (0.87\text{ A})(0.50\ \Omega) = 8.6\text{ V}.$$

(*c*) Now we can work back and get the current in the 6.0-Ω resistor. It must be the same as the current through the 8.7 Ω shown in Fig. 26–9c (why?). The voltage across that 8.7 Ω will be the emf of the battery minus the voltage drops across $r$ and the 5.0-Ω resistor: $V_{8.7} = 9.0\text{ V} - (0.87\text{ A})(0.50\ \Omega + 5.0\ \Omega)$. Applying Ohm's law, we get the current (call it $I'$)

$$I' = \frac{9.0\text{ V} - (0.87\text{ A})(0.50\ \Omega + 5.0\ \Omega)}{8.7\ \Omega} = 0.48\text{ A}.$$

This is the current through the 6.0-Ω resistor.

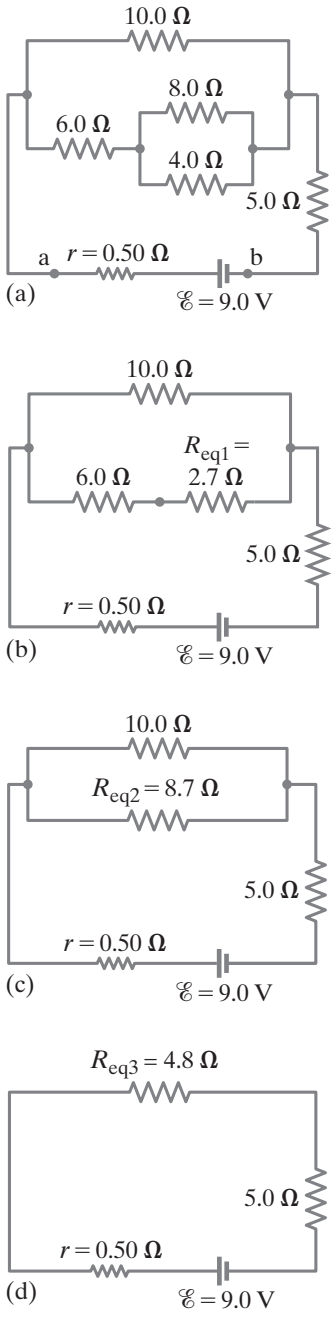


**FIGURE 26–9** Circuit for Example 26–7, where $r$ is the internal resistance of the battery.

# 26–3 Kirchhoff's Rules

In the last few Examples we have been able to find the currents in circuits by combining resistances in series and parallel, and using Ohm's law. This technique can be used for many circuits. However, some circuits are too complicated for that analysis. For example, we cannot find the currents in each part of the circuit shown in Fig. 26–10 simply by combining resistances as we did before.

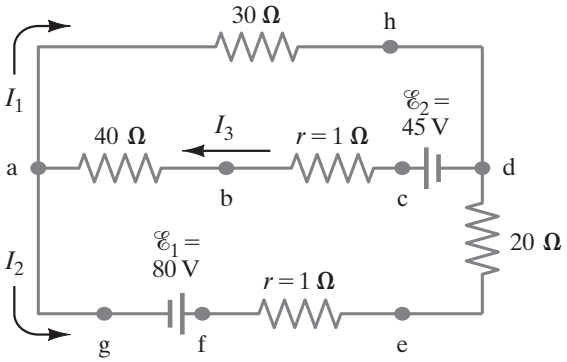

**FIGURE 26–10** Currents can be calculated using Kirchhoff's rules.

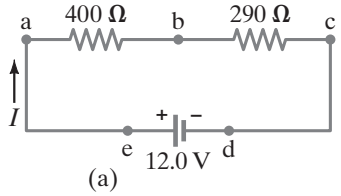
To deal with complicated circuits, we use Kirchhoff's rules, devised by G. R. Kirchhoff (1824–1887) in the mid-nineteenth century. There are two rules, and they are simply convenient applications of the laws of conservation of charge and energy.

**Kirchhoff's first rule** or **junction rule** is based on the conservation of electric charge (we already used it to derive the equation for parallel resistors). It states that

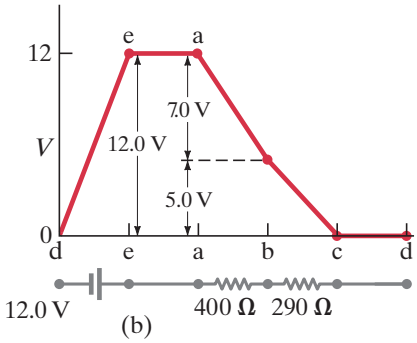
*Junction rule (conservation of charge)*

**at any junction point, the sum of all currents entering the junction must equal the sum of all currents leaving the junction.**



That is, whatever charge goes in must come out. For example, at the junction point a in Fig. 26–10, $I_3$ is entering whereas $I_1$ and $I_2$ are leaving. Thus Kirchhoff's junction rule states that $I_3 = I_1 + I_2$. We already saw an instance of this in the NOTE at the end of Example 26–4.

**Kirchhoff's second rule** or **loop rule** is based on the conservation of energy. It states that



*Loop rule (conservation of energy)*

**the sum of the changes in potential around any closed loop of a circuit must be zero.**

**FIGURE 26–11** Changes in potential around the circuit in (a) are plotted in (b).

(a)

(b)

To see why this rule should hold, consider a rough analogy with the potential energy of a roller coaster on its track. When the roller coaster starts from the station, it has a particular potential energy. As it is pulled up the first hill, its gravitational potential energy increases and reaches a maximum at the top. As it descends the other side, its potential energy decreases and reaches a local minimum at the bottom of the hill. As the roller coaster continues on its up and down path, its potential energy goes through more changes. But when it arrives back at the starting point, it has exactly as much potential energy as it had when it started at this point. Another way of saying this is that there was as much uphill as there was downhill.

Similar reasoning can be applied to an electric circuit. We will analyze the circuit of Fig. 26–10 shortly, but first we consider the simpler circuit in Fig. 26–11. We have chosen it to be the same as the equivalent circuit of Fig. 26–6b already discussed. The current in this circuit is $I = (12.0\ \text{V})/(690\ \Omega) = 0.0174\ \text{A}$, as we calculated in Example 26–3. (We keep an extra digit in $I$ to reduce rounding errors.) The positive side of the battery, point e in Fig. 26–11a, is at a high potential compared to point d at the negative side of the battery. That is, point e is like the top of a hill for a roller coaster. We follow the current around the circuit starting at any point. We choose to start at point d and follow a small positive test charge completely around this circuit. As we go, we note all changes in potential. When

the test charge returns to point d, the potential will be the same as when we started (total change in potential around the circuit is zero). We plot the changes in potential around the circuit in Fig. 26–11b; point d is arbitrarily taken as zero.

As our positive test charge goes from point d, which is the negative or low potential side of the battery, to point e, which is the positive terminal (high potential side) of the battery, the potential increases by 12.0 V. (This is like the roller coaster being pulled up the first hill.) That is,

$$V_{ed} = +12.0\,\text{V}.$$

When our test charge moves from point e to point a, there is no change in potential because there is no source of emf and negligible resistance in the connecting wires.

Next, as the charge passes through the 400-Ω resistor to get to point b, there is a decrease in potential of $V = IR = (0.0174\,\text{A})\,(400\,\Omega) = 7.0\,\text{V}$. The positive test charge is flowing "downhill" since it is heading toward the negative terminal of the battery, as indicated in the graph of Fig. 26–11b. Because this is a *decrease* in potential, we use a *negative* sign:

$$V_{ba} = V_b - V_a = -7.0\,\text{V}.$$

**PROBLEM SOLVING**
*Be consistent with signs when applying the loop rule*

As the charge proceeds from b to c there is another potential decrease (a "voltage drop") of $(0.0174\,\text{A}) \times (290\,\Omega) = 5.0\,\text{V}$, and this too is a decrease in potential:

$$V_{cb} = -5.0\,\text{V}.$$

There is no change in potential as our test charge moves from c to d as we assume negligible resistance in the wires.

The sum of all the changes in potential around the circuit of Fig. 26–11 is

$$+12.0\,\text{V} - 7.0\,\text{V} - 5.0\,\text{V} = 0.$$

This is exactly what Kirchhoff's loop rule said it would be.

PROBLEM SOLVING

## Kirchhoff's Rules

1. **Label the current** in each separate branch of the given circuit with a different subscript, such as $I_1, I_2, I_3$ (see Fig. 26–10). Each current refers to a segment of the circuit between two junctions. Choose the direction of each current, using an arrow. The direction can be chosen arbitrarily: if the current is actually in the opposite direction from what you chose, it will come out with a minus sign in the solution.
2. **Identify the unknowns**. You will need as many independent equations as there are unknowns. You may write down more equations than this, but you will find that some of the equations will be redundant (that is, not be independent in the sense of providing new information). You may use $V = IR$ for each resistor, which sometimes will reduce the number of unknowns.
3. **Apply Kirchhoff's junction rule** at one or more junctions.
4. **Apply Kirchhoff's loop rule** for one or more loops: follow each loop in one direction only. Pay careful attention to subscripts, and to signs:
   (a) For a resistor, apply Ohm's law; the potential difference is negative (a decrease) if your chosen loop direction is the same as the chosen current direction through that resistor. The potential difference is positive (an increase) if your chosen loop direction is *opposite* to the chosen current direction.
   (b) For a battery, the potential difference is positive if your chosen loop direction is from the negative terminal toward the positive terminal; the potential difference is negative if the loop direction is from the positive terminal toward the negative terminal.
5. **Solve the equations** algebraically for the unknowns. Be careful with signs. At the end, check your answers by plugging them into the original equations, or even by using any additional loop or junction rule equations not used previously.

**EXAMPLE 26–8** **Using Kirchhoff's rules.** Calculate the currents $I_1$, $I_2$, and $I_3$ in the three branches of the circuit in Fig. 26–12 (which is the same as Fig. 26–10).

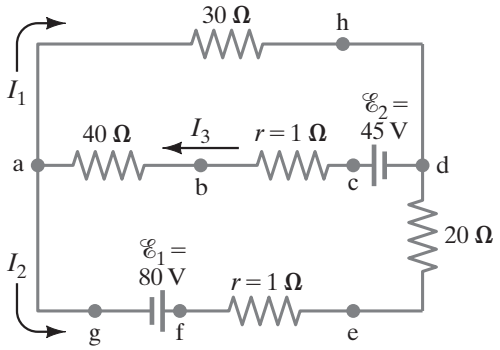


**FIGURE 26–12**
Currents can be calculated using Kirchhoff's rules.

## APPROACH and SOLUTION

**PROBLEM SOLVING**
*Choose current directions arbitrarily*

1. **Label the currents** and their directions. Figure 26–12 uses the labels $I_1$, $I_2$, and $I_3$ for the current in the three separate branches. Since (positive) current tends to move away from the positive terminal of a battery, we choose $I_2$ and $I_3$ to have the directions shown in Fig. 26–12. The direction of $I_1$ is not obvious in advance, so we arbitrarily chose the direction indicated. If the current actually flows in the opposite direction, our answer for $I_1$ will have a negative sign.
2. **Identify the unknowns**. We have three unknowns ($I_1$, $I_2$, and $I_3$) and therefore we need three equations, which we get by applying Kirchhoff's junction and loop rules.
3. **Junction rule**: We apply Kirchhoff's junction rule to the currents at point a, where $I_3$ enters and $I_2$ and $I_1$ leave:
$$I_3 = I_1 + I_2. \qquad \textbf{(i)}$$
This same equation holds at point d, so we get no new information by writing an equation for point d.
4. **Loop rule**: We apply Kirchhoff's loop rule to two different closed loops. First we apply it to the upper loop ahdcba. We start (and end) at point a. From a to h we have a potential decrease $V_{ha} = -(I_1)(30\ \Omega)$. From h to d there is no change, but from d to c the potential increases by 45 V: that is, $V_{cd} = +45$ V. From c to a the potential decreases through the two resistances by an amount $V_{ac} = -(I_3)(40\ \Omega + 1\ \Omega) = -(41\ \Omega)I_3$. Thus we have $V_{ha} + V_{cd} + V_{ac} = 0$, or
$$-30I_1 + 45 - 41I_3 = 0, \qquad \textbf{(ii)}$$
where we have omitted the units (volts and amps) so we can more easily see the algebra. For our second loop, we take the outer loop ahdefga. (We could have chosen the lower loop abcdefga instead.) Again we start at point a, and going to point h we have $V_{ha} = -(I_1)(30\ \Omega)$. Next, $V_{dh} = 0$. But when we take our positive test charge from d to e, it actually is going uphill, against the current—or at least against the *assumed* direction of the current, which is what counts in this calculation. Thus $V_{ed} = +I_2(20\ \Omega)$ has a *positive* sign. Similarly, $V_{fe} = +I_2(1\ \Omega)$. From f to g there is a decrease in potential of 80 V because we go from the high potential terminal of the battery to the low. Thus $V_{gf} = -80$ V. Finally, $V_{ag} = 0$, and the sum of the potential changes around this loop is
$$-30I_1 + (20 + 1)I_2 - 80 = 0. \qquad \textbf{(iii)}$$
Our major work is done. The rest is algebra.

**PROBLEM SOLVING**
*Be consistent with signs when applying the loop rule*

5. **Solve the equations**. We have three equations—labeled (i), (ii), and (iii)—and three unknowns. From Eq. (iii) we have
$$I_2 = \frac{80 + 30I_1}{21} = 3.8 + 1.4I_1. \qquad \textbf{(iv)}$$

From Eq. (ii) we have

$$I_3 = \frac{45 - 30I_1}{41} = 1.1 - 0.73I_1. \qquad \textbf{(v)}$$

We substitute Eqs. (iv) and (v) into Eq. (i):

$$I_1 = I_3 - I_2 = 1.1 - 0.73I_1 - 3.8 - 1.4I_1.$$

We solve for $I_1$, collecting terms:

$$3.1I_1 = -2.7$$
$$I_1 = -0.87\ \text{A}.$$

The negative sign indicates that the direction of $I_1$ is actually opposite to that initially assumed and shown in Fig. 26–12. The answer automatically comes out in amperes because our voltages and resistances were in the SI units of volts and ohms. From Eq. (iv) we have

$$I_2 = 3.8 + 1.4I_1 = 3.8 + 1.4(-0.87) = 2.6\ \text{A},$$

and from Eq. (v)

$$I_3 = 1.1 - 0.73I_1 = 1.1 - 0.73(-0.87) = 1.7\ \text{A}.$$

This completes the solution.

**PROBLEM SOLVING**
*$I_1$ is in the opposite direction from that assumed in Fig. 26–12*

**NOTE** The unknowns in different situations are not necessarily currents. It might be that the currents are given and we have to solve for unknown resistance or voltage. The variables are then different, but the technique is the same.

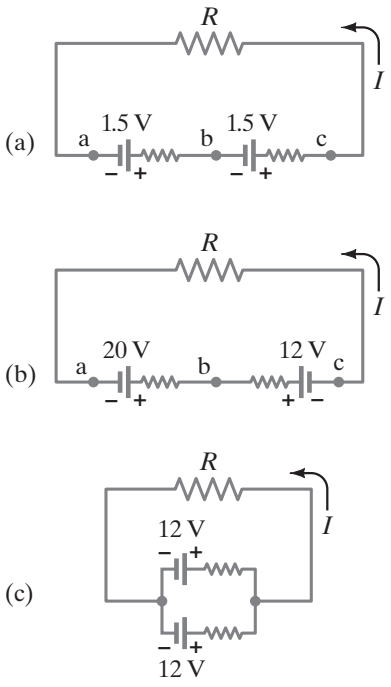
**EXERCISE D** Write the Kirchhoff equation for the lower loop abcdefga of Fig. 26–12 and Example 26–8, and show (assuming the currents calculated in this Example) that the potentials add to zero for this lower loop.

## 26–4 EMFs in Series and in Parallel; Charging a Battery

When two or more sources of emf, such as batteries, are arranged in series as in Fig. 26–13a, the total voltage is the algebraic sum of their respective voltages. On the other hand, when a 20-V and a 12-V battery are connected oppositely, as shown in Fig. 26–13b, the net voltage $V_{ca}$ is 8 V (ignoring voltage drop across internal resistances). That is, a positive test charge moved from a to b gains in potential by 20 V, but when it passes from b to c it drops by 12 V. So the net change is $20\ \text{V} - 12\ \text{V} = 8\ \text{V}$. You might think that connecting batteries in reverse like this would be wasteful. For most purposes that would be true. But such a reverse arrangement is precisely how a **battery charger** works. In Fig. 26–13b, the 20-V source is charging up the 12-V battery. Because of its greater voltage, the 20-V source is forcing charge back into the 12-V battery: electrons are being forced into its negative terminal and removed from its positive terminal.

An automobile alternator keeps the car battery charged in the same way. A voltmeter placed across the terminals of a (12-V) car battery with the engine running fairly fast can tell you whether or not the alternator is charging the battery. If it is, the voltmeter reads 13 or 14 V. If the battery is not being charged, the voltage will be 12 V, or less if the battery is discharging. Some batteries, including car batteries, can be recharged, but other batteries (ordinary inexpensive AA, AAA, C, D) are not rechargeable because the chemical reactions cannot be reversed. In such cases, the arrangement of Fig. 26–13b would simply waste energy.

Sources of emf can also be arranged in parallel, Fig. 26–13c, which—if the emfs are the same—can provide more energy when large currents are needed. Each of the cells in parallel has to produce only a fraction of the total current, so the energy loss due to internal resistance is less than for a single cell; and the batteries will go dead less quickly.



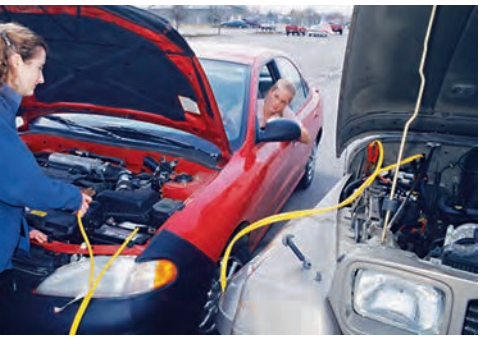


**FIGURE 26–13** Batteries in series, (a) and (b), and in parallel (c).

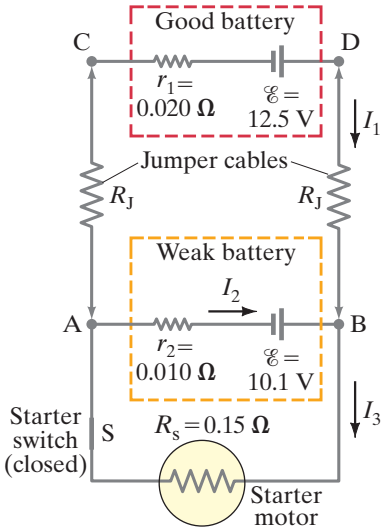

**FIGURE 26–14** Example 26–9, a jump start.

**EXAMPLE 26–9** **Jump starting a car.** A good car battery is being used to jump start a car with a weak battery. The good battery has an emf of 12.5 V and internal resistance $r_1 = 0.020\ \Omega$. Suppose the weak battery has an emf of 10.1 V and internal resistance $r_2 = 0.10\ \Omega$. Each copper jumper cable is 3.0 m long and 0.50 cm in diameter, and can be attached as shown in Fig. 26–14. Assume the starter motor can be represented as a resistor $R_s = 0.15\ \Omega$. Determine the current through the starter motor (*a*) if only the weak battery is connected to it, and (*b*) if the good battery is also connected, as shown in Fig. 26–14.

**APPROACH** We apply Kirchhoff's rules, but in (*b*) we will first need to determine the resistance of the jumper cables using their dimensions and the resistivity ($\rho = 1.68 \times 10^{-8}\ \Omega \cdot \text{m}$ for copper) as discussed in Section 25–4.

**SOLUTION** (*a*) The circuit with only the weak battery and no jumper cables is simple: an emf of 10.1 V connected to two resistances in series, $r_2 + R_s = 0.10\ \Omega + 0.15\ \Omega = 0.25\ \Omega$. Hence the current is $I = V/R = (10.1\ \text{V})/(0.25\ \Omega) = 40\ \text{A}$.

(*b*) We need to find the resistance of the jumper cables that connect the good battery to the weak one. From Eq. 25–3, each has resistance

$$R_J = \frac{\rho \ell}{A} = \frac{(1.68 \times 10^{-8}\ \Omega \cdot \text{m})(3.0\ \text{m})}{(\pi)(0.25 \times 10^{-2}\ \text{m})^2} = 0.0026\ \Omega.$$

Kirchhoff's loop rule for the full outside loop of Fig. 26–14 gives

$$12.5\ \text{V} - I_1(2R_J + r_1) - I_3 R_s = 0$$
$$12.5\ \text{V} - I_1(0.025\ \Omega) - I_3(0.15\ \Omega) = 0 \qquad \textbf{(i)}$$

since $(2R_J + r) = (0.0052\ \Omega + 0.020\ \Omega) = 0.025\ \Omega$. The loop rule for the lower loop, including the weak battery and the starter, gives

$$10.1\ \text{V} - I_3(0.15\ \Omega) - I_2(0.10\ \Omega) = 0. \qquad \textbf{(ii)}$$

The junction rule at point B gives

$$I_1 + I_2 = I_3. \qquad \textbf{(iii)}$$

We have three equations in three unknowns. From Eq. (iii),

$$I_1 = I_3 - I_2$$

and we substitute this into Eq. (i):

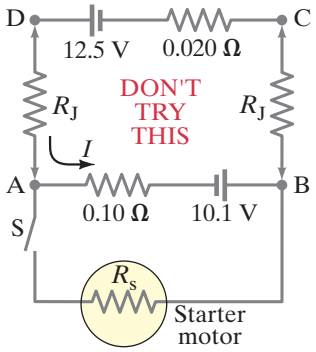
$$12.5\ \text{V} - (I_3 - I_2)(0.025\ \Omega) - I_3(0.15\ \Omega) = 0,$$
$$12.5\ \text{V} - I_3(0.175\ \Omega) + I_2(0.025\ \Omega) = 0.$$

We solve for $I_2$ in Eq. (ii) and insert that into this last equation:

$$12.5\ \text{V} - I_3(0.175\ \Omega) + \left(\frac{10.1\ \text{V} - I_3(0.15\ \Omega)}{0.10\ \Omega}\right)(0.025\ \Omega) = 0$$

or

$$I_3 = \frac{12.5\ \text{V} + 2.5\ \text{V}}{(0.175\ \Omega + 0.0375\ \Omega)} = 71\ \text{A},$$



quite a bit better than in part (*a*).

The other currents are $I_2 = -5\ \text{A}$ and $I_1 = 76\ \text{A}$. Note that $I_2 = -5\ \text{A}$ is in the opposite direction from what we assumed in Fig. 26–14. The terminal voltage of the weak 10.1-V battery when being charged is

$$V_{BA} = 10.1\ \text{V} - (-5\ \text{A})(0.10\ \Omega) = 10.6\ \text{V}.$$

**NOTE** The circuit in Fig. 26–14, without the starter motor, is how a battery can be charged. The stronger battery pushes charge back into the weaker battery.

**FIGURE 26–15** Exercise E.

**EXERCISE E** If the jumper cables of Example 26–9 are mistakenly connected in reverse, the positive terminal of each battery would be connected to the negative terminal of the other battery (Fig. 26–15). What would be the current $I$ even before the starter motor is engaged (the switch S in Fig. 26–15 is open)? Why could this cause the batteries to explode?

### Safety When Jump Starting

Before jump starting a car's weak battery, be sure both batteries are 12 V and check the polarity of both batteries. The following (cautious) procedure applies if the negative (−) terminal is ground (attached by a cable to the metal car frame and motor), and the "hot" terminal is positive (+) on both batteries, as is the case for most modern cars. The + terminal is usually marked by a red color, often a red cover. The safest procedure is to

1. connect the hot (+) terminal of the weak battery to the hot terminal of the good battery (using the cable with red clamps). Spread apart the handles of each clamp to squeeze the contacts tightly.
2. Then connect the black cable, first to the ground terminal of the good battery, and the other end to a clean exposed metal part (i.e., at ground) on the car with the weak battery. (This last connection should preferably be not too close to the battery, which in rare cases might leak $H_2$ gas that could ignite at the spark that may accompany the final connection.) This is safer than connecting directly to the ground terminal.
3. When you are ready to start the disabled car, it helps to have the good car running (to keep its battery fully charged). As soon as the disabled car starts, immediately detach the cables in the exact *reverse* order (ground cable first).

**⚠ CAUTION**
*Connect ground cable last*
*Disconnect ground cable first*

In the photo of Fig. 26–14, the above procedure is *not* being followed. Note the safety error: with ground terminals incorrectly connected first, if the red clamp (+12 V) touches a metal part (= ground), even if dropped by the person, a short circuit with damaging high electric current can occur (hundreds of amps).

**⚠ CAUTION**
*An unsafe procedure*

## 26–5 *RC* Circuits—Resistor and Capacitor in Series

Capacitors and resistors are often found together in a circuit. Such ***RC* circuits** are common in everyday life. They are used to control the speed of a car's windshield wipers and the timing of traffic lights; they are used in camera flashes, in heart pacemakers, and in many other electronic devices. Up to now in this Chapter we have been dealing with steady currents that do not change in time. The current in *RC* circuits *does* vary in time. In *RC* circuits, we are not so interested in the final "steady state" voltage and charge on the capacitor, but rather in how these variables change in time.

### Capacitor Charging

A simple *RC* circuit is shown in Fig. 26–16a. When the switch S is closed, current immediately begins to flow through the circuit. Electrons will flow out from the negative terminal of the battery, through the resistor $R$, and accumulate on the upper plate of the capacitor. And electrons will flow into the positive terminal of the battery, leaving a positive charge on the other plate of the capacitor. As charge accumulates on the capacitor, the potential difference across it increases $(V_C = Q/C)$, and the current is reduced because of this opposing voltage on the capacitor. Eventually the voltage across the capacitor equals the emf of the battery, $\mathscr{E}$. There is then no further current flow and no potential difference across the resistor. Potential difference $V_C$ across the capacitor, which is proportional to the charge on it $(V_C = Q/C,$ Eq. 24–1$)$, thus increases in time as shown in Fig. 26–16b. The mathematical form of this curve—that is, $V_C$ as a function of time—can be derived using conservation of energy (or Kirchhoff's loop rule). The emf $\mathscr{E}$ of the battery will equal the sum of the voltage drops across the resistor $(IR)$ and the capacitor $(Q/C)$:

$$\mathscr{E} = IR + \frac{Q}{C}. \qquad \textbf{(26–5)}$$

The resistance $R$ includes all resistance in the circuit, including the internal resistance of the battery; $I$ is the current at all points in the circuit at any instant, and $Q$ is the charge on the capacitor at that same instant. Although $\mathscr{E}$, $R$, and $C$ are constants, both $Q$ and $I$ are functions of time. The rate at which charge flows through the resistor $(I = dQ/dt)$ is equal to the rate at which charge accumulates on the capacitor. Thus we can write

$$\mathscr{E} = R\frac{dQ}{dt} + \frac{1}{C}Q.$$

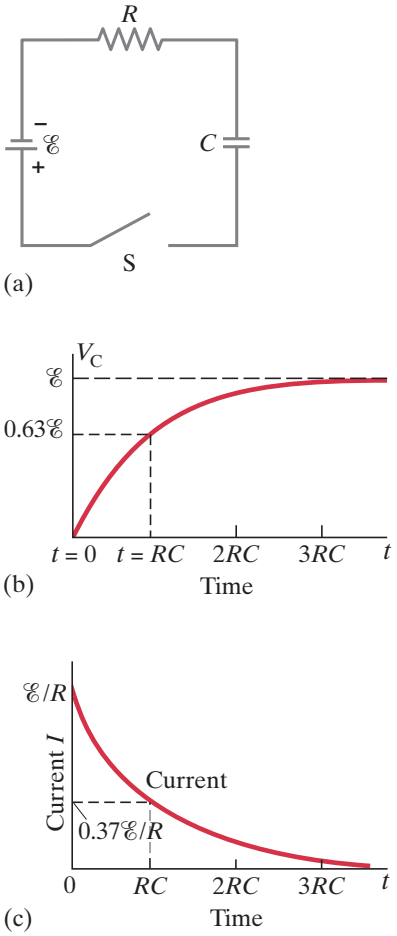


**FIGURE 26–16** After the switch S closes in the *RC* circuit shown in (a), the voltage across the capacitor increases with time as shown in (b), and the current through the resistor decreases with time as shown in (c).

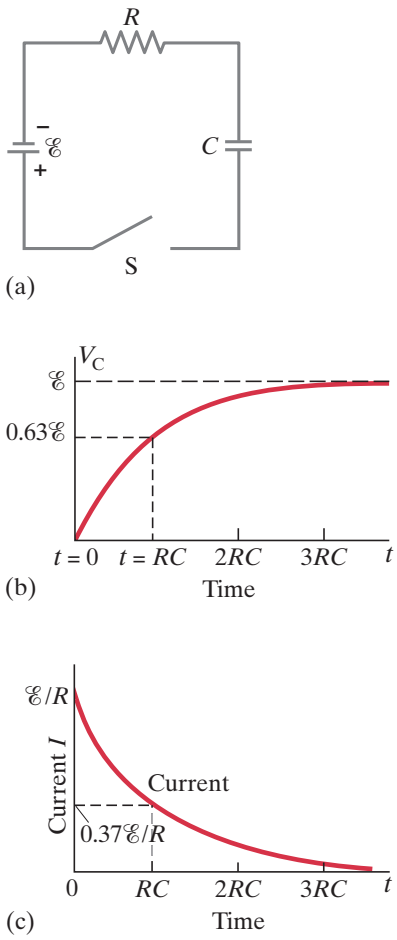

**FIGURE 26–16** (Repeated.) After the switch S closes in the *RC* circuit shown in (a), the voltage across the capacitor increases with time as shown in (b), and the current through the resistor decreases with time as shown in (c).

This equation, $\mathscr{E} = R(dQ/dt) + Q/C$, can be solved by rearranging it:

$$\frac{dQ}{C\mathscr{E} - Q} = \frac{dt}{RC}.$$

We now integrate from $t = 0$, when $Q = 0$, to time $t$ when a charge $Q$ is on the capacitor:

$$\int_0^Q \frac{dQ}{C\mathscr{E} - Q} = \frac{1}{RC}\int_0^t dt$$

$$-\ln(C\mathscr{E} - Q)\Big|_0^Q = \frac{t}{RC}\Big|_0^t$$

$$-\ln(C\mathscr{E} - Q) - (-\ln C\mathscr{E}) = \frac{t}{RC}$$

$$\ln(C\mathscr{E} - Q) - \ln(C\mathscr{E}) = -\frac{t}{RC}$$

$$\ln\left(1 - \frac{Q}{C\mathscr{E}}\right) = -\frac{t}{RC}.$$

We take the exponential[†] of both sides

$$1 - \frac{Q}{C\mathscr{E}} = e^{-t/RC}$$

or

$$Q = C\mathscr{E}(1 - e^{-t/RC}) = Q_0(1 - e^{-t/RC}), \qquad \textbf{(26–6a)}$$

where $Q_0 = C\mathscr{E}$ represents the maximum charge on the capacitor. [Careful: $Q_0$ here is not $Q$ at $t = 0$.] The potential difference across the capacitor is $V_C = Q/C$, so

$$V_C = \mathscr{E}(1 - e^{-t/RC}). \qquad \textbf{(26–6b)}$$

This Eq. 26–6b corresponds to the graph of Fig. 26–16b.

From Eqs. 26–6 we see that the charge $Q$ on the capacitor, and the voltage $V_C$ across it, increase from zero at $t = 0$ to maximum values $Q_0 = C\mathscr{E}$ and $V_C = \mathscr{E}$ after a very long time. The quantity $RC$ that appears in the exponent of Eqs. 26–6a and b is called the **time constant** $\tau$ of the circuit:

$$\tau = RC. \qquad \textbf{(26–7)}$$

It represents the time[‡] required for the capacitor to reach $(1 - e^{-1}) = 0.63$ or 63% of its full charge and voltage $(e^{-1} = 1/2.718 = 0.37)$. Thus the product $RC$ is a measure of how quickly the capacitor becomes charged. In a circuit, for example, where $R = 200\,\text{k}\Omega$ and $C = 3.0\,\mu\text{F}$, the time constant is $(2.0 \times 10^5\,\Omega)(3.0 \times 10^{-6}\,\text{F}) = 0.60\,\text{s}$. If the resistance is smaller, the time constant is smaller and the capacitor becomes charged more quickly. This makes sense, because a lower resistance will retard the flow of charge less. All circuits contain some resistance (if only the small amount in the connecting wires), so a capacitor never can be charged instantaneously when connected to a battery.

From Eqs. 26–6, it appears that $Q$ and $V_C$ never quite reach their maximum values within a finite time. However, they reach 86% of maximum in $2RC$, 95% in $3RC$, 98% in $4RC$, and so on. We say that $Q$ and $V_C$ approach their maximum values "asymptotically." For example, if $R = 20\,\text{k}\Omega$ and $C = 0.30\,\mu\text{F}$, the time constant is $(2.0 \times 10^4\,\Omega)(3.0 \times 10^{-7}\,\text{F}) = 6.0 \times 10^{-3}\,\text{s}$. So the capacitor is more than 98% charged in less than $\frac{1}{40}$ of a second.

The current $I$ through the circuit of Fig. 26–16a at any time $t$ can be obtained by differentiating Eq. 26–6a:

$$I = \frac{dQ}{dt} = \frac{\mathscr{E}}{R}e^{-t/RC}, \qquad \textbf{(26–8)}$$

which we call an **exponential decay**. Thus, at $t = 0$, just when the switch of the circuit in Fig. 26–16a is closed, the current is largest because there is no charge on the capacitor to impede it. That is, $I = I_0 = \mathscr{E}/R$, as expected for a circuit containing only a resistor. As charge builds up on the capacitor, the current decreases exponentially in time with a time constant equal to $RC$, as shown in Fig. 26–16c.

[†]The exponential constant $e$, known as the base for natural logarithms, has the value $e = 2.718\cdots$. See Appendix A–7. Do not confuse this $e$ with $e$ for the charge on the electron.

[‡]The units of $RC$ are $\Omega \cdot \text{F} = (\text{V/A})(\text{C/V}) = \text{C/(C/s)} = \text{s}$.

The time constant $RC$ represents the time required for the current to drop to $1/e \approx 0.37$ of its initial value.

**EXAMPLE 26–10** ***RC* circuit, with emf.** The capacitance in the circuit of Fig. 26–16a is $C = 0.30\,\mu\text{F}$, the total resistance is $R = 20\,\text{k}\Omega$, and the battery emf is 12 V. Determine (*a*) the time constant, (*b*) the maximum charge the capacitor could acquire, (*c*) the time it takes for the charge to reach 99% of this value, (*d*) the current $I$ when the charge $Q$ on the capacitor is half its maximum value, (*e*) the maximum current in the circuit, and (*f*) the charge $Q$ on the capacitor when the current $I$ is 0.20 of its maximum value.

**APPROACH** We use Fig. 26–16 and Eqs. 26–5, 6, 7, and 8.

**SOLUTION** (*a*) The time constant is $RC = (2.0 \times 10^4\,\Omega)(3.0 \times 10^{-7}\,\text{F}) = 6.0 \times 10^{-3}\,\text{s} = 6.0\,\text{ms}$.

(*b*) The maximum charge on the capacitor would occur when no further current flows, so $Q = Q_0 = C\mathscr{E} = (3.0 \times 10^{-7}\,\text{F})(12\,\text{V}) = 3.6\,\mu\text{C}$.

(*c*) In Eq. 26–6a, we set $Q = 0.99C\mathscr{E}$:

$$0.99C\mathscr{E} = C\mathscr{E}(1 - e^{-t/RC}),$$

or

$$e^{-t/RC} = 1 - 0.99 = 0.01.$$

We take the natural logarithm of both sides recalling that $\ln e^x = x$ (Appendix A–7):

$$\frac{t}{RC} = -\ln(0.01) = 4.6$$

so

$$t = 4.6RC = (4.6)(6.0 \times 10^{-3}\,\text{s}) = 28 \times 10^{-3}\,\text{s}$$

or 28 ms (less than $\frac{1}{30}$ s).

(*d*) From part (*b*) the maximum charge on the capacitor is $3.6\,\mu\text{C}$. When the charge is half this value, $1.8\,\mu\text{C}$, the current $I$ in the circuit can be found using the original differential equation, or Eq. 26–5:

$$I = \frac{1}{R}\left(\mathscr{E} - \frac{Q}{C}\right) = \frac{1}{2.0 \times 10^4\,\Omega}\left(12\,\text{V} - \frac{1.8 \times 10^{-6}\,\text{C}}{0.30 \times 10^{-6}\,\text{F}}\right) = 300\,\mu\text{A}.$$

(*e*) The current is a maximum at $t = 0$ (the moment when the switch is closed) and there is no charge yet on the capacitor $(Q = 0)$. So the maximum current is

$$I_0 = \frac{\mathscr{E}}{R} = \frac{12\,\text{V}}{2.0 \times 10^4\,\Omega} = 600\,\mu\text{A}.$$

(*f*) Again using Eq. 26–5, now with $I = 0.20I_0 = 120\,\mu\text{A}$, we have

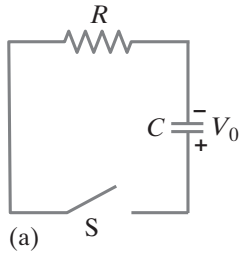
$$Q = C(\mathscr{E} - IR)$$
$$= (3.0 \times 10^{-7}\,\text{F})[12\,\text{V} - (1.2 \times 10^{-4}\,\text{A})(2.0 \times 10^4\,\Omega)] = 2.9\,\mu\text{C}.$$

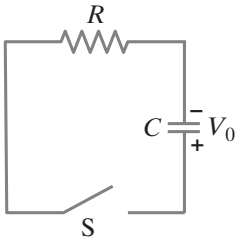
## Capacitor Discharging

The circuit just discussed involved the *charging* of a capacitor by a battery through a resistance. Now let us look at another situation: a capacitor is already charged to a voltage $V_0$ and charge $Q_0$, and it is then allowed to *discharge* through a resistance $R$ as shown in Fig. 26–17a. In this case there is no battery. When the switch S is closed, charge begins to flow through resistor $R$ from one side of the capacitor toward the other side, until the capacitor is fully discharged. The voltage across the resistor at any instant equals that across the capacitor:

$$IR = \frac{Q}{C}.$$

The rate at which charge leaves the capacitor equals the negative of the current in the resistor, $I = -dQ/dt$, because the capacitor is discharging ($Q$ is decreasing).





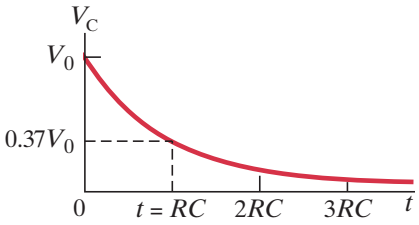


**FIGURE 26–17a** A simple *RC* circuit where the capacitor is initially charged and there is no battery. (Part (b) is on next page.)

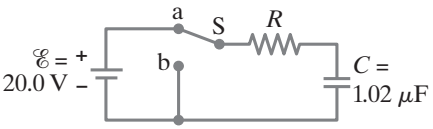

(a)

(b)

**FIGURE 26–17** For the *RC* circuit shown in (a), the voltage $V_C$ across the capacitor decreases with time, as shown in (b), after the switch S is closed at $t = 0$. The charge on the capacitor follows the same curve because $Q \propto V_C$.

**FIGURE 26–18** Example 26–11.

So, with $I = -dQ/dt$, we write the equation $IR = Q/C$ as

$$-\frac{dQ}{dt}R = \frac{Q}{C}.$$

We rearrange this to

$$\frac{dQ}{Q} = -\frac{dt}{RC}$$

and integrate it from $t = 0$ when the charge on the capacitor is $Q_0$, to some time $t$ later when the charge is $Q$:

$$\ln\left(Q/Q_0\right) = -\left(t/RC\right)$$

or

$$Q = Q_0 e^{-t/RC}. \qquad \textbf{(26–9a)}$$

The voltage across the capacitor $(V_C = Q/C)$ as a function of time is

$$V_C = V_0 e^{-t/RC}, \qquad \textbf{(26–9b)}$$

where the initial voltage $V_0 = Q_0/C$. Thus the charge on the capacitor, and the voltage across it, decrease exponentially in time with a time constant $RC$. This is shown in Fig. 26–17b. The current is

$$I = -\frac{dQ}{dt} = \frac{Q_0}{RC}e^{-t/RC} = I_0 e^{-t/RC}, \qquad \textbf{(26–10)}$$

and it too is seen to decrease exponentially in time with the same time constant $RC$. The charge on the capacitor, the voltage across it, and the current in the resistor all decrease to 37% of their original value in one time constant $t = \tau = RC$.

**EXERCISE F** In 10 time constants, the charge on the capacitor in Fig. 26–17 will be about (*a*) $Q_0/20{,}000$, (*b*) $Q_0/5000$, (*c*) $Q_0/1000$, (*d*) $Q_0/10$, (*e*) $Q_0/3$?

**EXAMPLE 26–11** **Discharging *RC* circuit.** In the *RC* circuit shown in Fig. 26–18, the battery has fully charged the capacitor, so $Q_0 = C\mathscr{E}$. Then at $t = 0$ the switch is thrown from position a to b. The battery emf is 20.0 V, and the capacitance $C = 1.02\,\mu\text{F}$. The current $I$ is observed to decrease to 0.50 of its initial value in 40 $\mu$s. (*a*) What is the value of $Q$, the charge on the capacitor, at $t = 0$? (*b*) What is the value of $R$? (*c*) What is $Q$ at $t = 60\,\mu$s?

**APPROACH** At $t = 0$, the capacitor has charge $Q_0 = C\mathscr{E}$, and then the battery is removed from the circuit and the capacitor begins discharging through the resistor, as in Fig. 26–17. At any time $t$ later (Eq. 26–9a) we have

$$Q = Q_0 e^{-t/RC} = C\mathscr{E}e^{-t/RC}.$$

**SOLUTION** (*a*) At $t = 0$, the charge on the capacitor is

$$Q_0 = C\mathscr{E} = \left(1.02\times10^{-6}\,\text{F}\right)(20.0\,\text{V}) = 2.04\times10^{-5}\,\text{C} = 20.4\,\mu\text{C}.$$

(*b*) To find $R$, we are given that at $t = 40\,\mu$s, $I = 0.50I_0$. Hence (Eq. 26–10):

$$0.50I_0 = I_0 e^{-t/RC}.$$

Taking natural logs on both sides $(\ln 0.50 = -0.693)$:

$$0.693 = \frac{t}{RC}$$

so

$$R = \frac{t}{(0.693)C} = \frac{\left(40\times10^{-6}\,\text{s}\right)}{(0.693)\left(1.02\times10^{-6}\,\text{F}\right)} = 57\,\Omega.$$

(*c*) At $t = 60\,\mu$s,

$$Q = Q_0 e^{-t/RC} = (20.4\times10^{-6}\,\text{C})e^{-\frac{60\times10^{-6}\,\text{s}}{(57\,\Omega)(1.02\times10^{-6}\,\text{F})}} = 7.3\,\mu\text{C}.$$

**EXAMPLE 26–12** **How quickly does voltage drop.** A charged capacitor, $C = 35\,\mu\text{F}$, is connected to a resistance $R = 120\,\Omega$ as in Fig. 26–17a. How much time will elapse until the voltage falls to 10% of its original (maximum) value?

**APPROACH** The voltage across the capacitor decreases according to $V_C = V_0 e^{-t/RC}$, Eq. 26–9b. We set $V_C = 0.10V_0$ (10% of $V_0$), but first we need to calculate $\tau = RC$.

**SOLUTION** The time constant for this circuit is given by

$$\tau = RC = (120\,\Omega)(35\times10^{-6}\,\text{F}) = 4.2\times10^{-3}\,\text{s}.$$

After a time $t$ the voltage across the capacitor will be

$$V_C = V_0 e^{-t/RC}.$$

We want to know the time $t$ for which $V_C = 0.10V_0$. We substitute into the above equation

$$0.10V_0 = V_0 e^{-t/RC}$$

so

$$e^{-t/RC} = 0.10.$$

The inverse operation to the exponential $e$ is the natural log, ln. Thus

$$\ln\left(e^{-t/RC}\right) = -\frac{t}{RC} = \ln 0.10 = -2.3.$$

Solving for $t$, we find the elapsed time is

$$t = 2.3(RC) = (2.3)\left(4.2\times10^{-3}\,\text{s}\right) = 9.7\times10^{-3}\,\text{s} = 9.7\,\text{ms}.$$

**NOTE** We can find the time for any specified voltage across a capacitor by using $t = RC\ln\left(V_0/V_C\right)$.

**CONCEPTUAL EXAMPLE 26–13** **Bulb in *RC* circuit.** In the circuit of Fig. 26–19, the capacitor is originally uncharged. Describe the behavior of the lightbulb from the instant switch S is closed until a long time later.

**RESPONSE** When the switch is first closed, the current in the circuit is high and the lightbulb burns brightly. As the capacitor charges, the voltage across the capacitor increases, causing the current to be reduced, and the lightbulb dims. As the potential difference across the capacitor approaches the same voltage as the battery, the current decreases toward zero and the lightbulb goes out.

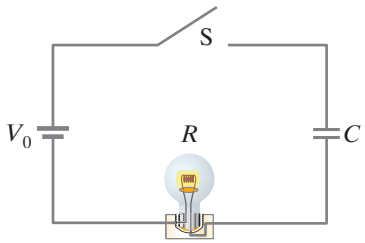

**FIGURE 26–19** Example 26–13.

## *Medical and Other Applications of *RC* Circuits

The charging and discharging in an *RC* circuit can be used to produce voltage pulses at a regular frequency. The charge on the capacitor increases to a particular voltage, and then discharges. One way of initiating the discharge of the capacitor is by the use of a gas-filled tube which has an electrical breakdown when the voltage across it reaches a certain value $V_0$. After the discharge is finished, the tube no longer conducts current and the recharging process repeats itself, starting at a lower voltage $V_0'$. Figure 26–20 shows a possible circuit, and the **sawtooth voltage** it produces.

**PHYSICS APPLIED**
*Sawtooth voltage*

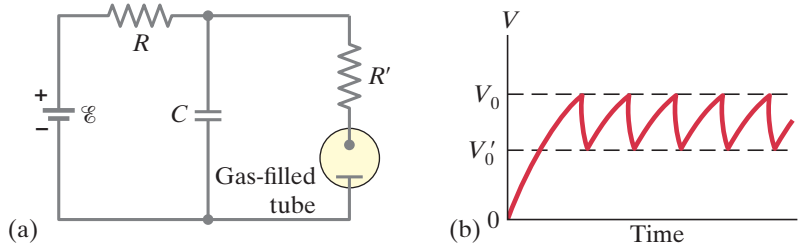

**FIGURE 26–20** (a) An *RC* circuit, coupled with a gas-filled tube as a switch, can produce (b) a repeating "sawtooth" voltage. (In (b) note the initial increase in voltage is like Fig. 26–16b.)

A simple blinking light can be an application of a sawtooth oscillator circuit. Here the emf is supplied by a battery; the neon bulb flashes on at a rate of perhaps 1 cycle per second. The main component of a "flasher unit" is a moderately large capacitor.

**PHYSICS APPLIED**
*Blinking flashers*

The intermittent windshield wipers of a car can also use an *RC* circuit. The *RC* time constant, which can be changed using a multi-positioned switch for different values of *R* with fixed *C*, determines the rate at which the wipers come on.

**PHYSICS APPLIED**
*Windshield wipers on "intermittent"*

**EXERCISE G** A typical turn signal flashes perhaps twice per second, so its time constant is on the order of 0.5 s. Estimate the resistance in the circuit, assuming a moderate capacitor of $C = 1\,\mu\text{F}$.

**PHYSICS APPLIED**
*Heart pacemaker*

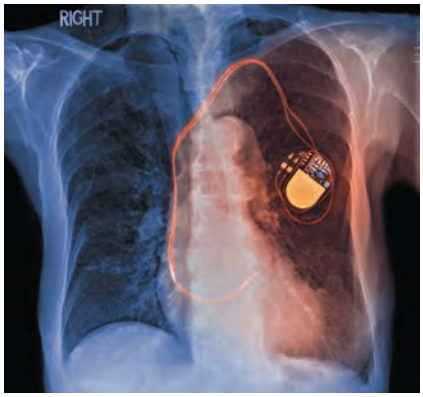

**FIGURE 26–21** Electronic battery-powered pacemaker can be seen on the rib cage in this X-ray (color added).

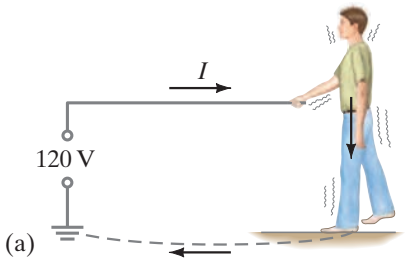
**PHYSICS APPLIED**
*Dangers of electricity*



An important medical use of an *RC* circuit is the electronic heart pacemaker, which can make a stopped heart start beating again by applying an electric stimulus through electrodes attached to the chest. The stimulus can be repeated at the normal heartbeat rate if necessary. The heart itself contains *pacemaker* cells, which send out tiny electric pulses at a rate of 60 to 80 per minute. These signals induce the start of each heartbeat. In some forms of heart disease, the natural pacemaker fails to function properly, and the heart loses its beat. Such patients use *electronic pacemakers* which produce a regular voltage pulse that starts and controls the frequency of the heartbeat. The electrodes are implanted in or near the heart (Fig. 26–21), and the circuit contains a capacitor and a resistor. The charge on the capacitor increases to a certain point and then discharges a pulse to the heart. Then it starts charging again. The pulsing rate depends on the time constant *RC*.

## 26–6 Electric Hazards and Safety

Excess electric current can overheat wires in buildings and cause fires, as discussed in Section 25–6. Electric current can also damage the human body or even be fatal. Electric current through the human body can cause damage in two ways: (1) heating tissue and causing burns; (2) stimulating nerves and muscles, and we feel a "shock." The severity of a shock depends on the magnitude of the current, how long it acts, and through what part of the body it passes. A current passing through vital organs such as the heart or brain is especially damaging.

A current of about 1 mA or more can be felt and may cause pain. Currents above 10 mA cause severe contraction of the muscles, and a person may not be able to let go of the source of the current (say, a faulty appliance or wire). Death from paralysis of the respiratory system can occur. Artificial respiration can sometimes revive a victim. If a current above about 80 to 100 mA passes across the torso, so that a portion passes through the heart for more than a second or two, the heart muscles will begin to contract irregularly and blood will not be properly pumped. This condition is called **ventricular fibrillation**. If it lasts for long, death results. Strangely enough, if the current is much larger, on the order of 1 A, death by heart failure may be less likely,[†] but such currents can cause serious burns if concentrated through a small area of the body.

**FIGURE 26–22** You can receive a shock when the circuit is completed.

(a)

(b)

It is current that harms, even though it is voltage that drives the current. The seriousness of an electric shock depends on the current and thus on the applied voltage and the effective resistance of the body. Living tissue has low resistance because the fluid of cells contains ions that can conduct quite well. However, the outer layer of skin, when dry, offers high resistance and is thus protective. The effective resistance between two points on opposite sides of the body when the skin is dry is on the order of $10^4$ to $10^6\ \Omega$. But when the skin is wet, the resistance may be $10^3\ \Omega$ or less. A person who is barefoot or wearing thin-soled shoes will be in good contact with the ground, and touching a 120-V line with a wet hand can result in a current

$$I = \frac{120\ \text{V}}{1000\ \Omega} = 120\ \text{mA}.$$

As we saw, this could be lethal.

You can get a shock by becoming part of a complete circuit. Figure 26–22 shows two ways the circuit might be completed when you accidentally touch a "hot" electric wire—"hot" meaning a high potential relative to ground such as 120 V (normal U.S. household voltage) or 240 V (many other countries). The other wire of building wiring is connected to ground—either by a wire connected to a buried conductor, or via a metal water pipe into the ground. The current in Fig. 26–22a passes from the high voltage wire through you to ground through your bare feet, and back along the ground (a fair conductor) to the ground terminal of the source. If you stand on a good insulator—thick rubber-soled shoes or a

[†]Larger currents apparently bring the entire heart to a standstill. Upon release of the current, the heart returns to its normal rhythm. This may not happen when fibrillation occurs because, once started, it can be hard to stop. Fibrillation may also occur as a result of a heart attack or during heart surgery. A device known as a *defibrillator* (described in Section 24–4) can apply a brief high current to the heart, causing complete heart stoppage which is often followed by resumption of normal beating.

dry wood floor—there will be much more resistance in the circuit and much less current through you. If you stand with bare feet on the ground, or in a bathtub, there is lethal danger because the resistance is much less and the current greater. In a bathtub (or swimming pool), not only are you wet, which reduces your resistance, but the water is in contact with the drain pipe which, if metal, leads to the ground. It is strongly recommended that you not touch anything electrical when wet or in bare feet. The use of non-metal pipes is important and protective.

In Fig. 26–22b, a person touches a "hot" wire in a faulty device with one hand, and the other hand touches a sink faucet (connected to ground via the pipe or even by water in a non-metal pipe). The current is particularly dangerous because it passes across the chest, through the heart and lungs. A useful rule: if one hand is touching something electrical, keep your other hand in your back pocket (don't use it!), and wear thick rubber-soled shoes. Also remove metal jewelry, especially rings (your finger is usually moist under a ring).

**CAUTION**
*Keep one hand in your pocket when the other touches electricity*

**PHYSICS APPLIED**
*Grounding and shocks*

You can come into contact with a hot wire by touching a bare wire whose insulation has worn off, or from a bare wire inside an appliance when you're tinkering with it. (Always unplug an electrical device before investigating its insides!)† Also, a wire inside a device may break or lose its insulation and come in contact with the case. If the case is metal, it will conduct electricity. A person could then suffer a severe shock merely by touching the case, as shown in Fig. 26–23b.

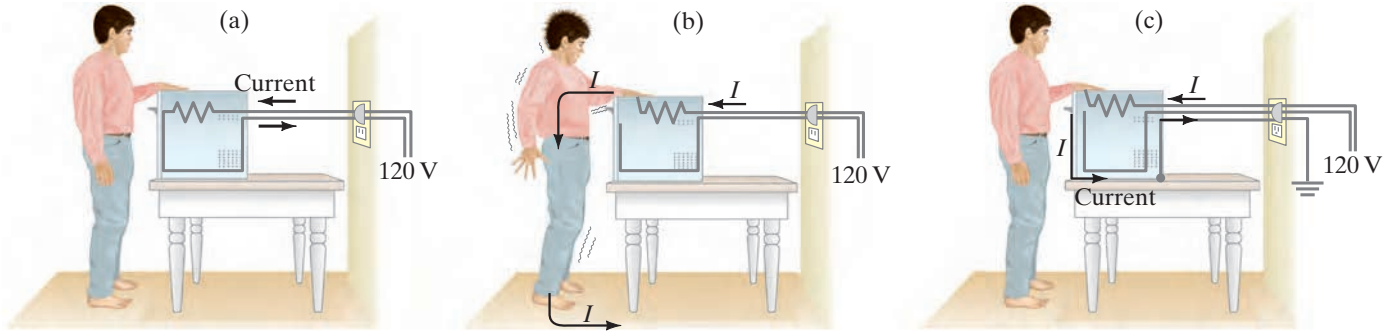


**FIGURE 26–23** (a) An electric oven operating normally with a 2-prong plug. (b) A short to a metal case which is ungrounded, causing a shock. (c) A short to the case which is grounded by a 3-prong plug; almost no current goes through the person.

To prevent an accident, metal cases are supposed to be connected directly to ground by a separate ground wire. Then if a "hot" wire touches the grounded case, a short circuit to ground immediately occurs internally, as shown in Fig. 26–23c, and most of the current passes through the low-resistance ground wire rather than through the person. Furthermore, the high current should open a fuse or circuit breaker. Grounding a metal case is done by a separate ground wire connected to the third (round) prong of a 3-prong plug. Never cut off the third prong of a plug—it could save your life. A three-prong plug, and an adapter, are shown in Figs. 26–24a and b.

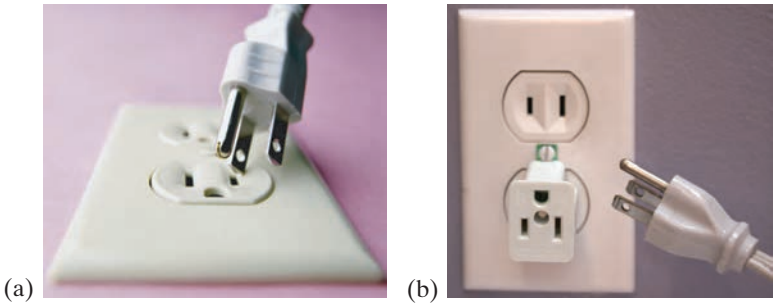

**FIGURE 26–24** (a) A 3-prong plug, and (b) an adapter (white) for old-fashioned 2-prong outlets—be sure to screw down the ground tab (green color in photo).

## Safe Wiring

Why is a third wire needed? The 120 V is carried by the other two wires—one **hot** (120 V ac), the other **neutral** ($\approx$ 0 V), which is itself grounded. The third "dedicated" ground wire with the round prong may seem redundant. But it is protection for two reasons: (1) It protects against internal wiring that may have been done incorrectly or is faulty as discussed above, Fig. 26–23.

**CAUTION**
*Necessity of third (ground) wire*

†Even then you can get a bad shock from a capacitor that hasn't been discharged until you touch it.

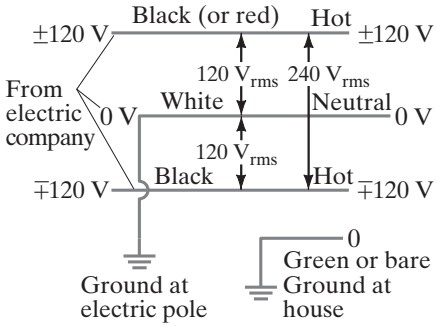

**FIGURE 26–25** A polarized 2-prong plug.

**CAUTION**

*Black wire may be either ground or hot. Beware!*

**FIGURE 26–26** Four wires entering a typical house (at the right). The color codes for wires are not always as shown here—be careful!

**PHYSICS APPLIED**

*Hospital patients with implanted electrodes are at great risk*

**PHYSICS APPLIED**

*CAUTION: Do not touch a downed electric wire—run away, one foot on the ground at a time*

(2) The *neutral* wire (≈ 0 V) carries the full normal current ("return" current from the hot 120 V) and it does have resistance—so there can be a voltage drop along the neutral wire, normally small; but if connections are poor or corroded, or the plug is loose, the resistance could be large enough that you might feel that voltage if you touched the neutral wire some distance from its grounding point.

Some electrical devices come with only two wires, and the plug's two prongs are of different widths; the plug can be inserted only one way into the outlet so that the intended neutral (wider prong) in the device is connected to neutral in the wiring (Fig. 26–25). For example, the screw threads of a lightbulb are meant to be connected to neutral (and the base contact to hot), to avoid shocks when changing a bulb in a possibly protruding socket. Devices with 2-prong plugs do *not* have their cases grounded; they are supposed to have double electric insulation (or have a nonmetal case). Take extra care anyway.

The insulation on a wire may be color coded. Hand-held meters (next Section) may have red (hot) and black (ground) lead wires. But in a U.S. house, the hot wire is often black (though it may be red), whereas white is neutral and green (or bare) is the dedicated ground, Fig. 26–26. But beware: these color codes cannot always be trusted.

[In the U.S., three wires normally enter a house: two *hot* wires at 120 V each (which add together to 240 V for appliances or devices that run on 240 V) plus the grounded *neutral* (carrying return current for the two hot wires). See Fig. 26–26. The "dedicated" *ground* wire (non-current carrying) is a fourth wire that does not come from the electric company but enters the house from a nearby heavy stake in the ground or a buried metal pipe. The two hot wires can feed separate 120-V circuits in the house, so each 120-V circuit inside the house has only three wires, including the dedicated ground.]

Normal circuit breakers (Sections 25–6 and 28–9) protect equipment and buildings from overload and fires. They protect humans only in some circumstances, such as the very high currents that result from a short, if they respond quickly enough. *Ground fault circuit interrupters* (GFCI or GFI), described in Section 29–9, are designed to protect people from the much lower currents (10 mA to 100 mA) that are lethal but would not throw a 15-A circuit breaker or blow a 20-A fuse. GFCI are our best protection, and should be installed in electric outlets if not already there, especially in bathrooms and kitchens.

Another danger is **leakage current**, by which we mean a current along an unintended path. Leakage currents are often "capacitively coupled." For example, a wire in a lamp or toaster forms a capacitor with the metal case; charges moving in one conductor attract or repel charge in the other, so there is a current. Typical electrical codes limit leakage currents to 1 mA for any device, which is usually harmless. It could be dangerous, however, to a hospital patient with implanted electrodes, due to the absence of the protective skin layer and because the current can pass directly through the heart. Although 100 mA may be needed to cause heart fibrillation when entering through the hands and spreading out through the body (very little of it actually passing through the heart), but as little as 0.02 mA can cause fibrillation when passing directly to the heart. Thus, a "wired" patient is in considerable danger from leakage current even from as simple an act as touching a lamp.

Finally, don't touch a downed power line (lethal!) or even get near it. A hot power line is at thousands of volts. Furthermore a huge current can flow along the ground from the point where the high-voltage wire touches the ground. This current is great enough that the voltage between your two feet could be large and dangerous. Tip: stand on one foot, or run so only one foot touches the ground at a time.

It is current that harms, but voltage drives the current. It is sometimes said that 30 V is the threshhold for serious danger. But even a 12-V car battery (which can supply large currents) can cause nasty burns and shock. Always be attentive with electricity: and keep one hand in your back pocket.

# 26–7 Ammeters and Voltmeters—Measurement Affects Quantity Measured

Measurement is a fundamental part of physics, and is not as simple as you might think. Measuring instruments can not be taken for granted; their results are not perfect and often need to be interpreted. As an illustration of measurement "theory" we examine here how electrical quantities are measured using meters. We also examine how meters affect the quantity they attempt to measure.

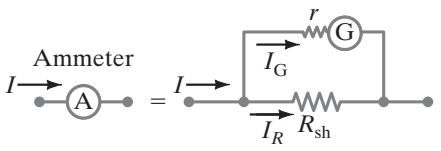
An **ammeter** measures current (amps), and a **voltmeter** measures potential difference or voltage. Each can be either: (1) an *analog* meter, which displays numerical values by the position of a pointer that can move across a scale (Fig. 26–27a); or (2) a *digital* meter, which displays the numerical value in numbers (Fig. 26–27b).We first examine how analog meters work.

## Ammeters and Voltmeters (Analog)

An analog ammeter or voltmeter, in which the reading is by a pointer on a scale (Fig. 26–27a), uses a **galvanometer**. A galvanometer works on the principle of the force between a magnetic field and a current-carrying coil of wire; it is straightforward to understand and will be discussed in Chapter 27. For now, we only need to know that the deflection of the needle of a galvanometer is proportional to the current flowing through it. The **full-scale current sensitivity** of a galvanometer, $I_m$, is the electric current needed to make the needle deflect full scale, typically about 50 $\mu$A.

A galvanometer whose sensitivity $I_m$ is 50 $\mu$A can measure currents from about 1 $\mu$A (currents smaller than this would be hard to read on the scale) up to 50 $\mu$A. To measure larger currents, a resistor is placed in parallel with the galvanometer. An analog **ammeter**, represented by the symbol •—Ⓐ—•, consists of a galvanometer (•—Ⓖ—•) in parallel with a resistor called the **shunt resistor**, as shown in Fig. 26–28. ("Shunt" is a synonym for "in parallel.") The shunt resistance is $R_{sh}$, and the resistance of the galvanometer coil is $r$. The value of $R_{sh}$ is chosen according to the full-scale deflection desired; $R_{sh}$ is normally very small—giving an ammeter a very small net resistance—so most of the current passes through $R_{sh}$ and very little ($\lesssim 50\,\mu$A) passes through the galvanometer to deflect the needle.

(a)



(b)

**FIGURE 26–27** (a) An analog multimeter. (b) An electronic digital meter measuring voltage at a circuit breaker.

**PHYSICS APPLIED**

*Ammeters use shunt resistor in parallel*

**FIGURE 26–28** An ammeter is a galvanometer in parallel with a (shunt) resistor with low resistance, $R_{sh}$.

**EXAMPLE 26–14** **Ammeter design.** Design an ammeter to read 1.0 A at full scale using a galvanometer with a full-scale sensitivity of 50 $\mu$A and a resistance $r = 30\,\Omega$. Check if the scale is linear.

**APPROACH** Only $50\,\mu\text{A}\ (= I_G = 0.000050\text{ A})$ of the 1.0-A current passes through the galvanometer to give full-scale deflection. The rest of the current $(I_R = 0.999950\text{ A})$ passes through the small shunt resistor, $R_{sh}$, Fig. 26–28. The potential difference across the galvanometer equals that across the shunt resistor (they are in parallel). We apply Ohm's law to find $R_{sh}$.

**SOLUTION** Because $I = I_G + I_R$, when $I = 1.0$ A flows into the meter, we want $I_R$ through the shunt resistor to be $I_R = 0.999950$ A. The potential difference across the shunt is the same as across the galvanometer, so

$$I_R R_{sh} = I_G r.$$

Then

$$R_{sh} = \frac{I_G r}{I_R} = \frac{(5.0 \times 10^{-5}\text{ A})(30\,\Omega)}{(0.999950\text{ A})} = 1.5 \times 10^{-3}\,\Omega,$$

or 0.0015 $\Omega$. The shunt resistor must thus have a *very* low resistance and most of the current passes through it.

Because $I_G = I_R(R_{sh}/r)$ and $(R_{sh}/r)$ is constant, we see that the scale is linear (because the needle deflection is proportional to $I_G$). If the current $I \approx I_R$ into the meter is half of full scale, 0.50 A, the current to the galvanometer will be $I_G = I_R(R_{sh}/r) = (0.50\text{ A})(1.5 \times 10^{-3}\,\Omega)/(30\,\Omega) = 25\,\mu$A, which would make the needle deflect halfway, as it should.

**PHYSICS APPLIED**
*Voltmeters use series resistor*

An analog **voltmeter** (•–Ⓥ–•) consists of a galvanometer and a resistor $R_{ser}$ connected in series, Fig. 26–29. $R_{ser}$ is usually large, giving a voltmeter a high internal resistance.

**FIGURE 26–29** A voltmeter is a galvanometer in series with a resistor with high resistance, $R_{ser}$.

**EXAMPLE 26–15** **Voltmeter design.** Using a galvanometer with internal resistance $r = 30\ \Omega$ and full-scale current sensitivity of $50\ \mu A$, design a voltmeter that reads from 0 to 15 V. Is the scale linear?

**APPROACH** When a potential difference of 15 V exists across the terminals of our voltmeter, we want $50\ \mu A$ to be passing through it so as to give a full-scale deflection.

**SOLUTION** From Ohm's law, $V = IR$, we have (Fig. 26–29)

$$15\ \text{V} = (50\ \mu\text{A})(r + R_{ser}),$$

so

$$R_{ser} = \frac{15\ \text{V}}{5.0 \times 10^{-5}\ \text{A}} - r = 300\ \text{k}\Omega - 30\ \Omega \approx 300\ \text{k}\Omega.$$

Notice that $r = 30\ \Omega$ is so small compared to the value of $R_{ser}$ that it doesn't influence the calculation significantly. The scale will again be linear: if the voltage to be measured is 6.0 V, the current passing through the voltmeter will be $(6.0\ \text{V})/(3.0 \times 10^5\ \Omega) = 2.0 \times 10^{-5}\ \text{A}$, or $20\ \mu A$. This will produce two-fifths of full-scale deflection, as required $(6.0\ \text{V}/15.0\ \text{V} = 2/5)$.

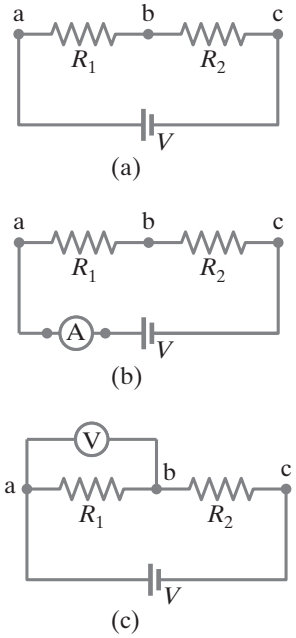


**FIGURE 26–30** Measuring current and voltage.

## How to Connect Meters

Suppose you wish to determine the current $I$ in the circuit shown in Fig. 26–30a, and the voltage $V$ across the resistor $R_1$. How exactly are ammeters and voltmeters connected to the circuit being measured?

Because an ammeter is used to measure the current flowing in the circuit, it must be inserted directly into the circuit, in series with the other elements, as shown in Fig. 26–30b. The smaller its internal resistance, the less it affects the circuit.

A voltmeter is connected "externally," in parallel with the circuit element across which the voltage is to be measured. It measures the potential difference between two points. Its two wire "leads" (connecting wires) are connected to the two points, as shown in Fig. 26–30c, where the voltage across $R_1$ is being measured.The larger its internal resistance ($R_{ser} + r$, Fig. 26–29), the less it affects the circuit being measured. Digital meters, discussed shortly, are connected in the same way and generally have less effect on the circuit.

## Effects of Meter Resistance

**PHYSICS APPLIED**
*Correcting for meter resistance*

It is important to know the sensitivity of a meter, for in many cases the resistance of the meter can seriously affect your results. Consider the following Example.

**EXAMPLE 26–16** **Voltage reading vs. true voltage.** An electronic circuit has two 15-kΩ resistors, $R_1$ and $R_2$, connected in series, Fig. 26–31a. The battery voltage is 8.0 V and it has negligible internal resistance. A voltmeter has resistance of 50 kΩ on the 5.0-V scale. What voltage does the meter read when connected across $R_1$, Fig. 26–31b, and what error is caused by the meter's finite resistance?

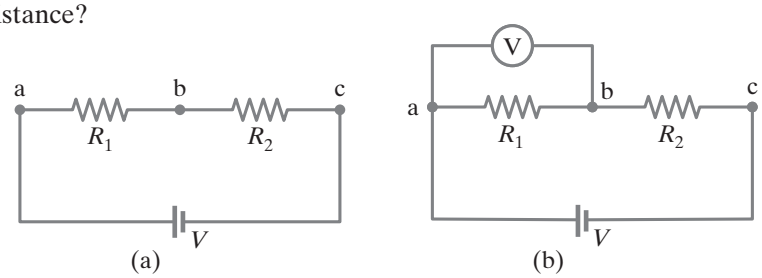

**FIGURE 26–31** Example 26–16.

**APPROACH** The meter acts as a resistor in parallel with $R_1$. We use parallel and series resistor analyses and Ohm's law to find currents and voltages.

**SOLUTION** The voltmeter resistance of 50,000 Ω is in parallel with $R_1 = 15\,\text{k}\Omega$, Fig. 26–31b. The net resistance $R_{\text{eq}}$ of these two is

$$\frac{1}{R_{\text{eq}}} = \frac{1}{50\,\text{k}\Omega} + \frac{1}{15\,\text{k}\Omega} = \frac{13}{150\,\text{k}\Omega};$$

so $R_{\text{eq}} = 11.5\,\text{k}\Omega$. This $R_{\text{eq}} = 11.5\,\text{k}\Omega$ is in series with $R_2 = 15\,\text{k}\Omega$, so the total resistance is now $26.5\,\text{k}\Omega$ (not the original $30\,\text{k}\Omega$). Hence the current from the battery is

$$I = \frac{8.0\,\text{V}}{26.5\,\text{k}\Omega} = 3.0 \times 10^{-4}\,\text{A} = 0.30\,\text{mA}.$$

Then the voltage drop across $R_1$, which is the same as that across the voltmeter, is $(3.0 \times 10^{-4}\,\text{A})(11.5 \times 10^{3}\,\Omega) = 3.5\,\text{V}$. [The voltage drop across $R_2$ is $(3.0 \times 10^{-4}\,\text{A})(15 \times 10^{3}\,\Omega) = 4.5\,\text{V}$, for a total of 8.0 V.] If we assume the meter is accurate, it reads 3.5 V. In the original circuit, without the meter, $R_1 = R_2$ so the voltage across $R_1$ is half that of the battery, or 4.0 V. Thus the voltmeter, because its internal resistance is not very large (a cheap meter), gives a low reading. It is off by 0.5 V, or more than 10%.

**NOTE** Often the **sensitivity** of a voltmeter is specified on its face as, for example, 10,000 Ω/V. Then on a 5.0-V scale, the voltmeter would have a resistance given by $(5.0\,\text{V})(10{,}000\,\Omega/\text{V}) = 50{,}000\,\Omega$. The meter's resistance depends on the scale used. Set on a 100-V scale, that meter would have an internal resistance of 1 MΩ.

Example 26–16 illustrates how seriously a meter can affect a circuit and give a misleading reading. If the resistance of a voltmeter is much higher than the resistance of the circuit, however, it will have little effect and its readings can be more accurate, at least to the manufactured precision of the meter, which for analog meters is typically 3% to 4% of full-scale deflection. Even an ammeter can interfere with a circuit, but the effect is minimal if its resistance is much less than that of the circuit as a whole. For both voltmeters and ammeters, the more sensitive the galvanometer, the less effect it will have on the circuit. [A 50,000-Ω/V meter is far better than a 1000-Ω/V meter.]

Whenever we make a measurement on a circuit, to some degree we affect that circuit (Example 26–16). This is true for other types of measurement as well: when we make a measurement on a system, we affect that system in some way. On a temperature measurement, for example, the thermometer can exchange heat with the system, thus altering the temperature it is measuring. It is important to be able to make needed corrections, as we saw in Example 26–16.

**⚠ CAUTION**
*Measurements affect the quantity being measured*

## Other Meters

The meters described above are for direct current. A dc meter can be modified to measure ac (alternating current, Section 25–7) with the addition of diodes (Chapter 40), which allow current to flow in one direction only. An ac meter can be calibrated to read rms or peak values.

Voltmeters and ammeters can have several series or shunt resistors to offer a choice of range. **Multimeters** can measure voltage, current, and resistance. Sometimes a multimeter is called a VOM (Volt-Ohm-Meter or Volt-Ohm-Milliammeter).

An **ohmmeter** measures resistance, and must contain a battery of known voltage connected in series to a resistor $(R_{\text{ser}})$ and to an ammeter which contains a shunt $R_{\text{sh}}$ (Fig. 26–32). The resistor whose resistance is to be measured completes the circuit, and must not be connected in a circuit containing a voltage source. The needle deflection of the meter is inversely proportional to the resistance.

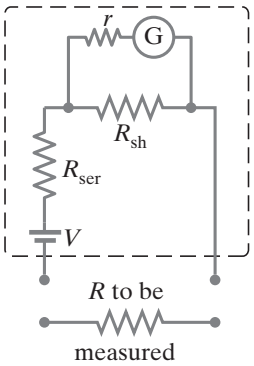

**FIGURE 26–32** An ohmmeter.

The scale calibration depends on the value of its series resistor, which is changeable in a multimeter. Because an ohmmeter sends a current through the device whose resistance is to be measured, it should not be used on very delicate devices that could be damaged by the current.

### Digital Meters

Digital meters (see Fig. 26–27b) are used in the same way as analog meters: they are inserted directly into the circuit, in series, to measure current (Fig. 26–30b), and connected "outside," in parallel with the circuit, to measure voltage (Fig. 26–30c).

The internal construction of digital meters is very different from analog meters. First, digital meters do not use a galvanometer, but rather semiconductor devices (Chapter 40). The electronic circuitry and digital readout are more sensitive than a galvanometer, and have less effect on the circuit to be measured. When we measure dc voltages, a digital voltmeter's resistance is very high, commonly on the order of 10 MΩ to 100 MΩ $(10^7$–$10^8\ \Omega)$, and doesn't change significantly when different voltage scales are selected. A 100-MΩ digital meter draws very little current when connected across even a 1-MΩ (one megaohm) resistance.

The precision of digital meters is exceptional, often one part in $10^4$ $(=0.01\%)$ or better. This precision is not the same as accuracy, however. A precise meter of internal resistance $10^8\ \Omega$ will not give accurate results if used to measure a voltage across a $10^8$-Ω resistor—in which case it is necessary to do a calculation like that in Example 26–16.

## Summary

A device that transforms another type of energy into electrical energy is called a **source** of **emf**. A battery behaves like a source of emf in series with an **internal resistance**. The emf is the potential difference determined by the chemical reactions in the battery and equals the terminal voltage when no current is drawn. When a current is drawn, the voltage at the battery's terminals is less than its emf by an amount equal to the potential decrease $Ir$ across the internal resistance.

When resistances are connected in **series** (end to end in a single linear path), the equivalent resistance is the sum of the individual resistances:

$$R_{\text{eq}} = R_1 + R_2 + \cdots . \qquad \textbf{(26–3)}$$

In a series combination, $R_{\text{eq}}$ is greater than any component resistance.

When resistors are connected in **parallel**, it is the reciprocals that add up:

$$\frac{1}{R_{\text{eq}}} = \frac{1}{R_1} + \frac{1}{R_2} + \cdots . \qquad \textbf{(26–4)}$$

In a parallel connection, the net resistance is less than any of the individual resistances, even the smallest one.

**Kirchhoff's rules** are useful in determining the currents and voltages in circuits. Kirchhoff's **junction rule** is based on conservation of electric charge and states that the sum of all currents entering any junction equals the sum of all currents leaving that junction. The second, or **loop rule**, is based on conservation of energy and states that the algebraic sum of the changes in electric potential around any closed path of the circuit must be zero.

When an ***RC* circuit** containing a resistor $R$ in series with a capacitance $C$ is connected to a dc source of emf, the voltage across the capacitor rises gradually in time characterized by an exponential of the form $(1 - e^{-t/RC})$, where the **time constant**

$$\tau = RC \qquad \textbf{(26–7)}$$

is the time it takes for the voltage to reach 63% of its maximum value.

A capacitor discharging through a resistor is characterized by the same time constant: in a time $\tau = RC$, the voltage across the capacitor drops to 37% of its initial value. The charge on the capacitor, and the voltage across it, decrease as $e^{-t/RC}$.

Electric shocks are caused by current passing through the body. To avoid shocks, your body must not become part of a complete circuit by allowing different parts of your body to touch objects at different potentials. Commonly, shocks are caused by one part of your body touching ground $(V = 0)$ and another part touching a nonzero electric potential.

An **ammeter** measures current. An analog ammeter consists of a galvanometer and a parallel **shunt resistor** that carries most of the current. An analog **voltmeter** consists of a galvanometer and a series resistor. An ammeter is inserted *into* the circuit whose current is to be measured. A voltmeter is external, being connected in parallel to the element whose voltage is to be measured. Digital voltmeters have greater internal resistance and so affect the circuit to be measured less than do analog meters.

# Questions

1. Explain why birds can sit on power lines safely, even though the wires have no insulation around them, whereas leaning a metal ladder up against a power line is extremely dangerous.
2. Discuss the advantages and disadvantages of Christmas tree lights connected in parallel versus being connected in series.
3. If all you have is a 120-V line, would it be possible to light several 6-V lamps without burning them out? How?
4. Two lightbulbs of resistance $R_1$ and $R_2$ $(R_2 > R_1)$ and a battery are all connected in series. Which bulb is brighter? What if they are connected in parallel? Explain.
5. Household outlets are often double outlets. Are these connected in series or parallel? How do you know?
6. With two identical lightbulbs and two identical batteries, explain how and why you would arrange the bulbs and batteries in a circuit to get the maximum possible total power to the lightbulbs. (Ignore internal resistance of batteries.)
7. If two identical resistors are connected in series to a battery, does the battery have to supply more power or less power than when only one of the resistors is connected? Explain.
8. You have a single 60-W bulb lit in your room. How does the overall resistance of your room's electric circuit change when you turn on an additional 100-W bulb? Explain.
9. Compare and discuss the formulas for resistors and for capacitors (Section 24–3) when connected in series and in parallel.
10. When applying Kirchhoff's loop rule (such as in Fig. 26–33), does the sign (or direction) of a battery's emf depend on the direction of current through the battery? What about the terminal voltage?

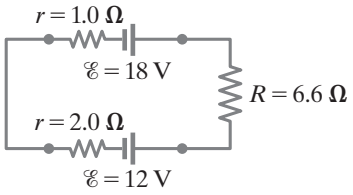

**FIGURE 26–33**
Question 10.

11. Different lamps might have batteries connected in either of the two arrangements shown in Fig. 26–34. What would be the advantages of each scheme?

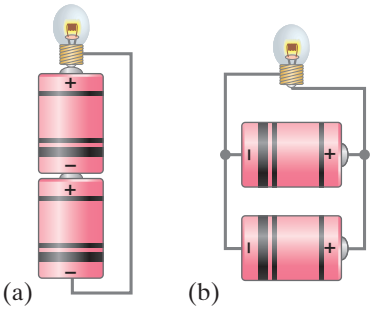

**FIGURE 26–34**
Question 11.

12. For what use are batteries connected in series? For what use are they connected in parallel? Does it matter if the batteries are nearly identical or not in either case?
13. Can the terminal voltage of a battery ever exceed its emf? Explain.
14. Explain in detail how you could measure the internal resistance of a battery.
15. In an *RC* circuit, current flows from a battery until the capacitor is completely charged. Is the total energy supplied by the battery equal to the total energy stored by the capacitor? If not, where does the extra energy go?
16. Given the circuit shown in Fig. 26–35, use the words "increases," "decreases," or "stays the same" to complete the following statements:
    (*a*) If $R_7$ increases, the potential difference between A and E _____. Assume no resistance in Ⓐ and ℰ.
    (*b*) If $R_7$ increases, the potential difference between A and E _____. Assume Ⓐ and ℰ have resistance.
    (*c*) If $R_7$ increases, the voltage drop across $R_4$ _____.
    (*d*) If $R_2$ decreases, the current through $R_1$ _____.
    (*e*) If $R_2$ decreases, the current through $R_6$ _____.
    (*f*) If $R_2$ decreases, the current through $R_3$ _____.
    (*g*) If $R_5$ increases, the voltage drop across $R_2$ _____.
    (*h*) If $R_5$ increases, the voltage drop across $R_4$ _____.
    (*i*) If $R_2$, $R_5$, and $R_7$ increase, ℰ $(r = 0)$ _____.

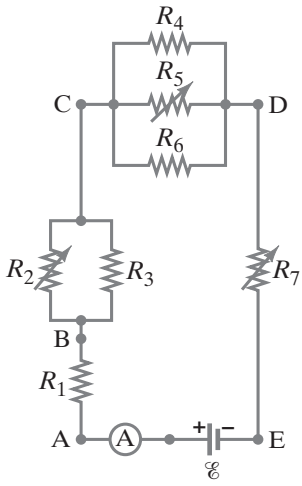

**FIGURE 26–35**
Question 16. $R_2$, $R_5$, and $R_7$ are **variable resistors** (you can change their resistance); they are, given the symbol ⟋.

17. Design a circuit in which two different switches of the type shown in Fig. 26–36 can be used to operate the same lightbulb from opposite sides of a room.

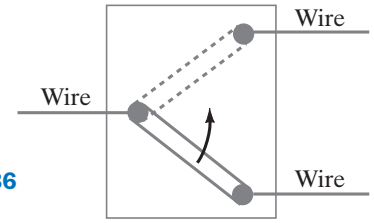

**FIGURE 26–36**
Question 17.

18. Why is it more dangerous to turn on an electric appliance when you are standing outside in bare feet than when you are inside wearing shoes with thick soles?
19. What is the main difference between an analog voltmeter and an analog ammeter?
20. What would happen if you mistakenly used an ammeter where you needed to use a voltmeter?
21. Explain why an ideal ammeter would have zero resistance and an ideal voltmeter infinite resistance.
22. A voltmeter connected across a resistor always reads *less* than the actual voltage (i.e., when the meter is not present). Explain.
23. A small battery-operated flashlight requires a single 1.5-V battery. The bulb is barely glowing. But when you take the battery out and check it with a digital voltmeter, it registers 1.5 V. How would you explain this?

# MisConceptual Questions

**1.** In which circuits shown in Fig. 26–37 are resistors connected in series?

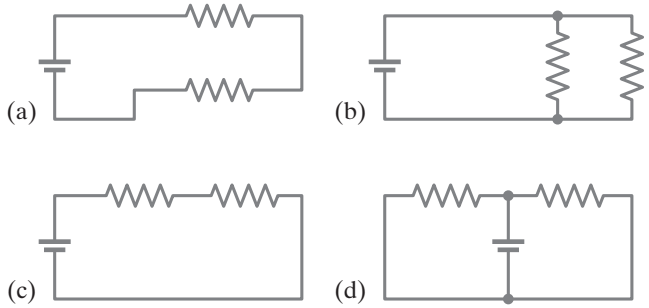

**FIGURE 26–37** MisConceptual Question 1.

**2.** Which resistors in Fig. 26–38 are connected in parallel?
(*a*) All three.
(*b*) $R_1$ and $R_2$.
(*c*) $R_2$ and $R_3$.
(*d*) $R_1$ and $R_3$.
(*e*) None of the above.

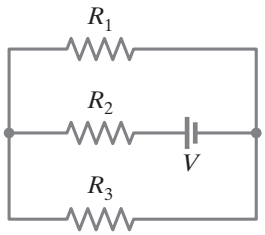

**FIGURE 26–38** MisConceptual Question 2.

**3.** A 10,000-Ω resistor is placed in series with a 100-Ω resistor. The current in the 10,000-Ω resistor is 10 A. If the resistors are swapped, how much current flows through the 100-Ω resistor?
(*a*) >10 A.
(*b*) <10 A.
(*c*) 10 A.
(*d*) Need more information about the circuit.

**4.** Figure 26–39 shows three identical bulbs in a circuit. What happens to the brightness of bulb A if you replace bulb B with just a connecting wire?
(*a*) Bulb A gets brighter.
(*b*) Bulb A gets dimmer.
(*c*) Bulb A's brightness does not change.
(*d*) Bulb A goes out.

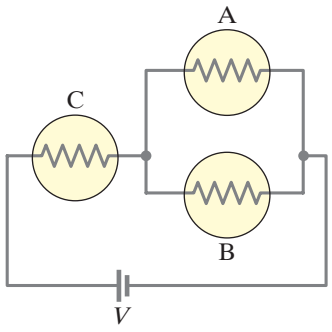

**FIGURE 26–39** MisConceptual Question 4.

**5.** When the switch shown in Fig. 26–40 is closed, what will happen to the voltage across resistor $R_4$? It will
(*a*) increase.
(*b*) decrease.
(*c*) stay the same.

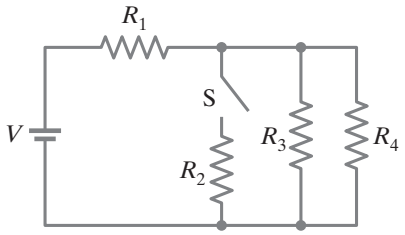

**FIGURE 26–40** MisConceptual Questions 5 and 6.

**6.** When the switch shown in Fig. 26–40 is closed, what will happen to the voltage across resistor $R_1$? It will
(*a*) increase.
(*b*) decrease.
(*c*) stay the same.

**7.** As a capacitor is being charged in an *RC* circuit, the current flowing through the resistor is
(*a*) increasing.
(*b*) decreasing.
(*c*) constant.
(*d*) zero.

**8.** For the circuit shown in Fig. 26–41, what happens when the switch S is closed?
(*a*) Nothing. Current cannot flow through the capacitor.
(*b*) The capacitor immediately charges up to the battery emf.
(*c*) The capacitor eventually charges up to the full battery emf at a rate determined by *R* and *C*.
(*d*) The capacitor charges up to a fraction of the battery emf determined by *R* and *C*.
(*e*) The capacitor charges up to a fraction of the battery emf determined by *R* only.

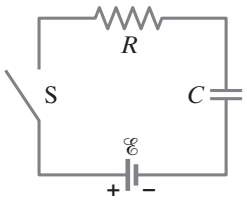

**FIGURE 26–41** MisConceptual Question 8.

**9.** Which resistor shown in Fig. 26–42 has the greatest current going through it? Assume they all have the same resistance *R*.
(*a*) $R_1$.
(*b*) $R_1$ and $R_2$.
(*c*) $R_3$ and $R_4$.
(*d*) $R_5$.
(*e*) All of them the same.

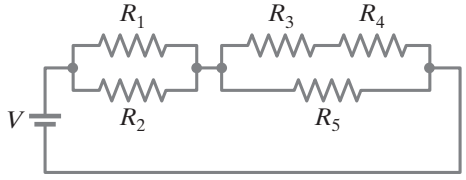

**FIGURE 26–42** MisConceptual Question 9.

**10.** The capacitor in the circuit shown in Fig. 26–43 has already been charged to an initial value $Q_0$. When the switch is closed, it discharges through the resistor. It takes 2.0 seconds for the charge to drop to $\frac{1}{2}Q_0$. How long does it take to drop to $\frac{1}{4}Q_0$?
(*a*) 3.0 seconds.
(*b*) 4.0 seconds.
(*c*) Between 2.0 and 3.0 seconds.
(*d*) Between 3.0 and 4.0 seconds.
(*e*) More than 4.0 seconds.

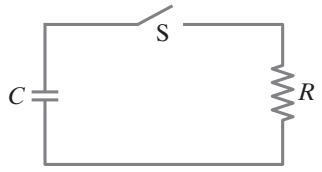

**FIGURE 26–43** MisConceptual Question 10.

**11.** A resistor and a capacitor are used in series to control the timing in the circuit of a heart pacemaker. To design a pacemaker that can double the heart rate when the patient is exercising, which statement below is true? The capacitor
(*a*) needs to discharge faster, so the resistance should be decreased.
(*b*) needs to discharge faster, so the resistance should be increased.
(*c*) needs to discharge slower, so the resistance should be decreased.
(*d*) needs to discharge slower, so the resistance should be increased.
(*e*) does not affect the timing, regardless of the resistance.

**12.** Why is an appliance cord with a three-prong plug safer than one with two prongs?
(*a*) The 120 V from the outlet is split among three wires, so it isn't as high a voltage as when it is only split between two wires.
(*b*) Three prongs fasten more securely to the wall outlet.
(*c*) The third prong grounds the case, so the case cannot reach a harmful voltage.
(*d*) The third prong acts as a ground wire, so the electrons have an easier time leaving the appliance. As a result, fewer electrons build up in the appliance.
(*e*) The third prong controls the capacitance of the appliance, so it can't build up a high voltage.

**13.** If ammeters and voltmeters are not to significantly alter the quantities they are measuring,
(*a*) the resistance of an ammeter and a voltmeter should be much higher than that of the circuit element being measured.
(*b*) the resistance of an ammeter should be much lower, and the resistance of a voltmeter should be much higher, than those of the circuit being measured.
(*c*) the resistance of an ammeter should be much higher, and the resistance of a voltmeter should be much lower, than those of the circuit being measured.
(*d*) the resistance of an ammeter and a voltmeter should be much lower than that of the circuit being measured.
(*e*) None of the above.

# Problems

## 26–1 Emf and Terminal Voltage

**1.** (I) Calculate the terminal voltage for a battery with an internal resistance of 0.900 Ω and an emf of 6.00 V when the battery is connected in series with (*a*) a 61.0-Ω resistor, and (*b*) a 610-Ω resistor.

**2.** (I) Four 1.50-V cells are connected in series to a 12-Ω lightbulb. If the resulting current is 0.47 A, what is the internal resistance of each cell, assuming they are identical and neglecting the resistance of the wires?

**3.** (II) A 1.5-V dry cell can be tested by connecting it to a low-resistance ammeter. It should be able to supply at least 25 A. What is the internal resistance of the cell in this case, assuming it is much greater than that of the ammeter?

**4.** (II) What is the internal resistance of a 12.0-V car battery whose terminal voltage drops to 8.2 V when the starter motor draws 95 A? What is the resistance of the starter?

## 26–2 Resistors in Series and Parallel

[In these Problems neglect the internal resistance of a battery unless the Problem refers to it.]

**5.** (I) A 720-Ω and an 1800-Ω resistor are connected in series with a 12-V battery. What is the voltage across the 1800-Ω resistor?

**6.** (I) Three 45-Ω lightbulbs and three 65-Ω lightbulbs are connected in series. (*a*) What is the total resistance of the circuit? (*b*) What is the total resistance if all six are wired in parallel?

**7.** (II) How many 10-Ω resistors must be connected in series to give an equivalent resistance to five 100-Ω resistors connected in parallel?

**8.** (II) Suppose that you have a 520-Ω, a 760-Ω, and a 1.20-kΩ resistor. What is (*a*) the maximum, and (*b*) the minimum resistance you can obtain by combining these?

**9.** (II) A 75-W, 120-V bulb is connected in parallel with a 25-W, 120-V bulb. What is the net resistance?

**10.** (II) Three 2.20-kΩ resistors can be connected together in four different ways, making combinations of series and/or parallel circuits. What are these four ways, and what is the net resistance in each case?

**11.** (II) A battery with an emf of 12.0 V shows a terminal voltage of 11.8 V when operating in a circuit with two lightbulbs, each rated at 3.0 W (at 12.0 V), which are connected in parallel. What is the battery's internal resistance?

**12.** (II) Eight identical bulbs are connected in series across a 120-V line. (*a*) What is the voltage across each bulb? (*b*) If the current is 0.65 A, what is the resistance of each bulb, and what is the power dissipated in each?

**13.** (II) Eight bulbs are connected in parallel to a 120-V source by two long leads of total resistance 1.4 Ω. If 210 mA flows through each bulb, what is the resistance of each, and what fraction of the total power is wasted in the leads?

**14.** (II) A close inspection of an electric circuit reveals that a 480-Ω resistor was inadvertently soldered in the place where a 330-Ω resistor is needed. How can this be fixed without removing anything from the existing circuit?

**15.** (II) Ten 7.0-W Christmas tree lights are connected in series to each other and to a 120-V source. What is the resistance of each bulb?

**16.** (II) Determine (*a*) the equivalent resistance of the circuit shown in Fig. 26–44, (*b*) the voltage across each resistor, and (*c*) the current through each resistor.

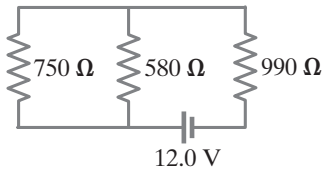

**FIGURE 26–44**
Problem 16.

**17.** (II) (*a*) Determine the equivalent resistance of the "ladder" of equal 215-Ω resistors shown in Fig. 26–45. In other words, what resistance would an ohmmeter read if connected between points A and B? (*b*) What is the current through each of the three resistors on the left if a 50.0-V battery is connected between points A and B?

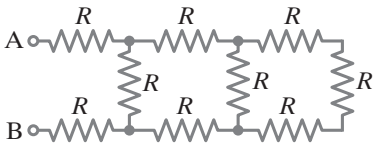

**FIGURE 26–45**
Problem 17.

**18.** (II) What is the net resistance of the circuit connected to the battery in Fig. 26–46?

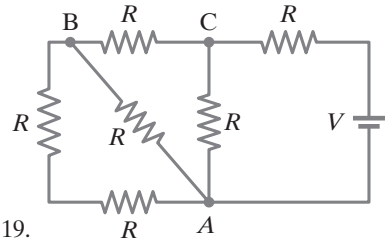

**FIGURE 26–46**
Problems 18 and 19.

**19.** (II) Calculate the current through each resistor in Fig. 26–46 if each resistance $R = 4.25\,\text{k}\Omega$ and $V = 12.0\,\text{V}$. What is the potential difference between points A and B?

**20.** (II) A power supply has a fixed output voltage of 12.0 V, but you need $V_T = 3.0\,\text{V}$ output for an experiment. (*a*) Using the **voltage divider** shown in Fig. 26–47, what should $R_2$ be if $R_1$ is 16.5 Ω? (*b*) What will the terminal voltage $V_T$ be if you connect a load to the 3.0-V output, assuming the load has a resistance of 7.0 Ω?

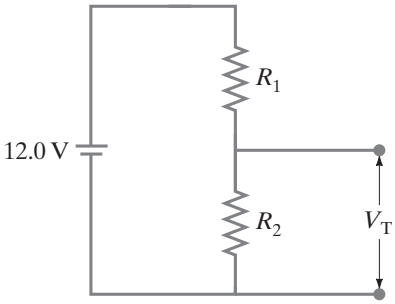

**FIGURE 26–47**
Problem 20.

**21.** (II) Suppose that you have a 9.0-V battery and wish to apply a voltage of only 3.5 V. Given an unlimited supply of 1.0-Ω resistors, how could you connect them to make a "voltage divider" that produces a 3.5-V output for a 9.0-V input?

**22.** (III) Two resistors when connected in series to a 120-V line use one-fourth the power that is used when they are connected in parallel. If one resistor is 4.3 kΩ, what is the resistance of the other?

**23.** (III) A 2.5-kΩ and a 3.7-kΩ resistor are connected in parallel; this combination is connected in series with a 1.4-kΩ resistor. If each resistor is rated at 1.0 W (maximum without overheating), what is the maximum voltage that can be applied across the whole network?

**24.** (III) Three equal resistors ($R$) are connected to a battery as shown in Fig. 26–48. Qualitatively, what happens to (*a*) the voltage drop across each of these resistors, (*b*) the current flow through each, and (*c*) the terminal voltage of the battery, when the switch S is opened, after having been closed for a long time? (*d*) If the emf of the battery is 9.0 V, what is its terminal voltage when the switch is closed if the internal resistance $r$ is 0.40 Ω and $R = 5.50\,\Omega$? (*e*) What is the terminal voltage when the switch is open?

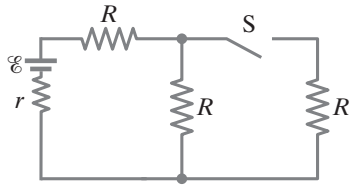

**FIGURE 26–48**
Problem 24.

**25.** (III) Consider the network of resistors shown in Fig. 26–49. Answer qualitatively: (*a*) What happens to the voltage across each resistor when the switch S is closed? (*b*) What happens to the current through each when the switch is closed? (*c*) What happens to the power output of the battery when the switch is closed? (*d*) Let $R_1 = R_2 = R_3 = R_4 = 135\,\Omega$ and $V = 22.0\,\text{V}$. Determine the current through each resistor before and after closing the switch. Are your qualitative predictions confirmed?

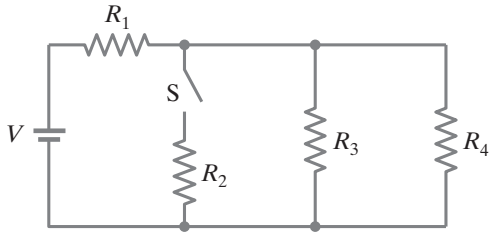

**FIGURE 26–49**
Problem 25.

**26.** (III) You are designing a wire resistance heater to heat an enclosed container of gas. For the apparatus to function properly, this heater must transfer heat to the gas at a very constant rate. While in operation, the resistance of the heater will always be close to the value $R = R_0$, but may fluctuate slightly causing its resistance to vary a small amount $\Delta R$ ($\ll R_0$). To maintain the heater at constant power, you design the circuit shown in Fig. 26–50, which includes two resistors, each of resistance $R'$. Determine the value for $R'$ so that the heater power $P$ will remain constant even if its resistance $R$ fluctuates by a small amount. [*Hint*: If $\Delta R \ll R_0$, then $\Delta P \approx \Delta R \left.\frac{dP}{dR}\right|_{R=R_0}$.]

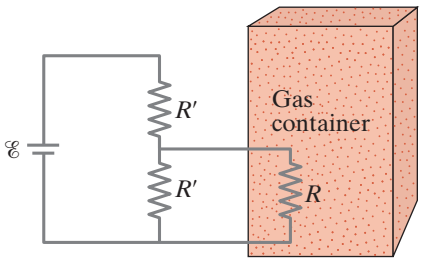

**FIGURE 26–50**
Problem 26.

## 26–3 Kirchhoff's Rules

**27.** (I) Calculate the current in the circuit of Fig. 26–51, and show that the sum of all the voltage changes around the circuit is zero.

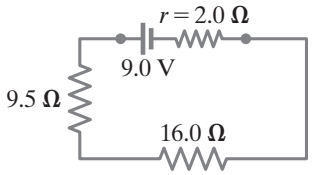

**FIGURE 26–51**
Problem 27.

**28.** (II) Determine the terminal voltage of each battery in Fig. 26–52.

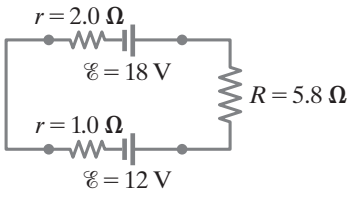

**FIGURE 26–52**
Problem 28.

**29.** (II) For the circuit shown in Fig. 26–53, find the potential difference between points a and b. Each resistor has $R = 180\ \Omega$ and each battery is 1.5 V.

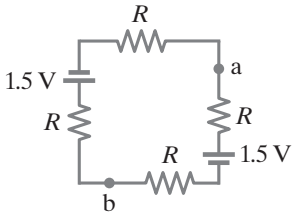

**FIGURE 26–53**
Problem 29.

**30.** (II) Calculate the magnitude and direction of the currents in each resistor of Fig. 26–54.

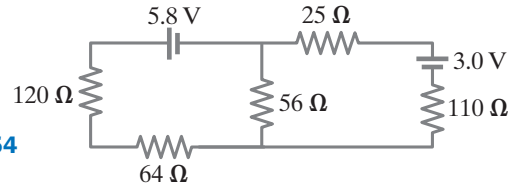

**FIGURE 26–54**
Problem 30.

**31.** (II) (*a*) What is the potential difference between points a and d in Fig. 26–55 (similar to Fig. 26–12, Example 26–8), and (*b*) what is the terminal voltage of each battery?

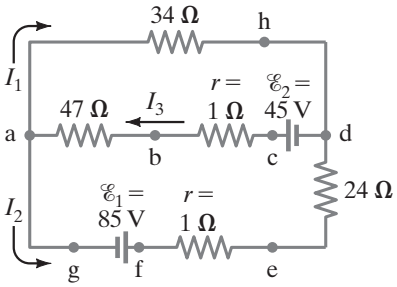

**FIGURE 26–55**
Problem 31.

**32.** (II) Determine the magnitudes and directions of the currents through $R_1$ and $R_2$ in Fig. 26–56.

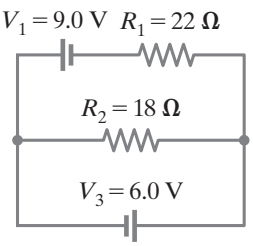

**FIGURE 26–56**
Problems 32 and 33.

**33.** (II) Repeat Problem 32, now assuming that each battery has an internal resistance $r = 1.2\ \Omega$.

**34.** (II) Determine the magnitudes and directions of the currents in each resistor shown in Fig. 26–57. The batteries have emfs of $\mathscr{E}_1 = 9.0$ V and $\mathscr{E}_2 = 12.0$ V and the resistors have values of $R_1 = 25\ \Omega$, $R_2 = 48\ \Omega$, and $R_3 = 35\ \Omega$. (*a*) Ignore internal resistance of the batteries. (*b*) Assume each battery has internal resistance $r = 1.0\ \Omega$.

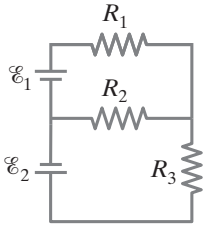

**FIGURE 26–57**
Problem 34.

**35.** (II) A voltage $V$ is applied to $n$ identical resistors connected in parallel. If the resistors are instead all connected in series with the applied voltage, show that the power transformed is decreased by a factor $n^2$.

**36.** (III) (*a*) Determine the currents $I_1$, $I_2$, and $I_3$ in Fig. 26–58. Assume the internal resistance of each battery is $r = 1.0\ \Omega$. (*b*) What is the terminal voltage of the 6.0-V battery?

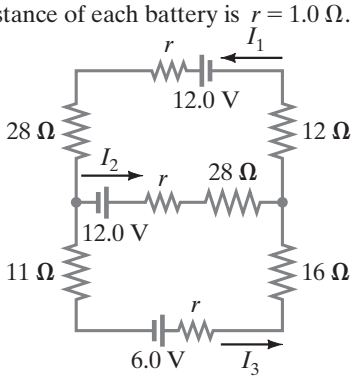

**FIGURE 26–58**
Problems 36 and 37.

**37.** (III) What would the current $I_1$ be in Fig. 26–58 if the 12-Ω resistor is shorted out (resistance = 0)? Let $r = 1.0\ \Omega$.

**38.** (III) Determine the current through each of the resistors in Fig. 26–59.

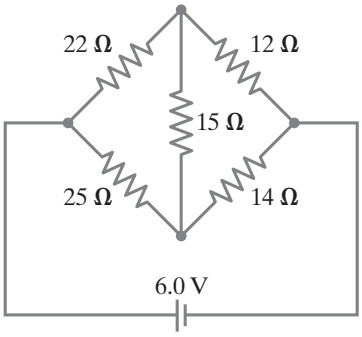

**FIGURE 26–59**
Problems 38 and 39.

**39.** (III) If the 25-Ω resistor in Fig. 26–59 is shorted out (resistance = 0), what then would be the current through the 15-Ω resistor?

**40.** (III) Twelve resistors, each of resistance $R$, are connected at the corners of a cube as shown in Fig. 26–60. Determine the equivalent resistance (*a*) between points a and b, the ends of a side; (*b*) between points a and c, the ends of a face diagonal; (*c*) between points a and d, the ends of the volume diagonal. [*Hint*: Apply an emf between the 2 points in each case and determine currents; use symmetry at junctions.]

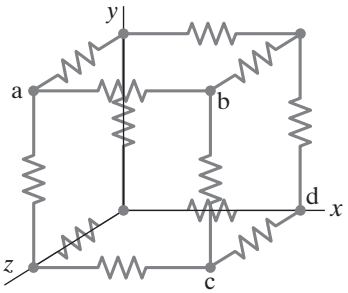

**FIGURE 26–60**
Problem 40.

**41.** (III) Determine the net resistance in Fig. 26–61 (*a*) between points a and c, and (*b*) between points a and b. Assume $R' \neq R$. [*Hint*: Apply an emf between the two points in each case and determine currents; use symmetry at junctions.]

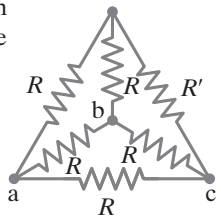

**FIGURE 26–61**
Problem 41.

**42.** (III) (*a*) A network of five equal resistors $R$ is connected to a battery $\mathscr{E}$ as shown in Fig. 26–62. Determine the current $I$ that flows out of the battery. (*b*) Use the value determined for $I$ to find the single resistor $R_{eq}$ that is equivalent to the five-resistor network.

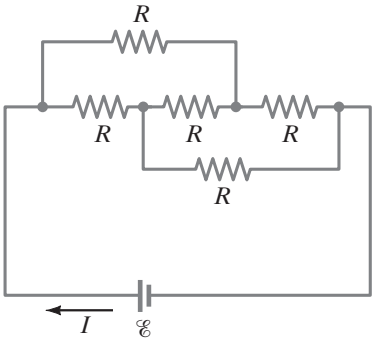

**FIGURE 26–62**
Problem 42.

## 26–4 Emfs Combined, Battery Charging

**43.** (II) Suppose two batteries, with unequal emfs of 2.00 V and 3.00 V, are connected as shown in Fig. 26–63. If each internal resistance is $r = 0.350\ \Omega$, and $R = 4.00\ \Omega$, what is the voltage across the resistor $R$?

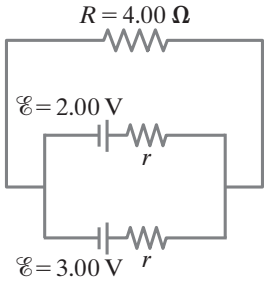

**FIGURE 26–63**
Problem 43.

## 26–5 *RC* Circuits

**44.** (I) Estimate the value of resistances needed to make a variable timer for intermittent windshield wipers: one wipe every 15 s, 8 s, 4 s, 2 s, 1 s. Assume the capacitor used is on the order of 1 $\mu$F. See Fig. 26–64.

**FIGURE 26–64** Problem 44.

**45.** (II) In Fig. 26–65 (same as Fig. 26–16a), the total resistance is 15.0 k$\Omega$, and the battery's emf is 24.0 V. If the time constant is measured to be 24.0 $\mu$s, calculate (*a*) the total capacitance of the circuit and (*b*) the time it takes for the voltage across the resistor to reach 14.0 V after the switch is closed.

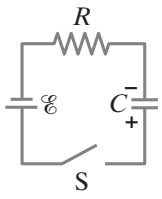

**FIGURE 26–65**
Problems 45 and 46.

**46.** (II) How long does it take for the energy stored in a capacitor in a series *RC* circuit (Fig. 26–65) to reach 75% of its maximum value? Express answer in terms of the time constant $\tau = RC$.

**47.** (II) Two 3.8-$\mu$F capacitors, two 2.2-k$\Omega$ resistors, and a 12.0-V source are connected in series. Starting from the uncharged state, how long does it take for the current to drop from its initial value to 1.35 mA?

**48.** (II) A parallel-plate capacitor is filled with a dielectric of dielectric constant $K$ and high resistivity $\rho$ (it conducts very slightly). This capacitor can be modeled as a pure capacitance $C$ in parallel with a resistance $R$. Assume a battery places a charge $+Q$ and $-Q$ on the capacitor's opposing plates and is then disconnected. Show that the capacitor discharges with a time constant $\tau = K\epsilon_0\rho$ (known as the *dielectric relaxation time*). Evaluate $\tau$ if the dielectric is glass with $\rho = 1.0 \times 10^{12}\ \Omega \cdot \text{m}$ and $K = 5.0$.

**49.** (II) The *RC* circuit of Fig. 26–66 (same as Fig. 26–17a) has $R = 8.7\ \text{k}\Omega$ and $C = 3.0\ \mu\text{F}$. The capacitor is at voltage $V_0$ at $t = 0$, when the switch is closed. How long does it take the capacitor to discharge to 0.25% of its initial voltage?

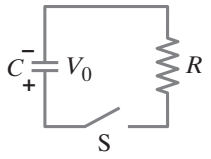

**FIGURE 26–66**
Problem 49.

**50.** (II) Consider the circuit shown in Fig. 26–67, where all resistors have the same resistance $R$. At $t = 0$, with the capacitor $C$ uncharged, the switch is closed. (*a*) At $t = 0$, the three currents can be determined by analyzing a simpler, but equivalent, circuit. Identify this simpler circuit and use it to find the values of $I_1, I_2$, and $I_3$ at $t = 0$. (*b*) At $t = \infty$, the currents can be determined by analyzing a simpler, equivalent circuit. Identify this simpler circuit and implement it in finding the values of $I_1, I_2$, and $I_3$ at $t = \infty$. (*c*) At $t = \infty$, what is the potential difference across the capacitor?

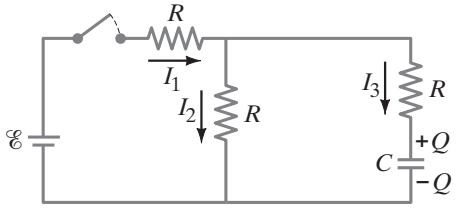

**FIGURE 26–67** Problem 50.

**51.** (II) In the circuit shown in Fig. 26–68, switch S is closed at time $t = 0$. (*a*) After the capacitor is fully charged, what is the voltage across it? How much charge is on it? (*b*) Switch S is now opened. How long does it now take for the capacitor to discharge until it has only 2.0% of its initial charge?

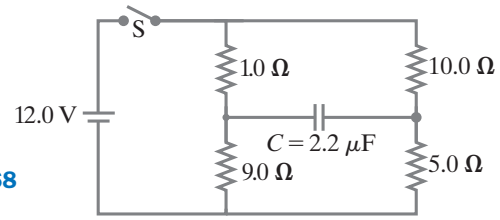

**FIGURE 26–68**
Problem 51.

**52.** (III) Determine the time constant for charging the capacitor in the circuit of Fig. 26–69. [*Hint*: Use Kirchhoff's rules.] (*b*) What is the maximum charge on the capacitor?

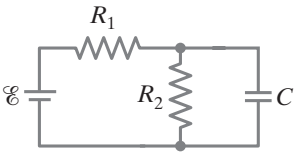

**FIGURE 26–69**
Problem 52.

**53.** (III) Two resistors and two uncharged capacitors are arranged as shown in Fig. 26–70. Then a potential difference of 24 V is applied across the combination as shown. (*a*) What is the potential at point a with switch S open? (Let $V = 0$ at the negative terminal of the source.) (*b*) What is the potential at point b with the switch open? (*c*) When the switch is closed, what is the final potential of point b? (*d*) How much charge flows through the switch S after it is closed?

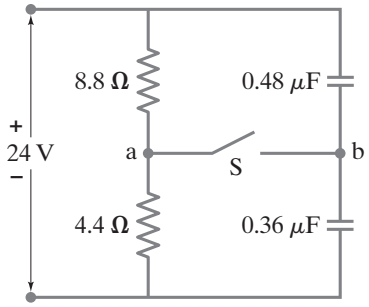

**FIGURE 26–70** Problems 53 and 54.

**54.** (III) Suppose the switch S in Fig. 26–70 is closed. What is the time constant (or time constants) for charging the capacitors after the 24 V is applied?

## 26–7 Ammeters and Voltmeters

**55.** (I) An ammeter has a sensitivity of 35,000 Ω/V. What current in the galvanometer produces full-scale deflection?

**56.** (I) What is the resistance of a voltmeter on the 250-V scale if the meter sensitivity is 35,000 Ω/V?

**57.** (II) A galvanometer has a sensitivity of 45 kΩ/V and internal resistance 20.0 Ω. How could you make this into (*a*) an ammeter that reads 1.0 A full scale, or (*b*) a voltmeter reading 1.00 V full scale?

**58.** (II) A galvanometer has an internal resistance of 32 Ω and deflects full scale for a 48-μA current. Describe how to use this galvanometer to make (*a*) an ammeter to read currents up to 25 A, and (*b*) a voltmeter to give a full scale deflection of 250 V.

**59.** (II) A particular *digital meter* is based on an electronic module that has an internal resistance of 120 MΩ and a *full-scale sensitivity* of 250 mV. Two resistors connected as shown in Fig. 26–71 can be used to change the voltage range. Assume $R_1 = 12$ MΩ. Find the value of $R_2$ that will result in a voltmeter with a full-scale range of 40 V.

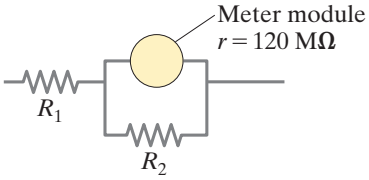

**FIGURE 26–71**
Problem 59.

**60.** (II) A milliammeter reads 25 mA full scale. It consists of a 0.20-Ω resistor in parallel with a 33-Ω galvanometer. How can you change this ammeter to a voltmeter giving a full scale reading of 25 V without taking the ammeter apart? What will be the sensitivity (Ω/V) of your voltmeter?

**61.** (II) A 35-V battery of negligible internal resistance is connected to a 44-kΩ and a 27-kΩ resistor in series. What reading will a voltmeter, of internal resistance 85 kΩ, give when used to measure the voltage across each resistor? What is the percent inaccuracy due to meter resistance for each case?

**62.** (II) An ammeter whose internal resistance is 53 Ω reads 5.25 mA when connected in a circuit containing a battery and two resistors in series whose values are 760 Ω and 480 Ω. What is the actual current when the ammeter is absent?

**63.** (II) A battery with $\mathscr{E} = 12.0$ V and internal resistance $r = 1.0$ Ω is connected to two 7.5-kΩ resistors in series. An ammeter of internal resistance 0.50 Ω measures the current, and at the same time a voltmeter with internal resistance 18 kΩ measures the voltage across one of the 7.5-kΩ resistors in the circuit. What do the ammeter and voltmeter read? What is the % "error" from the current and voltage *without* the meters?

**64.** (II) A 12.0-V battery (assume the internal resistance = 0) is connected to two resistors in series. A voltmeter whose internal resistance is 18.0 kΩ measures 5.5 V and 4.0 V, respectively, when connected across each of the resistors in turn. What is the resistance of each resistor?

**65.** (III) Two 8.4-kΩ resistors are placed in series and connected to a battery. A voltmeter of sensitivity 1000 Ω/V is on the 3.0-V scale and reads 2.3 V when placed across either resistor. What is the emf of the battery? (Ignore its internal resistance.)

**66.** (III) When the resistor $R$ in Fig. 26–72 is 45 Ω, the high-resistance voltmeter reads 9.7 V. When $R$ is replaced by a 14.0-Ω resistor, the voltmeter reading drops to 8.1 V. What are the emf and internal resistance of the battery?

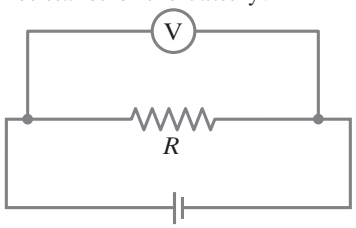

**FIGURE 26–72**
Problem 66.

**67.** (III) What internal resistance should the voltmeter of Example 26–16 have to be in error by less than 5%?

# General Problems

**68.** Suppose that you wish to apply a 0.25-V potential difference between two points on the human body. The resistance between those two points is about 1800 Ω, and you only have a 1.5-V battery. How can you connect up one or more resistors to produce the desired voltage? This is another example of a *voltage divider* (Problem 20).

**69.** Suppose you want to run some apparatus that is 45 m from an electric outlet. Each of the wires connecting your apparatus to the 120-V source has a resistance per unit length of 0.0065 Ω/m. If your apparatus draws 3.0 A, what will be the voltage drop across the connecting wires and what voltage will be applied to your apparatus?

**70.** For the circuit shown in Fig. 26–17a, show that the decrease in energy stored in the capacitor from $t = 0$ until one time constant has elapsed equals the energy dissipated as heat in the resistor.

**71.** A **Wheatstone bridge** is a type of "bridge circuit" used to make measurements of resistance. The unknown resistance to be measured, $R_x$, is placed in the circuit with accurately known resistances $R_1$, $R_2$, and $R_3$ (Fig. 26–73). One of these, $R_3$, is a variable resistor which is adjusted so that when the switch is closed momentarily, the ammeter Ⓐ shows zero current flow. (*a*) Determine $R_x$ in terms of $R_1$, $R_2$, and $R_3$. (*b*) If a Wheatstone bridge is "balanced" when $R_1 = 685\ \Omega$, $R_2 = 972\ \Omega$, and $R_3 = 78.6\ \Omega$, what is the value of the unknown resistance?

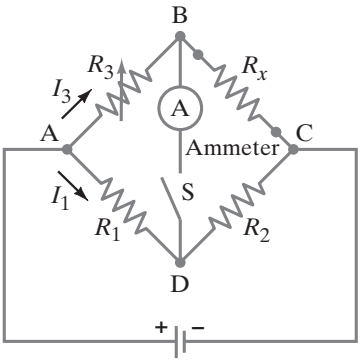

**FIGURE 26–73** Problems 71 and 72. Wheatstone bridge.

**72.** An unknown length of platinum wire 1.22 mm in diameter is placed as the unknown resistance in a Wheatstone bridge (see Problem 71, Fig. 26–73). Arms 1 and 2 have resistance of 38.0 Ω and 29.2 Ω, respectively. Balance is achieved when $R_3$ is 3.26 Ω. How long is the platinum wire?

**73.** The internal resistance of a 1.35-V mercury cell is 0.030 Ω, whereas that of a 1.5-V dry cell is 0.35 Ω. Explain why three mercury cells can more effectively power a 2.5-W hearing aid that requires 4.0 V than can three dry cells.

**74.** How many $\frac{1}{2}$-W resistors, each of the same resistance, must be used to produce an equivalent 3.2-kΩ, 4.5-W resistor? What is the resistance of each, and how must they be connected? Do not exceed $P = \frac{1}{2}$ W in each resistor. (See page 730.)

**75.** A **solar cell**, 3.0 cm square, has an output of 350 mA at 0.80 V when exposed to full sunlight. A solar panel that delivers close to 1.3 A of current at an emf of 120 V to an external load is needed. How many cells will you need to create the panel? How big a panel will you need, and how should you connect the cells to one another? How can you optimize the output of your solar panel?

**76.** A battery produces 40.8 V when 7.10 A is drawn from it, and 47.3 V when 2.80 A is drawn. What are the emf and internal resistance of the battery?

**77.** The current through the 4.0-kΩ resistor in Fig. 26–74 is 2.85 mA. What is the terminal voltage $V_{ba}$ of the "unknown" battery? (There are two answers. Why?)

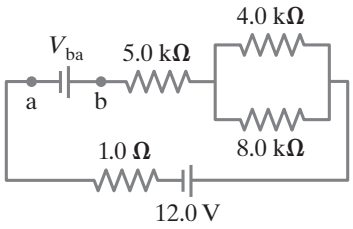

**FIGURE 26–74** Problem 77.

**78.** In the circuit shown in Fig. 26–75, the 33-Ω resistor dissipates 0.80 W. What is the battery voltage?

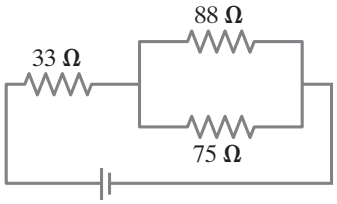

**FIGURE 26–75** Problem 78.

**79.** The current through the 20-Ω resistor in Fig. 26–76 does not change whether the two switches $S_1$ and $S_2$ are both open or both closed. Use this clue to determine the value of the unknown resistance $R$.

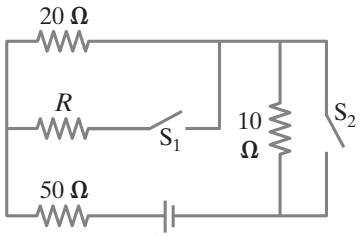

**FIGURE 26–76** Problem 79.

**80.** A **three-way lightbulb** using wire filaments can produce 50 W, 100 W, or 150 W, at 120 V. Such a bulb contains two filaments that can be connected to the 120 V individually or in parallel (Fig. 26–77). (*a*) Describe how the connections to the two filaments are made to give each of the three wattages. (*b*) What must be the resistance of each filament?

**FIGURE 26–77** Problem 80.

**81.** A 10.0-m length of wire consists of 5.0 m of copper followed by 5.0 m of aluminum, both of diameter 1.4 mm. A voltage difference of 75 mV is placed across the composite wire. (*a*) What is the total resistance (sum) of the two wires? (*b*) What is the current through the wire? (*c*) What are the voltages across the aluminum part and across the copper part?

**82.** Electrocardiographs are often connected as shown in Fig. 26–78. The lead wires to the legs are said to be capacitively coupled. A time constant of 3.0 s is typical and allows rapid changes in potential to be recorded accurately. If $C = 3.0\,\mu\text{F}$, what value must $R$ have? [*Hint*: Consider each leg as a separate circuit.]

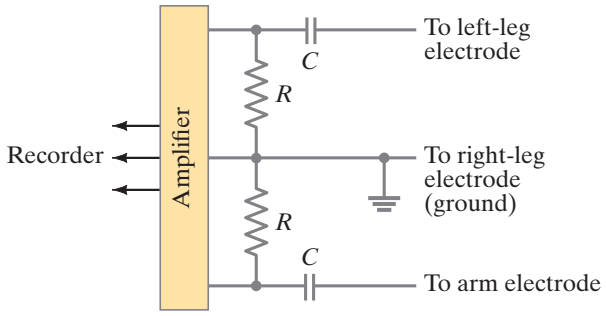

**FIGURE 26–78** Problem 82.

**83.** Electricity can be a hazard in hospitals, particularly to patients who are connected to electrodes, such as an ECG. Suppose that the motor of a motorized bed shorts out to the bed frame, and the bed frame's connection to a ground has broken (or was not there in the first place). If a nurse touches the bed and the patient at the same time, the nurse becomes a conductor and a complete circuit can be made through the patient to ground through the ECG apparatus. This is shown schematically in Fig. 26–79. Calculate the current through the patient.

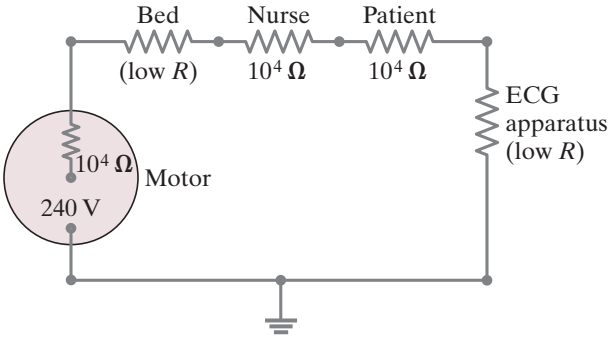

**FIGURE 26–79** Problem 83.

**84.** (*a*) What is the equivalent resistance of the circuit shown in Fig. 26–80? (*b*) What is the current in the 18-Ω resistor? (*c*) What is the current in the 12-Ω resistor? (*d*) What is the power dissipation in the 4.5-Ω resistor?

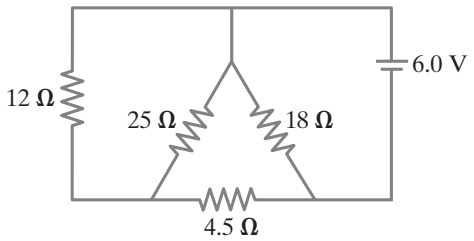

**FIGURE 26–80** Problem 84.

**85.** A flashlight bulb rated at 2.0 W and 3.0 V is operated by a 9.0-V battery. To light the bulb at its rated voltage and power, a resistor $R$ is connected in series as shown in Fig. 26–81. What value should the resistor have?

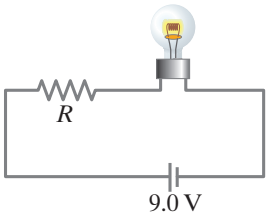

**FIGURE 26–81** Problem 85.

**86.** Some light-dimmer switches use a variable resistor as shown in Fig. 26–82. The slide moves from position $x = 0$ to $x = 1$, and the resistance up to slide position $x$ is proportional to $x$ (the total resistance is $R_{\text{var}} = 150\ \Omega$ at $x = 1$). What is the power expended in the lightbulb if (*a*) $x = 1.00$, (*b*) $x = 0.70$, (*c*) $x = 0.40$?

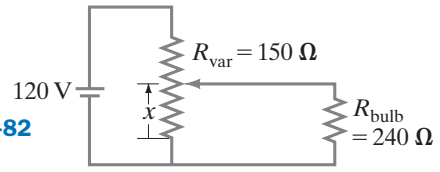

**FIGURE 26–82** Problem 86.

**87.** A heart pacemaker is designed to operate at 72 beats/min using a 5.2-$\mu$F capacitor in a simple $RC$ circuit. What value of resistance should be used if the pacemaker is to fire (capacitor discharge) when the voltage reaches 75% of maximum and then drops to 0 V (72 times a minute)?

**88.** Suppose that a person's body resistance is 950 Ω (moist skin). (*a*) What current passes through the body when the person accidentally is connected to 120 V? (*b*) If there is an alternative path to ground whose resistance is 25 Ω, what then is the current through the body? (*c*) If the voltage source can produce at most 1.5 A, how much current passes through the person in case (*b*)?

**89.** A **potentiometer** is a device to precisely measure potential differences or emf, using a "null" technique. In the simple potentiometer circuit shown in Fig. 26–83, $R'$ represents the total resistance of the resistor from A to B (which could be a long uniform "slide" wire), whereas $R$ represents the resistance of only the part from A to the movable contact at C. When the unknown emf to be measured, $\mathscr{E}_x$, is placed into the circuit as shown, the movable contact C is moved until the galvanometer G gives a null reading (i.e., zero) when the switch S is closed. The resistance between A and C for this situation we call $R_x$. Next, a standard emf, $\mathscr{E}_s$, which is known precisely, is inserted into the circuit in place of $\mathscr{E}_x$ and again the contact C is moved until zero current flows through the galvanometer when the switch S is closed. The resistance between A and C now is called $R_s$. Show that the unknown emf is given by

$$\mathscr{E}_x = \left(\frac{R_x}{R_s}\right)\mathscr{E}_s$$

where $R_x$, $R_s$, and $\mathscr{E}_s$ are all precisely known. The *working battery* (at top of circuit diagram), as well as the standard cell $\mathscr{E}_s$, are assumed to be fresh and to give a constant voltage.

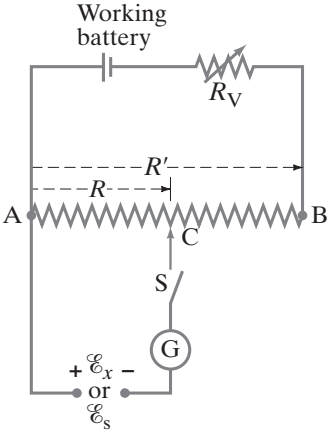

**FIGURE 26–83** Potentiometer circuit. Problem 89.

**90.** Electronic devices often use an *RC* circuit to protect against *power outages* as shown in Fig. 26–84. (*a*) If the protector circuit is supposed to keep the supply voltage at least 75% of full voltage for as long as 0.20 s, how big a resistance $R$ is needed? The capacitor is 7.6 $\mu$F. Assume the attached "electronics" draws negligible current. (*b*) Between which two terminals should the device be connected, a and b, b and c, or a and c?

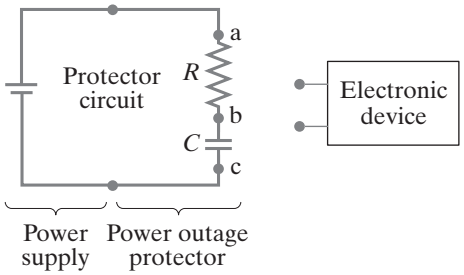

**FIGURE 26–84**
Problem 90.

**91.** (*a*) A voltmeter and an ammeter can be connected as shown in Fig. 26–85a to measure a resistance $R$. If $V$ is the voltmeter reading, and $I$ is the ammeter reading, the value of $R$ will not

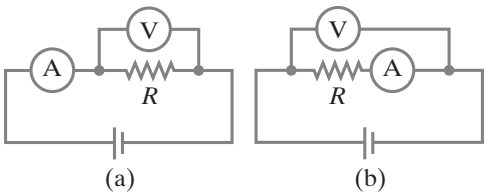

**FIGURE 26–85** Problem 91.

quite be $V/I$ (as in Ohm's law) because some current goes through the voltmeter. Show that the actual value of $R$ is

$$\frac{1}{R} = \frac{I}{V} - \frac{1}{R_V},$$

where $R_V$ is the voltmeter resistance. Note that $R \approx V/I$ if $R_V \gg R$. (*b*) A voltmeter and an ammeter can also be connected as shown in Fig. 26–85b to measure a resistance $R$. Show in this case that

$$R = \frac{V}{I} - R_A,$$

where $V$ and $I$ are the voltmeter and ammeter readings and $R_A$ is the resistance of the ammeter. Note that $R \approx V/I$ if $R_A \ll R$.

**92.** Figure 26–86 shows the circuit for a simple **sawtooth oscillator**. At time $t = 0$, its switch S is closed. The neon bulb has initially infinite resistance until the voltage across it reaches 90.0 V, and then it begins to conduct with very little resistance (essentially zero). It stops conducting (its resistance becomes essentially infinite) when the voltage drops down to 65.0 V. (*a*) At what time $t_1$ does the neon bulb reach 90.0 V and start conducting? (*b*) At what time $t_2$ does the bulb reach 90.0 V for a second time and again become conducting? (*c*) Sketch the sawtooth waveform between $t = 0$ and $t = 0.70$ s.

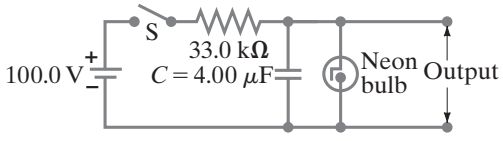

**FIGURE 26–86** Problem 92.

**93.** For the circuit shown in Fig. 26–87, determine (*a*) the current through the 16-V battery and (*b*) the potential difference between points a and b, $V_a - V_b$.

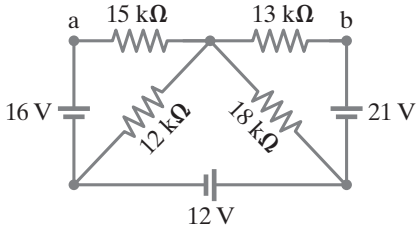

**FIGURE 26–87**
Problem 93.

**94.** The performance of the starter circuit in a car can be significantly degraded by a small amount of *corrosion* on a *battery terminal*. Figure 26–88a depicts a properly functioning circuit with a battery (12.5-V emf, 0.02-Ω internal resistance) attached via corrosion-free cables to a starter motor of resistance $R_s = 0.15\ \Omega$. Sometime later, corrosion between a battery terminal and a starter cable introduces an extra series resistance of only $R_C = 0.10\ \Omega$ into the circuit as suggested in Fig. 26–88b. Let $P_0$ be the power delivered to the starter in the circuit free of corrosion, and let $P$ be the power delivered to the starter with corrosion. Determine the ratio $P/P_0$.

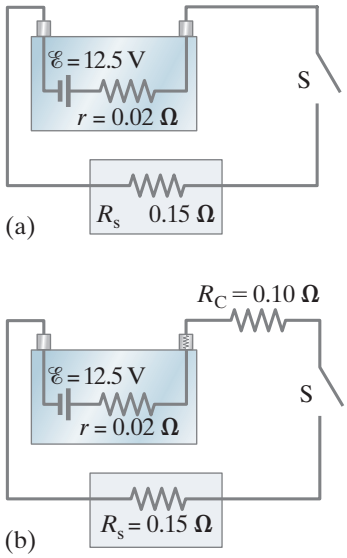

**FIGURE 26–88**
Problem 94.

**95.** The circuit shown in Fig. 26–89 is a primitive 4-bit **digital-to-analog converter (DAC)**. In this circuit, to represent each digit ($2^n$) of a binary number, a "1" has the $n^{\text{th}}$ switch closed whereas zero ("0") has the switch open. For example, 0010 is represented by closing switch $n = 1$, while all other switches are open. Show that the voltage $V$ across the 1.0-Ω resistor for the binary numbers 0001, 0010, 0100, and 1010 (which represent 1, 2, 4, 10) follows the pattern that you expect for a 4-bit DAC.

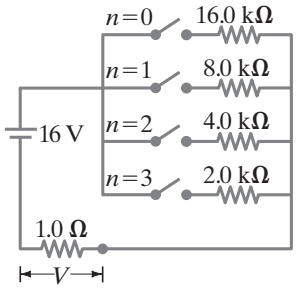

**FIGURE 26–89**
Problem 95.

**96.** *Cardiac defibrillators* are discussed in Section 24–4. (*a*) Choose a value for the resistance so that the 1.4-$\mu$F capacitor can be charged to 3100 V in 2.0 seconds. Assume that this 3100 V is 95% of the full source voltage. (*b*) The effective resistance of the human body is given in Section 26–6. If the defibrillator discharges with a time constant of 12 ms, what is the effective capacitance of the human body?

**97.** Determine the current in each resistor of the circuit shown in Fig. 26–90.

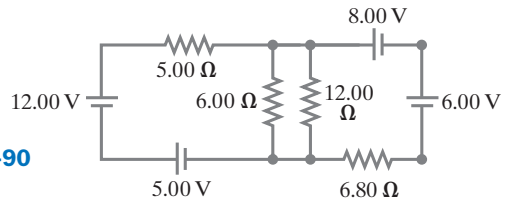

**FIGURE 26–90**
Problem 97.

**98.** The circuit shown in Fig. 26–91 uses a neon-filled tube as in Fig. 26–20a. This neon lamp has a threshold voltage $V_0$ for conduction, because no current flows until the neon gas in the tube is ionized by a sufficiently strong electric field. Once the threshold voltage $V_0$ is exceeded, the lamp has negligible resistance. The capacitor stores electrical energy, which can be released to flash the lamp. Assume that $C = 0.150\,\mu\text{F}$, $R = 2.15 \times 10^6\,\Omega$, $V_0 = 90.0\,\text{V}$, and $\mathcal{E} = 105\,\text{V}$. (*a*) Assuming the circuit is hooked up to the emf at time $t = 0$, at what time will the light first flash? (*b*) If the value of $R$ is increased, will the time you found in part (*a*) increase or decrease? (*c*) The flashing of the lamp is very brief. Why? (*d*) Explain what happens after the lamp flashes for the first time (see Fig. 26–20 and the text that refers to it).

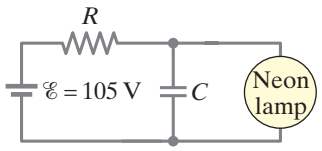

**FIGURE 26–91**
Problem 98.

**99.** Measurements made on circuits that contain large resistances can be confusing. Consider a circuit powered by a battery $\mathcal{E} = 15.000\,\text{V}$ with a 10.00-MΩ resistor in series with an unknown resistor $R$. As shown in Fig. 26–92, a particular voltmeter reads $V_1 = 366\,\text{mV}$ when connected across the 10.00-MΩ resistor, and this meter reads $V_2 = 7.317\,\text{V}$ when connected across $R$. Determine the value of $R$. [*Hint*: Define $R_\text{V}$ as the voltmeter's internal resistance.]

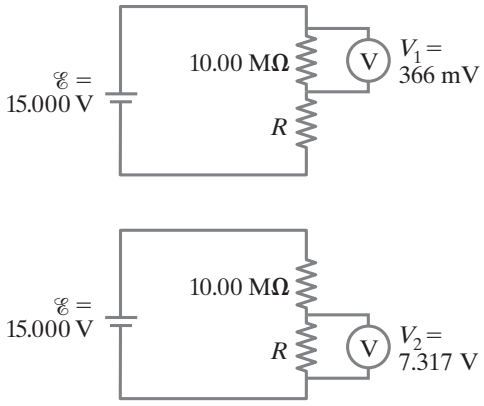

**FIGURE 26–92** Problem 99.

**100.** A typical voltmeter has an internal resistance of 10 MΩ and can only measure potential differences of up to several hundred volts. Figure 26–93 shows the design of a probe to measure a very high voltage $V$ using a voltmeter. If you want the voltmeter to read 50 V when $V = 50\,\text{kV}$, what value $R$ should be used in this probe?

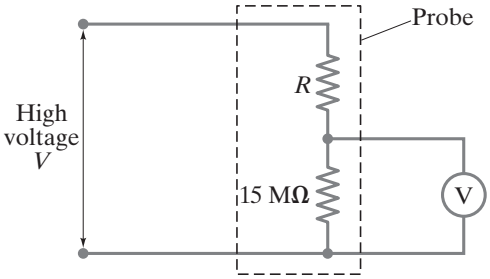

**FIGURE 26–93** Problem 100.

**101.** Consider two unequal resistors, of resistance $R_1$ and $R_2$, that are connected either in series or in parallel. Fill in the Table below assuming the electric potential on the low-voltage end of the combination is $V_\text{A}$ volts and the potential at the high-voltage end of the combination is $V_\text{B}$ volts. First draw diagrams.

| Property | Resistors are in Series | Resistors are in Parallel |
|---|---|---|
| Equivalent resistance | | |
| Current through equivalent resistance | | |
| Voltage across equivalent resistance | | |
| Voltage across the pair of resistors | | |
| Voltage across each resistor | $V_1 =$<br>$V_2 =$ | $V_1 =$<br>$V_2 =$ |
| Voltage at a point between the resistors | | Not applicable |
| Current through each resistor | $I_1 =$<br>$I_2 =$ | $I_1 =$<br>$I_2 =$ |

## ANSWERS TO EXERCISES

**A:** 6 Ω and 25 Ω.
**B:** (*b*).
**C:** (*a*) 60-W bulb; (*b*) 100-W bulb. [Can you explain why? In (*a*), note that the resistance $R$ is higher for the 60-W bulb $(P = V^2/R)$ and recall $P = I^2R$.]
**D:** $41I_3 - 45 + 21I_2 - 80 = 0$.
**E:** 180 A; this high current through the batteries could cause them to become very hot (and dangerous—possibly exploding): the power dissipated in the weak battery would be $P = I^2r = (180\,\text{A})^2(0.10\,\Omega) = 3200\,\text{W}$!
**F:** (*a*).
**G:** $\approx 500\,\text{k}\Omega$.

Magnets produce magnetic fields, but so do electric currents. Compass needles are magnets, and they align along the direction of any magnetic field present. Here, the compasses show the presence (and direction) of a magnetic field created by a current-carrying wire. We shall see in this Chapter how magnetic field is defined, and how magnetic fields exert forces on electric currents and on charged particles. We also discuss useful applications of the interaction between magnetic fields and electric currents and moving electric charges, such as motors and loudspeakers.

**CHAPTER-OPENING QUESTION—Guess now!**

Which of the following can experience a force when placed in the magnetic field of a magnet?

**(a)** An electric charge at rest.
**(b)** A moving electric charge.
**(c)** An electric current in a wire.
**(d)** Another magnet.

The history of magnetism began thousands of years ago when, in a region of Asia Minor known as Magnesia, rocks were found that could attract each other. These rocks were called "magnets" after their place of discovery.

Not until the nineteenth century, however, was it realized that magnetism and electricity are closely related. A crucial discovery was that electric currents produce magnetic effects (we will say "magnetic fields") like magnets do. All kinds of practical devices depend on magnetism, from compasses to motors, loudspeakers, earbuds, computer memory, electric generators, and even magnetic resonance imaging (discussed in Chapter 42).

## 27–1 Magnets and Magnetic Fields

You probably have observed a magnet attract paper clips, nails, and other objects made of iron, as in Fig. 27–1. Any magnet, whether it is in the shape of a bar or a horseshoe, has two ends or faces, called **poles**, which is where the magnetic effect is strongest. If a bar magnet is suspended from a fine thread, it is found that one pole of the magnet will always point toward the north. It is not known for sure when this fact was discovered, but it is known that the Chinese were making use of it as an aid to navigation by the eleventh century and perhaps earlier. This is the principle

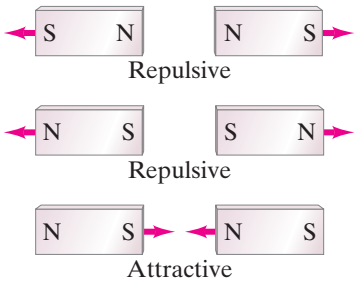
of a compass. A compass needle is simply a bar magnet which is supported at its center of gravity so that it can rotate freely. The pole of a freely suspended magnet that points toward geographic north is called the **north pole** of the magnet. The other pole points toward the south and is called the **south pole**.

It is a familiar observation that when two magnets are brought near one another, each exerts a force on the other. The force can be either attractive or repulsive and can be felt even when the magnets don't touch. If the north pole of one bar magnet is brought near the north pole of a second magnet, the force is repulsive. Similarly, if the south poles are brought close, the force is repulsive. But when the north pole of one magnet is brought near the south pole of another magnet, the force is attractive. These results are shown in Fig. 27–2, and are reminiscent of the forces between electric charges: like poles repel, and unlike poles attract. But *do not confuse magnetic poles with electric charge*. They are very different. One important difference is that a positive or negative electric charge can easily be isolated. But an isolated single magnetic pole has never been observed. If a bar magnet is cut in half, you do not obtain isolated north and south poles. Instead, two new magnets are produced, Fig. 27–3, each with north (N) and south (S) poles. If the cutting operation is repeated, more magnets are produced, each with a north and a south pole. Physicists have searched for isolated single magnetic poles (monopoles), but no **magnetic monopole** has ever been observed.

Besides iron, a few other materials, such as cobalt, nickel, gadolinium, and some of their oxides and alloys, show strong magnetic effects. They are said to be **ferromagnetic** (from the Latin word *ferrum* for iron). Other materials show some slight magnetic effect, but it is very weak and can be detected only with delicate instruments. We will look in more detail at ferromagnetism in Section 28–8.

In Chapter 21, we used the concept of an electric field surrounding an electric charge. In a similar way, we can picture a **magnetic field** surrounding a magnet. The force one magnet exerts on another magnet can then be described as the interaction between one magnet and the magnetic field of the other. Just as we drew electric field lines, we can also draw **magnetic field lines**. They can be drawn, as for electric field lines, so that

1. the direction of the magnetic field is tangent to a field line at any point, and
2. the number of lines per unit area is proportional to the strength of the magnetic field.



The *direction* of the magnetic field at a given location can be *defined* as the direction that the north pole of a compass needle would point if placed at that location. (We will give a more precise definition of magnetic field shortly.) Figure 27–4a shows how thin iron filings (acting like tiny magnets) reveal the magnetic field lines by lining up like the compass needles. The magnetic field determined in this way for the field surrounding a bar magnet is shown in Fig. 27–4b. Notice that because of our definition, the lines always point out from the north pole and in toward the south pole of a magnet (the north pole of a magnetic compass needle is attracted to the south pole of the magnet).

Magnetic field lines continue inside a magnet, as indicated in Fig. 27–4b. Indeed, given the lack of single magnetic poles, magnetic field lines always form closed loops, unlike electric field lines that begin on positive charges and end on negative charges.

**FIGURE 27–1** A horseshoe magnet attracts pins made of iron.

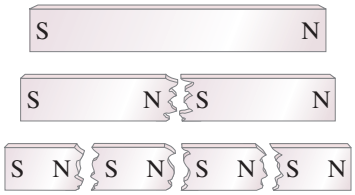


**FIGURE 27–2** Like poles of two magnets repel; unlike poles attract.

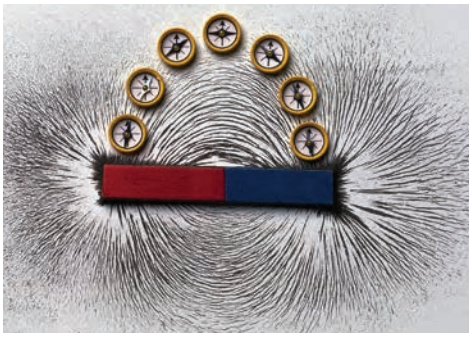
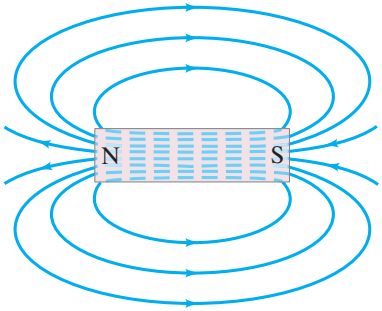
**CAUTION**



*Magnets do not attract all metals*

**FIGURE 27–3** If you split a magnet, you won't get isolated north and south poles; instead, two new magnets are produced, each with a north and a south pole.



**CAUTION**

*Magnetic field lines form closed loops, unlike electric field lines*

(a)

(b)

**FIGURE 27–4** (a) Visualizing magnetic field lines around a bar magnet, using iron filings and compass needles. The red end of the bar magnet is its north pole. The N pole of a nearby compass needle points away from the north pole of the magnet. (b) Diagram of magnetic field lines for a bar magnet.

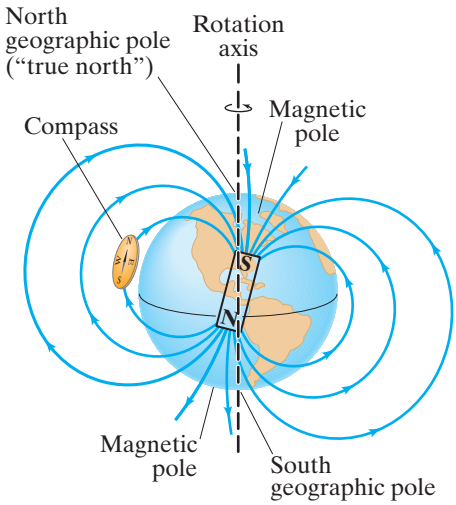


**FIGURE 27–5** The Earth acts like a huge magnet. But its magnetic poles are not at the geographic poles (on the Earth's rotation axis).

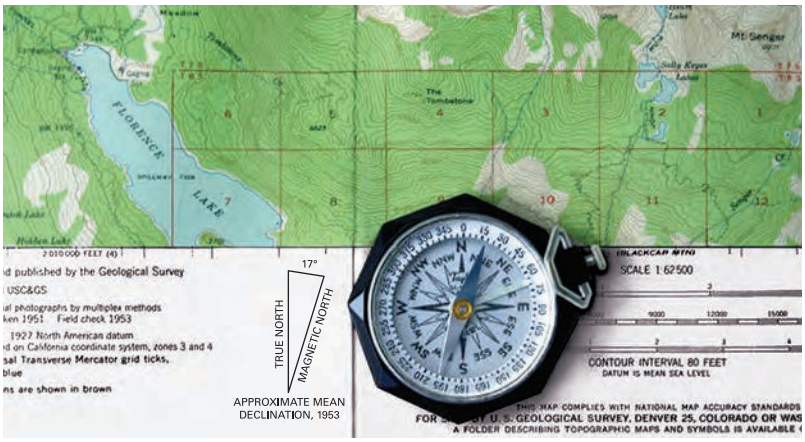
## Earth's Magnetic Field

The Earth's magnetic field is shown in Fig. 27–5, and is thought to be produced by electric currents in the Earth's molten iron outer core. The pattern of field lines is almost as though there were an imaginary bar magnet inside the Earth. Since the north pole (N) of a compass needle points north, the Earth's **magnetic pole** which is in the geographic north is magnetically a south pole, as indicated in Fig. 27–5 by the S on the schematic bar magnet inside the Earth. Remember that the north pole of one magnet is attracted to the south pole of another magnet. Nonetheless, Earth's pole in the north is still often called the "north magnetic pole," or "geomagnetic north," simply because it is in the north. Similarly, the Earth's southern magnetic pole, which is near the geographic south pole, is magnetically a north pole (N). The Earth's magnetic poles do not coincide with the **geographic poles**, which are on the Earth's axis of rotation. The north magnetic pole, for example, is in the Canadian Arctic, now on the order of 1000 km[†] from the geographic north pole, or **true north**. This difference must be taken into account for accurate use of a compass (Fig. 27–6). The angular difference between the direction of a compass needle (which points along the magnetic field lines) at any location and true (geographical) north is called the **magnetic declination**. In the U.S. it varies from 0° to about 20°, depending on location.

Notice in Fig. 27–5 that the Earth's magnetic field at most locations is not tangent to the Earth's surface. The angle that the Earth's magnetic field makes with the horizontal at any point is referred to as the **angle of dip**, or the "inclination." It is 67° at New York, for example, and 55° at Miami.

**EXERCISE A** Does the Earth's magnetic field have a greater magnitude near the poles or near the equator? [How can you tell using the field lines in Fig. 27–5?]

**PHYSICS APPLIED**
*Use of a compass*



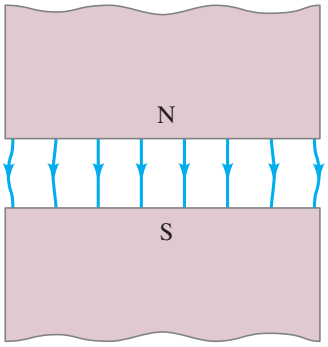


**FIGURE 27–6** Using a map and compass in the wilderness. First you align the compass case so the needle points away from true north (N) exactly the number of degrees of declination stated on the map (for this topographic map, it is 17° as shown just to the left of the compass). Then align the map with true north, as shown, *not* with the compass needle. [This is an old map (1953) of a part of California; on newer maps of this area the declination is only 13°, telling us the position of magnetic north has moved—see footnote below.]

## Uniform Magnetic Field

The simplest magnetic field is one that is uniform—it doesn't change in magnitude or direction from one point to another. A perfectly uniform field over a large area is not easy to produce. But the field between two flat parallel pole pieces of a magnet is nearly uniform if the area of the pole faces is large compared to their separation, as shown in Fig. 27–7. At the edges, the field "fringes" out somewhat: the magnetic field lines are no longer quite parallel and uniform. The parallel evenly spaced field lines in the central region of the gap indicate that the field is uniform at points not too near the edges, much like the electric field between two parallel plates (Fig. 23–16).

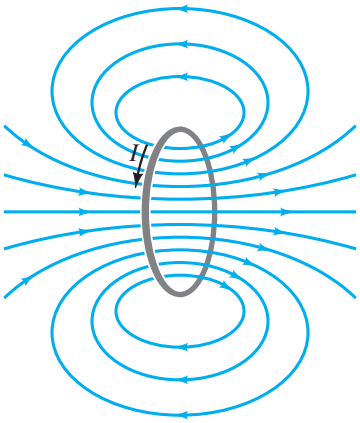
**FIGURE 27–7** Magnetic field between two wide poles of a magnet is nearly uniform, except near the edges.

[†]Earth's north magnetic pole has been moving over time, on the order of 10 km per year in recent decades. Magnetism in rocks solidified at various times in the past (age determined by radioactive dating—see Section 41–10) suggests that Earth's magnetic poles have not only moved significantly over geologic time, but have also reversed direction 400 times over the last 330 million years. Also note that a compass gives a false reading if you are standing on rock containing magnetized iron ore (as you move around, the compass needle is inconsistent).

(a) (b) (c) (d)

**FIGURE 27–8** (a) Deflection of compass needles near a current-carrying wire, showing the presence and direction of the magnetic field. (b) Iron filings also align along the direction of the magnetic field lines near a straight current-carrying wire. (c) Diagram of the magnetic field lines around an electric current in a straight wire. (d) Right-hand-rule-1 for remembering the direction of the magnetic field: when the thumb points in the direction of the conventional current, the fingers wrapped around the wire point in the direction of the magnetic field. ($\vec{\mathbf{B}}$ is the symbol for magnetic field.)

# 27–2 Electric Currents Produce Magnetic Fields



During the eighteenth century, many scientists sought to find a connection between electricity and magnetism. A stationary electric charge and a magnet were shown to have no influence on each other. But in 1820, Hans Christian Oersted (1777–1851) found that when a compass is placed near a wire, the compass needle deflects if (and only if) the wire carries an electric current. As we have seen, a compass needle is deflected by a magnetic field. So Oersted's experiment showed that **an electric current produces a magnetic field**. He had found a connection between electricity and magnetism.

A compass needle placed near a straight section of current-carrying wire experiences a force, causing the needle to align tangent to a circle around the wire, Fig. 27–8a. Thus, the magnetic field lines produced by a current in a straight wire are in the form of circles with the wire at their center, Figs. 27–8b and c. The direction of these lines is indicated by the north pole of the compasses in Fig. 27–8a. There is a simple way to remember the direction of the magnetic field lines in this case. It is called a **right-hand rule**: grasp the wire with your right hand so that your thumb points in the direction of the conventional (positive) current; then your fingers will encircle the wire in the direction of the magnetic field, Fig. 27–8d.

**Right-Hand-Rule-1:**
*Magnetic field direction produced by electric current*

The magnetic field lines due to a circular loop of current-carrying wire can be determined in a similar way by placing a compass at various locations near the loop. The result is shown in Fig. 27–9. Again the right-hand rule can be used, as shown in Fig. 27–10. Unlike the uniform field shown in Fig. 27–7, the magnetic fields shown in Figs. 27–8 and 27–9 are *not* uniform—the fields are different in magnitude and direction at different locations.

**FIGURE 27–9** Magnetic field lines due to a circular loop of wire.

**EXERCISE B** A straight wire carries a current directly toward you. In what direction are the magnetic field lines surrounding the wire?

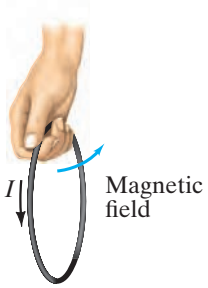


**FIGURE 27–10** Right-hand rule for determining the direction of the magnetic field relative to the current in a loop of wire.

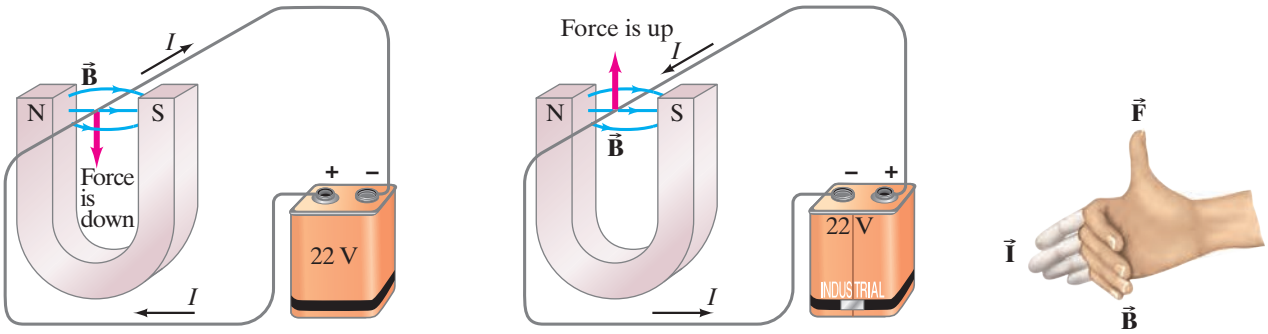

**FIGURE 27–11** (a) Force on a current-carrying wire placed in a magnetic field $\vec{\mathbf{B}}$; (b) same, but current reversed; (c) right-hand rule for setup in (b), with current $\vec{\mathbf{I}}$ shown as if a vector with direction. We call this right-hand-rule-2. (RHR-1 is shown in Fig. 27–8d.)

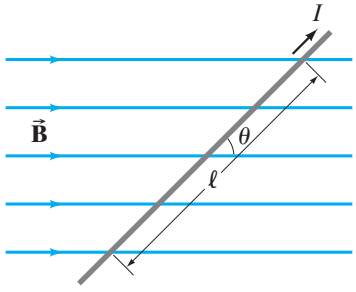
# 27–3 Force on an Electric Current in a Magnetic Field; Definition of $\vec{\mathbf{B}}$

In Section 27–2 we saw that an electric current exerts a force on a magnet, such as a compass needle. By Newton's third law, we might expect the reverse to be true as well: we should expect that *a magnet exerts a force on a current-carrying wire*. Experiments indeed confirm this effect, and it too was first observed by Oersted.

Suppose a straight wire is placed in the magnetic field between the poles of a horseshoe magnet as shown in Fig. 27–11, where the vector symbol $\vec{\mathbf{B}}$ represents the magnitude and direction of the magnetic field. When a current flows in the wire, experiment shows that a force is exerted on the wire. But this force is *not* toward one or the other pole of the magnet. Instead, the force is directed at right angles to the magnetic field direction, downward in Fig. 27–11a. If the current is reversed in direction, the force is in the opposite direction, upward as shown in Fig. 27–11b. Experiments show that *the direction of the force is always perpendicular to the direction of the current and also perpendicular to the direction of the magnetic field*, $\vec{\mathbf{B}}$.



**Right-Hand-Rule-2:**
*Force on current exerted by* $\vec{\mathbf{B}}$

The direction of the force is given by another **right-hand rule**, as illustrated in Fig. 27–11c. Orient your right hand until your outstretched fingers can point in the direction of the conventional current $I$, and when you bend your fingers they point in the direction of the magnetic field lines, $\vec{\mathbf{B}}$. Then your outstretched thumb will point in the direction of the force $\vec{\mathbf{F}}$ on the wire. We call this right-hand-rule-2 (RHR-2) to distinguish it from that shown in Fig. 27–8d (RHR-1).

This right-hand rule describes the direction of the force. What about the *magnitude* of the force on the wire? It is found experimentally that the magnitude of the force is directly proportional to the current $I$ in the wire, to the magnetic field $B$ (assumed uniform), and to the length $\ell$ of wire exposed to the magnetic field. The force also depends on the angle $\theta$ between the current direction and the magnetic field (Fig. 27–12), being proportional to $\sin\theta$. Thus, the force on a wire carrying a current $I$ with length $\ell$ in a uniform magnetic field $B$ is given by

$$F \propto I\ell B \sin\theta.$$

**FIGURE 27–12** Current-carrying wire in a magnetic field. Force on the wire is directed into the page.

When the current is perpendicular to the field lines ($\theta = 90°$ and $\sin 90° = 1$), the force is strongest. When the wire is parallel to the magnetic field lines ($\theta = 0°$), there is no force at all.

Up to now we have not defined the magnetic field strength precisely. In fact, the magnetic field $B$ can be conveniently defined in terms of the above proportion so that the proportionality constant is precisely 1. Thus we have

$$F = I\ell B \sin\theta. \qquad \textbf{(27–1)}$$

If the current's direction is perpendicular to the field $\vec{\mathbf{B}}$ ($\theta = 90°$), then the force is

$$F_{\text{max}} = I\ell B. \qquad [\text{current} \perp \vec{\mathbf{B}}] \qquad \textbf{(27–2)}$$

(If $B$ is not uniform, then $B$ in Eqs. 27–1 and 27–2 could be an average of the field over the length $\ell$ of the wire. Or calculus can be used, as we will see shortly.)

The magnitude of $\vec{\mathbf{B}}$ can be defined using Eq. 27–2 as $B = F_{\text{max}}/I\ell$, where $F_{\text{max}}$ is the magnitude of the force on a straight length $\ell$ of wire carrying a current $I$ when the wire is perpendicular to $\vec{\mathbf{B}}$.

The relation between the force $\vec{\mathbf{F}}$ on a wire carrying current $I$, and the magnetic field $\vec{\mathbf{B}}$ that causes the force, can be written as a vector equation. To do so, we recall that the direction of $\vec{\mathbf{F}}$ is given by right-hand-rule-2 (Fig. 27–11c), and the magnitude by Eq. 27–1. This is consistent with the definition of the vector cross product (see Section 11–2), so we can write

$$\vec{\mathbf{F}} = I\vec{\boldsymbol{\ell}} \times \vec{\mathbf{B}}; \tag{27–3}$$

here, $\vec{\boldsymbol{\ell}}$ is a vector whose magnitude is the length of the wire and its direction is along the wire (assumed straight) in the direction of the conventional (positive) current.

Equation 27–3 applies if the magnetic field is uniform and the wire is straight. If $\vec{\mathbf{B}}$ is not uniform, or if the wire does not everywhere make the same angle $\theta$ with $\vec{\mathbf{B}}$, then Eq. 27–3 can be written more generally as

$$d\vec{\mathbf{F}} = I\, d\vec{\boldsymbol{\ell}} \times \vec{\mathbf{B}}, \tag{27–4}$$

where $d\vec{\mathbf{F}}$ is the infinitesimal force acting on a differential length $d\vec{\boldsymbol{\ell}}$ of the wire. The total force on the wire is then found by integrating.

Equation 27–4 can serve (just as well as Eq. 27–2 or 27–3) as a practical *definition* of $\vec{\mathbf{B}}$. An equivalent way to define $\vec{\mathbf{B}}$, in terms of the force on a moving electric charge, is discussed in the next Section.

*Definition of magnetic field*

**EXERCISE C** A wire carrying current $I$ is perpendicular to a uniform magnetic field of strength $B$. Assuming a fixed length of wire, which of the following changes will reduce the force on the wire by a factor of 2? (*a*) Decrease the angle from 90° to 45°; (*b*) decrease the angle from 90° to 30°; (*c*) decrease the current in the wire to $I/2$; (*d*) decrease the magnetic field to $B/2$; (*e*) none of these will do it.

The SI unit for magnetic field $B$ is the **tesla** (T). From Eq. 27–1, 2, 3, or 4, we see that $1\,\text{T} = 1\,\text{N/A}\cdot\text{m}$. An older name for the tesla is the "weber per meter squared" $(1\,\text{Wb/m}^2 = 1\,\text{T})$.[†] Another unit sometimes used to specify magnetic field is a cgs unit, the **gauss** (G): $1\,\text{G} = 10^{-4}\,\text{T}$. A field given in gauss should always be changed to teslas before using with other SI units. To get a "feel" for these units, we note that the magnetic field of the Earth at Earth's surface is about $\frac{1}{2}$ G or $0.5 \times 10^{-4}\,\text{T}$. On the other hand, typical strong electromagnets can produce fields on the order of 2 T, and some specialized magnets can produce fields over 30 T.

**EXAMPLE 27–1** **Magnetic force on a current-carrying wire.** A wire carrying a steady (dc) 30-A current has a length $\ell = 12\,\text{cm}$ between the pole faces of a magnet. The wire is at an angle $\theta = 60°$ to the field (Fig. 27–13). The magnetic field is approximately uniform at 0.90 T. We ignore the field beyond the pole pieces. Determine the magnitude and direction of the force on the wire.

**APPROACH** We use Eq. 27–1, $F = I\ell B \sin\theta$.

**SOLUTION** The force $F$ on the 12-cm length of wire within the uniform field $B$ is

$$F = I\ell B \sin\theta = (30\,\text{A})(0.12\,\text{m})(0.90\,\text{T})(\sin 60°) = 2.8\,\text{N}.$$

We use right-hand-rule-2 to find the direction of $\vec{\mathbf{F}}$. Hold your right hand flat, pointing your fingers in the direction of the current. Then bend your fingers (maybe needing to rotate your hand) so they point along $\vec{\mathbf{B}}$, Fig. 27–13. Your thumb then points into the page, which is thus the direction of the force $F$.

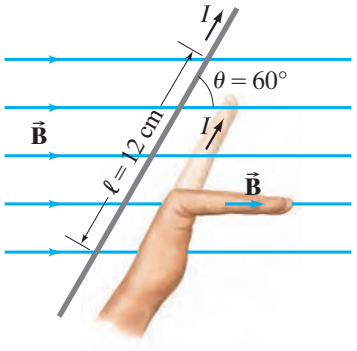


**FIGURE 27–13** Example 27–1. For right-hand-rule-2, the thumb points into the page. See Fig. 27–11c.

**EXERCISE D** A straight power line carries 30 A and is perpendicular to the Earth's magnetic field of $0.50 \times 10^{-4}\,\text{T}$. What magnitude force is exerted on 100 m of this power line?

[†]The "weber" is discussed in Section 29–2. For now, no worries.

On a diagram, when we want to represent an electric current or a magnetic field that is pointing *out* of the page (toward us) or *into* the page, we use $\odot$ or $\times$, respectively. The $\odot$ is meant to resemble the tip of an arrow pointing directly toward the reader, whereas the $\times$ or $\otimes$ resembles the tail of an arrow pointing away. See Fig. 27–14.

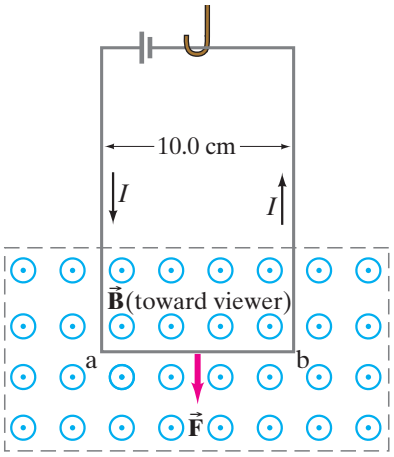

**FIGURE 27–14** Measuring a magnetic field $\vec{\mathbf{B}}$. Example 27–2.

**EXAMPLE 27–2** **Measuring a magnetic field.** A rectangular loop of wire hangs vertically as shown in Fig. 27–14. A magnetic field $\vec{\mathbf{B}}$ is directed horizontally, perpendicular to the plane of the loop, and points out of the page as represented by the symbol $\odot$. The magnetic field $\vec{\mathbf{B}}$ is very nearly uniform along the horizontal portion of wire ab (length $\ell = 10.0\,\text{cm}$) which is near the center of the gap of a large magnet producing the field. The top portion of the wire loop is out of the field. The loop hangs from a balance (reads 0 when $B = 0$) which measures a downward magnetic force of $F = 3.48 \times 10^{-2}\,\text{N}$ when the wire carries a current $I = 0.245\,\text{A}$. What is the magnitude of the magnetic field $B$?

**APPROACH** Three straight sections of the wire loop are in the magnetic field: a horizontal section and two vertical sections. We apply Eq. 27–1 to each section and use the right-hand rule.

**SOLUTION** Using right-hand-rule-2 (page 786), we see that the magnetic force on the left vertical section of wire points to the left, and the force on the vertical section on the right points to the right. These two forces are equal and in opposite directions and so add up to zero. Hence, the net magnetic force on the loop is that on the horizontal section ab, whose length is $\ell = 0.100\,\text{m}$. The angle $\theta$ between $\vec{\mathbf{B}}$ and the wire is $\theta = 90°$, so $\sin\theta = 1$. Thus Eq. 27–1 gives

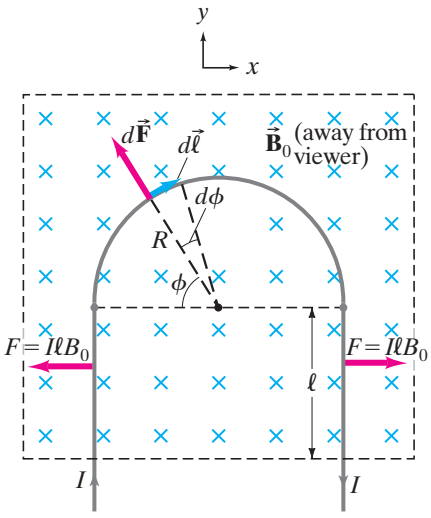
$$B = \frac{F}{I\ell} = \frac{3.48 \times 10^{-2}\,\text{N}}{(0.245\,\text{A})\,(0.100\,\text{m})} = 1.42\,\text{T}.$$

**NOTE** This technique can be a precise means of determining magnetic field strength.

**EXAMPLE 27–3** **Magnetic force on a semicircular wire.** A rigid wire, carrying a current $I$, consists of a semicircle of radius $R$ and two straight portions as shown in Fig. 27–15. The wire lies in a plane perpendicular to a uniform magnetic field $\vec{\mathbf{B}}_0$. Note choice of $x$ and $y$ axis. The straight portions each have length $\ell$ within the field. Determine the net force on the wire due to the magnetic field $\vec{\mathbf{B}}_0$.

**APPROACH** The forces on the two straight sections are equal $(= I\ell B_0)$ and in opposite directions, so they cancel. Hence the net force is that on the semicircular portion.

**SOLUTION** We divide the semicircle into short lengths $d\ell = R\,d\phi$ as indicated in Fig. 27–15, and use Eq. 27–4, $d\vec{\mathbf{F}} = I\,d\vec{\boldsymbol{\ell}} \times \vec{\mathbf{B}}$, to find



$$dF = IB_0 R\,d\phi,$$

where $dF$ is the force on the length $d\ell = R\,d\phi$, and the angle between $d\vec{\boldsymbol{\ell}}$ and $\vec{\mathbf{B}}_0$ all along the path is 90° (so $\sin\theta = 1$ in the cross product). The $x$ component of the force $d\vec{\mathbf{F}}$ on the segment $d\vec{\boldsymbol{\ell}}$ shown, and the $x$ component of $d\vec{\mathbf{F}}$ for a symmetrically located $d\vec{\boldsymbol{\ell}}$ on the other side of the semicircle, will cancel each other. Thus for the entire semicircle there will be no $x$ component of force. Hence we need be concerned only with the $y$ components, each equal to $dF\sin\phi$, and the total force will have magnitude

$$F = \int_0^\pi dF\sin\phi = IB_0 R\int_0^\pi \sin\phi\,d\phi = -IB_0 R\cos\phi\Big|_0^\pi = 2IB_0 R,$$

with direction vertically upward along the $y$ axis in Fig. 27–15.

**FIGURE 27–15** Example 27–3. A magnetic field, $\vec{\mathbf{B}}_0$, is uniform within the dashed area, and points *into* the page (symbols $\times$).

## 27–4 Force on an Electric Charge Moving in a Magnetic Field

We have seen that a current-carrying wire experiences a force when placed in a magnetic field. Since a current in a wire consists of moving electric charges, we might expect that freely moving charged particles (not in a wire) would also experience a force when passing through a magnetic field. Free electric charges may not be

as easy to produce in the lab as a current in a wire, but it can be done, and experiments do show that moving electric charges experience a force in a magnetic field.

From what we have already discussed, we can predict the force on a single electric charge moving in a magnetic field $\vec{\mathbf{B}}$. If $N$ such particles of charge $q$ pass by a given point in time $t$, they constitute a current $I = Nq/t$. We let $t$ be the time for a charge $q$ to travel a distance $\ell$ in a magnetic field $\vec{\mathbf{B}}$; then $\vec{\boldsymbol{\ell}} = \vec{\mathbf{v}}t$ where $\vec{\mathbf{v}}$ is the velocity of the particle. Thus, the force on these $N$ particles is, by Eq. 27–3, $\vec{\mathbf{F}} = I\vec{\boldsymbol{\ell}} \times \vec{\mathbf{B}} = (Nq/t)(\vec{\mathbf{v}}t) \times \vec{\mathbf{B}} = Nq\vec{\mathbf{v}} \times \vec{\mathbf{B}}$. The force on *one* of the $N$ particles is then

$$\vec{\mathbf{F}} = q\vec{\mathbf{v}} \times \vec{\mathbf{B}}. \qquad \textbf{(27–5a)}$$

*Alternate definition of magnetic field*

This basic and important result can be considered as an alternative way of *defining* the magnetic field $\vec{\mathbf{B}}$, in place of Eq. 27–4 or 27–3. The magnitude of the force in Eq. 27–5a is

$$F = qvB \sin\theta. \qquad \textbf{(27–5b)}$$

This gives the magnitude of the force on a particle of charge $q$ moving with velocity $\vec{\mathbf{v}}$ at a point where the magnetic field has magnitude $B$. The angle between $\vec{\mathbf{v}}$ and $\vec{\mathbf{B}}$ is $\theta$. The force is greatest when the particle moves perpendicular to $\vec{\mathbf{B}}$ ($\theta = 90°$):

$$F_{\text{max}} = qvB. \qquad [\vec{\mathbf{v}} \perp \vec{\mathbf{B}}]$$

**Right-Hand-Rule-3:**
*Force on moving charge exerted by* $\vec{\mathbf{B}}$

The force is *zero* if the particle moves *parallel* to the field lines ($\theta = 0°$ or $180°$). The *direction* of the force is perpendicular to the magnetic field $\vec{\mathbf{B}}$ and to the velocity $\vec{\mathbf{v}}$ of the particle. It is given again by a **right-hand rule** (as for any cross product), which we call right-hand-rule-3: you orient your right hand so that your outstretched fingers point along the direction of the particle's velocity ($\vec{\mathbf{v}}$), and when you bend your fingers they must point along the direction of $\vec{\mathbf{B}}$. Then your thumb will point in the direction of the force. This is true only for *positively* charged particles, and will be "up" for the positive particle shown in Fig. 27–16. For negatively charged particles, the force is in exactly the opposite direction, "down" in Fig. 27–16. You could also use an equivalent "left-hand" rule for negative charges and get the correct result.

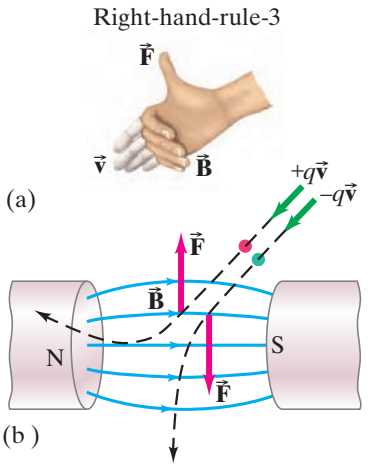


**FIGURE 27–16** (a) Right-hand-rule-3 is shown for the force on a positive charge, $+q$. (b) Force on charged particles due to a magnetic field is perpendicular to the magnetic field direction. If $\vec{\mathbf{v}}$ is horizontal, then $\vec{\mathbf{F}}$ is vertical.

**CONCEPTUAL EXAMPLE 27–4** **Negative charge near a magnet.** A negative charge $-Q$ is placed at rest near a magnet. Will the charge begin to move? Will it feel a force? What if the charge were positive, $+Q$?

**RESPONSE** No to all questions. A charge at rest has velocity equal to zero. Magnetic fields exert a force only on moving electric charges (Eqs. 27–5).

**EXERCISE E** Return to the Chapter-Opening Question, page 782, and answer it again now. Try to explain why you may have answered differently the first time.

**EXAMPLE 27–5** **Magnetic force on a proton.** A magnetic field exerts a force of $8.0 \times 10^{-14}$ N toward the west on a proton moving vertically upward (on this page) at a speed of $5.0 \times 10^{6}$ m/s (Fig. 27–17a). When moving horizontally in a northerly direction, the force on the proton is zero (Fig. 27–17b). Determine the magnitude and direction of the magnetic field in this region. (The charge on a proton is $q = +e = 1.6 \times 10^{-19}$ C.)

**APPROACH** Since the force on the proton is zero when moving north, the field must be in a north–south direction. To produce a force to the west when the proton moves up along this page, right-hand-rule-3 tells us that $\vec{\mathbf{B}}$ must point toward the north. (Your thumb points west and the outstretched fingers of your right hand point upward only when your bent fingers point north.) The magnitude of $\vec{\mathbf{B}}$ is found using Eq. 27–5b.

**SOLUTION** Equation 27–5b with $\theta = 90°$ gives

$$B = \frac{F}{qv} = \frac{8.0 \times 10^{-14}\,\text{N}}{(1.6 \times 10^{-19}\,\text{C})(5.0 \times 10^{6}\,\text{m/s})} = 0.10\,\text{T}.$$

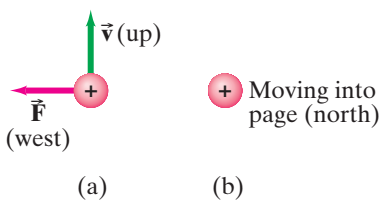

**FIGURE 27–17** Example 27–5.

**EXERCISE F** What is the force on the proton of Example 27–5 if it heads horizontally south?

**EXAMPLE 27–6** **ESTIMATE** **Magnetic force on ions during a nerve pulse.** Estimate the magnitude of the magnetic force due to the Earth's magnetic field on ions crossing a cell membrane during an action potential (Section 25–10). Assume the speed of the ions is $10^{-2}$ m/s.

**APPROACH** Using $F = qvB$, set the magnetic field of the Earth to be roughly $B \approx 10^{-4}$ T, and the charge $q \approx e \approx 10^{-19}$ C.

**SOLUTION** $F = qvB \approx (10^{-19}\,\text{C})(10^{-2}\,\text{m/s})(10^{-4}\,\text{T}) = 10^{-25}$ N.

**NOTE** This is an extremely small force. Yet it is thought that migrating animals do somehow detect the Earth's magnetic field, and this is an area of active research.

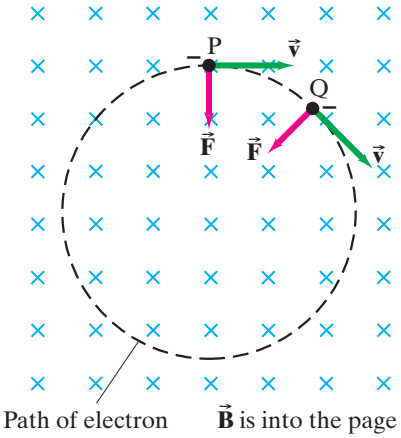

**FIGURE 27–18** Force exerted by a uniform magnetic field on a moving charged particle (in this case, an electron) produces a circular path.

The path of a charged particle moving in a plane perpendicular to a uniform magnetic field is a circle as we shall now show. In Fig. 27–18 the magnetic field is directed *into* the paper, as represented by ×'s. An electron at point P is moving to the right, and the force on it at this point is toward the bottom of the page as shown (use right-hand-rule-3 and reverse the direction for negative charge). The electron is thus deflected toward the page bottom. A moment later, when it reaches point Q, the force is still perpendicular to the velocity and is in the direction shown. Because the force is always perpendicular to $\vec{\mathbf{v}}$, the magnitude of $\vec{\mathbf{v}}$ does not change—the electron moves at constant speed. We saw in Chapter 5 that if the force on a particle is always perpendicular to its velocity $\vec{\mathbf{v}}$, the particle moves in a circle and has a centripetal acceleration of magnitude $a = v^2/r$ (Eq. 5–1). Thus a charged particle moves in a circular path with a centripetal acceleration of constant magnitude in a uniform magnetic field (see Fig. 27–19). The electron moves clockwise in Fig. 27–18. A positive particle in this field would experience a force in the opposite direction and would thus move counterclockwise.

**EXAMPLE 27–7** **Electron's path in a uniform magnetic field.** An electron travels at $1.5 \times 10^7$ m/s in a plane perpendicular to a uniform 0.010-T magnetic field. Describe its path quantitatively. Ignore gravity (= very small in comparison).

**APPROACH** The electron moves at speed $v$ in a curved path and so must have a centripetal acceleration $a = v^2/r$ (Eq. 5–1). We find the radius of curvature using Newton's second law $F_{\text{net}} = ma$. The force is given by Eq. 27–5b with $\sin\theta = 1$: $F = qvB$.

**SOLUTION** We insert $F$ and $a$ into Newton's second law:

$$\Sigma F = ma$$

$$qvB = \frac{mv^2}{r}.$$

We solve for $r$ and find

$$r = \frac{mv}{qB}.$$

Since $\vec{\mathbf{F}}$ is perpendicular to $\vec{\mathbf{v}}$, the magnitude of $\vec{\mathbf{v}}$ doesn't change. From this equation we see that if $\vec{\mathbf{B}}$ = constant, then $r$ = constant, and the curve must be a circle as we claimed above. See Fig. 27–19. To get $r$ we put in the numbers:

$$r = \frac{(9.1 \times 10^{-31}\,\text{kg})(1.5 \times 10^7\,\text{m/s})}{(1.6 \times 10^{-19}\,\text{C})(0.010\,\text{T})} = 0.85 \times 10^{-2}\,\text{m} = 8.5\,\text{mm}.$$

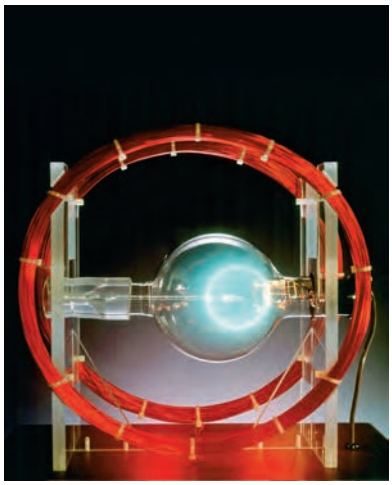

**FIGURE 27–19** The white ring inside the glass tube is the glow of a beam of electrons that ionize the gas molecules inside the tube. The red coils of current-carrying wire produce a nearly uniform magnetic field, illustrating the circular path of charged particles in a uniform magnetic field.

**EXERCISE G** If the magnetic field $B$ is larger, is the radius larger or smaller?

The time $T$ required for a particle of charge $q$ moving with constant speed $v$ to make one circular revolution in a uniform magnetic field $\vec{\mathbf{B}}$ ($\perp \vec{\mathbf{v}}$) is $T = 2\pi r/v$, where $2\pi r$ is the circumference of its circular path (speed = distance $(2\pi r)$/time $T$). From Example 27–7, $r = mv/qB$, so

$$T = \frac{2\pi m}{qB}.$$

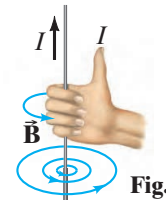
Since $T$ is the period for one revolution, the frequency is

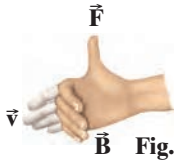
$$f = \frac{1}{T} = \frac{qB}{2\pi m}. \qquad \textbf{(27–6)}$$

This is often called the **cyclotron frequency** of a particle in a magnetic field because this is the frequency at which particles revolve in a cyclotron (see Problem 69).

**CONCEPTUAL EXAMPLE 27–8** **Stopping charged particles.** An electric charge $q$ moving in an electric field $\vec{\mathbf{E}}$ can be decelerated to a stop if the force $\vec{\mathbf{F}} = q\vec{\mathbf{E}}$ (Eq. 21–5) acts in the direction opposite to the charge's velocity. Can a magnetic field be used to stop a charged particle?

**RESPONSE** No, because the force is always *perpendicular* to the velocity of the particle and thus can only change the direction but not the magnitude of its velocity. Also the magnetic force cannot do work on the particle (force and displacement are perpendicular, Eq. 7–3) and so cannot change the kinetic energy of the particle, Eq. 7–11.





PROBLEM SOLVING

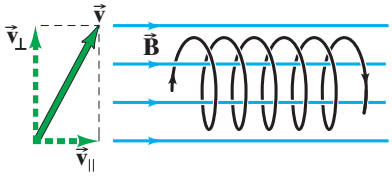
## Magnetic Fields

Magnetic fields are somewhat analogous to the electric fields of Chapter 21, but there are several important differences to recall:

1. The force experienced by a charged particle moving in a magnetic field is *perpendicular* to the direction of the magnetic field (and to the direction of the velocity of the particle), whereas the force exerted by an electric field is *parallel* to the direction of the field (and independent of the velocity of the particle).
2. The *right-hand rule*, in its different forms, is intended to help you determine the direction of magnetic field, and the force a field exerts, and/or the directions of electric current or charged particle velocity. The right-hand rules (Table 27–1) are designed to deal with the "perpendicular" nature of these quantities.

**TABLE 27–1 Summary of Right-hand Rules (= RHR)**

| Physical Situation | Example | How to Orient Right Hand | Result |
|---|---|---|---|
| **1.** Magnetic field produced by current (RHR-1) |   Fig. 27–8d | Wrap fingers around wire with thumb pointing in direction of current $I$ | Fingers curl in direction of $\vec{\mathbf{B}}$ |
| **2.** Force on electric current $I$ due to magnetic field (RHR-2) |   Fig. 27–11c | Fingers first point straight along current $I$, then bend along magnetic field $\vec{\mathbf{B}}$ | Thumb points in direction of the force $\vec{\mathbf{F}}$ |
| **3.** Force on a positive electric charge due to magnetic field (RHR-3) (Use left hand for a negative charge) |   Fig. 27–16 | Fingers first point along particle's velocity $\vec{\mathbf{v}}$, then along $\vec{\mathbf{B}}$ | Thumb points in direction of the force $\vec{\mathbf{F}}$ |



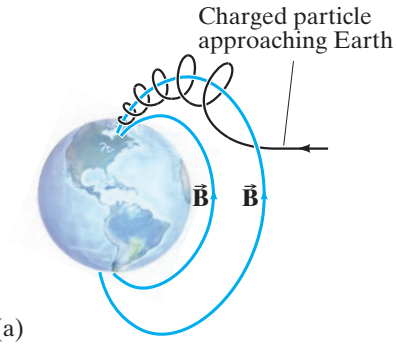


**FIGURE 27–20** Example 27–9.

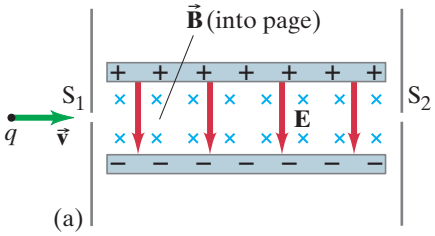
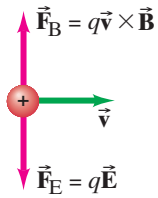
**FIGURE 27–21** (a) Diagram showing a charged particle that approaches the Earth and is "captured" by the magnetic field of the Earth. Such particles follow the field lines toward the poles as shown. (b) Photo of aurora borealis.



(a)



(b)

**FIGURE 27–22** (below) A velocity selector: if $v = E/B$, the particles passing through $S_1$ make it through $S_2$.

(a)

(b)

**CONCEPTUAL EXAMPLE 27–9** **A helical path.** What is the path of a charged particle in a uniform magnetic field if its velocity is *not* perpendicular to the magnetic field?

**RESPONSE** The velocity vector can be broken down into components parallel and perpendicular to the field. The velocity component parallel to the field lines experiences no force $(\theta = 0)$, so this component remains constant. The velocity component perpendicular to the field results in circular motion about the field lines. Putting these two motions together produces a helical (spiral) motion around the field lines as shown in Fig. 27–20.

**EXERCISE H** What is the sign of the charge in Fig. 27–20? How would you modify the drawing if the charge had the opposite sign?

## *Aurora Borealis

Charged ions approach the Earth from the Sun (the "solar wind") and enter the atmosphere mainly near the poles, sometimes causing a phenomenon called the **aurora borealis** or "northern lights" in northern latitudes. To see why, consider Example 27–9 and Fig. 27–21 (see also Fig. 27–20). In Fig. 27–21a we imagine a stream of charged particles approaching the Earth. The velocity component *perpendicular* to the field for each particle becomes a circular orbit around the field lines, whereas the velocity component *parallel* to the field carries the particle along the field lines toward the poles. As a particle approaches the Earth's North Pole, the magnetic field is stronger and the radius of the helical path becomes smaller (see Example 27–7, $r \propto 1/B$).

A high concentration of high-speed charged particles ionizes the air, and as the electrons recombine with atoms, light is emitted (Chapter 37) which is the aurora. Auroras are especially spectacular during periods of high sunspot activity when more charged particles are emitted and more come toward Earth.

## Lorentz Equation

If a particle of charge $q$ moves with velocity $\vec{\mathbf{v}}$ in the presence of both a magnetic field $\vec{\mathbf{B}}$ and an electric field $\vec{\mathbf{E}}$, it will feel a force

$$\vec{\mathbf{F}} = q(\vec{\mathbf{E}} + \vec{\mathbf{v}} \times \vec{\mathbf{B}}) \qquad \textbf{(27–7)}$$

where we have made use of Eqs. 21–5 and 27–5a. Equation 27–7 is often called the **Lorentz equation** and is considered one of the basic equations in physics.

**CONCEPTUAL EXAMPLE 27–10** **Velocity selector, or filter: Crossed $\vec{\mathbf{E}}$ and $\vec{\mathbf{B}}$ fields.** Some electronic devices and experiments need a beam of charged particles all moving at nearly the same velocity. This can be achieved using both a uniform electric field and a uniform magnetic field, arranged so they are at right angles to each other. As shown in Fig. 27–22a, particles of charge $q$ pass through slit $S_1$ and enter the region where $\vec{\mathbf{B}}$ points into the page and $\vec{\mathbf{E}}$ points down from the positive plate toward the negative plate. If the particles enter with different velocities, show how this device "selects" a particular velocity, and determine what this velocity is.

**RESPONSE** After passing through slit $S_1$, each particle is subject to two forces as shown in Fig. 27–22b. If $q$ is positive, the magnetic force is upwards and the electric force downwards. (Vice versa if $q$ is negative.) The exit slit, $S_2$, is assumed to be directly in line with $S_1$ and the particles have velocity $\vec{\mathbf{v}}$. Depending on the magnitude of $\vec{\mathbf{v}}$, some particles will be bent upwards and some downwards. The only ones to make it through the slit $S_2$ will be those for which the net force is zero: $\Sigma F = qvB - qE = 0$. Hence this device selects particles whose velocity is

$$v = \frac{E}{B}. \qquad \textbf{(27–8)}$$

This result does not depend on the sign of the charge $q$.

**EXERCISE I** A particle in a velocity selector as diagrammed in Fig. 27–22 hits below the exit hole, $S_2$. This means that the particle (*a*) is going faster than the selected speed; (*b*) is going slower than the selected speed; (*c*) answer *a* is true if $q > 0$, *b* is true if $q < 0$; (*d*) answer *a* is true if $q < 0$, *b* is true if $q > 0$.

## 27–5 Torque on a Current Loop; Magnetic Dipole Moment

When an electric current flows in a closed loop of wire placed in an external magnetic field, as shown in Fig. 27–23, the magnetic force on the current can produce a torque. This is the principle behind a number of important practical devices, including motors and analog voltmeters and ammeters, which we discuss in the next Section. The interaction between a current and a magnetic field is important in other areas as well, including atomic physics.

Current flows through the rectangular loop in Fig. 27–23a, whose face we assume is parallel to $\vec{\mathbf{B}}$. $\vec{\mathbf{B}}$ exerts no force and no torque on the horizontal segments of wire because they are parallel to the field and $\sin\theta = 0$ in Eq. 27–1. But the magnetic field does exert a force on each of the vertical sections of wire as shown, $\vec{\mathbf{F}}_1$ and $\vec{\mathbf{F}}_2$ (see also top view, Fig. 27–23b). By right-hand-rule-2 (Fig. 27–11c or Table 27–1) the direction of the force on the upward current on the left is in the opposite direction from the equal magnitude force $\vec{\mathbf{F}}_2$ on the downward current on the right. These forces give rise to a net torque that acts to rotate the loop about its vertical axis.

Let us calculate the magnitude of this torque. From Eq. 27–2 $(\text{current} \perp \vec{\mathbf{B}})$, the force $F = IaB$, where *a* is the length of the vertical arm of the loop (Fig. 27–23a). The lever arm for each force is $b/2$, where *b* is the width of the loop and the "axis" is at the midpoint. The torques around this axis produced by $\vec{\mathbf{F}}_1$ and $\vec{\mathbf{F}}_2$ act in the same direction (Fig. 27–23b), so the total torque is the sum of the two torques:

$$\tau = IaB\frac{b}{2} + IaB\frac{b}{2} = IabB = IAB,$$

where $A = ab$ is the area of the loop. If we have a coil that consists of *N* loops of wire, the current is then *NI*, so the torque becomes

$$\tau = NIAB.$$

If this coil makes an angle $\theta$ with the magnetic field, as shown in Fig. 27–23c, the forces are unchanged, but each lever arm is reduced from $\frac{1}{2}b$ to $\frac{1}{2}b\sin\theta$. Note that the angle $\theta$ is taken to be the angle between $\vec{\mathbf{B}}$ and the perpendicular to the face of the loop or coil, Fig. 27–23c. So the torque becomes

$$\tau = NIAB\sin\theta. \qquad \textbf{(27–9)}$$

This formula, derived here for a rectangular coil, is valid for any shape of flat coil.

The quantity *NIA* is called the **magnetic dipole moment** of the coil and is considered a vector:

$$\vec{\boldsymbol{\mu}} = NI\vec{\mathbf{A}}. \qquad \textbf{(27–10)}$$

The *direction* of $\vec{\mathbf{A}}$ (and therefore of $\vec{\boldsymbol{\mu}}$) is defined as *perpendicular* to the plane of the coil (the greenish-blue arrow in Fig. 27–23c) and consistent with another right-hand rule (cup your right hand so your fingers wrap around the loop in the direction of current flow, then your thumb points in the direction of $\vec{\boldsymbol{\mu}}$ and $\vec{\mathbf{A}}$). With this definition of $\vec{\boldsymbol{\mu}}$, we can rewrite Eq. 27–9 in vector form:

$$\vec{\boldsymbol{\tau}} = NI\vec{\mathbf{A}} \times \vec{\mathbf{B}}$$

or

$$\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\mathbf{B}}, \qquad \textbf{(27–11)}$$

which specifies both the magnitude and direction for the torque vector $\vec{\boldsymbol{\tau}}$.

Equation 27–11 has the same form as Eq. 21–9b for an electric dipole (with electric dipole moment $\vec{\mathbf{p}}$) in an electric field $\vec{\mathbf{E}}$, which is $\vec{\boldsymbol{\tau}} = \vec{\mathbf{p}} \times \vec{\mathbf{E}}$. And just as an electric dipole has potential energy given by $U = -\vec{\mathbf{p}} \cdot \vec{\mathbf{E}}$ when in an electric field, we expect a similar form for a magnetic dipole in a magnetic field. In order to rotate a current loop (Fig. 27–23) so as to increase $\theta$, we must do work against the torque due to the magnetic field.

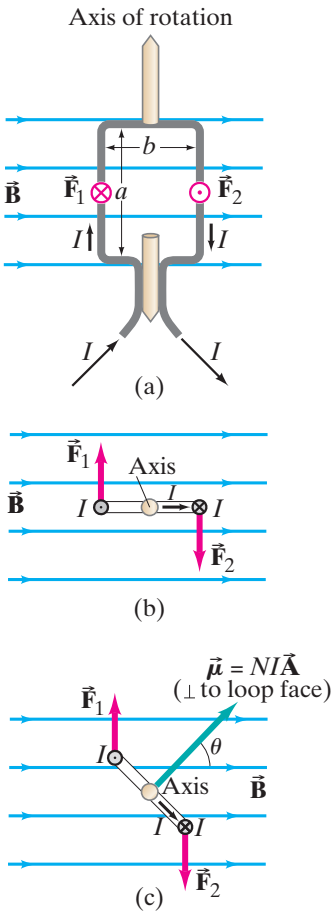


**FIGURE 27–23** Calculating the torque on a current loop in a magnetic field $\vec{\mathbf{B}}$. (a) Loop face parallel to $\vec{\mathbf{B}}$ field lines; (b) top view; (c) loop makes an angle to $\vec{\mathbf{B}}$, reducing the torque since the lever arm is reduced. The vector $\vec{\boldsymbol{\mu}}$ is the "magnetic moment."

Hence the potential energy depends on angle (see Eq. 10–22, the work-energy principle for rotational motion) as

$$U = \int \tau \, d\theta = \int NIAB \sin\theta \, d\theta = -\mu B \cos\theta + C.$$

If we choose $U = 0$ at $\theta = \pi/2$, then the arbitrary constant $C$ is zero and the potential energy is

$$U = -\mu B \cos\theta = -\vec{\boldsymbol{\mu}} \cdot \vec{\mathbf{B}}, \qquad \textbf{(27–12)}$$

as expected (compare Eq. 21–10). Bar magnets and compass needles, as well as current loops, can be considered as magnetic dipoles. Note the striking similarities of the fields produced by a bar magnet and a current loop, Figs. 27–4b and 27–9.

**EXAMPLE 27–11** **Torque on a coil.** A circular coil of wire has a diameter of 20.0 cm and contains 10 loops. The current in each loop is 3.00 A, and the coil is placed in a 2.00-T external magnetic field. Determine the maximum and minimum torque exerted on the coil by the field.

**APPROACH** Equation 27–9 is valid for any shape of coil, including circular loops. Maximum and minimum torque are determined by the angle $\theta$ the coil makes with the magnetic field.

**SOLUTION** The area of one loop of the coil is

$$A = \pi r^2 = \pi (0.100\,\text{m})^2 = 3.14 \times 10^{-2}\,\text{m}^2.$$

The maximum torque occurs when the coil's face is parallel to the magnetic field, so $\theta = 90°$ in Fig. 27–23c, and $\sin\theta = 1$ in Eq. 27–9:

$$\tau = NIAB \sin\theta = (10)(3.00\,\text{A})(3.14 \times 10^{-2}\,\text{m}^2)(2.00\,\text{T})(1) = 1.88\,\text{N}\cdot\text{m}.$$

The minimum torque occurs if $\sin\theta = 0$, for which $\theta = 0°$, and then $\tau = 0$ from Eq. 27–9.

**NOTE** If the coil is free to turn, it will rotate toward the orientation with $\theta = 0°$.

**EXAMPLE 27–12** **Magnetic moment of a hydrogen atom.** Determine the magnetic dipole moment of an electron orbiting the proton of a hydrogen atom at a given instant, assuming (in the simplistic "planetary" or Bohr model) the smallest circular orbit which has a radius $0.529 \times 10^{-10}$ m. [This is a very rough picture of atomic structure, but nonetheless gives an accurate result.]

**APPROACH** We start by setting the electrostatic force on the electron due to the proton equal to $ma = mv^2/r$ since the electron's acceleration is centripetal.

**SOLUTION** The electron is held in its orbit by the coulomb force, so Newton's second law, $F = ma$, gives

$$\frac{e^2}{4\pi\epsilon_0 r^2} = \frac{mv^2}{r};$$

so

$$v = \sqrt{\frac{e^2}{4\pi\epsilon_0 mr}} = \sqrt{\frac{(1/4\pi\epsilon_0)e^2}{mr}}$$

$$= \sqrt{\frac{(8.99 \times 10^9\,\text{N}\cdot\text{m}^2/\text{C}^2)(1.60 \times 10^{-19}\,\text{C})^2}{(9.11 \times 10^{-31}\,\text{kg})(0.529 \times 10^{-10}\,\text{m})}} = 2.19 \times 10^6\,\text{m/s}.$$

Since current is the electric charge that passes a given point per unit time, the revolving electron is equivalent to a current

$$I = \frac{e}{T} = \frac{ev}{2\pi r},$$

where $T = 2\pi r/v$ is the time required for one orbit (speed $= 2\pi r/T$). Since the area of the orbit is $A = \pi r^2$, the magnetic dipole moment is

$$\mu = IA = \frac{ev}{2\pi r}(\pi r^2) = \tfrac{1}{2} evr$$

$$= \tfrac{1}{2}(1.60 \times 10^{-19}\,\text{C})(2.19 \times 10^6\,\text{m/s})(0.529 \times 10^{-10}\,\text{m}) = 9.27 \times 10^{-24}\,\text{A}\cdot\text{m}^2,$$

or $9.27 \times 10^{-24}\,\text{J/T}$.

# 27–6 Applications: Motors, Loudspeakers, Galvanometers

There are many practical applications of the forces related to magnetism. Among the most common are motors and loudspeakers. First we look at the galvanometer, which is the easiest to explain, and which you find on the instrument panels of automobiles and other devices whose readout is via a pointer or needle.

## Galvanometer

The basic component of analog meters (those with pointer and dial), including analog ammeters, voltmeters, and ohmmeters, as well as gauges on car dashboards, is a galvanometer. We discussed in Section 26–7 how these meters are designed. Now we can examine how the crucial element works, the galvanometer. A **galvanometer** consists of a coil with $N$ loops of wire (with attached pointer) suspended in the magnetic field of a permanent magnet, as shown in Fig. 27–24 (only one loop of wire is shown).When current flows through the loop of wire, the magnetic field $B$ exerts a torque $\tau$ on the loop, as given by Eq. 27–9,

$$\tau = NIAB \sin\theta.$$

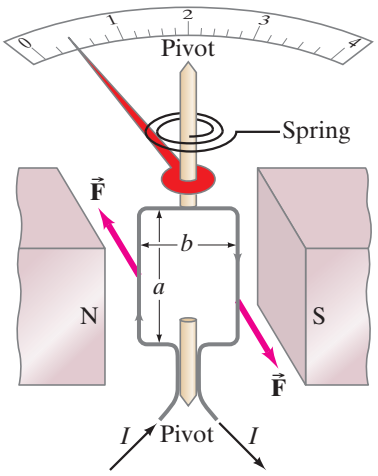
This torque is opposed by a spring which exerts a torque $\tau_s$ approximately proportional to the angle $\phi$ through which it is turned (Hooke's law). That is,

$$\tau_s = k\phi,$$

where $k$ is the stiffness constant of the spring. The coil and attached pointer rotate to the angle where the torques balance. When the needle is in equilibrium at rest, the torques have equal magnitude: $k\phi = NIAB \sin\theta$, so

$$\phi = \frac{NIAB \sin\theta}{k}.$$

The deflection of the pointer, $\phi$, is directly proportional to the current $I$ flowing in the coil, but also depends on the angle $\theta$ the coil makes with $\vec{\mathbf{B}}$. For a useful meter we need $\phi$ to depend only on the current $I$, independent of $\theta$. To solve this problem, magnets with curved pole pieces are used and the galvanometer coil is wrapped around a cylindrical iron core as shown in Fig. 27–25. The iron tends to concentrate the magnetic field lines so that $\vec{\mathbf{B}}$ always points parallel to the face of the coil at the wire outside the core. The force is then always perpendicular to the face of the coil, and the torque will not vary with angle. Thus $\phi$ will be proportional to $I$, as required for a useful meter.



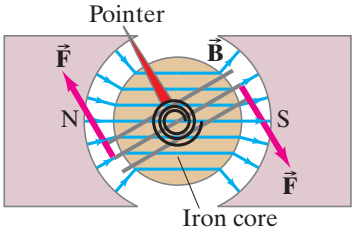


**FIGURE 27–24** Galvanometer. Only one loop of wire is shown.

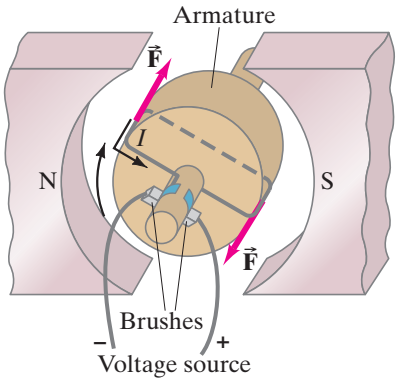

**FIGURE 27–25** Galvanometer coil (3 loops shown) wrapped on an iron core.

## Electric Motors

An **electric motor** converts electric energy into (rotational) mechanical energy. A motor works on the same principle as a galvanometer (a torque is exerted on a current-carrying coil of wire in a magnetic field) except that the coil must turn continuously in one direction for a useful motor. The coil is mounted on an iron cylinder called the **rotor** or **armature**, Fig. 27–26 (only one loop of wire is shown). The armature is mounted on a shaft or axle. When the armature is in the position shown in Fig. 27–26, the magnetic field exerts forces on the current in the loop as shown (perpendicular to $\vec{\mathbf{B}}$ and to the electric current direction). However, when the coil, which is rotating clockwise in Fig. 27–26, passes beyond the vertical position, the forces would then act to return it back toward the vertical if the current remained the same. But if the current could be reversed at that critical moment, the forces would reverse, and the coil would continue rotating in the same direction. Thus, alternation of the current is necessary if a motor is to turn continuously in one direction.

**FIGURE 27–26** Diagram of a simple dc motor. (Magnetic field lines are as shown in Fig. 27–25.)

**PHYSICS APPLIED**
*DC motor*

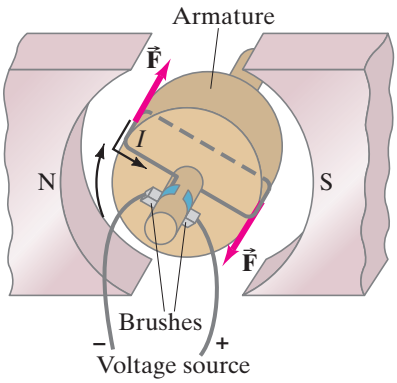

**FIGURE 27–26** (Repeated.) Simple dc motor.

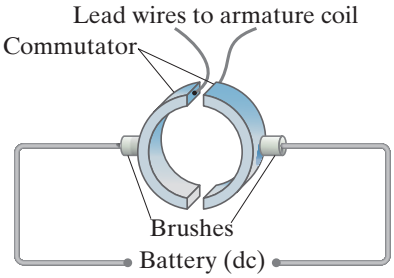
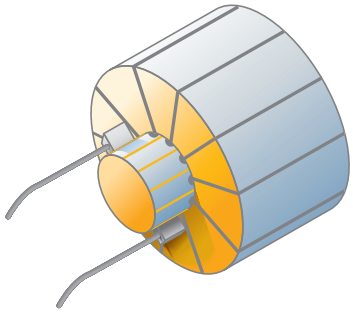
This can be achieved in a **dc motor** with the use of **commutators** and **brushes**. As shown in Fig. 27–27, input current passes through stationary brushes that rub against the conducting commutators mounted on the motor shaft. At every half revolution, each commutator changes its connection over to the other brush. Thus the current in the coil reverses every half revolution as required for continuous rotation.





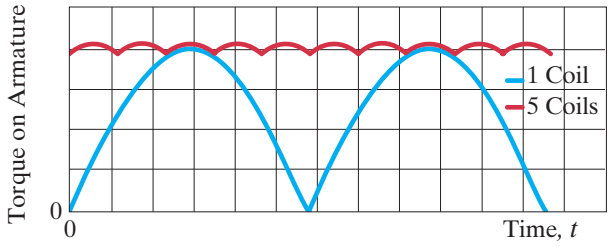


**FIGURE 27–27** (right) Commutator-brush arrangement in a dc motor ensures alternation of the current in the armature to keep rotation continuous in one direction. The commutators are attached to the motor shaft (Fig. 27–26) and turn with it, whereas the brushes remain stationary.

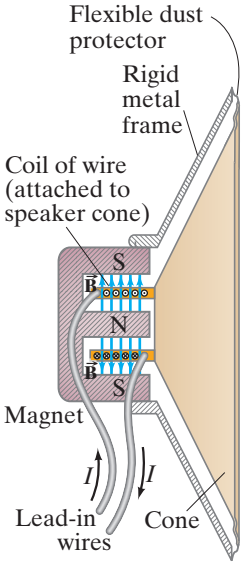
Most motors contain several coils, called *windings*, each connected to a different portion of the armature, Fig. 27–28a. Current flows through each coil only during a small part of a revolution, at the time when its orientation results in the maximum torque. In this way, a motor produces a much steadier torque than can be obtained from a single coil (Fig. 27–28b).

**FIGURE 27–28** (a) Motor with many windings. (b) Graph comparing the torque on a motor armature with one coil as in Fig. 27–26 (blue) vs. five coils (red).

(a)



(b)

**PHYSICS APPLIED**
*AC motor*

An **ac motor**, with ac current as input, can work without commutators since the current itself alternates. Many motors use wire coils to produce the magnetic field (electromagnets) instead of a permanent magnet. Indeed the design of most motors is more complex than described here, but the general principles remain the same.

**FIGURE 27–29** Loudspeaker.

## Loudspeakers and Headsets

**Loudspeakers**, audio headsets and earbuds also work on the principle that a magnet exerts a force on a current-carrying wire. The electrical output of a stereo or TV set is connected to the wire leads of the speaker or earbuds. The speaker leads are connected internally to a coil of wire, which is itself attached to the speaker cone, Fig. 27–29. The speaker cone is usually made of stiffened cardboard and is mounted so that it can move back and forth freely. A permanent magnet is mounted directly in line with the coil of wire. When the alternating current of an audio signal flows through the wire coil, which is free to move within the magnet, the coil experiences a force due to the magnetic field of the magnet. (The force is to the left at the instant shown in Fig. 27–29, RHR-2, page 791) As the current alternates at the frequency of the audio signal, the coil and attached speaker cone move back and forth at the same frequency, causing alternate compressions and rarefactions of the adjacent air, and sound waves are produced that flow outward to be heard by the listener. A speaker thus changes electrical energy into sound energy, and the frequencies and intensities of the emitted sound waves can be an accurate reproduction of the electrical input.

# 27–7 Discovery and Properties of the Electron

The electron plays a basic role in our understanding of electricity and magnetism today. But its existence was not suggested until the 1890s. We discuss it here because magnetic fields were crucial for measuring its properties.

Toward the end of the nineteenth century, studies were being done on the discharge of electricity through rarefied gases. One apparatus, diagrammed in Fig. 27–30, was a glass tube fitted with electrodes and evacuated so only a small amount of gas remained inside. When a very high voltage was applied to the electrodes, a dark space seemed to extend outward from the cathode (negative electrode) toward the opposite end of the tube; and that far end of the tube would glow. If one or more screens containing a small hole was inserted as shown, the glow was restricted to a tiny spot on the end of the tube. It seemed as though something being emitted by the cathode traveled across to the opposite end of the tube. These "somethings" were named **cathode rays**.

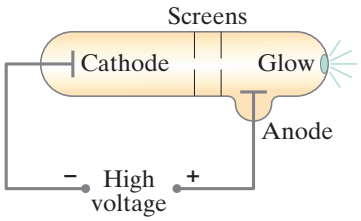


**FIGURE 27–30** Discharge tube. In some models, one of the screens is the anode (positive plate).

There was much discussion at the time about what these rays might be. Some scientists thought they might resemble light. But the observation that the bright spot at the end of the tube could be deflected to one side by an electric or magnetic field suggested that cathode rays were charged particles; and the direction of the deflection was consistent with a negative charge. Furthermore, if the tube contained certain types of rarefied gas, the path of the cathode rays was made visible by a slight glow.

Estimates of the charge $e$ of the cathode-ray particles, as well as of their charge-to-mass ratio $e/m$, had been made by 1897. But in that year, J. J. Thomson (1856–1940) was able to measure $e/m$ directly, using the apparatus shown in Fig. 27–31. Cathode rays are accelerated by a high voltage and then pass between a pair of parallel plates built into the tube. Another voltage applied to the parallel plates produces an electric field $\vec{\mathbf{E}}$, and a pair of coils produces a magnetic field $\vec{\mathbf{B}}$. If $E = B = 0$, the cathode rays follow path b in Fig. 27–31. When only the electric field is present, say with the upper plate positive, the cathode rays are deflected upward as in path a in Fig. 27–31. If only a magnetic field exists, say inward, the rays are deflected downward along path c. These observations are just what is expected for a negatively charged particle. The force on the rays due to the magnetic field is $F = evB$, where $e$ is the charge and $v$ is the velocity of the cathode rays. In the absence of an electric field, the rays are bent into a curved path, so from Newton's second law, $F = ma$ with $a =$ centripetal acceleration, we have

$$evB = m\frac{v^2}{r},$$

and thus

$$\frac{e}{m} = \frac{v}{Br}.$$

The radius of curvature $r$ can be measured and so can $B$. The velocity $v$ can be found by applying an electric field in addition to the magnetic field. The electric field $E$ is adjusted so that the cathode rays are undeflected and follow path b in Fig. 27–31.

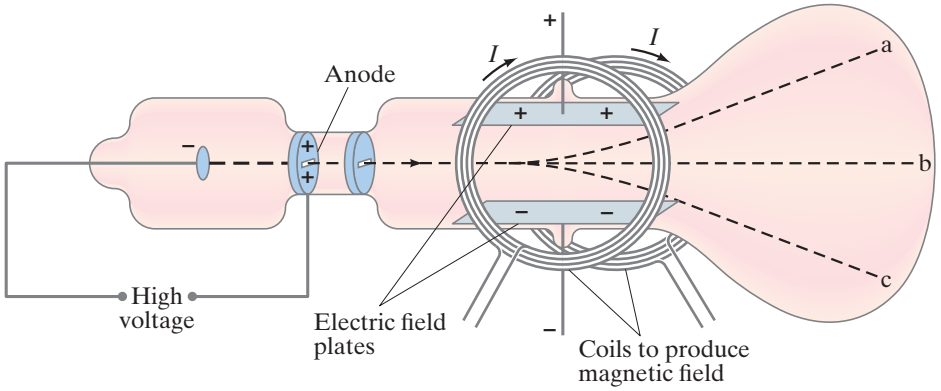

**FIGURE 27–31** Cathode rays deflected by electric and magnetic fields.

This is just like the velocity selector of Example 27–10 where the force due to the electric field, $F = eE$, is balanced by the force due to the magnetic field, $F = evB$. Thus $eE = evB$ and $v = E/B$. Substituting $v = E/B$ into the equation at the bottom of the previous page, $e/m = v/Br$, we have

$$\frac{e}{m} = \frac{v}{Br} = \frac{E}{B^2 r}. \qquad \textbf{(27–13)}$$

The quantities on the right side can all be measured, and although $e$ and $m$ could not be determined separately, the ratio $e/m$ could be determined. The accepted value today is $e/m = 1.76 \times 10^{11}$ C/kg. Cathode rays soon came to be called **electrons** ("carriers of electricity").

It is worth noting that the "discovery" of the electron, like many others in science, is not quite so obvious as discovering gold or oil. Should the discovery of the electron be credited to the person who first saw a glow in the tube? Or to the person who first called them cathode rays? Perhaps neither one, for they had no conception of the electron as we know it today. In fact, the credit for the discovery is generally given to Thomson, but not because he was the first to see the glow in the tube. Rather it is because he believed that this phenomenon was due to tiny negatively charged particles and made careful measurements on them. Furthermore he argued that these particles were constituents of atoms, and not ions or atoms themselves as many thought, and he developed an electron theory of matter. His view is close to what we accept today, and this is why Thomson is credited with the "discovery." Note, however, that neither he nor anyone else ever actually saw an electron itself. We discuss this briefly, for it illustrates the fact that discovery in science is not always a clear-cut matter. In fact some philosophers of science think the word "discovery" is often not appropriate, such as in this case.

## Electron Charge Measurement

Thomson believed that an electron was not an atom, but rather a constituent, or part, of an atom. Convincing evidence for this came soon with the determination of the charge and the mass of the cathode rays. Thomson's student J. S. Townsend made the first direct (but rough) measurements of $e$ in 1897. But it was the more refined **oil-drop experiment** of Robert A. Millikan (1868–1953) that yielded a precise value for the charge on the electron and showed that charge comes in discrete amounts. In this experiment, tiny droplets of mineral oil carrying an electric charge were allowed to fall under gravity between two parallel plates, Fig. 27–32. The electric field $E$ between the plates was adjusted until the drop was suspended in midair. The downward pull of gravity, $mg$, was then just balanced by the upward force due to the electric field. Thus $qE = mg$, so the charge $q = mg/E$. The mass of the droplet was determined by measuring its terminal velocity in the absence of the electric field. Often the droplet was charged negatively, but sometimes it was positive, suggesting that the droplet had acquired or lost electrons (by friction, leaving the atomizer). Millikan's painstaking observations and analysis presented convincing evidence that any charge was an integral multiple

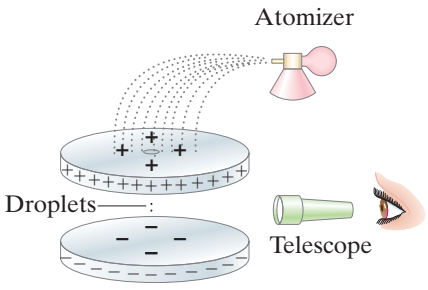

**FIGURE 27–32** Millikan's oil-drop experiment.

of a smallest charge, $e$, that was ascribed to the electron, and that the value of $e$ was $1.6 \times 10^{-19}$ C. This value of $e$, combined with the measurement of $e/m$, gives the mass of the electron to be $(1.6 \times 10^{-19}\,\text{C})/(1.76 \times 10^{11}\,\text{C/kg}) = 9.1 \times 10^{-31}$ kg. This mass is less than a thousandth the mass of the smallest atom, and thus confirmed the idea that the electron is only a part of an atom. The accepted value today for the mass of the electron is

$$m_e = 9.11 \times 10^{-31}\,\text{kg}.$$

The experimental result that any charge is an integral multiple of $e$ means that electric charge is *quantized* (exists only in discrete amounts). We start discussing "quantum theory" in Chapter 37.

### *CRT, Revisited

The cathode ray tube (CRT), which once served as the picture tube of TV sets, oscilloscopes, and computer monitors, was discussed in Chapter 23. There, in Fig. 23–28, was a design using electric deflection plates to maneuver the electron beam. Many CRTs used a magnetic field produced by coils to maneuver the electron beam, and operated much like the coils shown in Fig. 27–31.

## 27–8 The Hall Effect

When a current-carrying conductor is held fixed in a magnetic field, the field exerts a sideways force on the charges moving in the conductor. For example, if electrons move to the right in the rectangular conductor shown in Fig. 27–33a, the inward magnetic field will exert a downward force (Eq. 27–5a) on the electrons $\vec{\mathbf{F}}_B = -e\vec{\mathbf{v}}_d \times \vec{\mathbf{B}}$, where $\vec{\mathbf{v}}_d$ is the drift velocity of the electrons (Section 25–8). Thus the electrons will tend to move nearer to side D than side C, causing a potential difference between sides C and D of the conductor. This potential difference provides an electric field $\vec{\mathbf{E}}_H$ that exerts a force, $e\vec{\mathbf{E}}_H$, on the moving charges that is equal and opposite to the magnetic force $(ev_d B)$. This effect is called the **Hall effect** after E. H. Hall, who discovered it in 1879. The difference of potential produced is called the **Hall emf**.

The electric field due to the separation of charge is called the *Hall field*, $\vec{\mathbf{E}}_H$, and points downward in Fig. 27–33a, as shown. In equilibrium, the force due to this electric field is balanced by the magnetic force $ev_d B$, so

$$eE_H = ev_d B.$$

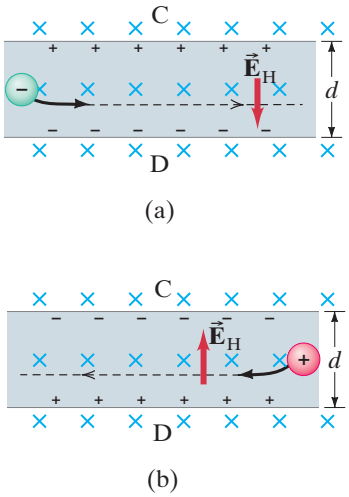
Hence $E_H = v_d B$. The Hall emf is then (Eq. 23–4b, assuming the conductor is long and thin so $E_H$ is uniform)

$$\mathscr{E}_H = E_H d = v_d B d, \qquad \textbf{(27–14)}$$

where $d$ is the width of the conductor.

A current of negative charges moving to the right is equivalent to positive charges moving to the left, at least for most purposes. But the Hall effect can distinguish these two. As can be seen in Fig. 27–33b, positive particles moving to the left are deflected downward, so that the bottom surface is positive relative to the top surface. The Hall emf is the reverse of part (a). Indeed, the direction of the emf in the Hall effect first revealed that it is negative particles (not positive ones) that move in metal conductors, and much later that positive "holes" move in $p$-type semiconductors. (Section 40–8).

Because the Hall emf is proportional to $B$, the Hall effect can be used to measure magnetic fields. A device to do so, called a *Hall probe*, is first calibrated with known magnetic fields. Then, for the same current, its emf output will be a measure of $B$. When $B$ is known, the Hall effect can be used to measure the drift speed of charge carriers. Such measurements also allow us to determine the density of charge carriers in a material.



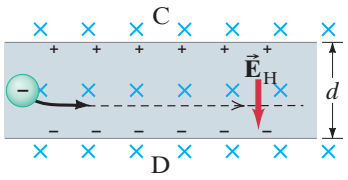


**FIGURE 27–33** The Hall effect. (a) Negative charges moving to the right as the current. (b) Positive charges moving to the left as the current.

(a)

**FIGURE 27–33a** (Repeated here for Example 27–13.)

**EXAMPLE 27–13** **Drift speed using the Hall effect.** A long copper strip 1.8 cm wide ($= d$) and thickness 1.0 mm is placed in a 1.2-T magnetic field as in Fig. 27–33a. When a steady current of 15 A passes through it, the Hall emf is measured to be 1.02 $\mu$V. Determine the drift speed of the electrons and the density of free (conducting) electrons (number per unit volume) in the copper.

**APPROACH** We use Eq. 27–14 to obtain the drift speed, and Eq. 25–13 of Chapter 25 to find the density of conducting electrons.

**SOLUTION** The drift speed (Eq. 27–14) is

$$v_d = \frac{\mathscr{E}_H}{Bd} = \frac{1.02 \times 10^{-6}\,\text{V}}{(1.2\,\text{T})(1.8 \times 10^{-2}\,\text{m})} = 4.7 \times 10^{-5}\,\text{m/s}.$$

The density of charge carriers $n$ is obtained from Eq. 25–13, $I = nev_d A$, where $A$ is the cross-sectional area through which the current $I$ flows. Then

$$n = \frac{I}{ev_d A} = \frac{15\,\text{A}}{(1.6 \times 10^{-19}\,\text{C})(4.7 \times 10^{-5}\,\text{m/s})(1.8 \times 10^{-2}\,\text{m})(1.0 \times 10^{-3}\,\text{m})}$$
$$= 11 \times 10^{28}\,\text{m}^{-3}.$$

This value for the density of free electrons in copper, $n = 11 \times 10^{28}$ per m$^3$, is the experimentally measured value. It represents *more* than one free electron per atom, which as we saw in Example 25–14 is $8.4 \times 10^{28}\,\text{m}^{-3}$.

## 27–9 Mass Spectrometer

**PHYSICS APPLIED**
*The mass spectrometer*

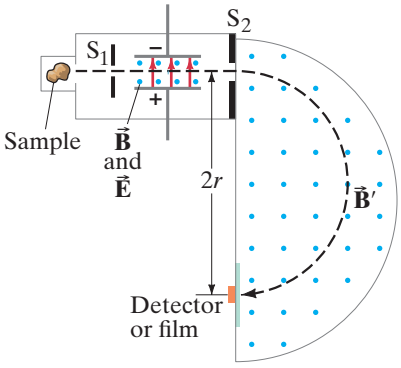

**FIGURE 27–34** Bainbridge-type mass spectrometer. The magnetic fields $B$ and $B'$ point out of the paper (indicated by the dots).

A **mass spectrometer** is a device to measure masses of atoms. It is used today not only in physics but also in chemistry, geology, and medicine, often to identify atoms (and their concentration) in given samples. Ions can be produced by heating the sample, or by using an electric current. As shown in Fig. 27–34, the ions (mass $m$, charge $q$) pass through slit $S_1$ and enter a region (before $S_2$) where there are crossed ($\perp$) electric and magnetic fields. Ions follow a straight-line path in this region if the electric force $qE$ (upward on a positive ion) is just balanced by the magnetic force $qvB$ (downward on a positive ion): that is, if $qE = qvB$, or

$$v = \frac{E}{B}.$$

Only those ions whose speed is $v = E/B$ will pass through undeflected and emerge through slit $S_2$ (just as in the "velocity selector" of Example 27–10). In the semicircular region, after $S_2$, there is only a magnetic field, $B'$, so the ions follow a circular path. The radius of the circular path is found from their mark on film, or by detectors, if $B'$ is fixed. If instead $r$ is fixed by the position of a detector, then $B'$ is varied until detection occurs. Newton's second law, $\Sigma F = ma$, applied to an ion moving in a circle under the influence only of the magnetic field $B'$ gives $qvB' = mv^2/r$. Since $v = E/B$, we have

$$m = \frac{qB'r}{v} = \frac{qBB'r}{E}. \qquad \textbf{(27–15)}$$

All the quantities on the right side are known or can be measured, and thus $m$ can be determined.

Historically, the masses of many atoms were measured this way. When a pure substance was used, it was sometimes found that two or more closely spaced marks would appear on the film. For example, neon produced two marks whose radii corresponded to atoms of 20 and 22 atomic mass units (u). Impurities were ruled out and it was concluded that there must be two types of neon with different masses. These different forms were called **isotopes**. It was soon found that most elements are mixtures of isotopes, and the difference in mass is due to different numbers of neutrons (discussed in Chapter 41).

**EXAMPLE 27–14** **Mass spectrometry.** Carbon atoms of atomic mass 12.0 u are found to be mixed with an unknown element. In a mass spectrometer with fixed $B'$, the carbon traverses a path of radius 22.4 cm and the unknown's path has a 26.2-cm radius. What is the unknown element? Assume the electric charge on both types of ion is the same (maybe $+1e$ or $-1e$).

**APPROACH** We assume the carbon and unknown atoms pass through the same electric and magnetic fields, so the velocity selector selects the same speed. Hence their masses are proportional to the radius of their respective paths (see Eq. 27–15).

**SOLUTION** We write a ratio for the masses, using Eq. 27–15:

$$\frac{m_x}{m_C} = \frac{qBB'r_x/E}{qBB'r_C/E} = \frac{r_x}{r_C}$$
$$= \frac{26.2\text{ cm}}{22.4\text{ cm}} = 1.17.$$

Thus $m_x = 1.17 \times 12.0\text{ u} = 14.0\text{ u}$. The other element is probably nitrogen (see the Periodic Table, inside the back cover).

**NOTE** The unknown could also be an isotope such as carbon-14 $\left({}^{14}_{6}\text{C}\right)$. See Appendix F. Further physical or chemical analysis would be needed.

# Summary

A magnet has two **poles**, north and south. The north pole is that end which points toward geographic north when the magnet is freely suspended. Like poles of two magnets repel each other, whereas unlike poles attract.

We can picture that a **magnetic field** surrounds every magnet. The SI unit for magnetic field is the **tesla** (T).

Electric currents produce magnetic fields. For example, the lines of magnetic field due to a current in a straight wire form circles around the wire, and the field exerts a force on magnets (or currents) near it.

A magnetic field exerts a force on an electric current. The force on an infinitesimal length of wire $d\vec{\boldsymbol{\ell}}$ carrying a current $I$ in a magnetic field $\vec{\mathbf{B}}$ is

$$d\vec{\mathbf{F}} = I\, d\vec{\boldsymbol{\ell}} \times \vec{\mathbf{B}}. \qquad \textbf{(27–4)}$$

If the field $\vec{\mathbf{B}}$ is uniform over a straight length $\vec{\boldsymbol{\ell}}$ of wire, then the force is

$$\vec{\mathbf{F}} = I\vec{\boldsymbol{\ell}} \times \vec{\mathbf{B}} \qquad \textbf{(27–3)}$$

which has magnitude

$$F = I\ell B \sin\theta \qquad \textbf{(27–1)}$$

where $\theta$ is the angle between magnetic field $\vec{\mathbf{B}}$ and the current direction. The direction of the force is perpendicular to the wire and to the magnetic field, and is given by the right-hand rule. This relation serves as the definition of magnetic field $\vec{\mathbf{B}}$.

Similarly, a magnetic field $\vec{\mathbf{B}}$ exerts a force on a charge $q$ moving with velocity $\vec{\mathbf{v}}$ given by

$$\vec{\mathbf{F}} = q\vec{\mathbf{v}} \times \vec{\mathbf{B}}. \qquad \textbf{(27–5a)}$$

The magnitude of the force is

$$F = qvB \sin\theta, \qquad \textbf{(27–5b)}$$

where $\theta$ is the angle between $\vec{\mathbf{v}}$ and $\vec{\mathbf{B}}$.

The path of a charged particle moving perpendicular to a uniform magnetic field is a circle.

If both electric and magnetic fields $\left(\vec{\mathbf{E}} \text{ and } \vec{\mathbf{B}}\right)$ are present, the force on a charge $q$ moving with velocity $\vec{\mathbf{v}}$ is

$$\vec{\mathbf{F}} = q\vec{\mathbf{E}} + q\vec{\mathbf{v}} \times \vec{\mathbf{B}}. \qquad \textbf{(27–7)}$$

The torque on a current loop in a magnetic field $\vec{\mathbf{B}}$ is

$$\vec{\boldsymbol{\tau}} = \vec{\boldsymbol{\mu}} \times \vec{\mathbf{B}}, \qquad \textbf{(27–11)}$$

where $\vec{\boldsymbol{\mu}}$ is the **magnetic dipole moment** of the loop or loops:

$$\vec{\boldsymbol{\mu}} = NI\vec{\mathbf{A}}. \qquad \textbf{(27–10)}$$

Here $N$ is the number of loops carrying current $I$ in the coil and $\vec{\mathbf{A}}$ is a vector perpendicular to the plane of the loop (use right-hand rule, fingers along current in loop) and has magnitude equal to the area of the loop.

The force or torque exerted on a current-carrying wire by a magnetic field is the basis for operation of many devices, such as **motors** and **loudspeakers**, and in **galvanometers** (used in analog electric meters).

The measurement of the charge-to-mass ratio $(e/m)$ of the electron was done using magnetic and electric fields. The charge $e$ on the electron was first measured in the Millikan oil-drop experiment and then its mass was obtained from the measured value of the $e/m$ ratio.

In the **Hall effect**, moving charges in a conductor placed in a magnetic field are forced to one side, producing an emf between the two sides of the conductor.

A **mass spectrometer** uses magnetic and electric fields to measure the mass of ions.

# Questions

1. A compass needle is not always balanced parallel to the Earth's surface, but one end may dip downward. Explain.
2. Explain why the Earth's "north pole" is really a magnetic south pole. Indicate how north and south magnetic poles were defined and how we can tell experimentally that the north pole is really a south magnetic pole.
3. Draw the magnetic field lines around a straight section of wire carrying a current horizontally to the left.
4. A horseshoe magnet is held vertically with the north pole on the left and south pole on the right. A wire passing between the poles, equidistant from them, carries a current directly away from you. In what direction is the force on the wire? Explain.
5. In the relation $\vec{\mathbf{F}} = I\vec{\ell} \times \vec{\mathbf{B}}$, which pairs of the vectors $(\vec{\mathbf{F}}, \vec{\ell}, \vec{\mathbf{B}})$ are always at 90°? Which can be at other angles?
6. The magnetic field due to current in wires in your home can affect a compass. Discuss the effect in terms of currents, including if they are ac or dc.
7. In Fig. 27–35, charged particles move in the vicinity of a current-carrying wire. For each charged particle, the arrow indicates the initial direction of motion of the particle, and the + or − indicates the sign of the charge. For each of the particles, indicate the direction of the initial magnetic force due to the magnetic field produced by the wire. Explain.

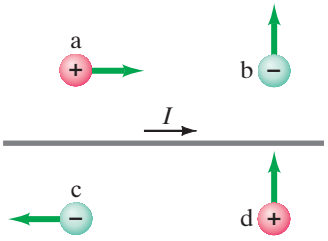

**FIGURE 27–35**
Question 7.

8. If a negatively charged particle enters a region of uniform magnetic field which is perpendicular to the particle's velocity, will the kinetic energy of the particle increase, decrease, or stay the same? Explain your answer. (Neglect gravity and assume there is no electric field.)
9. Note that the pattern of magnetic field lines surrounding a bar magnet is similar to that of the electric field around an electric dipole. From this fact, predict how the magnetic field will change with distance (*a*) when near one pole of a very long bar magnet, and (*b*) when far from a magnet as a whole.
10. Three particles, a, b, and c, enter a magnetic field and follow paths as shown in Fig. 27–36. What can you say about the charge on each particle? Explain.

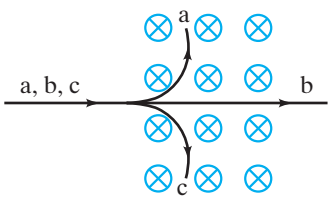

**FIGURE 27–36**
Question 10.

11. Describe the trajectory of a negatively charged particle in the velocity selector of Fig. 27–22 if its speed exceeds $E/B$. What is its trajectory if $v < E/B$? Would it make any difference if the particle were positively charged?
12. Can you set a resting electron into motion with a steady magnetic field? With an electric field? Explain.
13. A positively charged particle in a nonuniform magnetic field follows the trajectory shown in Fig. 27–37. For each of the labeled points (a, b, c, d, e), indicate the direction of the magnetic field near the path, assuming the path is always in the plane of the page, and indicate the relative magnitudes of the field near each point. Explain your answers.

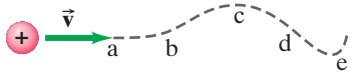

**FIGURE 27–37**
Question 13.

14. A charged particle is moving in a circle under the influence of a uniform magnetic field. If an electric field that points in the same direction as the magnetic field is turned on, describe the path the charged particle will take.
15. A beam of electrons is directed toward a horizontal wire carrying a current from left to right (Fig. 27–38). In what direction is the beam deflected?

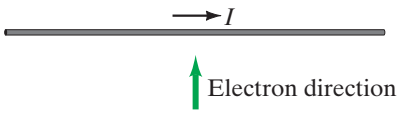

**FIGURE 27–38**
Question 15.

16. A charged particle moves in a straight line through a particular region of space. Could there be a nonzero magnetic field in this region? If so, give two possible situations.
17. If a moving charged particle is deflected sideways in some region of space, can we conclude, for certain, that $\vec{\mathbf{B}} \neq 0$ in that region? Explain.
18. How could you tell whether moving electrons in a certain region of space are being deflected by an electric field or by a magnetic field (or by both)?
19. How could you make a compass without using iron or other ferromagnetic material?
20. Describe how you could determine the dipole moment of a bar magnet or compass needle.
21. In what positions (if any) will a current loop placed in a uniform magnetic field be in (*a*) stable equilibrium, and (*b*) unstable equilibrium?
22. The force on a moving particle in a magnetic field is the idea behind **electromagnetic pumping**. It can be used to pump metallic fluids (such as sodium) and to pump blood in artificial heart machines. A basic design is shown in Fig. 27–39. For blood, an electric field is applied perpendicular to a blood vessel and to the magnetic field. Explain in detail how ions in the blood are caused to move. Do positive and negative ions feel a force in the same direction? Explain.

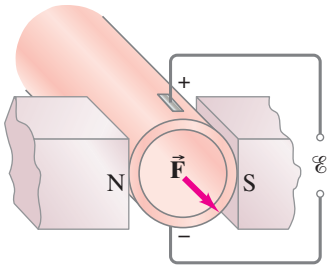

**FIGURE 27–39**
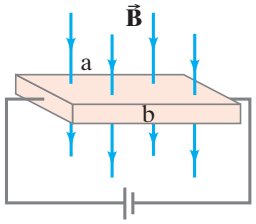
Electromagnetic pumping in a blood vessel.
Question 22.

**23.** A rectangular piece of semiconductor is inserted in a magnetic field and a battery is connected to its ends as shown in Fig. 27–40. When a sensitive voltmeter is connected between points a and b, it is found that point a is at a higher potential than b. What is the sign of the charge carriers in this semiconductor material?



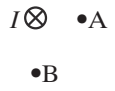


**FIGURE 27–40**
Question 23.

**24.** Two ions have the same mass, but one is singly ionized and the other is doubly ionized. How will their positions on the film of a mass spectrometer (Fig. 27–34) differ? Explain.

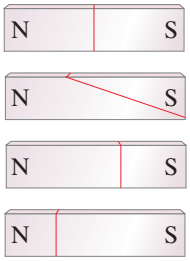
## MisConceptual Questions

**1.** A current in a wire points into the page as shown at the right. In which direction is the magnetic field at point A (choose below)?

(*a*) (*b*) (*c*) (*d*) (*e*) None of these.

**2.** In which direction (see above) is the magnetic field at point B?

**3.** How should you cut a bar magnet to create two magnetic poles for which the north pole is twice as strong as the south pole?



(*a*) Cut the magnet in half at the midpoint between the north and south ends.

(*b*) Cut the magnet on a diagonal as shown.

(*c*) Cut the magnet so 2/3 of the magnet ends up with the N side.

(*d*) Cut the magnet so 2/3 of the magnet ends up with the S side.

(*e*) No cut can meet this request.

**4.** A wire carries a current directly away from you. Which way do the magnetic field lines produced by this wire point?

(*a*) They point parallel to the wire in the direction of the current.

(*b*) They point parallel to the wire opposite the direction of the current.

(*c*) They point toward the wire.

(*d*) They point away from the wire.

(*e*) They make clockwise circles around the wire.

(*f*) They make counterclockwise circles around the wire.

**5.** As a proton moves through space, it creates

(*a*) an electric field only.

(*b*) a magnetic field only.

(*c*) both an electric field and a magnetic field.

(*d*) nothing; the electric field and magnetic fields cancel each other out.

**6.** Which statements about the force on a charged particle placed in a magnetic field are true?

(*a*) A magnetic force can be exerted only if the particle is moving.

(*b*) The force is a maximum if the particle is moving in the direction of the field.

(*c*) The force causes the particle to gain kinetic energy.

(*d*) The direction of the force is along the magnetic field.

(*e*) A magnetic field always exerts a force on a charged particle.

**7.** When a charged particle moves parallel to the direction of a magnetic field, the particle travels in a

(*a*) straight line.

(*b*) circular path.

(*c*) helical path.

(*d*) hysteresis loop.

**8.** Compare the magnetic force on a proton and on an electron, each traveling with the same speed in the same direction and perpendicular to the magnetic field.

(*a*) The magnitude and direction of the force is the same on the proton and the electron.

(*b*) The direction of the force is the same on the proton and the electron, but the force on the proton is larger.

(*c*) The direction of the force is the same on the proton and the electron, but the force on the electron is larger.

(*d*) The magnitude of the force is the same on the proton and the electron, but the direction of the force is opposite.

(*e*) There is no force on either the proton or the electron.

**9.** A proton enters a uniform magnetic field that is perpendicular to the proton's velocity (Fig. 27–41). What happens to the kinetic energy of the proton?

(*a*) It increases.

(*b*) It decreases.

(*c*) It stays the same.

(*d*) It depends on the velocity direction.

(*e*) It depends on the *B* field direction.

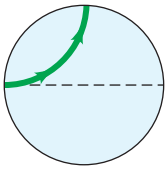


**FIGURE 27–41**
MisConceptual Question 9.

**10.** For a charged particle, a constant magnetic field can be used to change
(*a*) only the direction of the particle's velocity.
(*b*) only the magnitude of the particle's velocity.
(*c*) both the magnitude and direction of the particle's velocity.
(*d*) None of the above.

**11.** Which of the following statements about the force on a charged particle due to a magnetic field are not valid?
(*a*) It depends on the particle's charge.
(*b*) It depends on the particle's velocity.
(*c*) It depends on the strength of the external magnetic field.
(*d*) It acts at right angles to the direction of the particle's motion.
(*e*) None of the above; all of these statements are valid.

**12.** A magnetic field exists in the space surrounding a metallic wire that carries a steady electric current. But an electric field is not present in that space because
(*a*) moving charges create magnetic fields but not electric fields.
(*b*) the wire contains equal amounts of positive and negative charges.
(*c*) electrons and atoms move in different directions in the wire.
(*d*) the magnetic field cancels out the electric field.

**13.** Two particles follow the paths shown in Fig. 27–42. They move in a uniform magnetic field $\vec{\mathbf{B}}$ directed into the page. What is the charge on particle 1, and on particle 2?
(*a*) +, +  (*b*) −, +  (*c*) +, −  (*d*) −, −
(*e*) None of the above.

**FIGURE 27–42**
MisConceptual Question 13.

# Problems

## 27–1 Magnets and Magnetic Fields

**1.** (II) You go on a hike in a straight line, 35° east of north, using a compass and heading toward a point 3.0 km away according to a map. If you forget to correct for the difference between true north on the map and magnetic north, how far from your destination would you be after 3.0 km? Assume a magnetic declination of +13° for California. A positive declination means magnetic north is east of true geographic north.

**2.** (II) If you approximate the Earth's magnetic field as the field of a magnetic dipole, the field will decrease roughly as $1/r^3$, just as for an electric dipole field (Section 21–11, and see also Section 28–6 for confirmation). If the magnetic field is $0.50 \times 10^{-4}$ T at the Earth's surface, estimate the strength of the magnetic field at an altitude of (*a*) 0.20 Earth radii and (*b*) 2.0 Earth radii.

## 27–3 Force on Electric Current in Magnetic Field

**3.** (I) (*a*) What is the force per meter of length on a straight wire carrying a 7.40-A current when perpendicular to a 0.90-T uniform magnetic field? (*b*) What if the angle between the wire and field is 35.0°?

**4.** (I) How much current is flowing in a wire 4.20 m long if the maximum force on it is 0.625 N when placed in a uniform 0.0800-T field?

**5.** (I) A 240-m length of a nearly straight wire stretches between two towers and carries a 150-A current. Determine the magnitude of the force on the wire due to the Earth's magnetic field of $5.0 \times 10^{-5}$ T which makes an angle of 68° with the wire.

**6.** (I) A 2.6-m length of horizontal wire carries a 4.5-A current toward the south. The dip angle of the Earth's magnetic field makes an angle of 35° to the wire. Estimate the magnitude of the magnetic force on the wire due to the Earth's magnetic field of $5.5 \times 10^{-5}$ T.

**7.** (I) The magnetic force per meter on a wire is measured to be only 55% of its maximum possible value. What is the angle between the wire and the magnetic field?

**8.** (II) The force on a wire is a maximum of $7.50 \times 10^{-2}$ N when placed between the pole faces of a magnet. The current flows horizontally to the right and the magnetic field is vertical. The wire is observed to "jump" toward the observer when the current is turned on. (*a*) What type of magnetic pole is the horizontal upper pole face? (*b*) If the pole faces have a diameter of 10.0 cm, estimate the current in the wire if the field is 0.180 T. (*c*) If the wire is tipped so that it makes an angle of 10.0° with the horizontal, what force will it now feel? [*Hint*: What length of wire will now be in the field?]

**9.** (II) Suppose a straight 1.00-mm-diameter copper wire could just "float" horizontally in air because of the force due to the Earth's magnetic field $\vec{\mathbf{B}}$, which is horizontal, perpendicular to the wire, and of magnitude $5.0 \times 10^{-5}$ T. What current would the wire carry? Does the answer seem feasible? Explain briefly.

**10.** (II) The force on a wire carrying 6.45 A is a maximum of 1.64 N when placed between the pole faces of a magnet. If the pole faces are 55.5 cm in diameter, what is the approximate strength of the magnetic field?

**11.** (II) A stiff wire 50.0 cm long is bent at a right angle in the middle. One section lies along the $z$ axis and the other is along the line $y = 2x$ in the $xy$ plane. A current of 20.0 A flows in the wire—down the $z$ axis and out the wire in the $xy$ plane. The wire passes through a uniform magnetic field given by $\vec{\mathbf{B}} = (0.285\,\hat{\mathbf{i}})$T. Determine the magnitude and direction of the total force on the wire.

**12.** (II) A long wire stretches along the $x$ axis and carries a 3.0-A current to the right $(+x)$. The wire is in a uniform magnetic field $\vec{\mathbf{B}} = (0.20\,\hat{\mathbf{i}} - 0.42\,\hat{\mathbf{j}} + 0.25\,\hat{\mathbf{k}})$T. Determine the components of the force on the wire per cm of length.

**13.** (II) A 2.0-m-long wire carries a current of 7.4 A and is immersed within a uniform magnetic field $\vec{\mathbf{B}}$. When this wire lies along the $+x$ axis, a magnetic force $\vec{\mathbf{F}} = (-2.5\,\hat{\mathbf{j}})$N acts on the wire, and when it lies on the $+y$ axis, the force is $\vec{\mathbf{F}} = (2.5\,\hat{\mathbf{i}} - 5.0\,\hat{\mathbf{k}})$N. Find $\vec{\mathbf{B}}$.

**14.** (II) A current-carrying circular loop of wire (radius $r$, current $I$) is partially immersed in a magnetic field of constant magnitude $B_0$ directed out of the page as shown in Fig. 27–43. Determine the net force on the loop due to the field in terms of $\theta_0$. (Note that $\theta_0$ points to the dashed line, above which $B = 0$.)

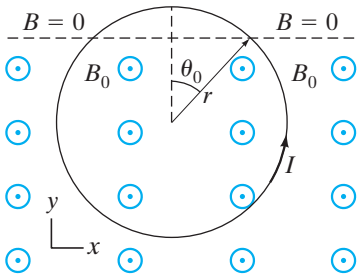

**FIGURE 27–43** Problem 14.

**15.** (III) A curved wire, connecting two points a and b, lies in a plane perpendicular to a uniform magnetic field $\vec{\mathbf{B}}$ and carries a current $I$. Show that the resultant magnetic force on the wire, no matter what its shape, is the same as that on a straight wire connecting the two points carrying the same current $I$. See Fig. 27–44.

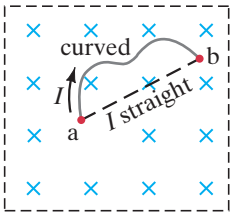

**FIGURE 27–44** Problem 15.

**16.** (III) A circular loop of wire, of radius $r$, carries current $I$. It is placed in a magnetic field whose straight lines seem to diverge from a point a distance $d$ below the loop on its axis. (That is, the field makes an angle $\theta$ with the loop at all points, Fig. 27–45, where $\tan\theta = r/d$.) Determine the force on the loop.

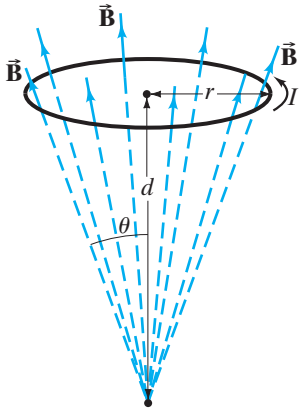

**FIGURE 27–45** Problem 16.

## 27–4 Force on Charge Moving in Magnetic Field

**17.** (I) Determine the magnetic magnitude and direction of the force on an electron traveling $7.75 \times 10^5$ m/s horizontally to the east in a vertically upward magnetic field of strength 0.65 T.

**18.** (I) An electron is projected vertically upward with a speed of $1.70 \times 10^6$ m/s into a uniform magnetic field of 0.550 T that is directed horizontally away from the observer. Describe the electron's path in this field.

**19.** (I) A small bird (mass = 20.0 grams) has acquired a charge of 15.0 $\mu$C. How fast would the bird have to fly for the magnetic force due to the Earth's 0.5-G field to equal 1/10 the bird's weight? Is this a realistic speed? Assume a 90° angle between the bird's velocity and the magnetic field.

**20.** (I) Alpha particles (charge $q = +2e$, mass $m = 6.6 \times 10^{-27}$ kg) move at $2.2 \times 10^6$ m/s. What magnetic field strength would be required to bend them into a circular path of radius $r = 0.14$ m?

**21.** (I) Find the direction of the force on a negative charge for each diagram shown in Fig. 27–46, where $\vec{\mathbf{v}}$ (green) is the velocity of the charge and $\vec{\mathbf{B}}$ (blue) is the direction of the magnetic field. (⊗ means the vector points inward. ⊙ means it points outward, toward you.)

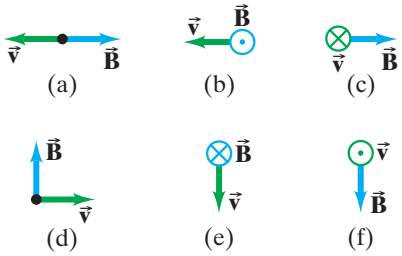

**FIGURE 27–46** Problem 21.

**22.** (II) Determine the direction of $\vec{\mathbf{B}}$ for each case in Fig. 27–47, where $\vec{\mathbf{F}}$ represents the maximum magnetic force on a positively charged particle moving with velocity $\vec{\mathbf{v}}$.

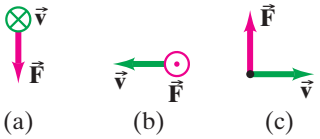

**FIGURE 27–47** Problem 22.

**23.** (II) A 720-KeV (kinetic energy) proton enters a 0.20-T field, in a plane perpendicular to the field. What is the radius of its path? See Section 23–8.

**24.** (II) An electron experiences the greatest force as it travels $2.8 \times 10^6$ m/s in a magnetic field when it is moving northward. The force is vertically upward and of magnitude $7.4 \times 10^{-13}$ N. What is the magnitude and direction of the magnetic field?

**25.** (II) A proton moves through a region of space where there is a magnetic field $\vec{\mathbf{B}} = (0.56\,\hat{\mathbf{i}} + 0.42\,\hat{\mathbf{j}})$ T and an electric field $\vec{\mathbf{E}} = (3.0\,\hat{\mathbf{i}} - 4.2\,\hat{\mathbf{j}}) \times 10^3$ V/m. At a given instant, the proton's velocity is $\vec{\mathbf{v}} = (6.0\,\hat{\mathbf{i}} + 3.0\,\hat{\mathbf{j}} - 5.0\,\hat{\mathbf{k}}) \times 10^3$ m/s. Determine the components of the total force on the proton.

**26.** (II) An electron experiences a force $\vec{\mathbf{F}} = (3.8\,\hat{\mathbf{i}} - 2.7\,\hat{\mathbf{j}}) \times 10^{-13}$ N when passing through a magnetic field $\vec{\mathbf{B}} = (0.74\,\text{T})\hat{\mathbf{k}}$. Determine the components of the electron's velocity.

**27.** (II) A particle of charge $q$ moves in a circular path of radius $r$ in a uniform magnetic field $\vec{\mathbf{B}}$. If the magnitude of the magnetic field is doubled, and the kinetic energy of the particle remains constant, what happens to the angular momentum of the particle?

**28.** (II) An electron moves with velocity $\vec{\mathbf{v}} = (6.0\,\hat{\mathbf{i}} - 7.0\,\hat{\mathbf{j}}) \times 10^4$ m/s in a magnetic field $\vec{\mathbf{B}} = (-0.80\,\hat{\mathbf{i}} + 0.60\,\hat{\mathbf{j}})$ T. Determine the magnitude and direction of the force on the electron.

**29.** (II) A helium ion ($Q = +2e$) whose mass is $6.6 \times 10^{-27}$ kg is accelerated by a voltage of 5200 V. (*a*) What is its speed? (*b*) What will be its radius of curvature if it moves in a plane perpendicular to a uniform 0.340-T field? (*c*) What is its period of revolution?

**30.** (II) For a particle of mass $m$ and charge $q$ moving in a circular path in a magnetic field $B$, (*a*) show that its kinetic energy is proportional to $r^2$, the square of the radius of curvature of its path. (*b*) Show that its angular momentum is $L = qBr^2$, around the center of the circle.

**31.** (II) A proton (mass $m_p$), a deuteron $(m = 2m_p,\ q = e)$, and an alpha particle $(m = 4m_p,\ q = 2e)$ are accelerated by the same potential difference $V$ and then enter a uniform magnetic field $\vec{\mathbf{B}}$, where they move in circular paths perpendicular to $\vec{\mathbf{B}}$. Determine the radius of the paths for the deuteron and alpha particle in terms of that for the proton.

**32.** (II) An electron enters a uniform magnetic field $B = 0.28\ \text{T}$ at a 45° angle to $\vec{\mathbf{B}}$. Determine the radius $r$ and pitch $p$ (distance between loops) of the electron's helical path assuming its speed is $2.2 \times 10^6\ \text{m/s}$. See Fig. 27–48.

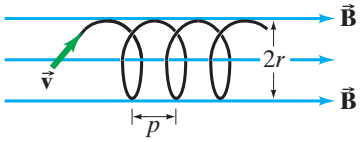

**FIGURE 27–48**
Problem 32.

**33.** (II) A particle with charge $q$ and momentum $p$, initially moving along the $x$ axis, enters a region where a uniform magnetic field $\vec{\mathbf{B}} = B_0\hat{\mathbf{k}}$ extends over a width $x = \ell$ as shown in Fig. 27–49. The particle is deflected a distance $d$ in the $+y$ direction as it traverses the field. Determine (*a*) whether $q$ is positive or negative, and (*b*) the magnitude of its momentum $p$ in terms of $q$, $B_0$, $\ell$, and $d$.

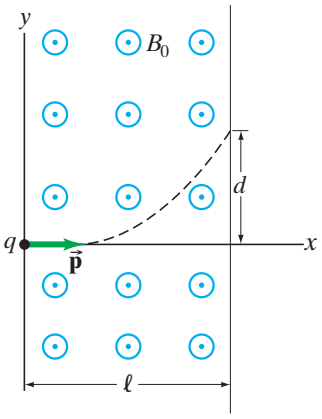

**FIGURE 27–49**
Problem 33.

**34.** (II) The path of protons emerging from an accelerator must be bent by 90° by a "bending magnet" so as not to strike a barrier in their path a distance $d$ from their exit hole in the accelerator. Show that the field $\vec{\mathbf{B}}$ in the bending magnet, which we assume is uniform and can extend over an area $d \times d$, must have magnitude $B \geq (2mK/e^2d^2)^{\frac{1}{2}}$, where $m$ is the mass of a proton and $K$ is its kinetic energy.

**35.** (III) A 3.40-g bullet moves with a speed of 155 m/s perpendicular to the Earth's magnetic field of $5.00 \times 10^{-5}\ \text{T}$. If the bullet possesses a net charge of $18.5 \times 10^{-9}\ \text{C}$, by what distance will it be deflected from its path due to the Earth's magnetic field after it has traveled 1.25 km?

**36.** (III) A proton moving with speed $v = 1.8 \times 10^5\ \text{m/s}$ in a field-free region abruptly enters an essentially uniform magnetic field $B = 0.850\ \text{T}\,(\vec{\mathbf{B}} \perp \vec{\mathbf{v}})$. If the proton enters the magnetic field region at a 45° angle as shown in Fig. 27–50, (*a*) at what angle does it leave, and (*b*) at what distance $x$ does it exit the field?

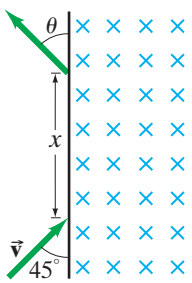

**FIGURE 27–50**
Problem 36.

**37.** (III) A particle with charge $+q$ and mass $m$ travels in a uniform magnetic field $\vec{\mathbf{B}} = B_0\hat{\mathbf{k}}$. At time $t = 0$, the particle's speed is $v_0$ and its velocity vector lies in the $xy$ plane directed at an angle of 30° with respect to the $y$ axis as shown in Fig. 27–51. At a later time $t = t_\alpha$, the particle will cross the $x$ axis at $x = \alpha$. In terms of $q$, $m$, $v_0$, and $B_0$, determine (*a*) $\alpha$, and (*b*) $t_\alpha$.

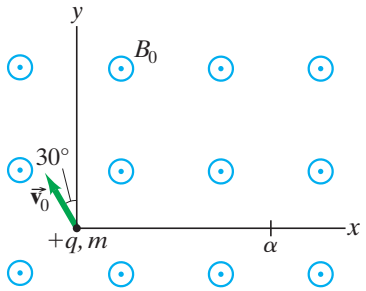

**FIGURE 27–51**
Problem 37.

## 27–5 Torque on a Current Loop; Magnetic Moment

**38.** (I) A 13.0-cm-diameter circular loop of wire is placed with the plane of the loop parallel to the uniform magnetic field between the pole pieces of a large magnet. When 3.80 A flows in the coil, the torque on it is $0.185\ \text{m} \cdot \text{N}$. What is the magnetic field strength?

**39.** (I) A single square loop of wire 22.0 cm on a side is placed with its face parallel to a 1.30-T magnetic field as in Fig. 27–23b. When 5.70 A flows in the coil, what is the torque on it?

**40.** (I) How much work is required to rotate the current loop (Fig. 27–23) in a uniform magnetic field $\vec{\mathbf{B}}$ from (*a*) $\theta = 0°\,(\vec{\boldsymbol{\mu}} \| \vec{\mathbf{B}})$ to $\theta = 180°$, (*b*) $\theta = 90°$ to $\theta = -90°$?

**41.** (II) A circular coil 18.0 cm in diameter and containing twelve loops lies flat on the ground. The Earth's magnetic field at this location has magnitude $5.50 \times 10^{-5}\ \text{T}$ and points into the Earth at an angle of 54.0° below a line pointing due north. If a 7.10-A clockwise current passes through the coil, (*a*) determine the torque on the coil; (*b*) which edge of the coil rises up: north, east, south, or west?

**42.** (II) Show that the magnetic dipole moment $\mu$ of an electron orbiting the proton nucleus of a hydrogen atom is related to the orbital momentum $L$ of the electron by

$$\mu = \frac{e}{2m}L.$$

**43.** (II) A 24-loop circular coil 22 cm in diameter lies in the $xy$ plane. The current in each loop of the coil is 7.6 A clockwise, and an external magnetic field $\vec{\mathbf{B}} = (0.55\hat{\mathbf{i}} + 0.60\hat{\mathbf{j}} - 0.65\hat{\mathbf{k}})\ \text{T}$ passes through the coil. Determine: (*a*) the magnetic moment of the coil, $\vec{\boldsymbol{\mu}}$; (*b*) the torque on the coil due to the external magnetic field; (*c*) the potential energy $U$ of the coil in the field (take the same zero for $U$ as we did in our discussion of Fig. 27–23).

**44.** (III) Suppose a nonconducting rod of length $d$ carries a uniformly distributed charge $Q$. It is rotated with angular velocity $\omega$ about an axis perpendicular to the rod at one end, Fig. 27–52. Show that the magnetic dipole moment of this rod is $\frac{1}{6}Q\omega d^2$. [*Hint*: Consider the motion of each infinitesimal length of the rod.]

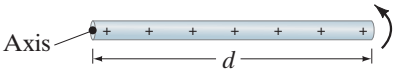

**FIGURE 27–52**
Problem 44.

## 27–6 Motors, Galvanometers

**45.** (I) If the current to an electric motor drops by 18%, by what factor does the output torque change?

**46.** (I) A galvanometer needle deflects full scale for a 63.0-$\mu$A current. What current will give full-scale deflection if the magnetic field weakens to 0.700 of its original value?

**47.** (I) If the restoring spring of a galvanometer weakens by 15% over the years, what current will give full-scale deflection if it originally required 25 $\mu$A?

## 27–7 Discovery of Electron

**48.** (I) What is the value of $q/m$ for a particle that moves in a circle of radius 8.0 mm in a 0.46-T magnetic field if a crossed 320-V/m electric field will make the path straight?

**49.** (II) (*a*) What is the velocity of a beam of electrons that go undeflected when passing through crossed (perpendicular) electric and magnetic fields of magnitude $1.52 \times 10^4$ V/m and $2.60 \times 10^{-3}$ T, respectively? (*b*) What is the radius of the electron orbit if the electric field is turned off?

**50.** (II) An oil drop whose mass is determined to be $3.8 \times 10^{-15}$ kg is held at rest between two large plates separated by 1.0 cm as in Fig. 27–32. If the potential difference between the plates is 340 V, how many excess electrons does this oil drop have?

## 27–8 Hall Effect

**51.** (II) A **Hall probe**, consisting of a rectangular slab of current-carrying material, is calibrated by placing it in a known magnetic field of magnitude 0.10 T. When the field is oriented normal to the slab's rectangular face, a Hall emf of 12 mV is measured across the slab's width. The probe is then placed in a magnetic field of unknown magnitude $B$, and a Hall emf of 63 mV is measured. Determine $B$ assuming that the angle $\theta$ between the unknown field and the plane of the slab's rectangular face is (*a*) $\theta = 90°$, and (*b*) $\theta = 60°$.

**52.** (II) A Hall probe used to measure magnetic field strengths consists of a rectangular slab of material (free-electron density $n$) with width $d$ and thickness $t$, carrying a current $I$ along its length $\ell$. The slab is immersed in a magnetic field of magnitude $B$ oriented perpendicular to its rectangular face (of area $\ell d$), so that a Hall emf $\mathcal{E}_H$ is produced across its width $d$. The probe's *magnetic sensitivity*, defined as $K_H = \mathcal{E}_H/IB$, indicates the magnitude of the Hall emf achieved for a given applied magnetic field and current. A slab with a large $K_H$ is a good candidate for use as a Hall probe. (*a*) Show that $K_H = 1/ent$. Thus, a good Hall probe has small values for both $n$ and $t$. (*b*) As possible candidates for the material used in a Hall probe, consider (i) a typical metal ($n \approx 1 \times 10^{29}/\text{m}^3$) and (ii) a (doped) semiconductor ($n \approx 3 \times 10^{22}/\text{m}^3$). Given that a semiconductor slab can be manufactured with a thickness of 0.15 mm, how thin (nm) should a metal slab be to yield a $K_H$ value equal to that of the semiconductor slab? Compare this metal slab thickness with the 0.3-nm size of a typical metal atom. (*c*) For the typical semiconductor slab described in part (*b*), what is the expected value for $\mathcal{E}_H$ when $I = 100$ mA and $B = 0.1$ T?

**53.** (II) A long copper strip is 3.0 cm wide and 1.0 mm thick. When it carries a steady 42-A current in a 0.80-T magnetic field it produces a 6.5-$\mu$V Hall emf. Determine: (*a*) the Hall field in the conductor; (*b*) the drift speed of the conduction electrons; (*c*) the density of free electrons in the metal.

**54.** (II) In a probe that uses the Hall effect to measure magnetic fields, a 12.0-A current passes through a 1.50-cm-wide strip ($= d$ in Fig. 27–33) of sodium metal that is 1.20 mm thick. If the Hall emf is 1.86 $\mu$V, what is the magnitude of the magnetic field (take it perpendicular to the flat face of the strip)? Assume one free electron per atom of Na, and take its specific gravity to be 0.971.

**55.** (III) The Hall effect can be used to measure **blood flow speed** because the blood contains ions that constitute an electric current. (*a*) Does the sign of the ions influence the emf? Explain. (*b*) Determine the flow speed in an artery 3.3 mm in diameter if the measured emf across the width of the artery is 0.13 mV and $B$ is 0.070 T. (In actual practice, an alternating magnetic field is used.)

## 27–9 Mass Spectrometer

**56.** (I) In a mass spectrometer, germanium atoms have radii of curvature equal to 21.0, 21.6, 21.9, 22.2, and 22.8 cm. The largest radius corresponds to an atomic mass of 76 u. What are the atomic masses of the other isotopes?

**57.** (II) One form of mass spectrometer accelerates ions by a voltage $V$ before they enter a magnetic field $B$. The ions are assumed to start from rest. Show that the mass of an ion is $m = qB^2R^2/2V$, where $R$ is the radius of the ions' path in the magnetic field and $q$ is their charge.

**58.** (II) Suppose the electric field between the electric plates in the mass spectrometer of Fig. 27–34 is $2.84 \times 10^4$ V/m and the magnetic fields are $B = B' = 0.58$ T. The source contains carbon isotopes of mass numbers 12, 13, and 14 from a long-dead piece of a tree. (To estimate atomic masses, multiply by $1.67 \times 10^{-27}$ kg.) (*a*) How far apart are the marks formed by the singly charged ions of each type on a detector or photographic film? (*b*) What if the ions were doubly charged? (*c*) Does it matter if the ion charge is positive (lost electrons) or negative (gained electrons)? Explain.

**59.** (II) An unknown particle moves in a straight line through crossed electric and magnetic fields with $E = 1.5$ kV/m and $B = 0.036$ T. If the electric field is turned off, the particle moves in a circular path of radius $r = 2.4$ cm. What might the two lightest possible particles be?

**60.** (II) Protons would move in a circle of radius 5.10 cm perpendicular to a 0.585-T magnetic field. What value of electric field could make their paths straight? In what direction must the electric field point?

**61.** (II) A mass spectrometer is monitoring air pollutants. It is difficult, however, to separate molecules of nearly equal mass such as CO (28.0106 u) and $N_2$ (28.0134 u). How large a radius of curvature must a spectrometer have (Fig. 27–34) if these two molecules are to be separated on the detector by 0.50 mm?

# General Problems

**62.** A proton and an electron have the same kinetic energy upon entering a region of constant magnetic field. What is the ratio of the radii of their circular paths?

**63.** A motor run by a 9.0-V battery has a 20-turn square coil with sides of length 5.0 cm and total resistance 24 Ω. When spinning, the magnetic field felt by the wire in the coil is 0.020 T. What is the maximum torque on the motor?

**64.** Two stiff parallel wires a distance $d$ apart in a horizontal plane act as rails to support a light metal rod of mass $m$ (perpendicular to each rail), Fig. 27–53. A magnetic field $\vec{\mathbf{B}}$, directed vertically upward (outward in diagram), acts throughout. At $t = 0$, a constant current $I$ begins to flow through the system. Determine the speed of the rod, which starts from rest at $t = 0$, as a function of time (*a*) assuming no friction between the rod and the rails, and (*b*) if the coefficient of friction is $\mu_k$. (*c*) In which direction does the rod move, east or west, if the current through it heads north?

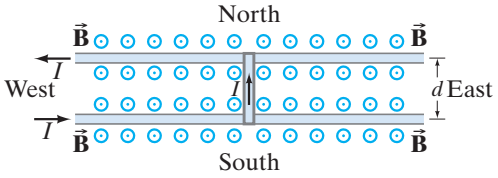

**FIGURE 27–53** Looking down on a rod sliding on rails. Problems 64 and 65.

**65.** Suppose the rod in Fig. 27–53 (Problem 64) has mass $m = 0.40$ kg and length 28 cm and the current through it is $I = 36$ A. If the coefficient of static friction is $\mu_s = 0.50$, determine the minimum magnetic field $\vec{\mathbf{B}}$ (not necessarily vertical) that will just cause the rod to slide. Give the magnitude of $\vec{\mathbf{B}}$ and its direction relative to the vertical (= out of the page).

**66.** Near the equator, the Earth's magnetic field points almost horizontally to the north and has magnitude $B = 0.50 \times 10^{-4}$ T. What should be the magnitude and direction for the velocity of an electron if its weight is to be exactly balanced by the magnetic force?

**67.** A uniform conducting rod of length $\ell$ and mass $m$ sits atop a fulcrum, which is placed a distance $\ell/4$ from the rod's left-hand end and is immersed in a uniform magnetic field of magnitude $B$ directed into the page (Fig. 27–54). An object whose mass $M$ is 7.0 times greater than the rod's mass is hung from the rod's left-hand end. What current (direction and magnitude) should flow through the rod in order for it to be "balanced" (i.e., be at rest horizontally) on the fulcrum? (Flexible connecting wires which exert negligible force on the rod are not shown.)

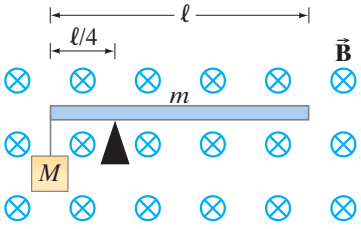

**FIGURE 27–54** Problem 67.

**68.** Protons with momentum $4.8 \times 10^{-21}$ kg · m/s are magnetically steered clockwise in a circular path 2.7 m in diameter. Determine the magnitude and direction of the field in the magnets surrounding the beam pipe.

**69.** The **cyclotron** (Fig. 27–55) is a device used to accelerate elementary particles such as protons to high speeds. Particles starting at point A with some initial velocity travel in semicircular orbits in the magnetic field $B$. The particles are accelerated to higher speeds each time they pass through the gap between the metal "dees," where there is an electric field $E$. (There is no electric field inside the hollow metal dees where the protons move in circular paths.) The electric field changes direction each half-cycle, owing to an ac voltage $V = V_0 \sin 2\pi ft$, so that the particles are increased in speed at each passage through the gap. (*a*) Show that the frequency $f$ of the voltage must be $f = Bq/2\pi m$, where $q$ is the charge on the particles and $m$ their mass. (*b*) Show that the kinetic energy of the particles increases by $2qV_0$ each revolution, assuming that the gap is small. (*c*) If the radius of the cyclotron is 2.0 m and the magnetic field strength is 0.50 T, what will be the maximum kinetic energy of accelerated protons in MeV?

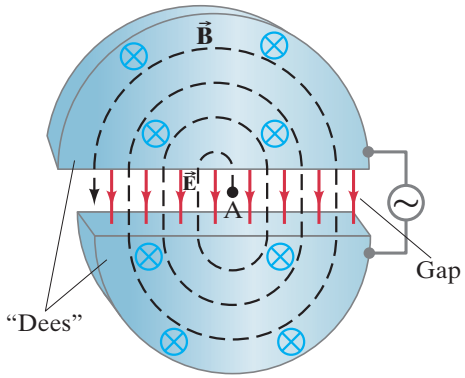

**FIGURE 27–55** A cyclotron. Problem 69.

**70.** Magnetic fields are very useful in particle accelerators for "beam steering"; that is, the magnetic fields can be used to change the direction of the beam of charged particles without altering their speed (Fig. 27–56). Show how this could work with a beam of protons. What happens to protons that are not moving with the speed for which the magnetic field was designed? If the field extends over a region 3.9 cm wide and has a magnitude of 0.32 T, by approximately what angle $\theta$ will a beam of protons traveling at $1.8 \times 10^6$ m/s be bent?

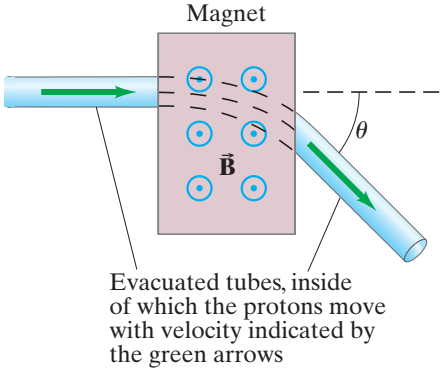

**FIGURE 27–56** Problem 70.

**71.** The magnetic field $B$ at the center of a circular coil of wire carrying a current $I$ (as in Fig. 27–9) is

$$B = \frac{\mu_0 NI}{2r},$$

where $N$ is the number of loops in the coil and $r$ is its radius. Imagine a simple model in which the Earth's magnetic field of about $1\,\text{G}\,(= 1 \times 10^{-4}\,\text{T})$ near the poles is produced by a single current loop around the equator. Roughly estimate the current this loop would carry.

**72.** A square loop of aluminum wire is 20.0 cm on a side. It is to carry 15.0 A and rotate in a uniform 1.35-T magnetic field as shown in Fig. 27–57. (*a*) Determine the minimum diameter of the wire so that it will not fracture from tension or shear. Assume a safety factor of 8. (See Table 12–2.) (*b*) What is the resistance of a single loop of this wire?

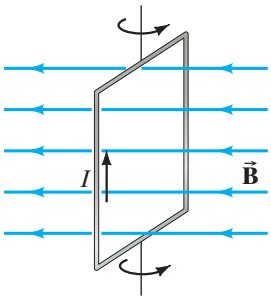

**FIGURE 27–57** Problem 72.

**73.** A sort of "projectile launcher" is shown in Fig. 27–58. A large current moves in a closed loop composed of fixed rails, a power supply, and a very light, almost frictionless plate (blue-green) touching the rails. A magnetic field is perpendicular to the plane of the circuit. If the bar has a length $\ell = 36$ cm, a mass of 45 g, and is placed in a field of 1.5 T, what constant current flow is needed to accelerate the bar from rest to 28 m/s in a distance of 1.0 m? In what direction must the magnetic field point?

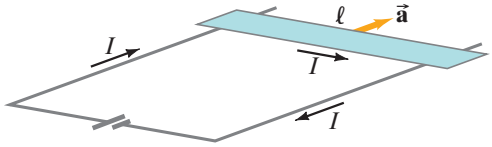

**FIGURE 27–58** Problem 73.

**74.** (*a*) What value of magnetic field would make a beam of electrons, traveling to the west at a speed of $4.2 \times 10^6$ m/s, go undeflected through a region where there is a uniform electric field of 12,000 V/m pointing south? (*b*) What is the direction of the magnetic field if it is perpendicular to the electric field? (*c*) What is the frequency of the circular orbit of the electrons if the electric field is turned off?

**75.** A proton follows a spiral path through a gas in a uniform magnetic field of 0.010 T, perpendicular to the plane of the spiral, as shown in Fig. 27–59. In two successive loops, at points P and Q, the radii are 10.0 mm and 8.5 mm, respectively. Calculate the change in the kinetic energy of the proton as it travels from P to Q, in eV.

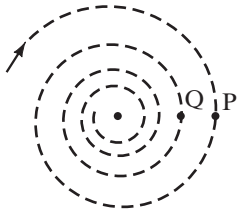

**FIGURE 27–59** Problem 75.

**76.** Suppose the Earth's magnetic field at the equator has magnitude $0.50 \times 10^{-4}\,\text{T}$ and a northerly direction at all points. Estimate the speed a singly ionized uranium ion $(m = 238\,\text{u},\ q = e)$ would need to circle the Earth 5.0 km above the equator. Can you ignore gravity? [Ignore relativity.]

**77.** The power cable for an electric trolley (Fig. 27–60) carries a horizontal current of 330 A toward the east. The Earth's magnetic field has a strength $5.0 \times 10^{-5}\,\text{T}$ and makes an angle of dip of 22° at this location. Calculate the magnitude and direction of the magnetic force on a 15-m length of this cable.

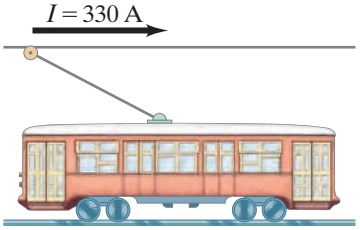

**FIGURE 27–60** Problem 77.

**78.** **Zeeman effect.** In the Bohr model of the hydrogen atom, the electron is held in its circular orbit of radius $r$ about its proton nucleus by electrostatic attraction. If the atoms are placed in a weak magnetic field $\vec{\mathbf{B}}$, the frequency of electrons revolving (in a circle) in a plane perpendicular to $\vec{\mathbf{B}}$ is changed by an amount

$$\Delta f = \pm \frac{eB}{4\pi m}$$

where $e$ and $m$ are the charge and mass of an electron. (*a*) Derive this result, assuming the force due to $\vec{\mathbf{B}}$ is much less than that due to electrostatic attraction of the nucleus. (*b*) What does the $\pm$ sign indicate?

**79.** The net force on a current loop whose face is perpendicular to a uniform magnetic field is zero (Fig. 27–61) because contributions to the net force from opposite sides of the loop cancel. However, if the field varies in magnitude from one side of the loop to the other, then there can be a net force on the loop. Consider a square loop with sides whose length is $a$, located with one side at $x = b$ in the $xy$ plane (Fig. 27–61). A magnetic field is directed along $z$, with a magnitude in the region shown that varies with $x$ according to

$$B = B_0\left(1 + \frac{x}{b}\right).$$

If the current in the loop circulates counterclockwise (that is, the magnetic dipole moment of the loop is along the $z$ axis), find an expression for the net force on the loop.

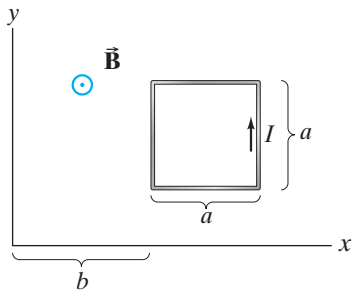

**FIGURE 27–61** Problem 79.

**80.** An electron is moving north at a constant speed of $3.0 \times 10^4$ m/s. (*a*) In what direction should an electric field point if the electron is to be accelerated to the east? (*b*) In what direction should a magnetic field point if the electron is to be accelerated to the west? (*c*) If the electric field of part *a* has a strength of 380 V/m, what magnetic field (magnitude and direction) will produce zero net force on the electron? (*d*) If the electron in part *c* is moving faster than $3.0 \times 10^4$ m/s, in which direction will it be accelerated? What if it is moving slower than $3.0 \times 10^4$ m/s? (*e*) Now consider electrons that move perpendicular to both a magnetic field and to an electric field, which are perpendicular to each other. If only electrons with speeds of $5.5 \times 10^4$ m/s go straight through undeflected, what is the ratio of the magnitudes of electric field to magnetic field? Without knowing the value of the electric field, can you know the value of the magnetic field?

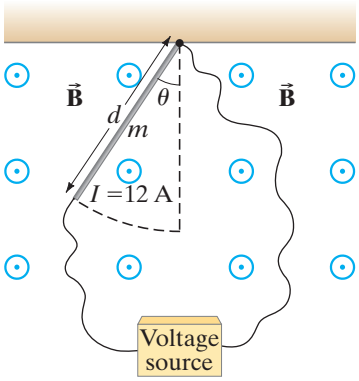
**81.** The rectangular loop of wire shown in Fig. 27–23 has mass $m$ and carries current $I$. Show that if the loop is oriented at an angle $\theta \ll 1$ (in radians), then when it is released it will execute simple harmonic motion about $\theta = 0$. Calculate the period of the motion.

**82.** A particle of charge $q$ moves in a circular path of radius $r$ perpendicular to a uniform magnetic field $B$. Determine its linear momentum in terms of the quantities given.

**83.** An airplane has acquired a net charge of 1160 $\mu$C. If the Earth's magnetic field of $5.0 \times 10^{-5}$ T is perpendicular to the airplane's velocity of magnitude 120 m/s, determine the force on the airplane.

**84.** Muons (mass = 207 times the electron mass, same charge $-e$) are accelerated horizontally by 65 kV. They then pass through a uniform magnetic field $B$ for a distance of 3.8 cm, which deflects them upward so they reach a detector 22 cm away, 11 cm above their original direction. Estimate the value of $B$.

**85.** In a simple device for measuring the magnitude $B$ of a magnetic field, a conducting rod (length $d = 1.0$ m, mass $m = 150$ g) hangs from a friction-free pivot and is oriented so that its axis of rotation is aligned with the direction of the magnetic field to be measured. Thin flexible wires (which exert negligible force on the rod) carry a current $I = 12$ A, which causes the rod to deflect an angle $\theta$ with respect to the vertical, where it remains at rest (Fig. 27–62). (*a*) Is the current flowing upward (toward the pivot) or downward in Fig. 27–62? (*b*) If $\theta = 13°$, determine $B$. (*c*) What is the largest magnetic field magnitude that can be measured using this device?



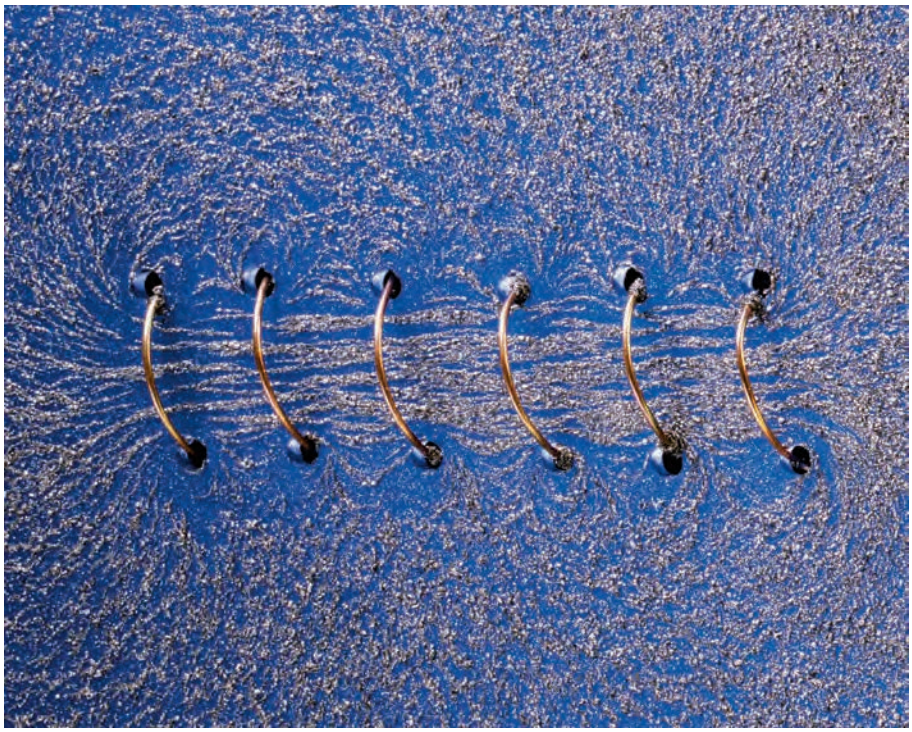


**FIGURE 27–62** Problem 85.

## ANSWERS TO EXERCISES

**A:** Near the poles, where the field lines are closer together.
**B:** Circles, pointing counterclockwise.
**C:** (*b*), (*c*), (*d*).
**D:** 0.15 N.
**E:** (*b*), (*c*), (*d*).
**F:** Zero.
**G:** Smaller.
**H:** Negative; the helical path would rotate in the opposite direction (still going to the right).
**I:** (*d*).

A long coil of wire with many closely spaced loops is called a solenoid. When a long solenoid carries an electric current, a nearly uniform magnetic field is produced within the loops as suggested by the alignment of the iron filings in this photo. The magnitude of the field inside a solenoid is readily found using Ampère's law, one of the great general laws of electromagnetism, relating magnetic fields and electric currents. We examine these connections in detail in this Chapter, as well as other means for producing magnetic fields.

CHAPTER 28

# Sources of Magnetic Field

**CHAPTER-OPENING QUESTION—Guess now!**

Which of the following will produce a magnetic field?

**(a)** An electric charge at rest.
**(b)** A moving electric charge.
**(c)** An electric current.
**(d)** The voltage of a battery not connected to anything.
**(e)** Any piece of iron.
**(f)** A piece of any metal.

In the previous Chapter, we discussed the effects (forces and torques) that a magnetic field has on electric currents and on moving electric charges. We also saw that magnetic fields are produced not only by magnets but also by electric currents (Oersted's great discovery). It is this aspect of magnetism, the production of magnetic fields, that we discuss in this Chapter. We will now see how to determine the magnetic field for some simple situations, and discuss some general relations between magnetic fields and their sources, electric current. Most elegant is Ampère's law. We also study the Biot-Savart law, which can be very helpful for solving practical problems.

# 28–1 Magnetic Field Due to a Straight Wire

We saw in Section 27–2 that the magnetic field due to the electric current in a long straight wire forms circles with the wire at the center (Fig. 28–1). You might expect that the field strength at a given point would be greater if the current flowing in the wire were greater; and that the field would be less at points farther from the wire. This is indeed the case. Careful experiments show that the magnetic field $B$ due to the current in a long straight wire is directly proportional to the current $I$ in the wire and inversely proportional to the distance $r$ from the wire:

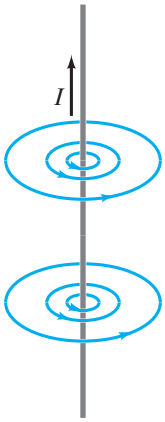
$$B \propto \frac{I}{r}.$$

This relation is valid as long as $r$, the perpendicular distance to the wire, is much less than the distance to the ends of the wire (i.e., the wire is long).

The proportionality constant is written as $\mu_0/2\pi$, so

$$B = \frac{\mu_0}{2\pi}\frac{I}{r}. \qquad \text{[near a long straight wire]} \quad \textbf{(28–1)}$$

The value of the constant $\mu_0$, which is called the **permeability of free space**,[†] is $\mu_0 = 4\pi \times 10^{-7}\,\text{T}\cdot\text{m/A}$.



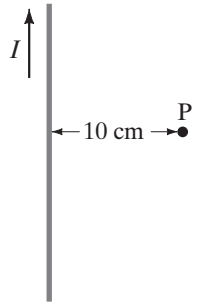


**FIGURE 28–1** Same as Fig. 27–8c. Magnetic field lines around a long straight wire carrying an electric current $I$.

**FIGURE 28–2** Example 28–1.

**EXAMPLE 28–1 Calculation of $\vec{B}$ near a wire.** An electric wire carries a dc current of 25 A vertically upward. What is the magnetic field due to this current at a point P, 10 cm due north of the wire (Fig. 28–2)?

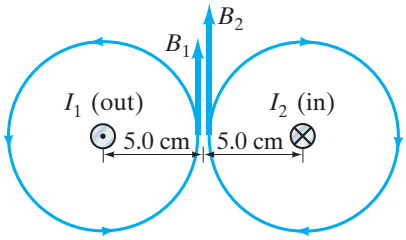
**APPROACH** We assume the wire is much longer than the 10-cm distance to the point P so we can apply Eq. 28–1.

**SOLUTION** According to Eq. 28–1:

$$B = \frac{\mu_0 I}{2\pi r} = \frac{(4\pi \times 10^{-7}\,\text{T}\cdot\text{m/A})(25\,\text{A})}{(2\pi)(0.10\,\text{m})} = 5.0 \times 10^{-5}\,\text{T},$$

or 0.50 G. By the right-hand rule (Table 27–1, page 791), the magnetic field due to the current points to the west (into the page in Fig. 28–2) at point P.

**NOTE** The magnetic field at P produced by this current has about the same magnitude as Earth's, so a compass at P would not point north but to the northwest.



**NOTE** Most electrical wiring is ac, which changes too rapidly to affect a compass. Besides, even for dc, wiring in buildings consists of cables with two wires in each cable. Since the two wires carry current in opposite directions, their magnetic fields cancel to a large extent, but may still affect sensitive electronic devices.

**CAUTION**

*A compass, near a dc current, may not point north*

**EXERCISE A** In Chapter 25 we saw that a typical lightning bolt produces a 100-A current for 0.2 s (Example 25–10). Estimate the magnetic field 10 m from a lightning bolt. Would it have a significant effect on a compass?

**FIGURE 28–3** Example 28–2. Wire 1 carrying current $I_1$ out towards us, and wire 2 carrying current $I_2$ into the page, produce magnetic fields whose lines are circles around their respective wires.

**EXAMPLE 28–2 Magnetic field midway between two currents.** Two parallel straight wires 10.0 cm apart carry dc currents in opposite directions (Fig. 28–3). Current $I_1 = 5.0\,\text{A}$ is out of the page, and $I_2 = 7.0\,\text{A}$ is into the page. Determine the magnitude and direction of the magnetic field halfway between the two wires.

**APPROACH** The magnitude of the field produced by each wire is calculated from Eq. 28–1. The direction of *each* wire's field is determined with the right-hand rule. The total field is the vector sum of the two fields at the midway point.

[†]The constant $\mu_0$ is chosen in this way so that Ampère's law (Section 28–4), which is considered a fundamental law of physics, has a simple and elegant form. Also, in the new SI (System of Units), described in Section 1–4, the value of $\mu_0$ is no longer exact, but does correspond to the $4\pi$ here to 10 decimal places, or 1 part in $10^{10}$. For convenience, we usually will use the traditional $4\pi$ in calculations so cancellation of terms is easy.

**SOLUTION** The magnetic field lines due to current $I_1$ form circles around the wire of $I_1$, and right-hand-rule-1 (Fig. 27–8d) tells us they point counterclockwise around the wire. The field lines due to $I_2$ form circles around the wire of $I_2$ and point clockwise, Fig. 28–3. At the midpoint, both fields point upward in Fig. 28–3, and so add together. The midpoint is 0.050 m from each wire. From Eq. 28–1 the magnitudes of $B_1$ and $B_2$ are

$$B_1 = \frac{\mu_0 I_1}{2\pi r} = \frac{(4\pi \times 10^{-7}\,\mathrm{T\cdot m/A})(5.0\,\mathrm{A})}{2\pi(0.050\,\mathrm{m})} = 2.0 \times 10^{-5}\,\mathrm{T};$$

$$B_2 = \frac{\mu_0 I_2}{2\pi r} = \frac{(4\pi \times 10^{-7}\,\mathrm{T\cdot m/A})(7.0\,\mathrm{A})}{2\pi(0.050\,\mathrm{m})} = 2.8 \times 10^{-5}\,\mathrm{T}.$$

The total field is *up* with a magnitude of

$$B = B_1 + B_2 = 4.8 \times 10^{-5}\,\mathrm{T}.$$

**EXERCISE B** Suppose both $I_1$ and $I_2$ point into the page in Fig. 28–3. What then is the magnetic field midway between the two wires?

**CONCEPTUAL EXAMPLE 28–3** **Magnetic field due to four wires.** Figure 28–4 shows four long parallel wires which carry equal dc currents into or out of the page as shown. In which configuration, (a) or (b), is the magnetic field greater at the center of the square?

**RESPONSE** It is greater in (a). The arrows illustrate the directions of the field produced by each wire; check it out, using right-hand-rule-1 to confirm these results. The net field at the center is the superposition of the four fields (which are of equal magnitude), which will point to the left in (a) and is zero in (b).

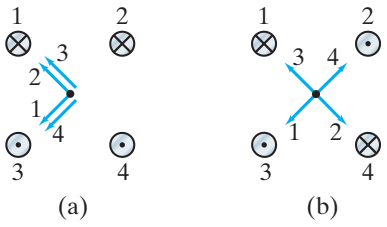


**FIGURE 28–4** Example 28–3.

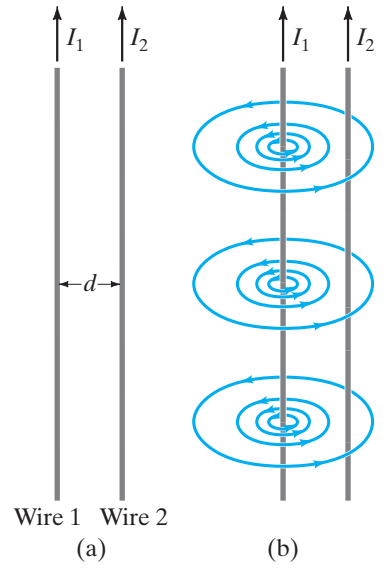
## 28–2 Force between Two Parallel Wires

We have seen that a wire carrying a current produces a magnetic field (magnitude given by Eq. 28–1 for a long straight wire). Also, a current-carrying wire feels a force when placed in a magnetic field (Section 27–3, Eq. 27–1). Thus, we expect that two current-carrying wires will exert a force on each other.

Consider two long parallel wires separated by a distance $d$, as in Fig. 28–5a. They carry dc currents $I_1$ and $I_2$, respectively. Each current produces a magnetic field that is "felt" by the other, so each must exert a force on the other. For example, the magnetic field $B_1$ produced by $I_1$ in Fig. 28–5 is given by Eq. 28–1, which at the location of wire 2 points into the page and has magnitude

$$B_1 = \frac{\mu_0}{2\pi}\frac{I_1}{d}.$$

See Fig. 28–5b, where the field due *only* to $I_1$ is shown. According to Eq. 27–2, the force $F_2$ exerted by $B_1$ on a length $\ell_2$ of wire 2, carrying current $I_2$, has magnitude



$$F_2 = I_2 \ell_2 B_1.$$

Note that the force on $I_2$ is due only to the field produced by $I_1$. Of course, $I_2$ also produces a field; but it does not exert a force on itself. We substitute $B_1$ into the formula for $F_2$ and find that the force on a length $\ell_2$ of wire 2 is

$$F_2 = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d}\ell_2. \qquad \text{[parallel wires]} \quad \textbf{(28–2)}$$

If we use right-hand-rule-1 of Fig. 27–8d, we see that the lines of $B_1$ are as shown in Fig. 28–5b. Then using right-hand-rule-2 of Fig. 27–11c, we see that the force exerted on $I_2$ will be to the left in Fig. 28–5b. (See page 791 for right-hand-rules.)

**FIGURE 28–5** (a) Two parallel conductors carrying dc currents $I_1$ and $I_2$. (b) Magnetic field $\vec{\mathbf{B}}_1$ produced by $I_1$. (Field produced by $I_2$ is not shown.) $\vec{\mathbf{B}}_1$ points into page at position of $I_2$.

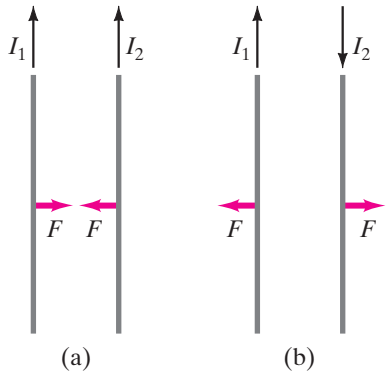


**FIGURE 28–6** (a) Parallel currents in the same direction exert an attractive force on each other. (b) Antiparallel currents (in opposite directions) exert a repulsive force on each other.

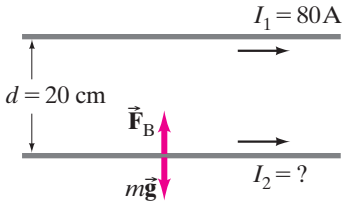
That is, $I_1$ exerts an attractive force on $I_2$ (Fig. 28–6a). This is true as long as the currents are in the same direction. If $I_2$ is in the opposite direction from $I_1$, right-hand-rule-2 indicates that the force is in the opposite direction. That is, $I_1$ exerts a repulsive force on $I_2$ (Fig. 28–6b).

Reasoning similar to that above shows that the magnetic field produced by $I_2$ exerts an equal but opposite force on $I_1$. We expect this to be true also from Newton's third law. Thus, as shown in Fig. 28–6, parallel currents in the same direction attract each other, whereas parallel currents in opposite directions repel.

**EXAMPLE 28–4** **Force between two current-carrying wires.** The two wires of a 2.0-m-long appliance cord are 3.0 mm apart and carry a current of 8.0 A dc. Calculate the force one wire exerts on the other.



**APPROACH** Each wire is in the magnetic field of the other when the current is on, so we can apply Eq. 28–2.

**SOLUTION** Equation 28–2 gives

$$F = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d}\ell_2 = \frac{(4\pi \times 10^{-7}\,\mathrm{T\cdot m/A})(8.0\,\mathrm{A})^2(2.0\,\mathrm{m})}{(2\pi)(3.0\times 10^{-3}\,\mathrm{m})} = 8.5\times 10^{-3}\,\mathrm{N}.$$

The currents are in opposite directions (one toward the appliance, the other away from it), so the force would be repulsive and tend to spread the wires apart.

**FIGURE 28–7** Example 28–5.

**EXAMPLE 28–5** **Suspending a wire with a current.** A horizontal wire carries a current $I_1 = 80$ A dc. A second parallel wire 20 cm below it (Fig. 28–7) must carry how much current $I_2$ so that it doesn't fall due to gravity? The lower wire has a mass of 0.12 g per meter of length.

**APPROACH** If wire 2 is not to fall under gravity, which acts downward, the magnetic force on it must be upward. This means that the current in the two wires must be in the same direction (Fig. 28–6). We can find the current $I_2$ by equating the magnitudes of the magnetic force and the gravitational force on the wire.

**SOLUTION** The force of gravity on wire 2 is downward. For each 1.0 m of wire length, the gravitational force has magnitude

$$F = mg = (0.12\times 10^{-3}\,\mathrm{kg/m})(1.0\,\mathrm{m})(9.8\,\mathrm{m/s^2}) = 1.18\times 10^{-3}\,\mathrm{N}.$$

The magnetic force on wire 2 must be upward, and Eq. 28–2 gives

$$F = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d}\ell$$

where $d = 0.20$ m and $I_1 = 80$ A. We solve this for $I_2$ and set the two force magnitudes equal (letting $\ell = 1.0$ m):

$$I_2 = \frac{2\pi d}{\mu_0 I_1}\left(\frac{F}{\ell}\right) = \frac{2\pi(0.20\,\mathrm{m})}{(4\pi\times 10^{-7}\,\mathrm{T\cdot m/A})(80\,\mathrm{A})}\frac{(1.18\times 10^{-3}\,\mathrm{N/m})}{(1.0\,\mathrm{m})} = 15\,\mathrm{A}.$$

## 28–3 Definitions of the Ampere and the Coulomb

You may have wondered how the constant $\mu_0$ in Eq. 28–1 could be exactly $4\pi\times 10^{-7}\,\mathrm{T\cdot m/A}$. Here is how it happened. With an older definition of the ampere, the unit of electric current, $\mu_0$ was measured experimentally to be very close to this value. Then, until recently, $\mu_0$ was *defined* to be exactly $4\pi\times 10^{-7}\,\mathrm{T\cdot m/A}$. This could not have been done if the ampere had been defined independently, so it was then defined in terms of the magnetic field $B$ it produced using the defined value of $\mu_0$.

In particular, in the traditional SI we use the force between two parallel current-carrying wires, Eq. 28–2, to define the ampere precisely. If $I_1 = I_2 = 1\,\text{A}$ exactly, and the two wires are exactly 1 m apart, then

$$\frac{F}{\ell} = \frac{\mu_0}{2\pi}\frac{I_1 I_2}{d} = \frac{(4\pi \times 10^{-7}\,\text{T}\cdot\text{m/A})}{(2\pi)}\frac{(1\,\text{A})(1\,\text{A})}{(1\,\text{m})} = 2 \times 10^{-7}\,\text{N/m},$$

exactly. Thus, *one* **ampere** *can be defined as that current flowing in each of two long parallel wires exactly 1 m apart, which results in a force of exactly* $2 \times 10^{-7}$ *N per meter of length of each wire.*

This has long been the precise definition of the ampere,[†] and because it is readily reproducible, is called an "operational definition." The **coulomb** is defined in terms of the ampere as being *exactly* one ampere-second: $1\,\text{C} = 1\,\text{A}\cdot\text{s}$.

### Operational Definitions

This may seem a roundabout way of defining quantities. The reason is the desire for **operational definitions**, definitions of quantities that can be readily reproducible given a definite set of operations to carry out. For example, the unit of charge, the coulomb, could be defined in terms of the force between two equal charges after defining a value for $\epsilon_0$ or $k$ in Eqs. 21–1 or 21–2. But to carry out an actual experiment to measure the force between two charges is difficult: any desired amount of charge is not easily obtained precisely, and charge tends to leak from objects into the air. The amount of current in a wire, on the other hand, can be varied accurately and continuously (by putting a variable resistor in a circuit). Thus the force between two current-carrying conductors is easier to measure precisely. This is why we first define the ampere, and then define the coulomb in terms of the ampere.

## 28–4 Ampère's Law

The relation between the current in a long straight wire and the magnetic field it produces is given by Eq. 28–1, Section 28–1. This equation is valid *only* for a long straight wire. Is there a general relation between a current in a wire of any shape and the magnetic field around it? The answer is yes: the French scientist André Marie Ampère (1775–1836) proposed such a relation shortly after Oersted's discovery. Consider any (arbitrary) closed path around a current, as shown in Fig. 28–8, and imagine this path as being made up of short segments each of length $\Delta\ell$. First, we take the product of the length of each segment times the component of magnetic field $\vec{\mathbf{B}}$ parallel to that segment (call this component $B_\parallel$). If we now sum all these terms, according to Ampère, the result will be equal to $\mu_0$ times the net current $I_{\text{encl}}$ that passes through the surface enclosed by the path:

$$\sum B_\parallel \,\Delta\ell = \mu_0 I_{\text{encl}}.$$

The lengths $\Delta\ell$ are chosen small enough so that $B_\parallel$ is essentially constant along each length. The sum $(=\Sigma)$ must be made over a *closed path*; and $I_{\text{encl}}$ is the net current passing through the surface bounded by this closed path (orange in Fig. 28–8). In the limit $\Delta\ell \to 0$, this relation becomes

$$\oint \vec{\mathbf{B}}\cdot d\vec{\ell} = \mu_0 I_{\text{encl}}, \qquad \textbf{(28–3)}$$

where $d\vec{\ell}$ is an infinitesimal length vector and the vector dot product assures that the parallel component of $\vec{\mathbf{B}}$ is taken. Equation 28–3 is known as **Ampère's law**. The integrand in Eq. 28–3 is taken around a closed path (a line integral) and $I_{\text{encl}}$ is the current passing through the space enclosed by the chosen path or loop.

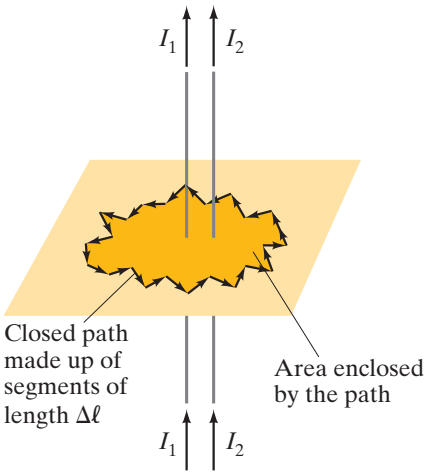


**FIGURE 28–8** Arbitrary path enclosing electric currents, for Ampère's law. The path is broken down into segments of length $\Delta\ell$. The total current enclosed by the path shown is $I_{\text{encl}} = I_1 + I_2$.

AMPÈRE'S LAW

[†]In the new SI (Section 1–4), 1 ampere is still 1 coulomb/s, and the Coulomb is defined by assigning the electron the exact value of $e = 1.602176634 \times 10^{-19}$ C.

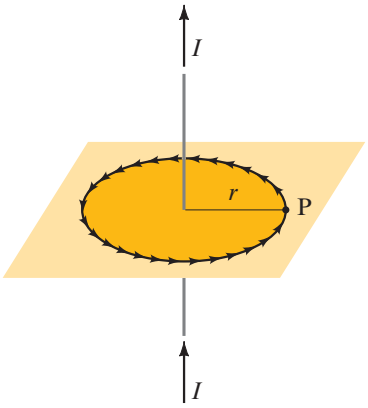

**FIGURE 28–9** Circular path of radius $r$.

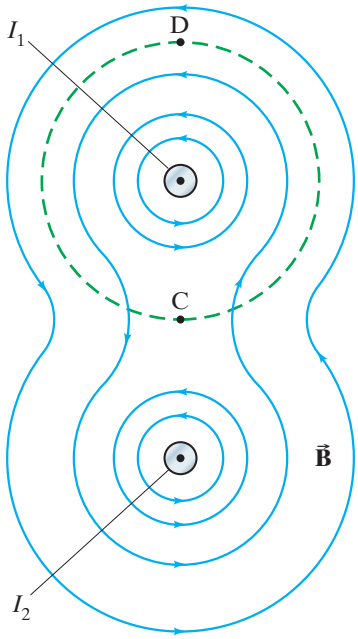
We can check Ampère's law by applying it to the simple case of a long straight wire carrying a current $I$, which we've already examined, and which served as an inspiration for Ampère himself. Let us find the magnitude of $\vec{\mathbf{B}}$ at point P, a distance $r$ from the wire in Fig. 28–9. The magnetic field lines are circles with the wire at their center. As the path to be used in Eq. 28–3, we choose a convenient one: a circle of radius $r$, because at any point on this path, $\vec{\mathbf{B}}$ will be tangent to this circle. All points on the path are the same distance from the wire, so by *symmetry* we expect $B$ to have the same magnitude at each point. For any short segment of the circle (Fig. 28–9), $\vec{\mathbf{B}}$ will be parallel to that segment, so $B_{\|} = B$. Then (setting $I_{\text{encl}} = I$) Ampère's law gives

$$\mu_0 I = \oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}}$$

$$= \oint B\, d\ell = B \oint d\ell = B(2\pi r),$$

where $\oint d\ell = 2\pi r$, the circumference of the circle. We solve for $B$ and obtain



$$B = \frac{\mu_0 I}{2\pi r}.$$

This is just Eq. 28–1 for the magnetic field near a long straight wire, so Ampère's law agrees with experiment in this case.

A great many experiments indicate that Ampère's law is valid in general. As with Gauss's law for the electric field, its practical value to calculate the magnetic field is limited, however, mainly to simple or symmetric situations. Its importance is that it relates the magnetic field to the current in a direct and mathematically elegant way. Ampère's law is considered one of the basic laws of electricity and magnetism. It is valid for any situation where the currents and fields are steady and not changing in time, and no magnetic materials are present.

We now can see why the constant in Eq. 28–1 is written $\mu_0/2\pi$: because then only $\mu_0$ appears in Eq. 28–3, rather than, say, $2\pi C$ if we had used $C$ in Eq. 28–1. In this way, the more fundamental equation, Ampère's law, has the simpler form.

**FIGURE 28–10** Magnetic field lines around two long parallel wires whose equal currents, $I_1$ and $I_2$, are coming out of the paper toward the viewer.

It should be noted that the $\vec{\mathbf{B}}$ in Ampère's law is not necessarily due only to the current $I_{\text{encl}}$. Ampère's law, like Gauss's law for the electric field, is valid in general. $\vec{\mathbf{B}}$ is the field at each point in space along the chosen path due to all sources—including the current $I$ enclosed by the path, but also due to any other sources. For example, the field surrounding two parallel current-carrying wires is the vector sum of the fields produced by each, and the field lines are shown in Fig. 28–10. If the path chosen for the integral (Eq. 28–3) is a circle centered on one of the wires with radius less than the distance between the wires (the dashed line in Fig. 28–10), only the current $(I_1)$ in the encircled wire is included on the right side of Eq. 28–3. $\vec{\mathbf{B}}$ on the left side of the equation must be the total $\vec{\mathbf{B}}$ at each point due to both wires. Note also that $\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}}$ for the path shown in Fig. 28–10 is the same whether the second wire is present or not (in both cases, it equals $\mu_0 I_1$ according to Ampère's law). How can this be? It can be so because the fields due to the two wires partially cancel one another at some points between them, such as point C in the diagram $(\vec{\mathbf{B}} = 0$ at a point midway between the wires if $I_1 = I_2)$; at other points, such as D in Fig. 28–10, the fields add together to produce a larger field. In the *sum*, $\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}}$, these effects just balance so that $\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = \mu_0 I_1$, whether the second wire is there or not. The integral $\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}}$ will be the same in each case, even though $\vec{\mathbf{B}}$ will not be the same at every point for each of the two cases.

**EXAMPLE 28–6** **Field inside and outside a wire.** A long straight cylindrical wire conductor of radius $R$ carries a dc current $I$ of uniform current density in the conductor. Determine the magnetic field due to this current at ($a$) points outside the conductor ($r > R$), and ($b$) points inside the conductor ($r < R$). See Fig. 28–11. Assume that $r$, the radial distance from the axis, is much less than the length of the wire. ($c$) If $R = 2.0\,\text{mm}$ and $I = 60\,\text{A}$, what is $B$ at $r = 1.0\,\text{mm}$, $r = 2.0\,\text{mm}$, and $r = 3.0\,\text{mm}$?

**APPROACH** We can use *symmetry*: Because the wire is long, straight, and cylindrical, we expect from symmetry that the magnetic field must be the same at all points that are the same distance from the center of the conductor. There is no reason why any such point should have preference over others at the same distance from the wire (they are physically equivalent), so $B$ must have the same value at all points the same distance from the center. This is what we mean by **symmetry**. We also expect $\vec{\mathbf{B}}$ to be tangent to circles around the wire (Fig. 28–1), so we choose a circular path of integration as we did in Fig. 28–9.

**SOLUTION** ($a$) We apply Ampère's law, integrating around a circle ($r > R$) centered on the wire (Fig. 28–11a), and then $I_{\text{encl}} = I$:

$$\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = B(2\pi r) = \mu_0 I_{\text{encl}}$$

or

$$B = \frac{\mu_0 I}{2\pi r}, \qquad [r > R]$$

which is the same result as for a thin wire, Eq. 28–1.

($b$) Inside the wire ($r < R$), we again choose a circular path concentric with the cylinder; we expect $\vec{\mathbf{B}}$ to be tangential to this path, and again, because of the symmetry, it will have the same magnitude at all points on the circle. The current enclosed in this case is less than $I$ by a factor of the ratio of the areas:

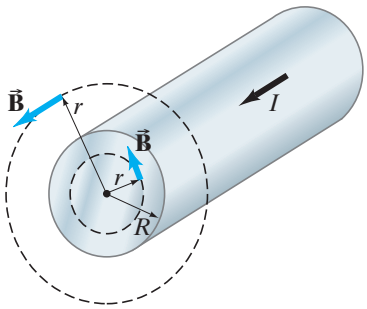
$$I_{\text{encl}} = I\frac{\pi r^2}{\pi R^2}.$$

So Ampère's law gives

$$\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = \mu_0 I_{\text{encl}}$$

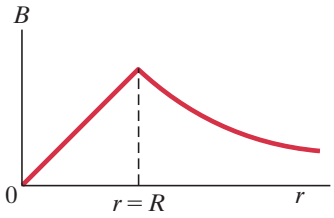
$$B(2\pi r) = \mu_0 I\left(\frac{\pi r^2}{\pi R^2}\right)$$

so



$$B = \left(\frac{\mu_0 I}{2\pi R^2}\right) r. \qquad [r < R]$$

The field is zero at the center of the conductor and increases linearly with $r$ until $r = R$; beyond $r = R$, $B$ decreases as $1/r$. This is shown in Fig. 28–11b. Note that these results are valid only at points close to the center of the conductor as compared to its length. For a current to flow, there must be connecting wires (to a battery, say), and the field due to these conducting wires, if not very far away, will destroy the assumed symmetry.



($c$) At $r = 2.0\,\text{mm}$, the surface of the wire, $r = R$, so

$$B = \frac{\mu_0 I}{2\pi R} = \frac{(4\pi \times 10^{-7}\,\text{T}\cdot\text{m/A})(60\,\text{A})}{(2\pi)(2.0 \times 10^{-3}\,\text{m})} = 6.0 \times 10^{-3}\,\text{T}.$$

We saw in ($b$) that inside the wire $B$ is linear in $r$. So at $r = 1.0\,\text{mm}$, $B$ will be half what it is at $r = 2.0\,\text{mm}$ or $3.0 \times 10^{-3}\,\text{T}$. Outside the wire, $B$ falls off as $1/r$, so at $r = 3.0\,\text{mm}$ it will be two-thirds as great as at $r = 2.0\,\text{mm}$, or $B = 4.0 \times 10^{-3}\,\text{T}$. To check, we use our result in ($a$), $B = \mu_0 I/2\pi r$, which gives the same result.

(a)

(b)

**FIGURE 28–11** Magnetic field inside and outside a cylindrical conductor (Example 28–6).

**⚠ CAUTION**
*Connecting wires can destroy assumed symmetry*

**PHYSICS APPLIED**
*Coaxial cable (shielding)*

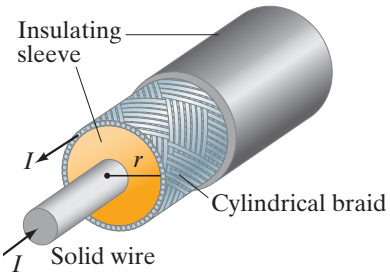


**FIGURE 28–12** Coaxial cable. Example 28–7.

**CONCEPTUAL EXAMPLE 28–7** **Coaxial cable.** A *coaxial cable* is a single wire surrounded by a cylindrical metallic braid, as shown in Fig. 28–12. The two conductors are separated by an insulator. The central wire carries current to the other end of the cable, and the outer braid carries the return current and is usually considered ground. Describe the magnetic field (*a*) in the space between the conductors, and (*b*) outside the cable.

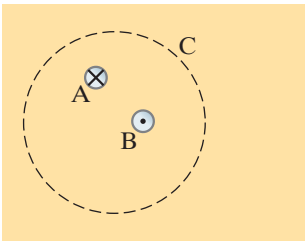
**RESPONSE** (*a*) In the space between the conductors, we can apply Ampère's law for a circular path around the center wire, just as we did for the case shown in Figs. 28–9 and 28–11. The magnetic field lines will be concentric circles centered on the center of the wire, and the magnitude is given by Eq. 28–3 or 28–1,

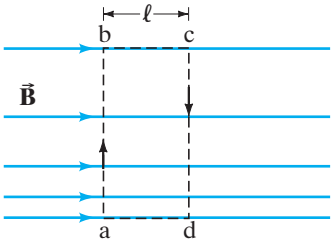
$$B = \mu_0 I/2\pi r$$

where $r$ is the distance from the center. The current in the outer conductor has no bearing on this result (it is not enclosed by the integral's loop).
(*b*) Outside the cable, we can draw a similar circular path, for we expect the field to have the same cylindrical symmetry. Now, however, there are two currents enclosed by the path, and they add up to zero. The field outside the cable is zero:

$$B = 0.$$

A key feature of coaxial cables is that they are self-shielding: no stray magnetic fields exist outside the cable. The outer cylindrical conductor also shields external electric fields from coming in (see also Example 21–15). This makes them ideal for carrying signals near sensitive equipment. Audiophiles use coaxial cables between stereo equipment components and to the loudspeakers.





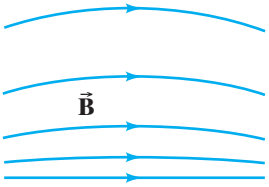


**FIGURE 28–13** Exercise C.

**EXERCISE C** In Fig. 28–13, A and B are wires each carrying a 3.0-A current but in opposite directions. On the circle C, which statement is true? (*a*) $B = 0$; (*b*) $\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = 0$; (*c*) $B = 3\mu_0$; (*d*) $B = -3\mu_0$; (*e*) $\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = 6\mu_0$.

**FIGURE 28–14** Example 28–8.

(a) (impossible)

(b) (possible)

**EXAMPLE 28–8** **A nice use for Ampère's law.** Use Ampère's law to show that in any region of space where there are no currents the magnetic field cannot be both unidirectional and nonuniform as shown in Fig. 28–14a.

**APPROACH** The wider spacing of lines near the top of Fig. 28–14a indicates the field $\vec{\mathbf{B}}$ has a smaller magnitude at the top than it does lower down. We apply Ampère's law to the rectangular path abcd shown dashed in Fig. 28–14a.

**SOLUTION** Because no current is enclosed by the chosen path, Ampère's law gives $\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}}$ is *zero*. The integral along sections ab and cd is zero, since $\vec{\mathbf{B}} \perp d\vec{\boldsymbol{\ell}}$. But along bc and da

$$\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = B_{\text{bc}}\ell - B_{\text{da}}\ell = (B_{\text{bc}} - B_{\text{da}})\ell,$$

which is *not* zero since the field $B_{\text{bc}}$ along the path bc is less than the field $B_{\text{da}}$ along path da. Hence we have a contradiction: $\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}}$ cannot be both zero (since $I = 0$) and nonzero. Thus we have shown that a nonuniform unidirectional field is not consistent with Ampère's law. A nonuniform field whose direction also changes, as in Fig. 28–14b, is consistent with Ampère's law (convince yourself this is so), and possible. The fringing of a permanent magnet's field (Fig. 27–7) has this shape.

PROBLEM SOLVING

## Ampère's Law

1. Ampère's law, like Gauss's law, is always a valid statement. But as a calculation tool it is limited mainly to systems with a high degree of symmetry. The first step in applying Ampère's law is to identify useful **symmetry**.
2. Choose an integration path that reflects the symmetry (see the Examples). Search for paths where $B$ has constant magnitude along the entire path or along segments of the path. Make sure your integration path passes through the point where you wish to evaluate the magnetic field.
3. Use symmetry to determine the direction of $\vec{\mathbf{B}}$ along the integration path. With a smart choice of path, $\vec{\mathbf{B}}$ will be either parallel or perpendicular to the path.
4. Determine the enclosed current, $I_{\text{encl}}$. Be careful with signs. Let the fingers of your right hand curl along the direction of $\vec{\mathbf{B}}$ so that your thumb shows the direction of positive current. If you have a solid conductor and your integration path does not enclose the full current, you can use the current density (current per unit area) multiplied by the enclosed area (as in Example 28–6).

# 28–5 Magnetic Field of a Solenoid and a Toroid

A long coil of wire consisting of many loops (or turns) of wire carrying a dc current is called a **solenoid**. The electric current in each loop produces a magnetic field as was shown in Fig. 27–9, and the total magnetic field is the sum of the fields due to each current loop, Fig. 28–15a. The direction of the magnetic field produced by the solenoid at any point is found using right-hand-rule-1, Fig. 27–8d. In Fig. 28–15a, we see the field due to a solenoid when the loops are far apart. Near each loop of wire, the field lines are very nearly circles as for a straight wire. Between any two loops, the fields due to each loop tend to cancel. Toward the center of the solenoid, the fields add up to give a field that can be large and fairly uniform. For a long solenoid with closely packed loops, the field is nearly uniform and parallel to the solenoid axis within the entire cross section, as shown in Fig. 28–15b. The field outside the solenoid is very small compared to the field inside, except near the ends. Note that the same number of field lines that are concentrated inside the solenoid, spread out into the vast open space outside, so the field is much weaker outside.

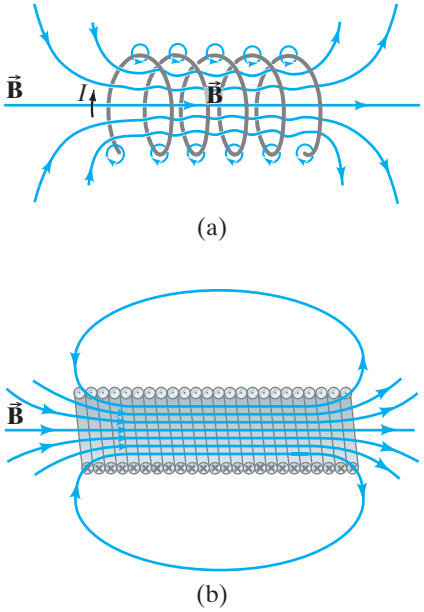

**FIGURE 28–15** Magnetic field due to a solenoid: (a) a few loosely spaced loops; (b) for many closely spaced loops, the field is nearly uniform.

We now use Ampère's law to determine the magnetic field inside a very long (ideally, infinitely long) closely packed solenoid. We choose the path abcd shown in red in Fig. 28–16, far from either end, for applying Ampère's law. We will consider this path as made up of four segments, the sides of the rectangle: ab, bc, cd, da. Then the left side of Eq. 28–3, Ampère's law, becomes

$$\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = \int_a^b \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} + \int_b^c \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} + \int_c^d \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} + \int_d^a \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}}.$$

The field outside the solenoid is so small as to be negligible compared to the field inside. So we set the first term in this sum equal to zero. Furthermore, $\vec{\mathbf{B}}$ is perpendicular to the segments bc and da inside the solenoid, and is nearly zero between and outside the wire loops, so these terms too are zero.

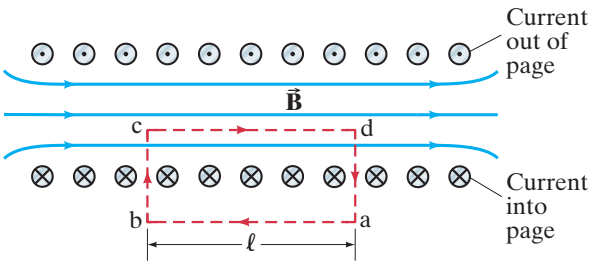

**FIGURE 28–16** Cross-sectional view into a solenoid. The magnetic field inside is straight except at the ends. Red dashed lines indicate the path chosen for use in Ampère's law. ⊙ and ⊗ are electric current direction (in the wire loops) out of the page and into the page.

Therefore we have reduced the integral to the segment cd where $\vec{\mathbf{B}}$ is the nearly uniform field inside the solenoid, and is parallel to $d\vec{\boldsymbol{\ell}}$, so

$$\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = \int_c^d \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = B\ell,$$

where $\ell$ is the length cd. Now, for the right side of Ampère's law, Eq. 28–3, we determine the current enclosed by our path abcd. If a current $I$ flows in the wire of the solenoid, the total current enclosed by our path abcd is $NI$ where $N$ is the number of loops our path encircles (five in Fig. 28–16). Thus Ampère's law gives us

$$B\ell = \mu_0 NI.$$

If we let $n = N/\ell$ be the *number of loops per unit length*, then

$$B = \mu_0 nI. \qquad \text{[solenoid]} \quad \textbf{(28–4)}$$

This is the magnitude of the magnetic field within a solenoid. Note that $B$ depends only on the number of loops per unit length, $n$, and the current $I$. The field does not depend on position within the solenoid, so $B$ is uniform. This is strictly true only for an infinite solenoid, but it is a good approximation for tightly wound real ones for points not close to the ends.

**EXERCISE D** A thin 10-cm-long solenoid used for fast electromechanical switching has 400 loops of wire and carries a current of 2.0 A. Estimate the field inside near the center.

The *direction* of the magnetic field inside a solenoid is found using right-hand-rule-1, Fig. 27–8d (see also Figs. 27–9 and 27–10), and is as shown for a tightly wound solenoid in Fig. 28–16.

A close look at Fig. 28–15 shows that the field outside of a solenoid is much like that of a bar magnet, Fig. 27–4. Indeed, a solenoid acts like a magnet, with one end acting as a north pole and the other as a south pole, depending on the direction of the current in the loops. Since magnetic field lines leave the north pole of a magnet, the north pole of the solenoid in Fig. 28–15b or 28–16 is on the right.

Solenoids have many practical applications, and we discuss some of them later in this Chapter, Section 28–9.

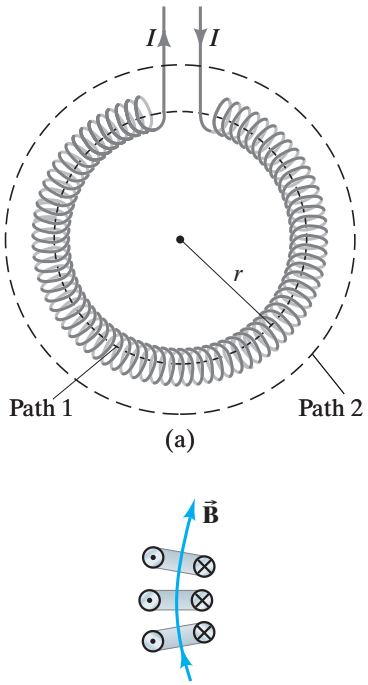

**FIGURE 28–17** (a) A toroid. (b) A section of the toroid showing direction of the current for three loops: ⊙ means current toward you, ⊗ means current away from you.

**EXAMPLE 28–9** **Toroid.** A toroid is like a solenoid bent into the shape of a circle as shown in Fig. 28–17a. Use Ampère's law to determine the magnetic field (*a*) inside the toroid's coil, and (*b*) outside the toroid.

**APPROACH** The magnetic field lines inside the toroid will be circles concentric with the toroid. (If you think of the toroid as a solenoid bent into a circle, the field lines bend along with the solenoid.) The direction of $\vec{\mathbf{B}}$ is clockwise. As our path of integration, we choose one of the field lines at radius $r$ inside the toroid as shown by the dashed line labeled "path 1" in Fig. 28–17a. We make this choice to use the *symmetry* of the situation, so $B$ will be tangent to the path and will have the same magnitude at all points along the path. ($B$ is not necessarily the same across the whole cross section of the toroid.) This chosen path encloses *all* the current loops; if there are $N$ loops, each carrying current $I$, then $I_{\text{encl}} = NI$.

**SOLUTION** (*a*) Ampère's law applied along this path 1 gives

$$\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = \mu_0 I_{\text{encl}}$$

$$B(2\pi r) = \mu_0 NI,$$

where $N$ is the total number of loops and $I$ is the current in each of the loops. Thus

$$B = \frac{\mu_0 NI}{2\pi r}.$$

The magnetic field $B$ is not uniform within the toroid: it is largest along the inner edge (where $r$ is smallest) and smallest at the outer edge. However, if the toroid is large, but thin (so that the difference between the inner and outer radii is small compared to the average radius), the field will be essentially uniform within the toroid. In this case, the formula for $B$ reduces to that for a straight solenoid $B = \mu_0 nI$ where $n = N/(2\pi r)$ is the number of loops per unit length.

(*b*) Outside the toroid, we choose our path of integration to be a circle concentric with the toroid, "path 2" in Fig. 28–17a. This path encloses $N$ loops carrying current $I$ in one direction and $N$ loops carrying the same current in the opposite direction. (Figure 28–17b shows the directions of the current for the parts of the loop on the inside and outside of the toroid.) Thus the net current enclosed by path 2 is zero. For a very tightly packed toroid, all points on path 2 are equidistant from the toroid and equivalent, so we expect $B$ to be the same at all points along the path. Hence, Ampère's law gives

$$\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = \mu_0 I_{\text{encl}}$$

$$B(2\pi r) = 0$$

or

$$B = 0.$$

For a path taken at a radius *smaller* than the inner edge of the toroid (in the "hole of the donut"), $I_{\text{encl}} = 0$ and $B = 0$. So there is no field exterior to a very tightly wound toroid. The magnetic field is all inside the loops.

# 28–6 Biot-Savart Law

The usefulness of Ampère's law for determining the magnetic field $\vec{\mathbf{B}}$ due to particular electric currents is restricted to situations where the symmetry of the given currents allows us to evaluate $\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}}$ readily. This does not, of course, invalidate Ampère's law nor does it reduce its fundamental importance. Recall the electric case, where Gauss's law is considered fundamental but is limited in its use for actually calculating $\vec{\mathbf{E}}$. We must often determine the electric field $\vec{\mathbf{E}}$ by another method: summing over contributions due to infinitesimal charge elements $dq$ via Coulomb's law: $dE = (1/4\pi\epsilon_0)(dq/r^2)$. A magnetic equivalent to this infinitesimal form of Coulomb's law would be helpful for currents that do not have great symmetry. Such a law was developed by Jean Baptiste Biot (1774–1862) and Felix Savart (1791–1841) shortly after Oersted's discovery in 1820 that a current produces a magnetic field.

According to Biot and Savart, a current $I$ flowing in any path can be considered as many tiny (infinitesimal) current elements, such as in the wire of Fig. 28–18. If $d\vec{\boldsymbol{\ell}}$ represents any infinitesimal length along which the current is flowing, then the magnetic field, $d\vec{\mathbf{B}}$, at any point P in space, due to this element of current, is given by

$$d\vec{\mathbf{B}} = \frac{\mu_0 I}{4\pi} \frac{d\vec{\boldsymbol{\ell}} \times \hat{\mathbf{r}}}{r^2}, \qquad \textbf{(28–5)} \quad \textit{Biot-Savart law}$$

where $\vec{\mathbf{r}}$ is the displacement vector from the element $d\vec{\boldsymbol{\ell}}$ to the point P, and $\hat{\mathbf{r}} = \vec{\mathbf{r}}/r$ is the unit vector (magnitude = 1) in the direction of $\vec{\mathbf{r}}$ (see Fig. 28–18).

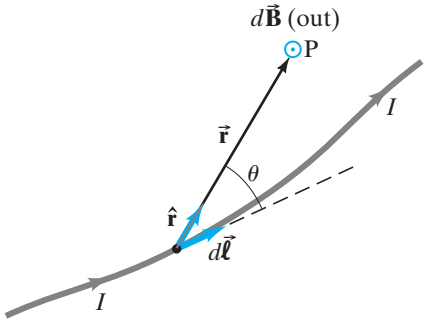

**FIGURE 28–18** Biot-Savart law: the field at P due to current element $Id\vec{\boldsymbol{\ell}}$ is $d\vec{\mathbf{B}} = (\mu_0 I/4\pi)(d\vec{\boldsymbol{\ell}} \times \hat{\mathbf{r}}/r^2)$.

Equation 28–5 is known as the **Biot-Savart law**. The magnitude of $d\vec{\mathbf{B}}$ is

$$dB = \frac{\mu_0 I d\ell \sin\theta}{4\pi r^2}, \qquad \textbf{(28–6)}$$

where $\theta$ is the angle between $d\vec{\boldsymbol{\ell}}$ and $\vec{\mathbf{r}}$ (Fig. 28–18). The total magnetic field at point P is then found by summing (integrating) over all current elements:

$$\vec{\mathbf{B}} = \int d\vec{\mathbf{B}} = \frac{\mu_0 I}{4\pi} \int \frac{d\vec{\boldsymbol{\ell}} \times \hat{\mathbf{r}}}{r^2}.$$

Note that this is a *vector* sum. The Biot-Savart law is the magnetic equivalent of Coulomb's law in its infinitesimal form. It is even an inverse square law, like Coulomb's law.

An important difference between the Biot-Savart law and Ampère's law (Eq. 28–3) is that in Ampère's law $\left[\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = \mu_0 I_{\text{encl}}\right]$, $\vec{\mathbf{B}}$ is not necessarily due only to the current enclosed by the path of integration. But in the Biot-Savart law the field $d\vec{\mathbf{B}}$ in Eq. 28–5 is due only, and entirely, to the current element $Id\vec{\boldsymbol{\ell}}$. To find the total $\vec{\mathbf{B}}$ at any point in space, it is necessary to include *all* currents.

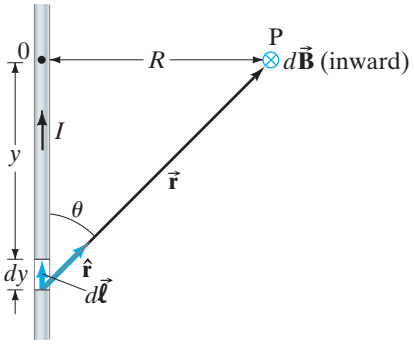

**FIGURE 28–19** Determining $\vec{\mathbf{B}}$ due to a long straight wire using the Biot-Savart law. Example 28–10.

**EXAMPLE 28–10** **$\vec{\mathbf{B}}$ due to current $I$ in a straight wire.** For the field near a long straight wire carrying a current $I$, show that the Biot-Savart law gives the same result as Eq. 28–1, $B = \mu_0 I/2\pi r$.

**APPROACH** We calculate the magnetic field in Fig. 28–19 at point P, which is a perpendicular distance $R$ from an infinitely long wire. The current is moving upwards, and both $d\vec{\boldsymbol{\ell}}$ and $\hat{\mathbf{r}}$, which appear in the cross product of Eq. 28–5, are in the plane of the page. Hence the direction of the field $d\vec{\mathbf{B}}$ due to each element of current must be directed into the plane of the page as shown (right-hand rule for the cross product $d\vec{\boldsymbol{\ell}} \times \hat{\mathbf{r}}$). Thus all the $d\vec{\mathbf{B}}$ have the same direction at point P, and add up to give $\vec{\mathbf{B}}$ the same direction consistent with our previous results (Figs. 28–1 and 28–11).

**SOLUTION** The magnitude of $\vec{\mathbf{B}}$ will be

$$B = \frac{\mu_0 I}{4\pi}\int_{y=-\infty}^{+\infty}\frac{dy\sin\theta}{r^2},$$

where $dy = d\ell$ and $r^2 = R^2 + y^2$. Note that we are integrating over $y$ (the position of each point of the wire) so $R$ is considered constant. Note also that we measure $y$ as positive upward from point 0, so for the current element shown in Fig. 28–19 $y < 0$. Both $y$ and $\theta$ are variables, but they are not independent. In fact, $y = -R/\tan\theta$, so $dy$ is given by (see Appendices B–1 and B–2)

$$dy = -R\frac{d}{d\theta}\left(\frac{1}{\tan\theta}\right)d\theta = +R\frac{1}{\tan^2\theta}\frac{d}{d\theta}(\tan\theta)\,d\theta$$
$$= \frac{R\,d\theta}{\tan^2\theta\cos^2\theta} = \frac{R\,d\theta}{\sin^2\theta} = \frac{R\,d\theta}{(R/r)^2} = \frac{r^2\,d\theta}{R}.$$

From Fig. 28–19 we can see that $y = -\infty$ corresponds to $\theta = 0$ and that $y = +\infty$ corresponds to $\theta = \pi$ radians. So our integral becomes

$$B = \frac{\mu_0 I}{4\pi}\frac{1}{R}\int_{\theta=0}^{\pi}\sin\theta\,d\theta = -\frac{\mu_0 I}{4\pi R}\cos\theta\Big|_0^{\pi} = \frac{\mu_0 I}{2\pi R}.$$

This is just Eq. 28–1 for the field near a long wire, where $R$ has been used instead of $r$.

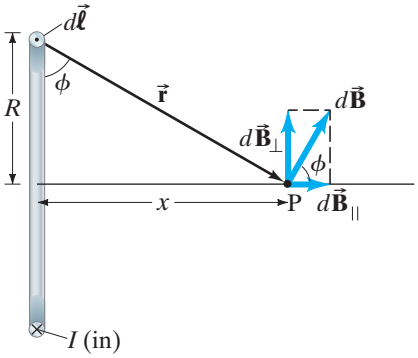

**FIGURE 28–20** Determining $\vec{\mathbf{B}}$ due to a current loop. Example 28–11.

**EXAMPLE 28–11** **Current loop.** Determine $\vec{\mathbf{B}}$ for points on the axis of a circular loop of wire of radius $R$ carrying a current $I$, Fig. 28–20.

**APPROACH** For an element of current at the top of the loop, the magnetic field $d\vec{\mathbf{B}}$ at point P on the axis is perpendicular to $\vec{\mathbf{r}}$ as shown, and has magnitude (Eq. 28–5)

$$dB = \frac{\mu_0 I\,d\ell}{4\pi r^2}$$

since $d\vec{\boldsymbol{\ell}}$ is perpendicular to $\vec{\mathbf{r}}$ so $|d\vec{\boldsymbol{\ell}} \times \hat{\mathbf{r}}| = d\ell$. We can break $d\vec{\mathbf{B}}$ down into components $dB_\parallel$ and $dB_\perp$, which are parallel and perpendicular to the axis as shown.

**SOLUTION** When we sum over all the elements of the loop, *symmetry* tells us that the perpendicular components will cancel on opposite sides, so $B_\perp = 0$. Hence, the total $\vec{\mathbf{B}}$ will point along the axis, and will have magnitude

$$B = B_\parallel = \int dB\cos\phi = \int dB\frac{R}{r} = \int dB\frac{R}{(R^2 + x^2)^{\frac{1}{2}}},$$

where $x$ is the distance of P from the center of the ring, and $r^2 = R^2 + x^2$. Now we put in $dB$ from the equation above (see APPROACH) and integrate around the current loop, noting that all segments $d\vec{\boldsymbol{\ell}}$ of current are the same distance, $(R^2 + x^2)^{\frac{1}{2}}$, from point P:

$$B = \frac{\mu_0 I}{4\pi}\frac{R}{(R^2 + x^2)^{\frac{3}{2}}}\int d\ell = \frac{\mu_0 I R^2}{2(R^2 + x^2)^{\frac{3}{2}}}$$

since $\int d\ell = 2\pi R$, the circumference of the loop.

**NOTE** At the very center of the loop (where $x = 0$) the field has its maximum value

$$B = \frac{\mu_0 I}{2R}. \qquad \text{[at center of current loop]}$$

**EXAMPLE 28–12** **$\vec{\mathbf{B}}$ due to a wire segment.** One quarter of a circular loop of wire carries a current $I$ as shown in Fig. 28–21. The current $I$ enters and leaves on straight segments of wire, as shown; the straight wires are along the radial direction from the center C of the circular portion. Find the magnetic field at point C.

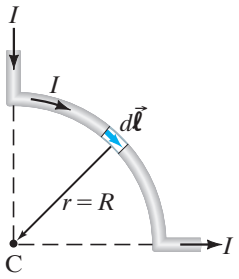

**FIGURE 28–21** Example 28–12.

**APPROACH** The current in the straight sections produces no magnetic field at point C because $d\vec{\ell}$ and $\hat{\mathbf{r}}$ in the Biot-Savart law (Eq. 28–5) are parallel in those straight sections and therefore $d\vec{\ell} \times \hat{\mathbf{r}} = 0$. Each piece $d\vec{\ell}$ of the curved section of wire produces a field $d\vec{\mathbf{B}}$ that points into the page at C (right-hand rule).

**SOLUTION** The magnitude of each $d\vec{\mathbf{B}}$ due to each $d\ell$ of the circular portion of wire is (we can use Eq. 28–6)

$$dB = \frac{\mu_0 I\, d\ell}{4\pi R^2}$$

where $r = R$ is the radius of the curved section, and $\sin\theta$ in Eq. 28–6 is $\sin 90° = 1$. With $r = R$ for all pieces $d\vec{\ell}$, we integrate over a quarter of a circle.

$$B = \int dB = \frac{\mu_0 I}{4\pi R^2}\int d\ell = \frac{\mu_0 I}{4\pi R^2}\left(\frac{1}{4}2\pi R\right) = \frac{\mu_0 I}{8R}.$$

## Magnetic Dipole Field

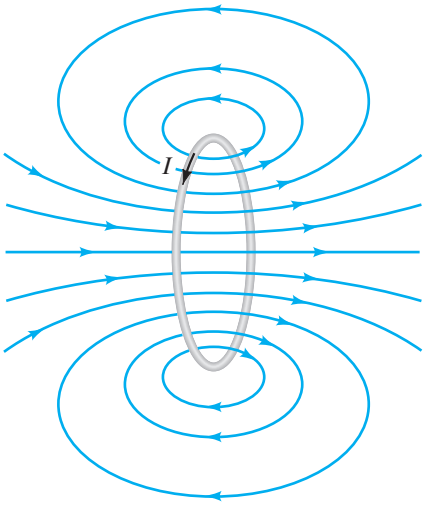
Recall from Section 27–5 that a current loop, such as that discussed in Example 28–11 (Fig. 28–20), is considered a **magnetic dipole**. We saw there that a current-carrying coil has a magnetic dipole moment

$$\mu = NIA,$$

where $A$ is the area of the coil and $N$ is the number of loops in the coil, each carrying current $I$. We also saw in Chapter 27 that a magnetic dipole placed in an external magnetic field experiences a torque and possesses potential energy, just like an electric dipole. In Example 28–11, we looked at another aspect of a magnetic dipole: the magnetic field *produced by* a magnetic dipole has magnitude, along the dipole axis, of

$$B = \frac{\mu_0 I R^2}{2\left(R^2 + x^2\right)^{\frac{3}{2}}}.$$

We can write this in terms of the magnetic dipole moment $\mu = IA = I\pi R^2$ (for a single loop $N = 1$):



$$B = \frac{\mu_0}{2\pi}\frac{\mu}{\left(R^2 + x^2\right)^{\frac{3}{2}}}. \qquad \text{[magnetic dipole]} \quad \textbf{(28–7a)}$$

(Be careful to distinguish $\mu$ for dipole moment from $\mu_0$, the magnetic permeability constant.) For distances far from the loop, $x \gg R$, this becomes

$$B \approx \frac{\mu_0}{2\pi}\frac{\mu}{x^3}. \qquad \left[\begin{array}{c}\text{on axis,}\\ \text{magnetic dipole, } x \gg R\end{array}\right] \quad \textbf{(28–7b)}$$

The magnetic field on the axis of a magnetic dipole decreases with the cube of the distance, just as the electric field does for an electric dipole. $B$ decreases as the cube of the distance also for points not on the axis, although the multiplying factor is not the same. The magnetic field due to a current loop can be determined at various points using the Biot-Savart law and the results are in accord with experiment. The field lines around a current loop are shown in Fig. 28–22.

**FIGURE 28–22** Magnetic field due to a circular loop of wire. (Same as Fig. 27–9.)

## 28–7 Magnetic Field Due to a Single Moving Charge

It might be tempting to use the Biot-Savart law (Eq. 28–5) to apply to a single point charge $q$ moving with a constant velocity $\vec{\mathbf{v}}$. A moving electric charge should indeed produce a magnetic field. We might try to determine such a field by relating the current $I$ (in the Biot-Savart law) to moving charges $q$ in a wire as we did in Chapter 27. In Section 27–4, we wrote a current $I = Nq/t$ where $N$ is the number of charges $q$ passing a given point in time $t$. Let us let $dt$ be the very brief time for a tiny charge $dq$ to travel a very tiny distance $d\ell$ at velocity $\vec{\mathbf{v}}$, then $\vec{\mathbf{v}} = d\vec{\boldsymbol{\ell}}/dt$ and $I\,d\vec{\boldsymbol{\ell}}$ in Eq. 28–5 is $I\,d\vec{\boldsymbol{\ell}} = Ndq\,d\vec{\boldsymbol{\ell}}/dt = N\vec{\mathbf{v}}dq$. If we substitute this expression into the Biot-Savart law, Eq. 28–5, setting $N = 1$ for the one single charge and integrating over that one moving charge $q$, we get $\vec{\mathbf{B}} = \int(\mu_0 I\,d\vec{\boldsymbol{\ell}} \times \hat{\mathbf{r}})/4\pi r^2 = \int \mu_0 Ndq\,\vec{\mathbf{v}} \times \hat{\mathbf{r}}/4\pi r^2 = \mu_0 q\vec{\mathbf{v}} \times \hat{\mathbf{r}}/4\pi r^2$.

But there is a problem with our derivation of this equation, and therefore with the equation itself. Our "derivation" started with the Biot-Savart law which works for steady electric currents that do not change in time moving in a significant length of wire, whereas one moving charge is at one spot at a given time and continually changing—it is changing position in time and its magnetic field is changing at any given location. So the equation we "derived" for $\vec{\mathbf{B}}$ above can not be trusted. Here are two more problems. (1) That "derived" equation would be difficult to verify experimentally because a single particle would shoot out of your lab before your instruments could measure $B$ accurately, unless the speed $v$ was very small—in which case $B$ would probably be too small to measure. (2) We expect the magnetic field lines to be circles around the direction of motion of the charged particle, just as for a current in a wire, Figs. 28–1 and 28–19. See Fig. 28–23. At any point in space, $B$ is largest when the moving charge is nearest that point; as the charge speeds away, $B$ decreases at that point. So $B$ is a function of time at any point. Here now is the fun: if you jumped on the particle, you might expect its magnetic field lines to be circles around it, something like in Fig. 28–23 (with $v = 0$). But no. If you are in the reference frame of the charge, the charge is at rest. A charge at rest produces no magnetic field! How could a particle have a magnetic field in one reference frame, and zero magnetic field in another? This contradiction, or paradox, and others like it, helped Einstein to develop his theory of Special Relativity, which resolved this inconsistency. Part of the answer, complicated though it seems, is that a magnetic field in one reference frame can be an electric field in a different reference frame. Observers in two different reference frames, moving relative to each other, will not observe the same $\vec{\mathbf{E}}$ and $\vec{\mathbf{B}}$ fields.

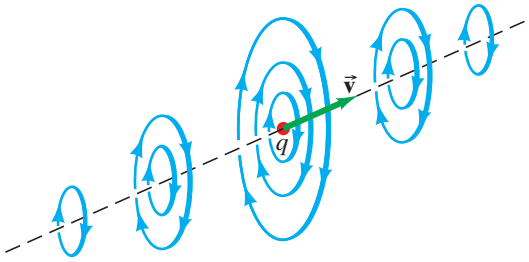


**FIGURE 28–23** The magnetic field at one single instant due to a single positive charge $q$, moving at velocity $\vec{\mathbf{v}}$.

## 28–8 Magnetic Materials—Ferromagnetism

Magnetic fields can be produced (1) by magnetic materials (magnets) and (2) by electric currents. Common magnetic materials include ordinary magnets, iron cores in motors and electromagnets, recording tape, computer hard drives, and magnetic stripes on credit cards. We saw in Section 27–1 that iron (and a few other materials) can be made into strong magnets. These materials are said to be **ferromagnetic**. We now look into the sources of ferromagnetism.

A bar magnet, with its two opposite poles near either end, resembles an electric dipole (equal-magnitude positive and negative charges separated by a distance). Indeed, a bar magnet is sometimes referred to as a "magnetic dipole."

There are opposite "poles" separated by a distance. And the magnetic field lines of a bar magnet form a pattern much like that for the electric field of an electric dipole: compare Fig. 21–35a with Fig. 27–4.

Microscopic examination reveals that a piece of iron is made up of tiny regions known as **domains**, less than 1 mm in length or width. Each domain behaves like a tiny magnet with a north and a south pole. In an unmagnetized piece of iron, these domains are arranged randomly, Fig. 28–24a. The magnetic effects of the domains cancel each other out, so this piece of iron does not behave as a magnet. In a magnet, the domains are preferentially aligned in one direction as shown in Fig. 28–24b (downward in this case). A magnet can be made from an unmagnetized piece of iron by placing it in a strong magnetic field. (You can make a needle magnetic, for example, by stroking it with one pole of a strong magnet.) The magnetization direction of domains may actually rotate slightly to be more nearly parallel to the external field, and the borders of domains may move so domains with magnetic orientation parallel to the external field grow larger (compare Figs. 28–24a and b).

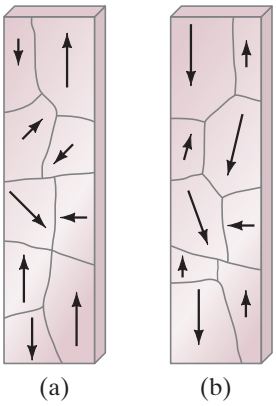

**FIGURE 28–24** (a) An unmagnetized piece of iron is made up of domains that are randomly arranged. Each domain is like a tiny magnet; the arrows represent the magnetization direction, with the arrowhead being the N pole. (b) In a magnet, the domains are preferentially aligned in one direction (down in this case), and may be altered in size by the magnetization process.

We can now explain how a magnet can pick up unmagnetized pieces of iron like paper clips. Consider the north pole of a permanent magnet. The magnet's field causes a slight realignment of the domains in the unmagnetized paper clip, so that it becomes a temporary magnet with its south pole facing the north pole of the permanent magnet; thus, attraction results. Similarly, elongated iron filings in a magnetic field acquire aligned domains and align themselves to reveal the shape of the magnetic field, Fig. 28–25.

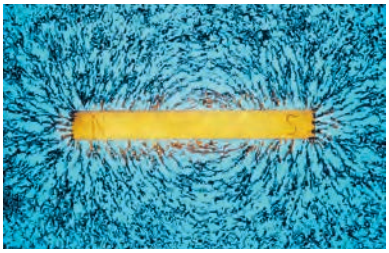

**FIGURE 28–25** Iron filings line up along magnetic field lines due to a permanent magnet.

An iron magnet can remain magnetized for a long time, and is referred to as a "permanent magnet." But if you drop a magnet on the floor or strike it with a hammer, you can jar the domains into randomness and the magnet loses some or all of its magnetism. Heating a permanent magnet can also cause loss of magnetism, because raising the temperature increases the random thermal motion of atoms, which tends to randomize the domains. Above a certain temperature known as the **Curie temperature** (1043 K for iron), a magnet cannot be made at all. Iron, nickel, cobalt, gadolinium, and certain alloys are ferromagnetic at room temperature; several other elements and alloys are ferromagnetic only at low temperatures. Most other metals, such as aluminum and copper, do not show any noticeable magnetic effect (but see Section 28–11).

The striking similarity between the fields produced by a bar magnet and by a loop of electric current (Figs. 27–4b and 28–22) offers a clue that perhaps magnetic fields produced by electric currents may have something to do with ferromagnetism. According to an early atomic model, atoms can be roughly visualized as having electrons that orbit around a central nucleus. The electrons are charged, and so constitute an electric current and therefore produce a magnetic field. But the fields due to orbiting electrons end up adding to zero. Electrons themselves produce an additional magnetic field, almost as if they and their electric charge were spinning about their own axes. It is the magnetic field due to electron **spin**[†] that is believed to produce ferromagnetism in most ferromagnetic materials.

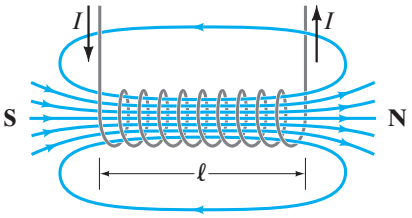
It is believed today that probably *all* magnetic fields are caused by electric currents. This means that magnetic field lines always form closed loops, unlike electric field lines which begin on positive charges and end on negative charges.

**CAUTION**
$\vec{\mathbf{B}}$ *lines form closed loops,*
$\vec{\mathbf{E}}$ *start on* ⊕ *and end on* ⊖

**EXERCISE E** Return to the Chapter-Opening Question, page 811, and answer it again now. Try to explain why you may have answered differently the first time.

[†]The name "spin" comes from an early suggestion that this intrinsic magnetic moment arises from the electron "spinning" on its axis (as well as "orbiting" the nucleus) to produce the extra field. However this view of a spinning electron is oversimplified and not valid (Chapters 38 and 39).

# 28–9 Electromagnets and Solenoids—Applications



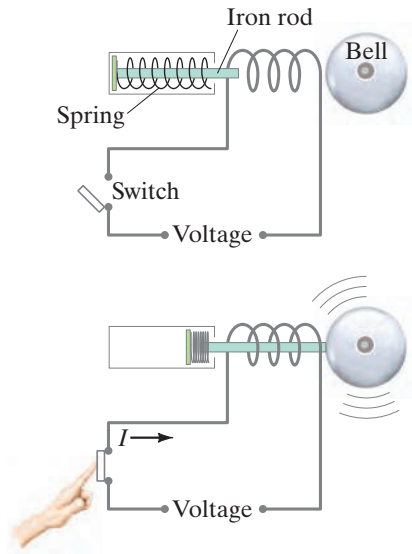


**FIGURE 28–26** Magnetic field of a solenoid. The north pole of this solenoid, thought of as a magnet, is on the right, and the south pole is on the left.

**PHYSICS APPLIED**
*Electromagnets and solenoids*

**FIGURE 28–27** Solenoid used as a doorbell.

**PHYSICS APPLIED**
*Doorbell, car starter*

**PHYSICS APPLIED**
*Magnetic circuit breakers*

A long coil of wire consisting of many loops of wire is called a **solenoid**, as we saw in Section 28–5. The magnetic field within a solenoid can be fairly large because it is the sum of the fields due to the current in each loop (Fig. 28–26). A solenoid acts like a magnet; one end can be considered the north pole and the other the south pole, depending on the direction of the current in the loops (use the right-hand rule). Since the magnetic field lines leave the north pole of a magnet, the north pole of the solenoid in Fig. 28–26 is on the right.

If a piece of iron is placed inside a solenoid, the magnetic field is increased greatly because the domains of the iron are aligned by the magnetic field produced by the current; that is, the iron becomes a magnet. The resulting magnetic field is the sum of the field due to the solenoid's current and the field due to the iron, and can be hundreds or thousands of times larger than the field due to the current alone (see Section 28–10). Such an iron-core solenoid is an **electromagnet**. The alloys of iron used in electromagnets acquire and lose their magnetism quite readily when the current is turned on or off, and so are referred to as "soft iron." (It is "soft" only in a magnetic sense.) Iron that holds its magnetism even when there is no externally applied field is called "hard iron." Hard iron is used in permanent magnets. Soft iron is usually used in electromagnets so that the field can be turned on and off readily. Whether iron is hard or soft depends on heat treatment, type of alloy, and other factors.

Electromagnets have many practical applications, from use in motors and generators to producing large magnetic fields for research. Sometimes an iron core is not present—the magnetic field then comes only from the current in the wire loops. A large field $B$ in this case requires a large current $I$, which produces a large amount of waste heat $(P = I^2R)$. But if the current-carrying wires are made of superconducting material kept below the transition temperature (Section 25–9), then very high magnetic fields can be produced, and no electric power is needed to maintain the large current in the superconducting coils. Energy is required, however, to refrigerate the coils at the low temperatures where they superconduct.

Another useful device consists of a solenoid into which a moveable rod of iron is partially inserted, and can be used as a switch. This combination is also referred to as a **solenoid**. One simple use is as a doorbell (Fig. 28–27). When the circuit is closed by pushing the button, the coil effectively becomes a magnet and exerts a force on the iron rod. The rod is pulled into the coil and strikes the bell. A large solenoid is used in the starter of a car: when you engage the starter, you are closing a circuit that not only turns the starter motor, but first activates a solenoid that moves the starter into direct contact with the gears on the engine's flywheel. Solenoids are often used as switches in cars and many other devices. They have the advantage of moving mechanical parts quickly and accurately.

## Magnetic Circuit Breakers

Modern circuit breakers that protect houses and buildings from overload and fire contain not only a "thermal" part (bimetallic strip as described in Section 25–6, Fig. 25–19) but also a magnetic sensor. If the current is above a certain level, the magnetic field the current produces pulls an iron plate that breaks the same contact points as in Figs. 25–19b and c. Such magnetic circuit breakers act quickly ($< 10$ ms), and for buildings are designed to react to the high currents of short circuits, but not shut off for the start-up surges of motors.

In more sophisticated circuit breakers, including ground fault circuit interrupters (GFCIs—discussed in Section 29–9), a solenoid is used. The iron rod of Fig. 28–27, instead of striking a bell, strikes one side of a pair of electric contact points, opening them and opening the circuit. They react very quickly $(\approx 1$ ms$)$ and to very small currents $(\approx 5$ mA$)$ and thus protect humans (not just property) and save lives. They should be installed in every kitchen and bathroom especially.

# 28–10 Magnetic Fields in Magnetic Materials; Hysteresis

The magnetic field inside a long solenoid is directly proportional to the current, as we saw in Eq. 28–4:

$$B_0 = \mu_0 nI. \tag{28–4}$$

We write $B_0$ to indicate there is only air inside the solenoid, and $n$ is the number of loops per unit length. If a piece of ferromagnetic material like iron is placed inside a solenoid to form an electromagnet (Section 28–9), the magnetic field increases greatly over that produced by the current in the solenoid loops alone, often by hundreds or thousands of times. This happens because the domains in the iron become aligned by the external field produced by the current in the solenoid coil. The total magnetic field $\vec{\mathbf{B}}$ is then the sum of two terms,

$$\vec{\mathbf{B}} = \vec{\mathbf{B}}_0 + \vec{\mathbf{B}}_\mathrm{M}. \tag{28–8}$$

$\vec{\mathbf{B}}_0$ is the field due to the current in the solenoid coil and $\vec{\mathbf{B}}_\mathrm{M}$ is the additional field due to the magnetic material (typically iron). Often $B_\mathrm{M} \gg B_0$.

The total field can also be written by replacing the constant $\mu_0$ in Eq. 28–4 by another parameter called the **magnetic permeability** $\mu$, which is characteristic of the magnetic material inside the coil. Then

$$B = \mu nI. \tag{28–9}$$

(Do not confuse this $\mu$ with $\vec{\boldsymbol{\mu}}$ for magnetic dipole moment.) For ferromagnetic materials, $\mu$ is much greater than $\mu_0$. For all other materials, its value is very close to $\mu_0$ (Section 28–11). The value of $\mu$, however, is not constant for ferromagnetic materials; it depends on the value of the "external field" $B_0$, as the following experiment shows.

## Hysteresis

Measurements on magnetic materials often use a **torus** or **toroid**, which is like a long solenoid bent into the shape of a donut (Fig. 28–28), so practically all the lines of $\vec{\mathbf{B}}$ remain within the toroid. Consider a toroid with an iron core that is initially unmagnetized and there is no current in the wire loops. Then the current $I$ is slowly increased, and $B_0$ (which is due only to $I$) increases linearly with $I$. The total field $B$ also increases, but follows the curved line shown in Fig. 28–29 which is a graph of total $B$ vs. $B_0$. Initially, point a on the graph, the domains are randomly oriented. As $B_0$ increases, the domains become more and more aligned until at point b, nearly all are aligned. The iron is said to be approaching **saturation**. Next, suppose current in the coil is reduced, so the field $B_0$ decreases. If the current (and $B_0$) is reduced to zero, point c in Fig. 28–30, the domains do *not* become completely random. Instead, some permanent magnetism remains in the iron core. If the current is increased in the opposite direction, enough domains can be turned around so the total $B$ becomes zero at point d. As the reverse current is increased further, the iron approaches saturation in the opposite direction, point e in Fig. 28–30. Finally, if the current is again reduced to zero (point f) and then increased in the original direction, the total field follows the path efgb, again approaching saturation at point b.

Notice that the field did not pass through the origin (point a) in this cycle. The fact that the curve does not retrace itself on the same path is called **hysteresis**. The curve bcdefgb is called a **hysteresis loop**. In such a cycle, much energy is transformed to thermal energy (friction) due to realigning of the domains. [It can be shown that the energy dissipated in this way is proportional to the area of the hysteresis loop.]

At points c and f, the iron core is magnetized even though there is no current in the coils. These points correspond to a permanent magnet. For a permanent magnet, it is desired that ac and af be as large as possible. Materials for which this is true are said to have high **retentivity**.

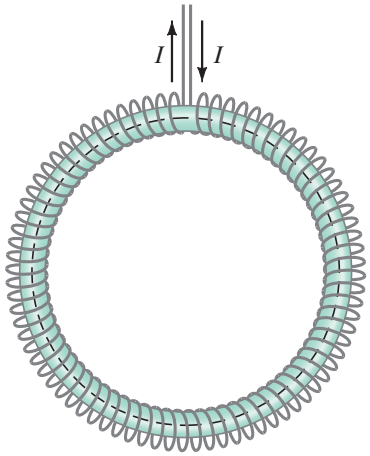

**FIGURE 28–28** Iron-core toroid.

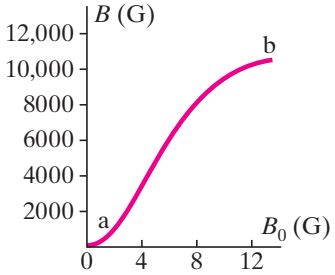
**FIGURE 28–29** Total magnetic field $B$ in an iron-core toroid as a function of the external field $B_0$ ($B_0$ is caused by the current $I$ in the coil). We use gauss ($1\,\mathrm{G} = 10^{-4}\,\mathrm{T}$) so that labels are clear.



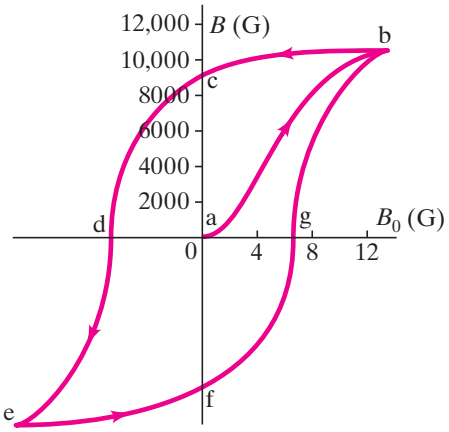


**FIGURE 28–30** Hysteresis curve.

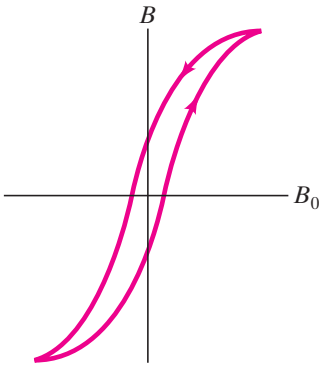

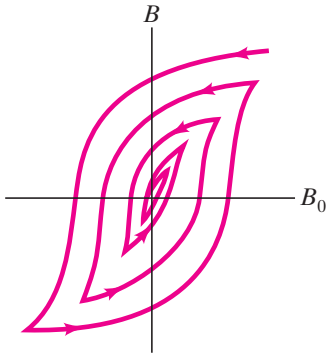

**FIGURE 28–31** Hysteresis curve for soft iron.

**FIGURE 28–32** Successive hysteresis loops during demagnetization.

Iron alloys with a broad hysteresis curve as in Fig. 28–30 hold their magnetism even when the current is off; they are referred to as "hard iron," and make good permanent magnets. On the other hand, a hysteresis curve such as that in Fig. 28–31 occurs for "soft iron," which is preferred for electromagnets and transformers (Section 29–6) since the field can be more readily switched off, and the field can be reversed with less loss of energy.

A magnetized ferromagnetic material can be demagnetized—that is, made unmagnetized. This can be done by reversing the magnetizing current repeatedly while decreasing its magnitude. This results in the curve of Fig. 28–32. Watches, the heads of a tape recorder, and other objects made of iron are demagnetized in this way. The alternating magnetic field due to a handheld demagnetizer is strong when the demagnetizer is placed near the object and decreases as it is moved slowly away. Computer hard disks, magnetic tape, and other magnetic storage devices can be erased and ruined by a magnetic field, as can the magnetic strips on credit cards.

## *28–11 Paramagnetism and Diamagnetism

All materials are magnetic to at least a tiny extent. Nonferromagnetic materials fall into two principal classes: *paramagnetic*, in which the magnetic permeability $\mu$ is very slightly greater than $\mu_0$; and *diamagnetic*, in which $\mu$ is very slightly less than $\mu_0$. The ratio of $\mu$ to $\mu_0$ for any material is called the **relative permeability** $K_m$:

$$K_m = \frac{\mu}{\mu_0}.$$

Another useful parameter is the **magnetic susceptibility** $\chi_m$ defined as

$$\chi_m = K_m - 1.$$

Paramagnetic substances have $K_m > 1$ and $\chi_m > 0$, whereas diamagnetic substances have $K_m < 1$ and $\chi_m < 0$. See Table 28–1, and note how small the effect is.

**TABLE 28–1 Paramagnetism and Diamagnetism: Magnetic Susceptibilities**

| Paramagnetic substance | $\chi_m$ | Diamagnetic substance | $\chi_m$ |
|---|---|---|---|
| Aluminum | $2.3 \times 10^{-5}$ | Copper | $-9.8 \times 10^{-6}$ |
| Calcium | $1.9 \times 10^{-5}$ | Diamond | $-2.2 \times 10^{-5}$ |
| Magnesium | $1.2 \times 10^{-5}$ | Gold | $-3.6 \times 10^{-5}$ |
| Oxygen (STP) | $2.1 \times 10^{-6}$ | Lead | $-1.7 \times 10^{-5}$ |
| Platinum | $2.9 \times 10^{-4}$ | Nitrogen (STP) | $-5.0 \times 10^{-9}$ |
| Tungsten | $6.8 \times 10^{-5}$ | Silicon | $-4.2 \times 10^{-6}$ |

The difference between paramagnetic and diamagnetic materials can be understood theoretically at the molecular level on the basis of whether or not the molecules have a permanent magnetic dipole moment. One type of **paramagnetism** occurs in materials whose molecules (or ions) have a permanent magnetic dipole moment.[†] In the absence of an external field, the molecules are randomly oriented and no magnetic effects are observed. However, when an external magnetic field is applied, say, by putting the material in a solenoid, the applied field exerts a torque on the magnetic dipoles (Section 27–5), tending to align them parallel to the field. The total magnetic field (external plus that due to aligned magnetic dipoles) will be slightly greater than $B_0$. The thermal motion of the molecules

[†]Other types of paramagnetism also occur whose origin is different from that described here, such as in metals where free electrons can contribute.

reduces the alignment, however. A useful quantity is the **magnetization vector**, $\vec{\mathbf{M}}$, which is useful for any magnetic material (even ferromagnetism), defined as the magnetic dipole moment per unit volume,

$$\vec{\mathbf{M}} = \frac{\vec{\boldsymbol{\mu}}}{V},$$

where $\vec{\boldsymbol{\mu}}$ is the *magnetic dipole moment* of the sample and $V$ its volume. (This $\vec{\boldsymbol{\mu}}$, also used on page 823, is magnetic moment, and *not* the $\mu$ and $\mu_0$ that stands for the constant *magnetic permeability* as on pages 827 and 828.) It is found experimentally that $M$ is directly proportional to the external magnetic field $B$ (tending to align the dipoles) and inversely proportional to the kelvin temperature $T$ (tending to randomize dipole directions). This is called *Curie's law*, after Pierre Curie (1859–1906), who first noted it:

$$M = C\frac{B}{T},$$

where $C$ is a constant. If the ratio $B/T$ is very large ($B$ very large or $T$ very small) Curie's law is no longer accurate; as $B$ is increased (or $T$ decreased), the magnetization approaches some maximum value, $M_{\text{max}}$. This makes sense, of course, since $M_{\text{max}}$ corresponds to complete alignment of all the permanent magnetic dipoles. However, even for very large magnetic fields, $\approx$2.0 T, deviations from Curie's law are normally noted only at very low temperatures, on the order of a few kelvins.

Ferromagnetic materials, as mentioned in Section 28–7, are no longer ferromagnetic above a characteristic temperature called the Curie temperature (1043 K for iron). Above this Curie temperature, they generally are paramagnetic.

**Diamagnetic** materials (for which the magnetic permeability $\mu$ is slightly less than $\mu_0$) are made up of molecules that have no permanent magnetic dipole moment. When an external magnetic field is applied, magnetic dipoles are induced, but the induced magnetic dipole moment is in the direction *opposite* to that of the field: the effect of the external field—in the crude model of electrons orbiting nuclei—is to increase the "orbital" speed of electrons revolving in one direction, and to decrease the speed of electrons revolving in the other direction. The net result is a net dipole moment opposing the external field. Hence the total field will be slightly less than the external field. Diamagnetism is present in all materials, but is weaker even than paramagnetism and so is overwhelmed by paramagnetic and ferromagnetic effects in materials that display these other forms of magnetism.

# Summary

The magnetic field $B$ at a distance $r$ from a long straight wire is directly proportional to the current $I$ in the wire and inversely proportional to $r$:

$$B = \frac{\mu_0}{2\pi}\frac{I}{r}. \qquad \textbf{(28–1)}$$

The magnetic field lines are circles centered on the straight wire.

The force that one long current-carrying wire exerts on a second parallel current-carrying wire 1 m away serves as the definition of the ampere unit, and ultimately of the coulomb as well.

**Ampère's law** states that the line integral of the magnetic field $\vec{\mathbf{B}}$ around any closed path is equal to $\mu_0$ times the total net current $I_{\text{encl}}$ enclosed by that path:

$$\oint \vec{\mathbf{B}} \cdot d\vec{\boldsymbol{\ell}} = \mu_0 I_{\text{encl}}. \qquad \textbf{(28–3)}$$

The magnetic field inside a long tightly wound solenoid is

$$B = \mu_0 nI \qquad \textbf{(28–4)}$$

where $n$ is the number of loops per unit length and $I$ is the current in each loop.

The **Biot-Savart law** is useful for determining the magnetic field due to a known arrangement of currents. It states that

$$d\vec{\mathbf{B}} = \frac{\mu_0 I}{4\pi}\frac{d\vec{\boldsymbol{\ell}} \times \hat{\mathbf{r}}}{r^2}, \qquad \textbf{(28–5)}$$

where $d\vec{\mathbf{B}}$ is the contribution to the total field at some point P due to a current $I$ along an infinitesimal length $d\vec{\boldsymbol{\ell}}$ of its path, and $\hat{\mathbf{r}}$ is the unit vector along the direction of the displacement vector $\vec{\mathbf{r}}$ from $d\vec{\boldsymbol{\ell}}$ to P. The total field $\vec{\mathbf{B}}$ will be the integral over all $d\vec{\mathbf{B}}$.

Iron and a few other materials that are **ferromagnetic** can be made into strong permanent magnets. Ferromagnetic materials are made up of tiny **domains**—each a tiny magnet—which are preferentially aligned in a permanent magnet, but randomly aligned in a nonmagnetized sample.

When iron or other ferromagnetic material is placed in a magnetic field $B_0$ due to a current (as inside a solenoid or toroid) the iron becomes magnetized. When the current is turned off, the material remains magnetized; when the current is increased in the opposite direction, a graph of the total field $B$ versus $B_0$ is a **hysteresis loop**, and the fact that the curve does not retrace itself is called **hysteresis**.

[*All materials exhibit some magnetic effects. Nonferromagnetic materials have much smaller **paramagnetic** or **diamagnetic** properties.]

# Questions

1. The magnetic field due to current in wires in your home may affect a compass. Discuss the problem in terms of currents, depending on whether they are ac or dc, and their distance away.
2. Compare and contrast the magnetic field due to a long straight current and the electric field due to a long straight line of electric charge at rest (Section 21–7).
3. Two insulated long wires carrying equal currents $I$ cross at right angles to each other. Describe the magnetic force one exerts on the other.
4. A horizontal wire carries a large current. A second wire carrying a current in the same direction is suspended below it. Can the current in the upper wire hold the lower wire in suspension against gravity? Under what conditions will the lower wire be in equilibrium?
5. (*a*) Write Ampère's law for a path that surrounds both conductors in Fig. 28–10. (*b*) Repeat, assuming the lower current, $I_2$, is in the opposite direction $(I_2 = -I_1)$.
6. Explain why a field such as that shown in Fig. 28–14b is consistent with Ampère's law. Could the lines curve upward instead of downward?
7. What would be the effect on $B$ inside a long solenoid if the solenoid's length was halved along with a doubling in the total number of loops?
8. Use the Biot-Savart law to show that the field of the current loop in Fig. 28–21 is correct as shown for points off the axis.
9. Do you think $\vec{\mathbf{B}}$ will be the same for all points in the plane of the current loop of Fig. 28–22? Explain.
10. Why does twisting the lead-in wires to electrical devices reduce the magnetic effects of the leads?
11. Compare the Biot-Savart law with Coulomb's law. What are the similarities and differences?
12. How might you measure the magnetic dipole moment of the Earth?
13. A type of magnetic switch similar to a solenoid is a **relay** (Fig. 28–33). A relay is an electromagnet (the iron rod inside the coil does not move) which, when activated, attracts a strip of iron on a pivot. Design a relay to close an electrical switch. A relay is used when you need to switch on a circuit carrying a very large current but you do not want that large current flowing through the main switch. For example, a car's starter switch is connected to a relay so that the large current needed for the starter doesn't pass to the dashboard switch.

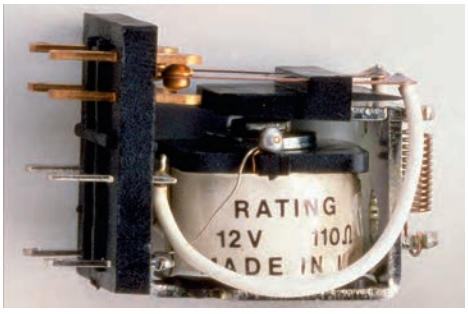

**FIGURE 28–33** Question 13.

14. A heavy block of iron, at rest, is attracted by a heavy magnet. Before striking the magnet the block has acquired considerable kinetic energy. (*a*) What is the source of this kinetic energy? (*b*) When the block strikes the magnet, some of the latter's domains may be jarred into randomness; describe the energy transformations.
15. A bar magnet exerts a force on a paper clip (page 825) or another bar magnet only because its magnetic field is non-uniform. To see why, show that a uniform magnetic field exerts no force on a bar magnet (see Fig. 27–7 on page 784). Also note there is no net force on the magnetic dipole in Fig. 27–23.
16. Will a magnet attract any metallic object, such as those made of aluminum or copper? (Try it and see.) Why is this so?
17. An unmagnetized nail will not attract an unmagnetized paper clip. However, if one end of the nail is in contact with a magnet, the other end *will* attract a paper clip. Explain.
18. Can an iron rod attract a magnet? Can a magnet attract an iron rod? What must you consider to answer these questions?
19. Why will either pole of a magnet attract an unmagnetized piece of iron?
20. Suppose you have three iron rods, two of which are magnetized but the third is not. How would you determine which two are the magnets without using any additional objects?
21. Two iron bars attract each other no matter which ends are placed close together. Are both magnets? Explain.
22. Sketch a magnet with domains as in Fig. 28–24b whose magnetic field would be in the opposite direction and half as strong as the magnet in Fig. 28–24b.

*23. Can all materials be considered (*a*) diamagnetic, (*b*) paramagnetic, (*c*) ferromagnetic? Explain.

*24. Describe the magnetization curve for (*a*) a paramagnetic substance and (*b*) a diamagnetic substance, and compare to that for a ferromagnetic substance (Fig. 28–30).

*25. Fill in each blank with the correct choice of ferromagnetic, paramagnetic, or diamagnetic, or state the sentence is not true for any of these terms.

(*a*) For _____ materials placed in a strong magnetic field, the induced dipole moment points in the opposite direction of the external field.

(*b*) _____ materials have stronger magnetic fields than either _____ or _____ materials.

(*c*) _____ materials are no longer _____ above the Curie temperature.

(*d*) All materials are _____.

# MisConceptual Questions

**1.** Which of the following statements is false? The magnetic field of a current-carrying wire
(*a*) is directed circularly around the wire.
(*b*) decreases inversely with the distance from the wire.
(*c*) exists only if the current in the wire is changing.
(*d*) depends on the magnitude of the current.

**2.** A horizontal current-carrying wire, free to move in Earth's gravitational field, is suspended directly above a parallel, current-carrying wire. In what direction is the current in the lower wire?
(*a*) Same direction as the upper one.
(*b*) Opposite to the direction in the upper one.
(*c*) Zero.
(*d*) Not enough information given.

**3.** Two parallel wires are vertical. The one on the left carries a 10-A current upward. The other carries 5-A current downward. Compare the magnitude of the force that each wire exerts on the other.
(*a*) The wire on the left carries twice as much current, so it exerts twice the force on the right wire as the right one exerts on the left one.
(*b*) The wire on the left exerts a smaller force. It creates a magnetic field twice that due to the wire on the right; and therefore has less energy to cause a force on the wire on the right.
(*c*) The two wires exert the same force on each other.
(*d*) Not enough information; we need the length of the wire.

**4.** What would be the effect on $B$ inside a long solenoid if (i) the diameter of all the loops was doubled, (ii) the spacing between loops instead was doubled?
(*a*) Nothing; nothing.
(*b*) Halved; nothing.
(*c*) Doubled; nothing.
(*d*) Nothing; doubled.
(*e*) Nothing; halved.

**5.** What would be the effect on $B$ inside a long solenoid if the solenoid's length was doubled along with a doubling in the total number of loops?
(*a*) Doubled.
(*b*) Four times larger.
(*c*) Halved.
(*d*) $\frac{1}{4}$ as large.
(*e*) No change.

**6.** Two long straight current-carrying wires are perpendicular, and pass near each other but do not touch. What can you say about the magnetic force between the two wires?
(*a*) There is no force between the two wires.
(*b*) Near where the wires cross, the force is about the same as for parallel wires.
(*c*) Each wire exerts a circularly directed force on the other.

**7.** Suppose the cylindrical conductor of Fig. 28–11a has a concentric cylindrical hollow cavity inside it (so it looks like a pipe). What can you say about $\vec{\mathbf{B}}$ in the cavity?
(*a*) $B \propto r$. (*b*) $B \propto 1/r$. (*c*) $B \propto 1/R$. (*d*) $B = 0$.

**8.** A mosquito carries a positive charge and is flying parallel to a wire carrying current in the same direction. The wire has no net charge. Which statement(s) below is/are true?
(*a*) There is no electric or magnetic force on the mosquito.
(*b*) The mosquito is attracted to the wire.
(*c*) The mosquito is repelled by the wire.
(*d*) There is a force on the mosquito, but it is not toward or away from the wire.

**9.** A thick straight copper wire carries a dc current. What is true about the magnetic field inside the wire?
(*a*) The field is strongest just inside the surface and drops to zero at the center.
(*b*) The field is zero inside the wire.
(*c*) The field is greatest at the center and drops off toward the surface.
(*d*) The field is uniform but not zero inside the wire.

**10.** Four wires are positioned at the corners of a square, Fig. 28–34. Each wire carries a current (note directions), all four of the same magnitude. What is the direction of the magnetic field at point P at the center of the square?

(a) (d)
(b) (e) $B = 0$.
(c)

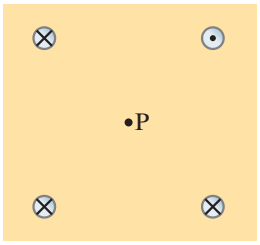

**FIGURE 28–34** MisConceptual Question 10.

**11.** The magnetic field at distance $x$ from the current in a long, straight conductor has magnitude $B$. What is the magnitude of the field at twice the distance from the conductor?
(*a*) $2B$.
(*b*) $B$.
(*c*) $B/4$.
(*d*) $4B$.
(*e*) $B/2$.

**12.** As an electron moves through space, it creates
(*a*) an electric field only.
(*b*) a magnetic field only.
(*c*) both an electric field and a magnetic field.
(*d*) nothing; the electric and magnetic fields cancel each other out.

**13.** Two long concentric pipes are cylindrical conductors as shown in Fig. 28–35. The inner pipe carries 5 A into the page and the outer pipe carries 5 A out of the page. In which region or regions does the magnetic field have the lowest magnitude?

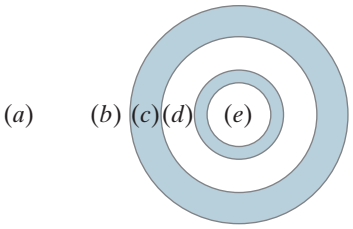

**FIGURE 28–35** MisConceptual Question 13.

**14.** Which of the following will reduce the magnetic field in a moderately strong magnet? Select as many answers as are true.
(*a*) Heat the magnet above the Curie temperature.
(*b*) Heat the magnet, but keep below the Curie temperature.
(*c*) Put the magnet in an alternating magnetic field that gradually decreases.
(*d*) Hold the magnet in a very strong magnetic field for an hour and then remove the magnet.
(*e*) Strike the magnet sharply.

# Problems

## 28–1 and 28–2 Straight Wires, Magnetic Field, and Force

1. (I) Jumper cables used to start a stalled vehicle often carry a 65-A current. How strong is the magnetic field 5.0 cm from one cable? Compare to the Earth's magnetic field $(5.0 \times 10^{-5}\,\text{T})$.
2. (I) If an electric wire is allowed to produce a magnetic field no larger than that of the Earth $(0.50 \times 10^{-4}\,\text{T})$ at a distance of 12 cm from the wire, what is the maximum dc current the wire can carry?
3. (I) Determine the magnitude and direction of the force between two long parallel wires 35 m long and 4.0 cm apart, each carrying 35 A in the same direction.
4. (I) A long straight vertical wire carrying an upward 22-A current exerts an attractive force per unit length of $7.8 \times 10^{-4}\,\text{N/m}$ on a second parallel wire 9.0 cm away. What current (magnitude and direction) flows in the second wire?
5. (II) In Fig. 28–36, a long straight wire carries current $I$ out of the page toward you. Indicate, with appropriate arrows, the direction and (relative) magnitude of $\vec{\mathbf{B}}$ at each of the points C, D, and E in the plane of the page.

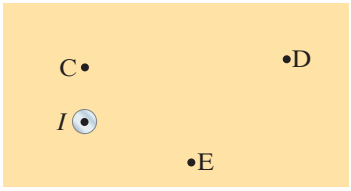

**FIGURE 28–36** Problem 5.

6. (II) An experiment on the Earth's magnetic field is being carried out 1.00 m from an electric cable. What is the maximum allowable dc current in the cable if the experiment is to be accurate to $\pm 5.0\%$?
7. (II) Two long thin parallel wires 13.0 cm apart carry 25-A currents in the same direction. Determine the magnetic field vector at a point 10.0 cm from one wire and 6.0 cm from the other (Fig. 28–37). [*Hint*: You could try using the law of cosines, Appendix A.]

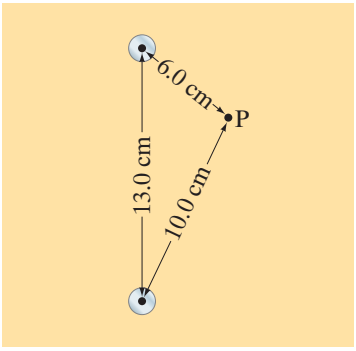

**FIGURE 28–37** Problem 7.

8. (II) A horizontal compass is placed 24 cm due south from a straight vertical wire carrying a 48-A dc current downward. In what direction does the compass needle point at this location? Assume the horizontal component of the Earth's field at this point is $0.45 \times 10^{-4}\,\text{T}$ and the magnetic declination is 0°.
9. (II) A long horizontal wire carries 24.0 A of dc current due north. What is the net magnetic field 20.0 cm due west of the wire if the Earth's field there points downward, 38° below the horizontal, and has magnitude $5.0 \times 10^{-5}\,\text{T}$?
10. (II) Determine the magnetic field midway between two long straight wires 2.0 cm apart in terms of the current $I$ in one when the other carries 25 A dc. Assume these currents are (*a*) in the same direction, and (*b*) in opposite directions.
11. (II) A continuous straight stream of protons passes a given point in space at a rate of $2.5 \times 10^{9}$ protons/s. What magnetic field do they produce 1.8 m from the beam?
12. (II) Two straight parallel wires are separated by 6.0 cm. There is a 2.0-A dc current flowing in the first wire. If the magnetic field strength is found to be zero between the two wires at a distance of 2.2 cm from the first wire, what is the magnitude and direction of the current in the second wire?
13. (II) Two long straight wires each carry a dc current $I$ out of the page toward the viewer, Fig. 28–38. Indicate, with appropriate arrows, the direction of $\vec{\mathbf{B}}$ at each of the points 1 to 6 in the plane of the page. State if the field is zero at any of the points.

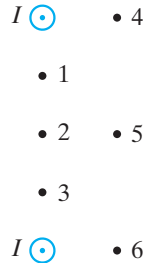

**FIGURE 28–38** Problem 13.

14. (II) A long pair of insulated wires serves to conduct 35.0 A of dc current to and from an instrument. If the wires are of negligible diameter but are 2.8 mm apart, what is the magnetic field 10.0 cm from their midpoint, in their plane (Fig. 28–39)? Compare to the magnetic field of the Earth.

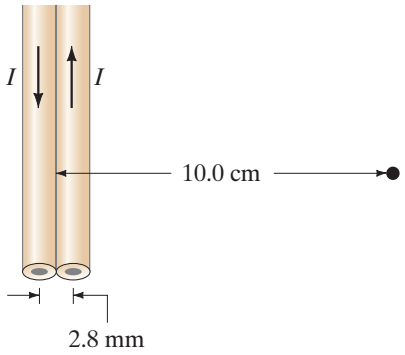

**FIGURE 28–39** Problems 14 and 15.

15. (II) A third wire is placed in the plane of the two wires shown in Fig. 28–39 parallel and just to the right. If it carries 25.0 A upward, what force per meter of length does it exert on each of the other two wires? Assume it is 2.8 mm from the nearest wire, center to center.
16. (II) A dc power line carries a current of 85 A west along the tops of 8.5-m-high poles. (*a*) What is the magnitude and direction of the magnetic field produced by this wire at the ground directly below? How does this compare with the Earth's field of about $\frac{1}{2}$ G? (*b*) Where would the current's magnetic field cancel the Earth's field?
17. (II) A compass needle points 13° E of N outdoors. However, when it is placed 16.0 cm to the east of a vertical wire inside a building, it points 55° E of N. What is the magnitude and direction of the current in the wire? The Earth's field there is $0.50 \times 10^{-4}\,\text{T}$ and is horizontal.

**18.** (II) A rectangular loop of wire is placed next to a straight wire, as shown in Fig. 28–40. There is a dc current of 3.5 A in both wires. Determine the magnitude and direction of the net force on the loop.

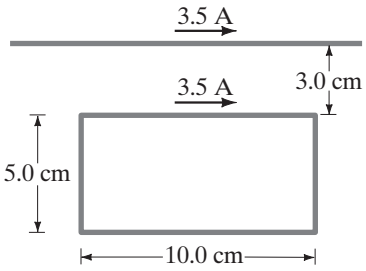

**FIGURE 28–40**
Problem 18.

**19.** (II) Let two long parallel wires, a distance $d$ apart, carry equal dc currents $I$ in the same direction. One wire is at $x = 0$, the other at $x = d$, Fig. 28–41. Determine $\vec{\mathbf{B}}$ along the $x$ axis between the wires as a function of $x$.

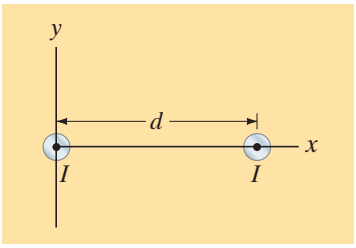

**FIGURE 28–41**
Problems 19 and 20.

**20.** (II) Repeat Problem 19 if the wire at $x = 0$ carries twice the current ($2I$) as the other wire, and in the opposite direction.

**21.** (II) Two long wires are oriented so that they are perpendicular to each other. At their closest, they are 20.0 cm apart (Fig. 28–42). What is the magnitude of the magnetic field at a point midway between them if the top one carries a current of 18.0 A and the bottom one carries 12.0 A?

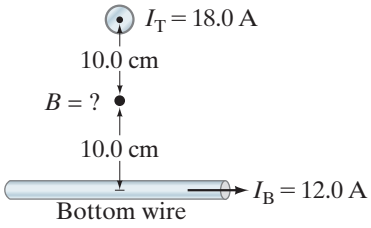

**FIGURE 28–42**
Problem 21.

**22.** (II) Two long parallel wires are 15 cm apart. The dc current in wire A is 20.0 A and that in B is 30.0 A. (*a*) In what relative direction (same or opposite) must the currents flow for there to be a point between the wires where $\vec{\mathbf{B}}$ is zero? (*b*) How far from wire A is that point?

**23.** (II) Two long parallel wires 8.20 cm apart carry 19.5-A dc currents in the same direction. Determine the magnetic field vector at a point P, 12.0 cm from one wire and 13.0 cm from the other. See Fig. 28–43. [*Hint*: Use the law of cosines. See Appendix A or inside rear cover.]

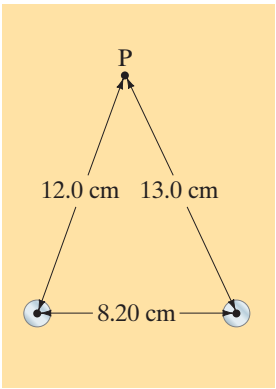

**FIGURE 28–43**
Problem 23.

**24.** (III) A very long flat conducting strip of width $\ell$ and negligible thickness lies in a horizontal plane and carries a uniform current $I$ across its cross section. (*a*) Show that at points a distance $y$ directly above its center, the field is given by

$$B = \frac{\mu_0 I}{\pi \ell} \tan^{-1} \frac{\ell}{2y},$$

assuming the strip is infinitely long. [*Hint*: Divide the strip into many thin "wires," and sum (integrate) over these.] (*b*) What value does $B$ approach for $y \gg \ell$? Does this make sense? Explain.

**25.** (III) A triangular loop of side length $a$ carries a current $I$ (Fig. 28–44). If this loop is placed a distance $d$ away from a very long straight wire carrying a current $I'$, determine the force on the loop due to $I'$.

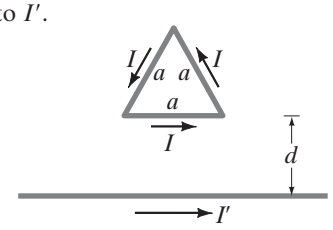

**FIGURE 28–44**
Problem 25.

## 28–3 Definitions of Ampere and Coulomb

**26.** (I) Consider the fundamental units to be kilograms, meters, seconds, and amperes. Write the following units in terms of these fundamental units: (*a*) coulombs, (*b*) volts, (*c*) teslas, (*d*) ohms.

## 28–4 and 28–5 Ampère's Law; Solenoids and Toroids

**27.** (I) A 40.0-cm-long solenoid 1.35 cm in diameter is to produce a field of 0.385 mT at its center. How much current should the solenoid carry if it has 675 turns of wire?

**28.** (I) A 32-cm-long solenoid, 1.8 cm in diameter, is to produce a 0.30-T magnetic field at its center. If the maximum current is 5.4 A, how many turns must the solenoid have?

**29.** (I) A 2.5-mm-diameter copper wire carries a 28-A dc current (uniform across its cross section). Determine the magnetic field: (*a*) at the surface of the wire; (*b*) inside the wire, 0.50 mm below the surface; (*c*) outside the wire 2.5 mm from the surface.

**30.** (II) A toroid (Fig. 28–17) has a 50.0-cm inner diameter and a 54.0-cm outer diameter. It carries a 25.0-A dc current in its 785 loops. Determine the range of values for $B$ inside the toroid.

**31.** (II) A 20.0-m-long copper wire, 2.00 mm in diameter including insulation, is tightly wrapped in a single layer with adjacent loops touching, to form a solenoid of diameter 2.50 cm (outer edge). What is (*a*) the length of the solenoid and (*b*) the field at the center when the current in the wire is 15.0 A?

**32.** (II) (*a*) Use Eq. 28–1, and the vector nature of $\vec{\mathbf{B}}$, to show that the magnetic field lines around two long parallel wires carrying equal currents $I_1 = I_2$ are as shown in Fig. 28–10. (*b*) Draw the equipotential lines around two stationary positive electric charges. (*c*) Are these two diagrams similar? Identical? Why or why not?

**33.** (II) A 650-turn horizontal solenoid is 15 cm long. The current in its loops is 38 A. A straight wire cuts through the center of the solenoid, along a 3.0-cm diameter. This wire carries a 22-A current downward (and is connected by other wires that don't concern us). What is the force on this wire assuming the solenoid's field points due east?

**34.** (III) A coaxial cable consists of a solid inner conductor of radius $R_1$, surrounded by a concentric cylindrical tube of inner radius $R_2$ and outer radius $R_3$ (Fig. 28–45). The conductors carry equal and opposite currents $I_0$ distributed uniformly across their cross sections. Determine the magnetic field at a distance $R$ from the axis for: (*a*) $R < R_1$; (*b*) $R_1 < R < R_2$; (*c*) $R_2 < R < R_3$; (*d*) $R > R_3$. (*e*) Let $I_0 = 1.50$ A, $R_1 = 1.00$ cm, $R_2 = 2.00$ cm, and $R_3 = 2.50$ cm. Graph $B$ from $R = 0$ to $R = 3.00$ cm.

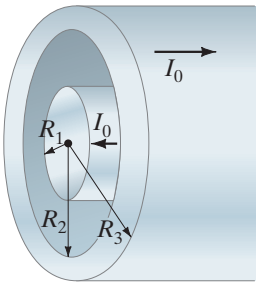

**FIGURE 28–45**
Problems 34 and 35.

**35.** (III) Suppose the current in the coaxial cable of Problem 34, Fig. 28–45, is not uniformly distributed, but instead the current density $j$ varies linearly with distance from the center: $j_1 = C_1 R$ for the inner conductor and $j_2 = C_2 R$ for the outer conductor. Each conductor still carries the same total current $I_0$, in opposite directions. Determine the magnetic field in terms of $I_0$ in the same four regions of space as in Problem 34.

## 28–6 Biot-Savart Law

**36.** (I) The Earth's magnetic field is essentially that of a magnetic dipole. If the field near the North Pole is about $1.0 \times 10^{-4}$ T, what will it be (approximately) 13,000 km above the surface at the North Pole?

**37.** (II) A wire, in a plane, has the shape shown in Fig. 28–46, two arcs of a circle connected by radial lengths of wire. Determine $\vec{\mathbf{B}}$ at point C in terms of $R_1$, $R_2$, $\theta$, and the current $I$.

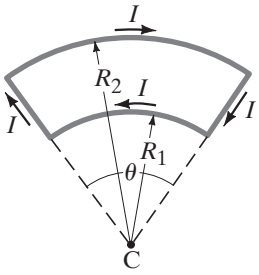

**FIGURE 28–46**
Problem 37.

**38.** (II) A circular conducting ring of radius $R$ is connected to two exterior straight wires at two ends of a diameter (Fig. 28–47). The current $I$ splits into unequal portions as shown (unequal resistance) while passing through the ring. What is $\vec{\mathbf{B}}$ at the center of the ring?

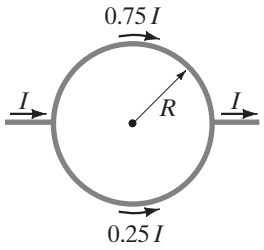

**FIGURE 28–47**
Problem 38.

**39.** (II) A small loop of wire of radius 1.8 cm is placed at the center of a wire loop with radius 25.0 cm. The planes of the loops are perpendicular to each other, and a 6.0-A current flows in each. Estimate the torque the large loop exerts on the smaller one. What simplifying assumption did you make?

**40.** (II) A wire is formed into the shape of two half circles connected by equal-length straight sections as shown in Fig. 28–48. A current $I$ flows in the circuit clockwise as shown. Determine (*a*) the magnitude and direction of the magnetic field at the center, C, and (*b*) the magnetic dipole moment of the circuit.

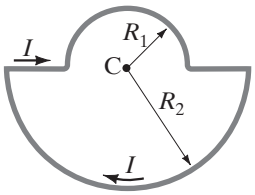

**FIGURE 28–48**
Problem 40.

**41.** (II) A single point charge $q$ is moving with velocity $\vec{\mathbf{v}}$. Show that the Biot-Savart law predicts the magnetic field $\vec{\mathbf{B}}$ produced at a point P, whose position vector relative to the charge is $\vec{\mathbf{r}}$ (Fig. 28–49), is given by

$$\vec{\mathbf{B}} = \frac{\mu_0}{4\pi}\frac{q\vec{\mathbf{v}} \times \vec{\mathbf{r}}}{r^3}.$$

This result is only an estimate, and a reasonable one only for low speeds $v$. (See Section 28–7.)

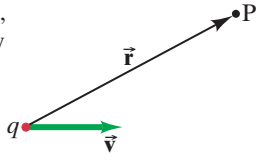

**FIGURE 28–49**
Problem 41.

**42.** (II) A nonconducting circular disk, of radius $R$, carries a uniformly distributed electric charge $Q$. The plate is set spinning with angular velocity $\omega$ about an axis perpendicular to the plate through its center (Fig. 28–50). Determine (*a*) its magnetic dipole moment and (*b*) the magnetic field at points on its axis a distance $x$ from its center; (*c*) does Eq. 28–7b apply in this case for $x \gg R$?

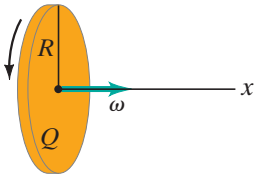

**FIGURE 28–50**
Problem 42.

**43.** (II) Consider a straight section of wire of length $d$, as in Fig. 28–51, which carries a current $I$. (*a*) Show that the magnetic field at a point P a distance $R$ from the wire along its perpendicular bisector is

$$B = \frac{\mu_0 I}{2\pi R}\frac{d}{(d^2 + 4R^2)^{\frac{1}{2}}}.$$

(*b*) Show that this is consistent with Example 28–10 for an infinite wire.

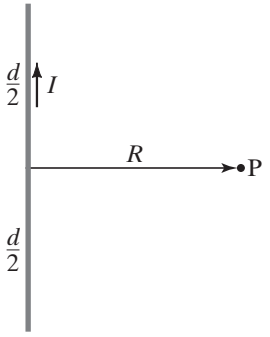

**FIGURE 28–51**
Problem 43.

**44.** (II) A segment of wire of length $\ell$ carries a dc current $I$ as shown in Fig. 28–52. (*a*) Show that for points along the positive $x$ axis (the axis of the wire), such as point Q, the magnetic field $\vec{\mathbf{B}}$ is zero. (*b*) Determine a formula for the field at points along the $y$ axis, such as point P.

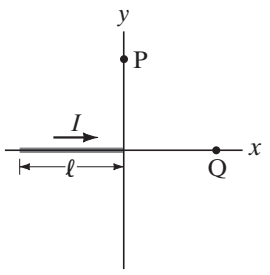

**FIGURE 28–52**
Problem 44.

**45.** (III) Use the result of Problem 44 to find the magnetic field at point P in Fig. 28–53 due to the current in the square loop.

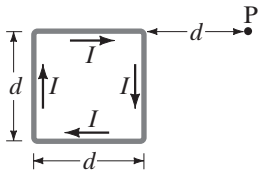

**FIGURE 28–53** Problem 45.

**46.** (III) A wire is bent into the shape of a regular polygon with $n$ sides whose vertices are a distance $R$ from the center. (See Fig. 28–54, which shows the special case of $n = 6$.) If the wire carries a current $I_0$, (*a*) determine the magnetic field at the center; (*b*) if $n$ is allowed to become very large ($n \to \infty$), show that the formula in part (*a*) reduces to that for a circular loop (Example 28–11).

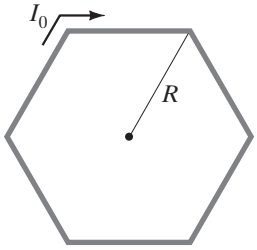

**FIGURE 28–54** Problem 46.

**47.** (III) Start with the result of Example 28–11 for the magnetic field along the axis of a single circular loop of wire carrying a dc current $I$ to obtain the field along the central axis inside a very long solenoid with $n$ turns per meter (Eq. 28–4) that stretches from $+\infty$ to $-\infty$.

**48.** (III) A single rectangular loop of wire, with sides $a$ and $b$, carries a dc current $I$. An $xy$ coordinate system has its origin at the lower left corner of the rectangle with the $x$ axis parallel to side $b$ (Fig. 28–55) and the $y$ axis parallel to side $a$. Determine the magnetic field $B$ at all points $(x, y)$ within the loop.

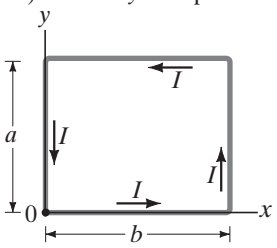

**FIGURE 28–55**
Problem 48.

**49.** (III) A square loop of wire, of side $d$, carries a current $I$. (*a*) Determine the magnetic field $B$ at points on a line (call it the $x$ axis) perpendicular to the plane of the square which passes through the center of the square (Fig. 28–56). Express $B$ as a function of $x$, the distance from the center of the square. (*b*) For $x \gg d$, does the square appear to be a magnetic dipole? If so, what is its dipole moment?

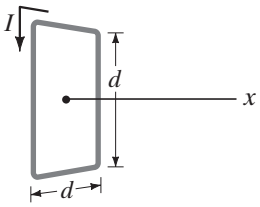

**FIGURE 28–56**
Problem 49.

## 28–8 Magnetic Materials—Ferromagnetism

**50.** (II) An iron atom has a magnetic dipole moment of about $1.8 \times 10^{-23}\ \text{A} \cdot \text{m}^2$. (*a*) Determine the dipole moment of an iron bar 15 cm long, 1.2 cm wide, and 1.0 cm thick, if it is 100 percent saturated. (*b*) What torque would be exerted on this bar when placed in a 0.80-T field acting at right angles to the bar?

## 28–10 Magnetic Materials; Hysteresis

**51.** (I) A long thin iron-core solenoid has 350 loops of wire per meter, and a 350-mA current flows through the wire. If the permeability of the iron is $3000\mu_0$, what is the total field $B$ inside the solenoid?

**52.** (I) A large thin toroid has 315 loops of wire per meter wrapped around an iron core. A 3.0-A dc current flows through the wire. If the relative permeability of the iron is $\mu/\mu_0 = 2200$, what is the total field $B$ inside the toroid?

**53.** (II) The following are some values of $B$ and $B_0$ for a piece of annealed iron as it is being magnetized (note different units):

| $B_0(10^{-4}\,\text{T})$ | 0.0 | 0.13 | 0.25 | 0.50 | 0.63 | 0.78 | 1.0 | 1.3 |
|---|---|---|---|---|---|---|---|---|
| $B$(T) | 0.0 | 0.0042 | 0.010 | 0.028 | 0.043 | 0.095 | 0.45 | 0.67 |
| $B_0(10^{-4}\,\text{T})$ | 1.9 | 2.5 | 6.3 | 13.0 | 130 | 1300 | 10,000 | |
| $B$(T) | 1.01 | 1.18 | 1.44 | 1.58 | 1.72 | 2.26 | 3.15 | |

Determine the magnetic permeability $\mu$ for each value and plot a graph of $\mu$ versus $B_0$.

**54.** (II) An iron-core solenoid is 38 cm long and 1.8 cm in diameter, and has 640 turns of wire. The magnetic field inside the solenoid is 2.2 T when 42 A flows in the wire. What is the permeability $\mu$ at this high field strength?

# General Problems

**55.** Three long parallel wires are 3.5 cm from one another. (Looking along them, they are at three corners of an equilateral triangle.) The current in each wire is 9.50 A, but its direction in wire M is opposite to that in wires N and P (Fig. 28–57). Determine the magnetic force per unit length on each wire due to the other two.

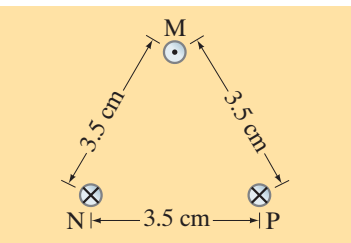

**FIGURE 28–57**
Problems 55, 56, and 57.

**56.** In Fig. 28–57, determine the magnitude and direction of the magnetic field midway between points M and N.

**57.** In Fig. 28–57 the top wire is 1.00-mm-diameter copper wire and is suspended in air due to the two magnetic forces from the bottom two wires. The current is 35.0 A in each of the two bottom wires. Calculate the required current in the suspended wire (M).

**58.** Two long straight parallel wires are 18 cm apart. Wire A carries 3.0-A current. Wire B's current is 6.0 A in the same direction. (*a*) Determine the magnetic field due to wire A at the position of wire B. (*b*) Determine the magnetic field due to wire B at the position of wire A. (*c*) Are these two magnetic fields equal and opposite? Why or why not? (*d*) Determine the force on wire A due to wire B, and the force on wire B due to wire A. Are these two forces equal and opposite? Why or why not?

**59.** A rectangular loop of wire carries a 2.0-A dc current and lies in a plane which also contains a very long straight wire carrying a 10.0-A current as shown in Fig. 28–58. Determine (*a*) the net force and (*b*) the net torque on the loop due to the straight wire.

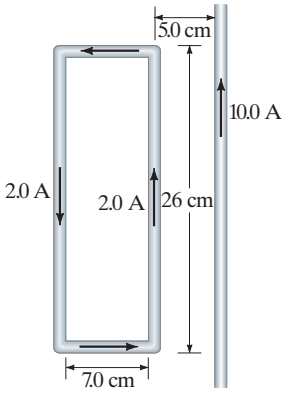

**FIGURE 28–58**
Problem 59.

**60.** A very large flat conducting sheet of thickness $t$ carries a uniform current density $\vec{\mathbf{j}}$ throughout (Fig. 28–59). Determine the magnetic field (magnitude and direction) at a distance $y$ above the plane. (Assume the plane is infinitely long and wide.)

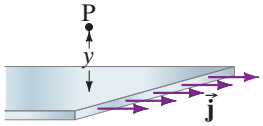

**FIGURE 28–59**
Problem 60.

**61.** A long horizontal wire carries a current of 42 A. A second wire, made of 1.00-mm-diameter copper wire and parallel to the first, is kept in suspension magnetically 5.0 cm below (Fig. 28–60). (*a*) Determine the magnitude and direction of the current in the lower wire. (*b*) Is the lower wire in stable equilibrium? (*c*) Repeat parts (*a*) and (*b*) if the second wire is suspended 5.0 cm *above* the first due to the first's magnetic field.

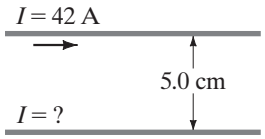

**FIGURE 28–60**
Problem 61.

**62.** **Helmholtz coils** are two identical circular coils having the same radius $R$ and the same number of turns $N$, separated by a distance equal to the radius $R$ and carrying the same dc current $I$ in the same direction. (See Fig. 28–61.) They are used in scientific instruments to generate nearly uniform magnetic fields. (They can be seen in the photo, Fig. 27–19.) (*a*) Determine the magnetic field $B$ at points $x$ along the line joining their centers. Let $x = 0$ at the center of one coil, and $x = R$ at the center of the other. (*b*) Show that the field midway between the coils is particularly uniform by showing that $\frac{dB}{dx} = 0$ and $\frac{d^2B}{dx^2} = 0$ at the midpoint between the coils. (*c*) If $R = 10.0\,\text{cm}$, $N = 85$ turns and $I = 3.0\,\text{A}$, what is the field at the midpoint between the coils, $x = R/2$?

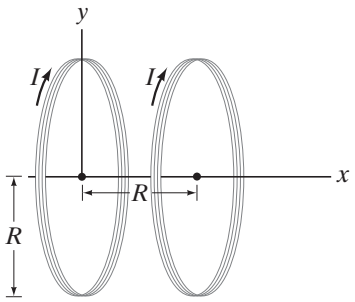

**FIGURE 28–61**
Problems 62 and 63.

**63.** A set of Helmholtz coils (see Problem 62, Fig. 28–61) have a radius $R = 10.0\,\text{cm}$ and are separated by a distance $R = 10.0\,\text{cm}$. Each coil has 85 loops carrying a current $I = 2.0\,\text{A}$. (*a*) Determine the total magnetic field $B$ along the $x$ axis (the center line for the two coils) in steps of 0.2 cm from the center of one coil $(x = 0)$ to the center of the other $(x = R)$. (*b*) Graph $B$ as a function of $x$. (*c*) By what % does $B$ vary from $x = 5.0\,\text{cm}$ to $x = 6.0\,\text{cm}$?

**64.** Near the Earth's poles the magnetic field is about 1 G $(1 \times 10^{-4}\,\text{T})$. Imagine a simple model in which the Earth's field is produced by a single current loop around the equator. Estimate roughly the current this loop would carry.

**65.** A 175-g model airplane charged to 18.0 mC and traveling at 2.8 m/s passes within 7.8 cm of a wire, nearly parallel to its path, carrying a 25-A dc current. What acceleration (in $g$'s) does this interaction give the airplane?

**66.** Four long straight parallel wires located at the corners of a square of side $d$ carry equal currents $I_0$ perpendicular to the page as shown in Fig. 28–62. Determine the magnitude and direction of $\vec{\mathbf{B}}$ at the center C of the square.

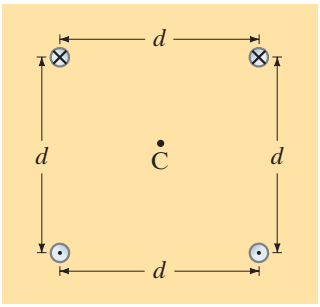

**FIGURE 28–62**
Problem 66.

**67.** Determine the magnetic field at a point P due to a very long wire with a square bend as shown in Fig. 28–63. The point P is halfway between the two corners.

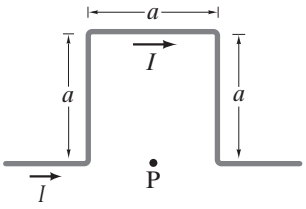

**FIGURE 28–63**
Problem 67.

**68.** A thin 12-cm-long solenoid has a total of 370 turns of wire and carries a current of 2.0 A. Calculate the field inside the solenoid near the center.

**69.** You have 1.0 kg of copper and want to make a practical solenoid that produces the greatest possible magnetic field for a given voltage. Should you make your copper wire long and thin, short and fat, or something else? Consider other variables, such as solenoid diameter, length, and so on. Explain your reasoning.

**70.** A small solenoid (radius $r_a$) is inside a larger solenoid (radius $r_b > r_a$). They are coaxial with $n_a$ and $n_b$ turns per unit length, respectively. The solenoids carry the same current, but in opposite directions. Let $r$ be the radial distance from the common axis of the solenoids. If the magnetic field inside the inner solenoid $(r < r_a)$ is to be in the opposite direction as the field between the solenoids $(r_a < r < r_b)$, but have half the magnitude, determine the required ratio $n_b/n_a$.

**71.** Find $B$ at the center of the 5.0-cm-radius semicircle (point P) in Fig. 28–64. The straight wires extend a great distance outward to the left and carry a current $I = 9.0\,\text{A}$.

**FIGURE 28–64**
Problem 71.

**72.** The design of a magneto-optical atom trap requires a magnetic field $B$ that is directly proportional to position $x$ along an axis. Such a field perturbs the absorption of laser light by atoms in the manner needed to spatially confine atoms in the trap. Let us demonstrate that "anti-Helmholtz" coils will provide the required field $B = Cx$, where $C$ is a constant. Anti-Helmholtz coils consist of two identical circular wire coils, each with radius $R$ and $N$ turns, carrying current $I$ in opposite directions (Fig. 28–65). The coils share a common axis (defined as the $x$ axis with $x = 0$ at the midpoint (0) between the coils). Assume that the centers of the coils are separated by a distance equal to the radius $R$ of the coils. (*a*) Show that the magnetic field at position $x$ along the $x$ axis is given by

$$B(x) = \frac{4\mu_0 NI}{R}\left\{\left[4+\left(1-\frac{2x}{R}\right)^2\right]^{-\frac{3}{2}} - \left[4+\left(1+\frac{2x}{R}\right)^2\right]^{-\frac{3}{2}}\right\}.$$

(*b*) For small excursions from the origin where $|x| \ll R$, show that the magnetic field is given by $B \approx Cx$, where the constant $C = 48\,\mu_0 NI/25\sqrt{5}\,R^2$. (*c*) For optimal atom trapping, $dB/dx$ should be about 0.15 T/m. Assume an atom trap uses anti-Helmholtz coils with $R = 4.0$ cm and $N = 150$. What current should flow through the coils? [Coil separation equal to coil radius, as assumed in this Problem, is not a strict requirement for anti-Helmholtz coils.]

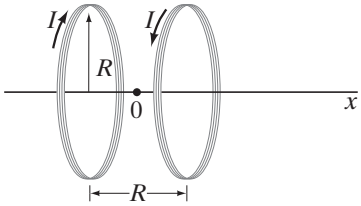

**FIGURE 28–65**
Problem 72.

**73.** A bolt of lightning strikes a metal flag pole, one end of which is anchored in the ground. Estimate the force the Earth's magnetic field can exert on the flag pole while the lightning-induced current flows. See Example 25–10.

**74.** You want to get an idea of the magnitude of magnetic fields produced by overhead power lines. You estimate that a transmission wire is about 12 m above the ground. The local power company tells you that the lines operate at 145 kV and provide a maximum of 45 MW to the local area. Estimate the maximum magnetic field you might experience walking under one such power line, and compare to the Earth's field. [For an ac current, values are rms, and the magnetic field will be changing.]

**75.** A circular current loop of radius 15 cm containing 220 turns carries a current of 2.0 A. Its center is at the origin and its axis lies along the $x$ axis. Calculate the magnetic field $B$ at a point $x$ on the $x$ axis for $x = -40$ cm to $+40$ cm in steps of 2 cm and make a graph of $B$ as a function of $x$.

**76.** Suppose that an electromagnet uses a coil 2.0 m in diameter made from square copper wire 2.0 mm on a side. The power supply produces 35 V at a maximum power output of 1.5 kW. (*a*) How many turns are needed to run the power supply at maximum power? (*b*) What is the magnetic field strength at the center of the coil? (*c*) If you use a greater number of turns and this same power supply, will a greater magnetic field result? Explain.

**77.** Two long straight aluminum wires, each of diameter 0.42 mm, carry the same current but in opposite directions. They are suspended by 0.50-m-long strings as shown in Fig. 28–66. If the suspension strings make an angle of 3.0° with the vertical and are hanging freely, what is the current in the wires?

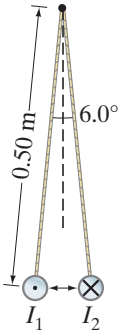

**FIGURE 28–66**
Problem 77.

**78.** A small but rigid U-shaped wire carrying a 5.0-A current (Fig. 28–67) is placed inside a solenoid. The solenoid is 15.0 cm long and has 600 loops of wire, and the current in each loop is 7.0 A. What is the net force on the U-shaped wire?

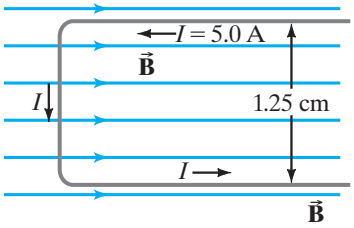

**FIGURE 28–67**
Problem 78.

**79.** Part of a long, thin insulated straight wire is formed into a single circular loop of radius $R$ (Fig. 28–68) and carries a current $I$. (*a*) What is the magnitude and direction of the magnetic field at the center of the loop? (*b*) If the plane of the loop is twisted 90 degrees so that the plane is perpendicular to the straight part of the wire (i.e., in the $yz$ plane) what is the magnitude and direction of the field now at the center of the loop?

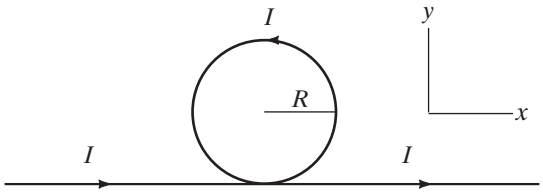

**FIGURE 28–68** Problem 79.

**80.** A toroid is fabricated with a circular shape and loops with a square cross section as shown in Fig. 28–69. The cross section of a loop is a square of side 6.0 cm. The inner radius of the whole circular toroid is 3.0 m. There are 320 loops of wire which carry a 45-A dc current using a nearby power supply at 20.0 V. The arrows show the current flow in and out of the toroid. The current flows up at the inner diameter and down at the outer diameter. (*a*) Calculate the strength of the magnetic field at the center of the square's cross section at point P. (*b*) Is the magnetic field pointing clockwise or counterclockwise? (*c*) The square cross sectional area of the *wire* is uniformly 0.10 $cm^2$. What is the resistivity of the wire?

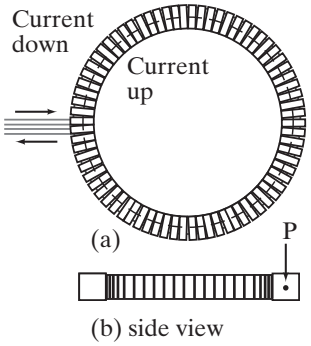

**FIGURE 28–69**
Problem 80.

## ANSWERS TO EXERCISES

**A:** $2 \times 10^{-6}$ T; not at this distance, and then only briefly.
**B:** $0.8 \times 10^{-5}$ T, up.
**C:** (*b*).
**D:** $1.0 \times 10^{-2}$ T.
**E:** (*b*), (*c*).

One of the great laws of physics is Faraday's law of induction, which says that a changing magnetic flux produces an induced emf. This photo shows a bar magnet moving into (or out of) a coil of wire, and the galvanometer registers an induced current. This phenomenon of electromagnetic induction is the basis for many practical devices, including generators, alternators, transformers, magnetic recording on tape or disk (hard drive), and computer memory.

CHAPTER 29

# Electromagnetic Induction and Faraday's Law

## CONTENTS

29–2 Faraday's Law of Induction; Lenz's Law
29–3 EMF Induced in a Moving Conductor
29–4 Electric Generators
29–5 Back EMF and Counter Torque; Eddy Currents
29–6 Transformers and Transmission of Power
29–7 A Changing Magnetic Flux Produces an Electric Field
*29–8 Information Storage: Magnetic and Semiconductor
*29–9 Applications of Induction: Microphone, Seismograph, GFCI

**CHAPTER-OPENING QUESTION—Guess now!**

In the photograph above, the bar magnet is inserted down into the coil of wire, and is left there for 1 minute; then it is pulled up and out from the coil. What would an observer watching the galvanometer see?

**(a)** No change (pointer stays on zero): without a battery there is no current to detect.
**(b)** A small current flows while the magnet is inside the coil of wire.
**(c)** A current spike as the magnet enters the coil, and then nothing.
**(d)** A current spike as the magnet enters the coil, and then a steady small current.
**(e)** A current spike as the magnet enters the coil, then nothing (pointer at zero), then a current spike in the opposite direction as the magnet exits the coil.

In Chapter 27, we discussed two ways in which electricity and magnetism are related: (1) an electric current produces a magnetic field; and (2) a magnetic field exerts a force on an electric current or on a moving electric charge. These discoveries were made in 1820–1821. Scientists then began to wonder: if electric currents produce a magnetic field, is it possible that a magnetic field can produce an electric current? Ten years later the American Joseph Henry (1797–1878) and the Englishman Michael Faraday (1791–1867) independently found that it was possible. Henry actually made the discovery first. But Faraday published his results earlier and investigated the subject in more detail. We now discuss this phenomenon and some of its world-changing applications including the electric generator.

# 29–1 Induced EMF

In his attempt to produce an electric current from a magnetic field, Faraday used an apparatus like that shown in Fig. 29–1. A coil of wire, X, was connected to a battery. The current that flowed through X produced a magnetic field that was intensified by the ring-shaped iron core around which the wire was wrapped. Faraday hoped that a strong steady current in X would produce a great enough magnetic field to produce a current in a second coil Y wrapped on the same iron ring.

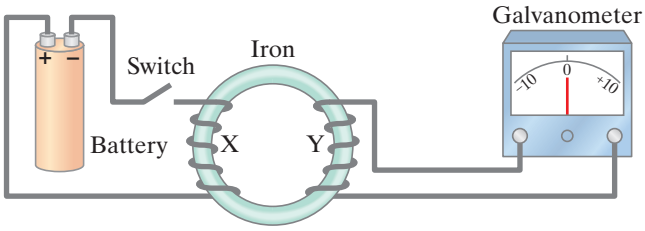

**FIGURE 29–1** Faraday's experiment to induce an emf. Note that the galvanometer zero is at the center of the scale and the needle deflects left or right, depending on the direction of the current.

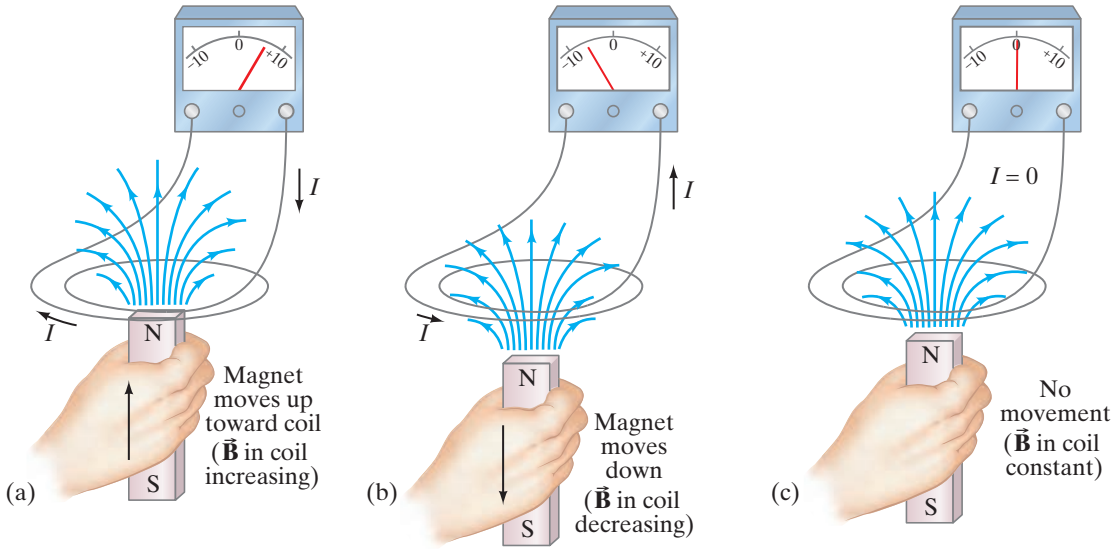
This second circuit, Y, contained a galvanometer to detect any current but contained no battery. He met no success with constant currents. But the long-sought effect was finally observed when Faraday noticed the galvanometer in circuit Y deflect strongly at the moment he closed the switch in circuit X. And the galvanometer deflected strongly in the opposite direction when he opened the switch in X. A constant current in X produced a constant magnetic field which produced *no* current in Y. Only when the current in X was starting or stopping was a current produced in Y.

Faraday concluded that although a constant magnetic field produces no current in a conductor, a *changing* magnetic field can produce an electric current. Such a current is called an **induced current**. When the magnetic field through coil Y changes, a current occurs in Y as if there were a source of emf in circuit Y. We therefore say that



**a changing magnetic field induces an emf.**

**CAUTION**
*Changing $\vec{\mathbf{B}}$, not $\vec{\mathbf{B}}$ itself, induces current*

Faraday did further experiments on **electromagnetic induction**, as this phenomenon is called. For example, Fig. 29–2 shows that if a magnet is moved quickly into a coil of wire, a current is induced in the wire. If the magnet is quickly removed, a current is induced in the opposite direction ($\vec{\mathbf{B}}$ through the coil decreases). Furthermore, if the magnet is held steady and the coil of wire is moved toward or away from the magnet, again an emf is induced and a current flows. Motion or change is required to induce an emf. It doesn't matter whether the magnet or the coil moves. It is their *relative motion* that counts.

**CAUTION**
*Relative motion—magnet or coil moving induces current*

**FIGURE 29–2** (a) A current is induced when a magnet is moved toward a coil, momentarily increasing the magnetic field through the coil. (b) The induced current is opposite when the magnet is moved away from the coil ($\vec{\mathbf{B}}$ decreases). In (c), no current is induced if the magnet does not move relative to the coil. It is the relative motion that counts here: the magnet can be held steady and the coil moved, which also induces an emf.

**EXERCISE A** Return to the Chapter-Opening Question, page 838, and answer it again now. Try to explain why you may have answered differently the first time.

## 29–2 Faraday's Law of Induction; Lenz's Law

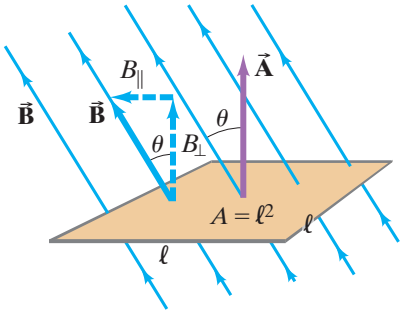


**FIGURE 29–3** Determining the flux through a flat loop of wire. This loop is square, of side $\ell$ and area $A = \ell^2$.

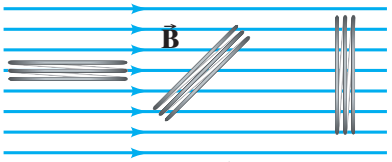
**FIGURE 29–4** Magnetic flux $\Phi_B$ is proportional to the number of lines of $\vec{\mathbf{B}}$ that pass through the loops of a coil (here with 3 loops).



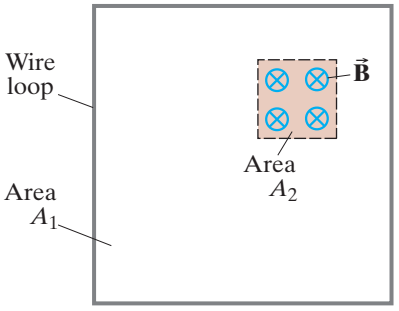


**FIGURE 29–5** Example 29–1.

Faraday investigated quantitatively what factors influence the magnitude of the emf induced. He found first of all that the more rapidly the magnetic field changes, the greater the induced emf. He also found that the induced emf depends on the area of the circuit loop (and also the angle it makes with $\vec{\mathbf{B}}$). In fact, it is found that the emf is proportional to the rate of change of the **magnetic flux**, $\Phi_B$, passing through the circuit or loop of area $A$. Magnetic flux for a uniform magnetic field through a loop of area $A$ is defined in the same way we did for electric flux in Chapter 22, as

$$\Phi_B = B_\perp A = BA\cos\theta = \vec{\mathbf{B}}\cdot\vec{\mathbf{A}}. \qquad [\vec{\mathbf{B}} \text{ uniform}] \quad \textbf{(29–1a)}$$

Here $B_\perp$ is the component of the magnetic field $\vec{\mathbf{B}}$ perpendicular to the face of the loop, and $\theta$ is the angle between $\vec{\mathbf{B}}$ and the vector $\vec{\mathbf{A}}$ (representing the area) whose direction is perpendicular to the face of the loop. These quantities are shown in Fig. 29–3 for a square loop of side $\ell$ whose area is $A = \ell^2$. If the area is of some other shape, or $\vec{\mathbf{B}}$ is not uniform, the magnetic flux can be written

$$\Phi_B = \int \vec{\mathbf{B}}\cdot d\vec{\mathbf{A}}, \qquad \textbf{(29–1b)}$$

where the integral is taken over the area $A$.†

We saw in Chapter 27 that the lines of $\vec{\mathbf{B}}$ (like lines of $\vec{\mathbf{E}}$) can be drawn so that the number of lines per unit area is proportional to the field strength. Then the flux $\Phi_B$ can be thought of as being proportional to the *total number of lines passing through the area enclosed by the loop*. This is illustrated in Fig. 29–4, where three wire loops of a coil are viewed from the side (on edge). For $\theta = 90°$, no magnetic field lines pass through the loop and $\Phi_B = 0$, whereas $\Phi_B$ is a maximum when $\theta = 0°$. The unit of magnetic flux is the tesla-meter$^2$, and is called a **weber**: $1\ \text{Wb} = 1\ \text{T}\cdot\text{m}^2$.

**CONCEPTUAL EXAMPLE 29–1** **Determining flux.** A square loop of wire encloses area $A_1$ as shown in Fig. 29–5. A uniform magnetic field $\vec{\mathbf{B}}$ perpendicular to the loop extends over the area $A_2$. What is the magnetic flux through the loop $A_1$?

**RESPONSE** We assume that the magnetic field is zero outside the area $A_2$. The total magnetic flux through area $A_1$ is the flux through area $A_2$, which by Eq. 29–1a for a uniform field is $BA_2$, plus the flux through the remaining area $(= A_1 - A_2)$, which is zero because $B = 0$. So the total flux is $\Phi_B = BA_2 + 0(A_1 - A_2) = BA_2$. It is *not* equal to $BA_1$ because $\vec{\mathbf{B}}$ is not uniform over $A_1$.

With our definition of flux, Eqs. 29–1, we can write down the results of Faraday's investigations: The emf $\mathscr{E}$ induced in a circuit is equal to the rate of change of magnetic flux through the circuit:

*FARADAY'S LAW OF INDUCTION*

$$\mathscr{E} = -\frac{d\Phi_B}{dt}. \qquad [1\ \text{loop}] \quad \textbf{(29–2a)}$$

This fundamental result is known as **Faraday's law of induction**, and is one of the basic laws of electromagnetism.

†The integral is taken through an ordinary area that is bounded by a closed curve, such as a circle or square. The area is not an entirely enclosed surface (like a football) as we used in Gauss's law, Chapter 22.

If the circuit contains $N$ loops that are closely wrapped so the same flux passes through each, the emfs induced in each loop add together, so the total emf is

$$\mathscr{E} = -N\frac{d\Phi_B}{dt}. \qquad [N \text{ loops}] \quad \textbf{(29–2b)}$$

*FARADAY'S LAW OF INDUCTION*

**EXAMPLE 29–2** **A loop of wire in a magnetic field.** A square loop of wire of side $\ell = 5.0\,\text{cm}$ is in a uniform magnetic field $B = 0.16\,\text{T}$. What is the magnetic flux in the loop (*a*) when $\vec{\mathbf{B}}$ is perpendicular to the face of the loop and (*b*) when $\vec{\mathbf{B}}$ is at an angle of 30° to the area $\vec{\mathbf{A}}$ of the loop? (*c*) What is the magnitude of the average current in the loop, if it has a resistance of 0.012 Ω, while it is rotated from position (*b*) to position (*a*) in 0.14 s?

**APPROACH** We use the definition $\Phi_B = \vec{\mathbf{B}} \cdot \vec{\mathbf{A}}$ to calculate the magnetic flux. Then we use Faraday's law of induction to find the induced emf in the coil, and from that the induced current $(I = \mathscr{E}/R)$.

**SOLUTION** The area of the coil is $A = \ell^2 = (5.0 \times 10^{-2}\,\text{m})^2 = 2.5 \times 10^{-3}\,\text{m}^2$, and the direction of $\vec{\mathbf{A}}$ is perpendicular to the face of the loop (Fig. 29–3).
(*a*) $\vec{\mathbf{B}}$ is perpendicular to the coil's face, and thus parallel to $\vec{\mathbf{A}}$ (Fig. 29–3), so

$$\Phi_B = \vec{\mathbf{B}} \cdot \vec{\mathbf{A}}$$
$$= BA\cos 0° = (0.16\,\text{T})(2.5 \times 10^{-3}\,\text{m}^2)(1) = 4.0 \times 10^{-4}\,\text{T}\cdot\text{m}^2$$

or $4.0 \times 10^{-4}\,\text{Wb}$.
(*b*) The angle $\theta$ between $\vec{\mathbf{B}}$ and $\vec{\mathbf{A}}$ is 30°, and $\cos 30° = 0.866$, so

$$\Phi_B = \vec{\mathbf{B}} \cdot \vec{\mathbf{A}}$$
$$= BA\cos\theta = (0.16\,\text{T})(2.5 \times 10^{-3}\,\text{m}^2)\cos 30° = 3.5 \times 10^{-4}\,\text{T}\cdot\text{m}^2$$

or $3.5 \times 10^{-4}\,\text{Wb}$, a bit less than in part (*a*).
(*c*) The magnitude of the induced emf (Eq. 29–2a) during the 0.14-s time interval is

$$\mathscr{E} = \frac{\Delta\Phi_B}{\Delta t} = \frac{(4.0 \times 10^{-4}\,\text{T}\cdot\text{m}^2) - (3.5 \times 10^{-4}\,\text{T}\cdot\text{m}^2)}{0.14\,\text{s}} = 3.6 \times 10^{-4}\,\text{V}.$$

Before and after the loop rotates, when it is at rest, the emf is zero. The current in the wire loop (Ohm's law) while it is rotating averages

$$I = \frac{\mathscr{E}}{R} = \frac{3.6 \times 10^{-4}\,\text{V}}{0.012\,\Omega} = 0.030\,\text{A} = 30\,\text{mA}.$$

The minus signs in Eqs. 29–2a and b are there to remind us in which direction the induced emf acts. Experiments show that

**a current produced by an induced emf creates a magnetic field that opposes the original change in magnetic flux.**

This is known as **Lenz's law**. Be aware that we are now discussing two distinct magnetic fields: (1) the changing magnetic field or flux that induces the current, and (2) the magnetic field produced by the induced current (all currents produce a magnetic field). The second (induced) field opposes the *change* in the first.

⚠ **CAUTION**
*Distinguish two different magnetic fields*

Lenz's law can be said another way:

**an induced emf is always induced in a direction that opposes the original change in flux that caused it,**

and this is valid even if no current can flow (as when a circuit is not complete).

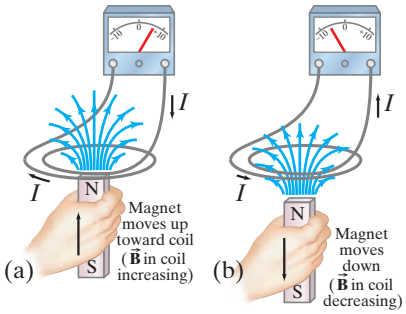

**FIGURE 29–2** (Repeated.)

Let us apply Lenz's law to the relative motion between a magnet and a coil, Fig. 29–2 on page 839 (repeated here, but smaller, in the margin). The changing flux through the coil when the magnet moves in or out induces an emf in the coil, producing a current. This induced current produces its own magnetic field. In Fig. 29–2a the distance between the coil and the magnet decreases. The magnet's magnetic field (and number of field lines) through the coil increases, and therefore the flux increases. The magnetic field of the magnet points upward. To oppose the upward increase of the magnet's field through the coil, the new induced magnetic field produced by the induced current needs to point *downward* inside the coil. Thus, Lenz's law tells us the current moves as shown in Fig. 29–2a (use the right-hand rule). In Fig. 29–2b, the flux *decreases* (because the magnet is moved away and $B$ through the coil decreases), so the induced current in the coil produces an *upward* magnetic field through the coil that is "trying" to maintain the status quo. Thus the current in Fig. 29–2b is in the opposite direction from Fig. 29–2a.

It is important to note that an emf is induced whenever there is a change in *flux* through the coil, and we now consider some more possibilities.

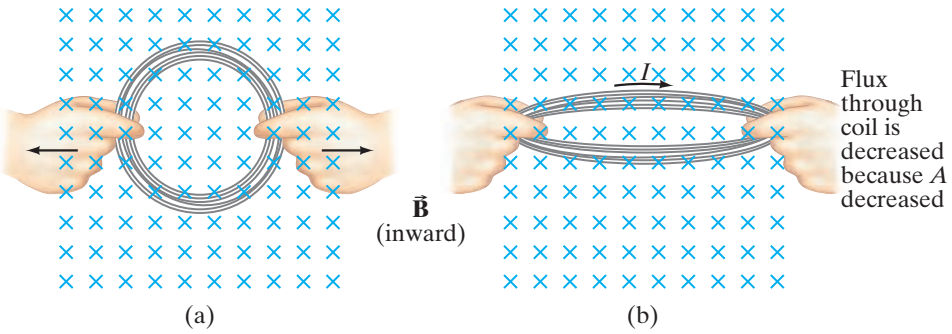

**FIGURE 29–6** A current can be induced by changing the coil's area, even though $B$ doesn't change. Here the area $A$ is reduced by pulling on the sides of the coil: the *flux* through the coil is reduced as we go from (a) to (b). The brief induced current acts in the direction shown so as to try to maintain the original flux $(\Phi = BA)$ by producing its own magnetic field into the page. That is, as area $A$ decreases, the current acts to increase $B$ in the original (inward) direction.

Magnetic flux $\Phi_B = \int \vec{\mathbf{B}} \cdot d\vec{\mathbf{A}} = \int B \cos\theta \, dA$, so an emf can be induced in three ways: (1) by a changing magnetic field $B$; (2) by changing the area $A$ of the loop in the field; or (3) by changing the loop's orientation $\theta$ with respect to the field. Figures 29–1 and 29–2 showed case 1. Examples of cases 2 and 3 are shown in Figs. 29–6 and 29–7.

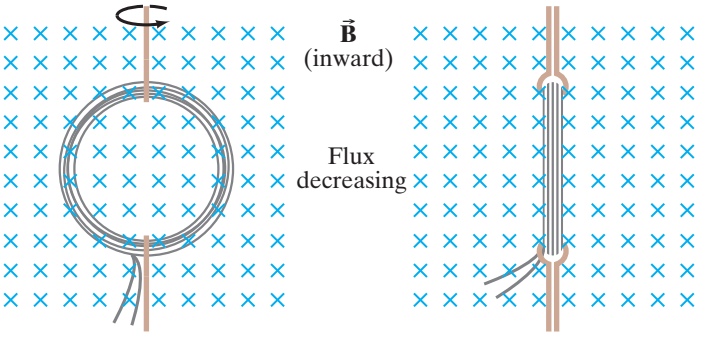

**FIGURE 29–7** A current can be induced by rotating a coil in a magnetic field. The flux through the coil changes from (a) to (b) because $\theta$ (in Eq. 29–1a, $\Phi = BA\cos\theta$) went from $0°$ $(\cos\theta = 1)$ to $90°$ $(\cos\theta = 0)$.

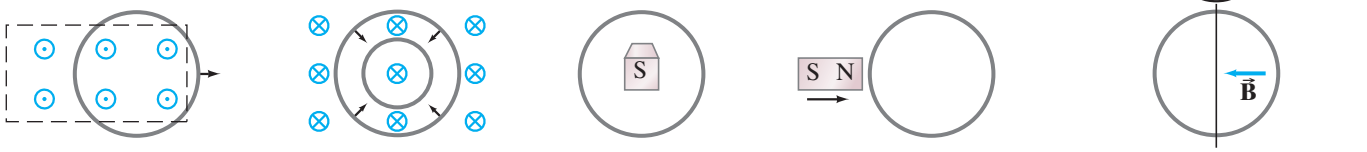
**FIGURE 29–8** Example 29–3: An induction stove, heating soup but not burning the hand.

**CONCEPTUAL EXAMPLE 29–3** **Induction stove.** In an induction stove (Fig. 29–8), an ac current exists in a coil that is the "burner" (a burner that never gets hot). Why will it heat a metal pan, usually iron, but not a glass container?

**RESPONSE** The current is ac, so it induces a changing magnetic field that passes through the pan bottom. This changing magnetic field induces a current in the pan, and since the metal pan offers electric resistance, electric energy is transformed to thermal energy which heats the pan and its contents. If the pan is iron, magnetic hysteresis due to the changing current produces additional heating. A glass container offers such high resistance that little current is induced and little energy is transferred $(P = V^2/R)$.

PROBLEM SOLVING



## Lenz's Law

Lenz's law is used to determine the direction of the (conventional) electric current *induced* in a loop due to a change in magnetic flux inside the loop. (The loop may already be carrying its own ordinary current.) To produce an *induced* current you need

**(a)** a closed conducting loop, and

**(b)** an external magnetic flux through the loop that is changing in time.

1. Determine whether the magnetic flux ($\Phi_B = BA\cos\theta$) inside the loop is decreasing, increasing, or unchanged.
2. The magnetic field due to the *induced* current: (a) points in the same direction as the external field if the flux is decreasing; (b) points in the opposite direction from the external field if the flux is increasing; or (c) is zero if the flux is not changing.
3. Once you know the direction of the induced magnetic field, use the right-hand-rule-1 (page 791, Chapter 27) to find the direction of the induced current that would give this induced $\vec{\mathbf{B}}$.
4. Always keep in mind that there are two magnetic fields: (1) an external field whose flux must be changing if it is to induce an electric current, and (2) a magnetic field produced by the induced current.
5. If a wire is already carrying an electric current, the total current while the magnetic field is changing will be the algebraic sum of the original current and the induced current.

(a) Pulling a round loop to the right out of a magnetic field which points out of the page

(b) Shrinking a loop in a magnetic field pointing into the page

(c) S magnetic pole moving from below, up toward the loop

(d) N magnetic pole moving toward loop in the plane of the loop

(e) Rotating the loop by pulling the left side toward us and pushing the right side in; the magnetic field points from right to left

**FIGURE 29–9** Example 29–4.

**CONCEPTUAL EXAMPLE 29–4** **Practice with Lenz's law.** In which direction is the current induced in the circular loop for each situation in Fig. 29–9?

**RESPONSE** In (*a*), the magnetic field pointing out of the page initially passes through the entire loop. If you pull the loop out of the field, magnetic flux through the loop decreases (to zero). So the induced current will be in a direction to maintain the decreasing flux through the loop: the current will be counterclockwise to produce a magnetic field outward (toward the reader).

(*b*) The external field is into the page. The coil area gets smaller, so the flux will decrease; hence the induced current will be clockwise, producing its own field into the page to oppose the flux decrease.

(*c*) Magnetic field lines point into the S pole of a magnet, so as the magnet moves toward us and the loop, the magnet's field points into the page and is getting stronger. The current in the loop will be induced in the counterclockwise direction in order to produce a field $\vec{\mathbf{B}}$ *out* of the page.

(*d*) The magnetic field is in the plane of the loop, so no magnetic field lines pass through the loop and the flux through the loop is zero throughout the process; hence there is no change in flux and no induced emf or current in the loop.

(*e*) Initially there is no flux through the loop: the $\vec{\mathbf{B}}$ field is in the plane of the loop. When you start to rotate the loop, the external field through the loop begins increasing to the left. To counteract this change in flux, the loop will have current induced in a counterclockwise direction so as to produce its own field to the right.

**CAUTION**

*Magnetic field created by induced current opposes change in external flux, not necessarily opposing the external field*

**EXERCISE B** What is the direction of the induced current in the circular loop due to the current shown in each part of Fig. 29–10?

**FIGURE 29–10** Exercise B.

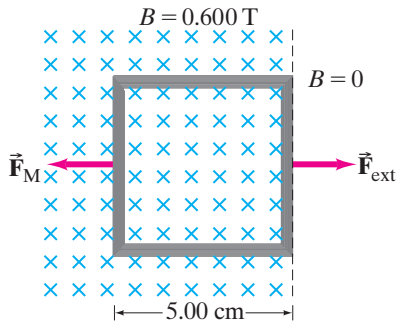


**FIGURE 29–11** Example 29–5. The square coil in a magnetic field $B = 0.600\,\text{T}$ is pulled abruptly to the right to a region where $B = 0$. (The forces shown are discussed in the alternate solution at the end of Example 29–5.)

**EXAMPLE 29–5** **Pulling a coil from a magnetic field.** A 100-loop square coil of wire, with side $\ell = 5.00\,\text{cm}$ and total resistance $R = 100\,\Omega$, is positioned perpendicular to a uniform magnetic field $B = 0.600\,\text{T}$, as shown in Fig. 29–11. It is quickly pulled from the field at constant speed (moving perpendicular to $\vec{\mathbf{B}}$) to a region where $B$ drops abruptly to zero. At $t = 0$, the right edge of the coil is at the edge of the field. It takes 0.100 s for the whole coil to reach the field-free region. Determine (*a*) the rate of change in flux through one loop of the coil, and (*b*) the total emf and current induced in the 100-loop coil. (*c*) How much energy is dissipated in the coil? (*d*) What was the average force required ($F_{\text{ext}}$)?

**APPROACH** We start by finding how the magnetic flux, $\Phi_B = BA\cos 0° = BA$, changes during the time interval $\Delta t = 0.100\,\text{s}$. Faraday's law then gives the induced emf and Ohm's law gives the current.

**SOLUTION** (*a*) The coil's area is $A = \ell^2 = (5.00 \times 10^{-2}\,\text{m})^2 = 2.50 \times 10^{-3}\,\text{m}^2$. The flux through one loop is initially $\Phi_B = BA = (0.600\,\text{T})(2.50 \times 10^{-3}\,\text{m}^2) = 1.50 \times 10^{-3}\,\text{T}\cdot\text{m}^2$. After 0.100 s, the flux is zero. The rate of change in flux is constant (because the coil is square), and for one loop is equal to

$$\frac{\Delta\Phi_B}{\Delta t} = \frac{0 - (1.50 \times 10^{-3}\,\text{T}\cdot\text{m}^2)}{0.100\,\text{s}} = -1.50 \times 10^{-2}\,\text{T}\cdot\text{m}^2/\text{s}.$$

(*b*) The emf induced (Eq. 29–2) in the 100-loop coil during this 0.100-s interval is

$$\mathscr{E} = -N\frac{\Delta\Phi_B}{\Delta t} = -(100)(-1.50 \times 10^{-2}\,\text{T}\cdot\text{m}^2/\text{s}) = 1.50\,\text{V}.$$

The current is found by applying Ohm's law to the 100-Ω coil:

$$I = \frac{\mathscr{E}}{R} = \frac{1.50\,\text{V}}{100\,\Omega} = 1.50 \times 10^{-2}\,\text{A} = 15.0\,\text{mA}.$$

By Lenz's law, the current must be clockwise to produce more $\vec{\mathbf{B}}$ into the page and thus oppose the decreasing flux into the page.

(*c*) The total energy dissipated in the coil is the product of the power ($= I^2R$) and the time:

$$E = Pt = I^2Rt = (1.50 \times 10^{-2}\,\text{A})^2(100\,\Omega)(0.100\,\text{s}) = 2.25 \times 10^{-3}\,\text{J}.$$

(*d*) We can use the result of part (*c*) and apply the work-energy principle: the energy dissipated $E$ is equal to the work $W$ needed to pull the coil out of the field (Chapters 7 and 8). Because $W = \bar{F}_{\text{ext}}\,d$ where $d = 5.00\,\text{cm}$, then

$$\bar{F}_{\text{ext}} = \frac{W}{d} = \frac{2.25 \times 10^{-3}\,\text{J}}{5.00 \times 10^{-2}\,\text{m}} = 0.0450\,\text{N}.$$

***Alternate Solution*** (*d*) We can also calculate the force directly using $\vec{\mathbf{F}} = I\vec{\boldsymbol{\ell}} \times \vec{\mathbf{B}}$, Eq. 27–3, which here for constant $\vec{\mathbf{B}}$ is $F = I\ell B$. The force the magnetic field exerts on the top and bottom sections of the square coil of Fig. 29–10 are in opposite directions and cancel each other. The magnetic force $\vec{\mathbf{F}}_{\text{M}}$ exerted on the left vertical section of the square coil acts to the left as shown because the current is up (clockwise, as in part *b*). The right side of the loop is in the region where $\vec{\mathbf{B}} = 0$. Hence the external force, to the right, needed to just overcome the magnetic force to the left (on $N = 100$ loops) is

$$F_{\text{ext}} = NI\ell B = (100)(0.0150\,\text{A})(0.0500\,\text{m})(0.600\,\text{T}) = 0.0450\,\text{N},$$

which is the same answer, confirming our use of energy conservation above.

**EXAMPLE 29–6** **Initial dc current in the coil.** Suppose the 100 loops of wire in Fig. 29–11, Example 29–5, are connected to an emf that produces a counterclockwise 60.0-mA dc current in the wire. When the square coil is pulled from the magnetic field, what then is the current in the wire?

**SOLUTION** As the square loop is pulled to the right, out of the magnetic field, a 15.0-mA clockwise current is induced in the wire as we saw in Example 29–5. So the current in the wire is $(60.0 - 15.0)\,\text{mA} = 45.0\,\text{mA}$. Once the whole coil is outside the magnetic field, the current returns to 60.0 mA.

# 29–3 EMF Induced in a Moving Conductor

Another way to induce an emf is shown in Fig. 29–12a, and this situation helps illuminate the nature of the induced emf. Assume that a uniform magnetic field $\vec{\mathbf{B}}$ is perpendicular to the area bounded by the U-shaped conductor and the movable rod resting on it. If the rod is made to move at a speed $v$ to the right, it travels a distance $dx = v\,dt$ in a time $dt$. Therefore, the area of the loop increases by an amount $dA = \ell\,dx = \ell v\,dt$ in a time $dt$. By Faraday's law there is an induced emf $\mathcal{E}$ whose magnitude is given by

$$\mathcal{E} = \frac{d\Phi_B}{dt} = \frac{B\,dA}{dt} = \frac{B\ell v\,dt}{dt} = B\ell v. \qquad \textbf{(29–3)}$$

The induced current is clockwise (to counter the increasing flux).

Equation 29–3 is valid as long as $B, \ell$, and $v$ are mutually perpendicular. (If they are not, we use only the components of each that are mutually perpendicular.) An emf induced on a conductor moving in a magnetic field is sometimes called *motional emf*.

We can also obtain Eq. 29–3 without using Faraday's law. We saw in Chapter 27 that a charged particle moving perpendicular to a magnetic field $B$ with speed $v$ experiences a force $\vec{\mathbf{F}} = q\vec{\mathbf{v}} \times \vec{\mathbf{B}}$ (Eq. 27–5a). When the rod of Fig. 29–12a moves to the right with velocity $\vec{\mathbf{v}}$, the electrons in the rod also move with this velocity. Therefore, since $\vec{\mathbf{v}} \perp \vec{\mathbf{B}}$, each electron feels a force $F = qvB$, which acts up the page as the red arrow in Fig. 29–12b shows. If the rod is not in contact with the U-shaped conductor, electrons would collect at the upper end of the rod, leaving the lower end positive (see signs in Fig. 29–12b). There must thus be an induced emf. If the rod is in contact with the U-shaped conductor (Fig. 29–12a), the electrons will flow into the U. There will then be a clockwise (conventional) current in the loop. To calculate the emf, we determine the work $W$ needed to move a charge $q$ from one end of the rod to the other against this potential difference: $W = \text{force} \times \text{distance} = (qvB)(\ell)$. The emf equals the work done per unit charge, so $\mathcal{E} = W/q = qvB\ell/q = B\ell v$, the same result† as from Faraday's law above, Eq. 29–3.

**EXERCISE C** In what direction will the electrons flow in Fig. 29–12 if the rod moves to the left, decreasing the area of the current loop?

**EXAMPLE 29–7** **ESTIMATE** **Does a moving airplane develop a large emf?** An airplane travels 1000 km/h in a region where the Earth's magnetic field is about $5 \times 10^{-5}$ T and is nearly vertical (Fig. 29–13). What is the potential difference induced between the wing tips that are 70 m apart?

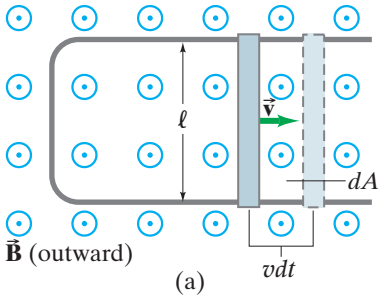
**APPROACH** We consider the wings to be a 70-m-long conductor moving through the Earth's magnetic field. We use Eq. 29–3 to get the emf.

**SOLUTION** Since $v = 1000\,\text{km/h} = 280\,\text{m/s}$, and $\vec{\mathbf{v}} \perp \vec{\mathbf{B}}$, we have

$$\mathcal{E} = B\ell v = (5 \times 10^{-5}\,\text{T})(70\,\text{m})(280\,\text{m/s}) \approx 1\,\text{V}.$$

**NOTE** Not much to worry about.

**EXAMPLE 29–8** **Electromagnetic blood-flow measurement.** The rate of blood flow in our body's vessels can be measured using the apparatus shown in Fig. 29–14, since blood contains charged ions. Suppose that the blood vessel is 2.0 mm in diameter, the magnetic field is 0.080 T, and the measured emf is 0.10 mV. What is the flow velocity $v$ of the blood?



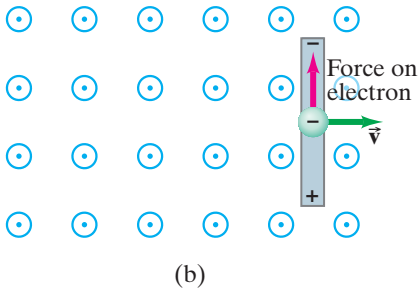
**APPROACH** The magnetic field $\vec{\mathbf{B}}$ points horizontally from left to right (N pole toward S pole). The induced emf acts over the width $\ell = 2.0\,\text{mm}$ of the blood vessel, perpendicular to $\vec{\mathbf{B}}$ and $\vec{\mathbf{v}}$ (Fig. 29–14), just as in Fig. 29–12. We can then use Eq. 29–3 to get $v$.

**SOLUTION** We solve for $v$ in Eq. 29–3:

$$v = \frac{\mathcal{E}}{B\ell} = \frac{(1.0 \times 10^{-4}\,\text{V})}{(0.080\,\text{T})(2.0 \times 10^{-3}\,\text{m})} = 0.63\,\text{m/s}.$$

**NOTE** In actual practice, an alternating current is used to produce an alternating magnetic field. The induced emf is then alternating (ac).

†This force argument, which is basically the same as for the Hall effect (Section 27–8), explains this one way of inducing an emf. It does not explain the general case of electromagnetic induction.



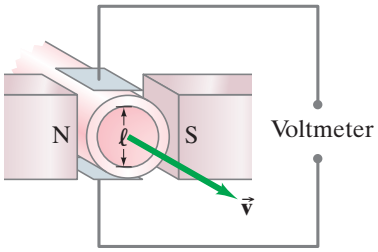


**FIGURE 29–12** (a) A conducting rod is moved to the right on the smooth surface of a U-shaped conductor in a uniform magnetic field $\vec{\mathbf{B}}$ that points out of the page. The induced current is clockwise. (b) Force on an electron in the metal rod (moving to the right) is upward due to $\vec{\mathbf{B}}$ pointing out of the page. Hence electrons can collect at the top of the rod, leaving + charge at the bottom.

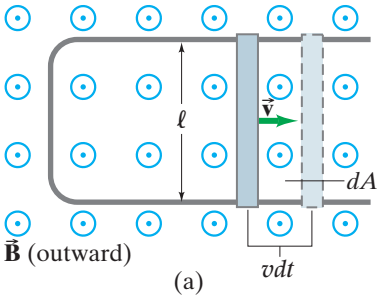

**FIGURE 29–13** Example 29–7.

**PHYSICS APPLIED**
*Blood-flow measurement*

**FIGURE 29–14** Measurement of blood velocity from the induced emf. Example 29–8.

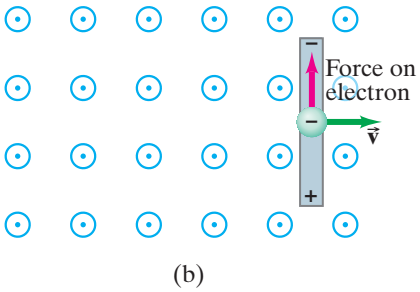

**FIGURE 29–12** (Repeated.)

**EXAMPLE 29–9** **Force on the rod.** To make the rod of Fig. 29–12a move to the right at constant speed $v$, you need to apply an external force on the rod to the right. (*a*) Explain and determine the magnitude of the required force. (*b*) What external power is needed to move the rod? (Do not confuse this external force on the rod with the upward force on the electrons shown in Fig. 29–12b.)

**APPROACH** When the rod moves to the right, electrons flow upward in the rod according to the right-hand rule. So the conventional current is downward in the rod. We can see this also from Lenz's law: the outward magnetic flux through the loop is increasing, so the induced current must oppose the increase. Thus the current is clockwise so as to produce a magnetic field into the page (right-hand rule), opposite to the outward $\vec{\mathbf{B}}$ shown. The magnetic force on the moving rod is $\vec{\mathbf{F}} = I\vec{\ell} \times \vec{\mathbf{B}}$ for a constant $\vec{\mathbf{B}}$ (Eq. 27–3). The right-hand rule tells us this magnetic force is to the left, and is thus a "drag force" opposing our effort to move the rod to the right.

**SOLUTION** (*a*) The magnitude of the external force, to the right, needs to balance the magnetic force $F = I\ell B$, to the left. The current $I = \mathscr{E}/R = B\ell v/R$ (see Eq. 29–3), and the resistance $R$ is that of the whole circuit: the rod and the U-shaped conductor. The force $F$ required to move the rod is thus

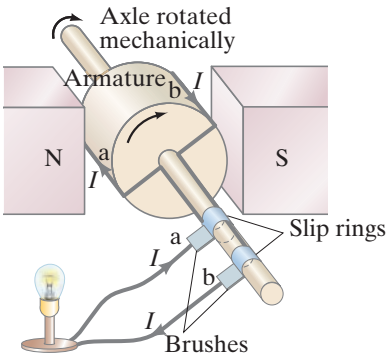
$$F = I\ell B = \left(\frac{B\ell v}{R}\right)\ell B = \frac{B^2\ell^2}{R}v.$$

If $B$, $\ell$, and $R$ are constant, then a constant speed $v$ is produced by a constant external force. (Constant $R$ implies that the parallel rails have negligible resistance.)

(*b*) The external power needed to move the rod for constant $R$ is

$$P_{\text{ext}} = Fv = \frac{B^2\ell^2v^2}{R}.$$

The power dissipated in the resistance is $P = I^2R$. With $I = \mathscr{E}/R = B\ell v/R$,



$$P_{\text{R}} = I^2R = \frac{B^2\ell^2v^2}{R},$$

so the power input equals the power dissipated in the resistance at any moment.

# 29–4 Electric Generators

We discussed alternating currents (ac) briefly in Section 25–7. Now we examine how ac is generated: by an **electric generator** or **dynamo**, an indispensable practical result of Faraday's discovery. A generator is the main way electricity is produced for practical purposes (some by batteries and solar cells), and it does so by transforming mechanical energy into electric energy (this is just the opposite of what a motor does).

**FIGURE 29–15** An ac generator.

A simplified diagram of an **ac generator** is shown in Fig. 29–15. A generator consists of many loops of wire (only one is shown) wound on an **armature** that can rotate in a magnetic field. The axle is turned by some mechanical means (falling water at a dam, steam turbine, car motor belt), and an emf is induced in the rotating coil. An ac electric current is thus the *output* of a generator. Suppose in Fig. 29–15 that the armature is rotating clockwise; then $\vec{\mathbf{F}} = q\vec{\mathbf{v}} \times \vec{\mathbf{B}}$ applied to charged particles in the wire (or Lenz's law) tells us that the (conventional) current in the wire labeled b on the armature is outward, toward us; therefore the current is outward through brush b. Each brush is fixed and presses against a *continuous* slip ring that rotates with the armature. After one-half revolution, wire b will be where wire a is now in Fig. 29–15, and the current then at brush b will be inward. Thus the current produced is alternating (AC).

Let us assume the loop is being made to rotate in a uniform magnetic field $\vec{\mathbf{B}}$ with constant angular velocity $\omega$. From Faraday's law (Eq. 29–2a), the induced emf is

$$\mathscr{E} = -\frac{d\Phi_B}{dt} = -\frac{d}{dt}\int \vec{\mathbf{B}} \cdot d\vec{\mathbf{A}} = -\frac{d}{dt}[BA\cos\theta]$$

where $A$ is the area of the loop and $\theta$ is the angle between $\vec{\mathbf{B}}$ and $\vec{\mathbf{A}}$.

Since $\omega = d\theta/dt$, then $\theta = \theta_0 + \omega t$. We choose $\theta_0 = 0$, so

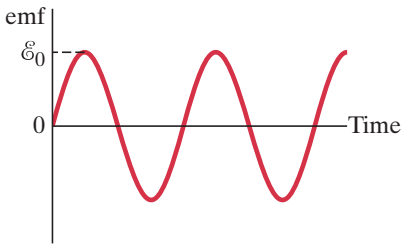
$$\mathscr{E} = -BA\frac{d}{dt}(\cos\omega t) = BA\omega\sin\omega t.$$

If the rotating coil contains $N$ loops,

$$\mathscr{E} = NBA\omega\sin\omega t = \mathscr{E}_0\sin\omega t. \qquad \textbf{(29–4)}$$

Thus the output emf is sinusoidal (Fig. 29–16) with amplitude $\mathscr{E}_0 = NBA\omega$. Such a rotating coil in a magnetic field is the basic operating principle of an *ac generator*. The rms output (Section 25–7) is

$$\mathscr{E}_{\text{rms}} = \frac{NB\omega A}{\sqrt{2}} = \frac{\mathscr{E}_0}{\sqrt{2}}.$$



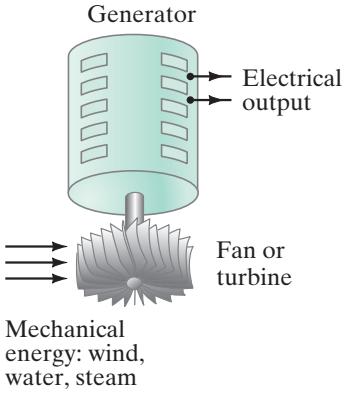


**FIGURE 29–16** An ac generator produces an alternating current. The output emf $\mathscr{E} = \mathscr{E}_0\sin\omega t$, where $\mathscr{E}_0 = NAB\omega$ (Eq. 29–4).

The frequency $f\ (= \omega/2\pi)$ is 60 Hz for general use in the United States, Canada, and a few other countries, whereas 50 Hz is used in Europe and most other countries. Most of the power generated in the United States is done at steam plants, where the burning of fossil fuels (coal, oil, natural gas) boils water to produce high-pressure steam that turns a turbine connected to the generator axle, Fig. 29–17. Turbines can also be turned by water gushing from beneath a dam (hydroelectric) and by wind, Section 20–11 and Table 20–3. At nuclear power plants, the nuclear energy released is used to produce steam to turn turbines. Indeed, a heat engine (Chapter 20) connected to a generator is the principal means of generating electric power. The frequency of 60 Hz or 50 Hz is maintained very precisely by power companies, and in doing Problems, we will assume it is as precise as other numbers given.

**PHYSICS APPLIED**
*Power plants*

**FIGURE 29–17** A generator axle can be turned by various mechanical means to produce electricity: steam, wind, and water gushing out at the base of a dam.

**EXAMPLE 29–10** **An ac generator.** The armature of a 60-Hz ac generator rotates in a 0.15-T magnetic field. If the area of the coil is $2.0\times10^{-2}\,\text{m}^2$, how many loops must the coil contain if the peak output is to be $\mathscr{E}_0 = 170\,\text{V}$?

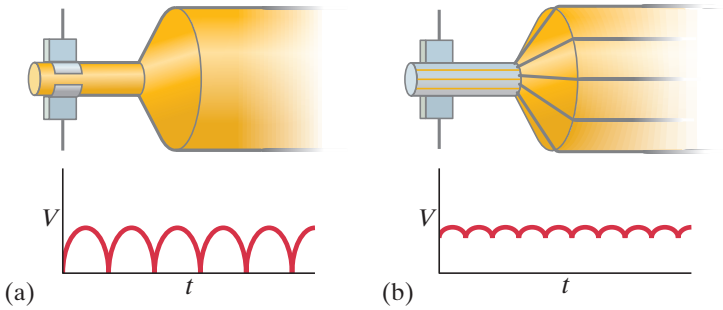
**APPROACH** From Eq. 29–4 we see that the maximum emf is $\mathscr{E}_0 = NBA\omega$.

**SOLUTION** We solve Eq. 29–4 for $N$ with $\omega = 2\pi f = (6.28)(60\,\text{s}^{-1}) = 377\,\text{s}^{-1}$ (a useful number to remember):

$$N = \frac{\mathscr{E}_0}{BA\omega} = \frac{170\,\text{V}}{(0.15\,\text{T})(2.0\times10^{-2}\,\text{m}^2)(377\,\text{s}^{-1})} = 150\ \text{turns}.$$

A **dc generator** is much like an ac generator, except the slip rings are replaced by split-ring commutators, Fig. 29–18a, just as in a dc motor (Section 27–6). The output of a dc generator is as shown by the red curves, and can be smoothed out by placing a capacitor in parallel with the output† (Section 26–5). More common is the use of many armature windings, as in Fig. 29–18b, which produces a smoother output.

**PHYSICS APPLIED**
*DC generator*



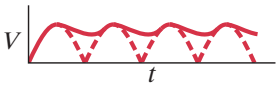


**FIGURE 29–18** (a) A dc generator with one set of commutators, and (b) a dc generator with many sets of commutators and windings.

†A capacitor tends to store charge and, if the time constant $RC$ is long enough, helps to smooth out the voltage as shown in the figure to the right.

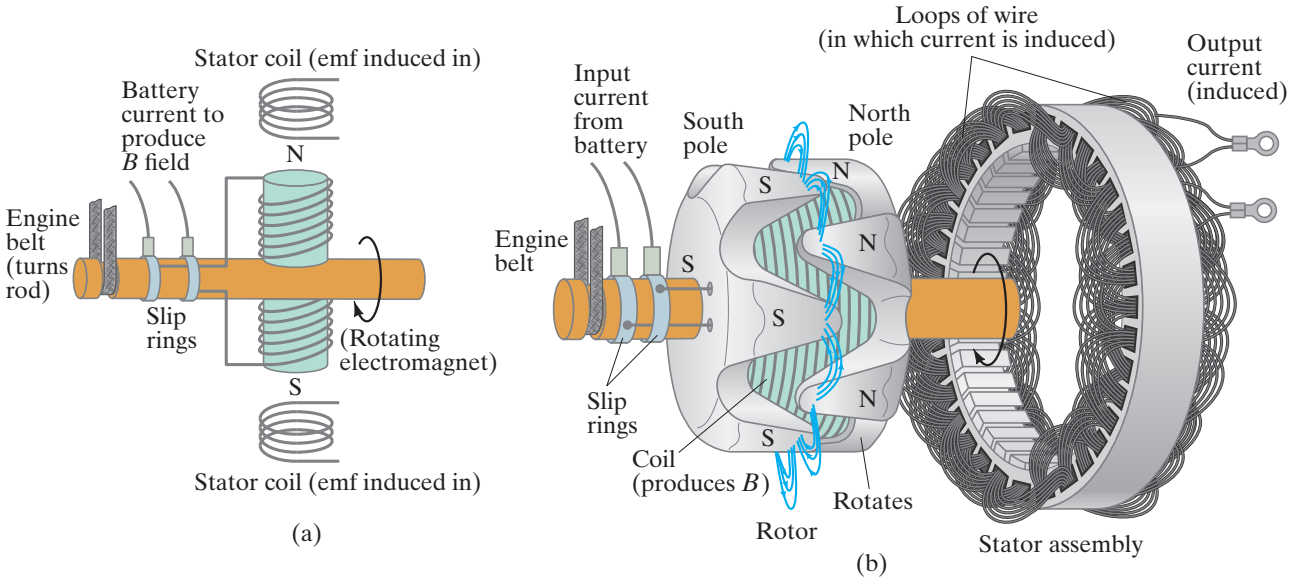

**FIGURE 29–19** (a) Simplified schematic diagram of an alternator. The input current to the rotor from the battery is connected through continuous slip rings. Sometimes the rotor electromagnet is replaced by a permanent magnet (no input current). (b) Actual shape of an alternator. The rotor is made to turn by a belt from the engine. The current in the wire coil of the rotor (green) produces a magnetic field inside it along its axis that points horizontally from left to right (not shown), thus making north and south poles of the odd-shaped metal plates attached at either end. These end plates are made with triangular fingers that are bent over the coil—hence there are N and S poles quite close to one another, with magnetic field lines between them as shown by the blue lines. As the rotor turns, these field lines pass through the fixed stator coils (shown on the right for clarity, but in fact the rotor rotates inside the stator), inducing a current in them, which is the output.

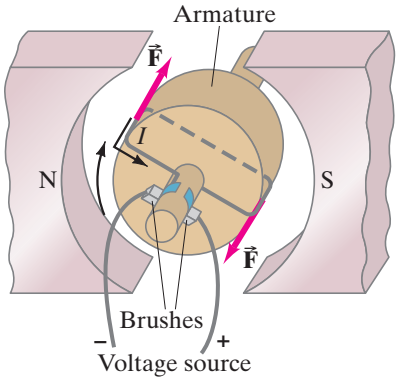

**PHYSICS APPLIED**
*Alternators*

Automobiles used to use dc generators. Today they mainly use **alternators**, which avoid the problems of wear and electrical arcing (sparks) across the split-ring commutators of dc generators. Alternators differ from generators in that an electromagnet, called the **rotor**, is fed by current from the battery and is made to rotate by a belt from the engine. The magnetic field of the turning rotor passes through a surrounding set of stationary coils called the **stator** (Fig. 29–19), inducing an alternating current in the stator coils, which is the output. This ac output is changed to dc for charging the battery by the use of semiconductor diodes, which allow current flow in one direction only. Note: the battery sends a current to the rotor, and the mechanical work done by the car engine produces *more* current to send back to the battery.

# 29–5 Back EMF and Counter Torque; Eddy Currents

## Back EMF, in a Motor

**FIGURE 27–26** (Repeated.) A simple dc motor.

A motor turns and produces mechanical energy when a current is made to flow in it. From our description in Section 27–6 of a simple dc motor, you might expect that the armature in Fig. 27–26 (shown again here in the margin) would accelerate indefinitely due to the torque on it. However, as the armature of the motor turns, the magnetic flux through the coil changes and an emf is generated. This induced emf acts to oppose the motion (Lenz's law) and is called the **back emf** or **counter emf**. The greater the speed of the motor, the greater the back emf. A motor normally rotates and does work on something ("the load"), but if there were no load to push (or rotate), the motor's speed would increase until the back emf equaled the input voltage. When there is a mechanical load, the speed of the motor is limited also by that load. The back emf will then be less than the external applied voltage. The greater the mechanical load, the slower the motor rotates and the lower is the back emf ($\mathscr{E} \propto \omega$, Eq. 29–4).

**EXAMPLE 29–11** **Back emf in a motor.** The armature windings of a dc motor have a resistance of 5.0 Ω. The motor is connected to a 120-V line, and when the motor reaches full speed against its normal load, the back emf is 108 V. Calculate (*a*) the current into the motor when it is just starting up, and (*b*) the current when the motor reaches full speed.

**APPROACH** As the motor is just starting up, it is turning very slowly, so there is negligible back emf. The only voltage is the 120-V line. The current is given by Ohm's law with $R = 5.0\ \Omega$. At full speed, we must include as emfs both the 120-V applied emf and the opposing back emf.

**SOLUTION** (*a*) At start up, the current is controlled by the 120 V applied to the coil's 5.0-Ω resistance. By Ohm's law,

$$I = \frac{V}{R} = \frac{120\ \text{V}}{5.0\ \Omega} = 24\ \text{A}.$$

(*b*) When the motor is at full speed, the back emf must be included in the equivalent circuit shown in Fig. 29–20. In this case, Ohm's law (or Kirchhoff's rule, Chapter 26) gives

$$120\ \text{V} - 108\ \text{V} = I(5.0\ \Omega).$$

Therefore

$$I = \frac{12\ \text{V}}{5.0\ \Omega} = 2.4\ \text{A}.$$

**NOTE** This result shows that the current can be very high when a motor first starts up. This is why the lights in your house may dim when the motor of the refrigerator (or other large motor) starts up. The large initial refrigerator current causes the voltage to the lights and at the outlets to drop because the house wiring has resistance and there is noticeable voltage drop across it when large currents are drawn.

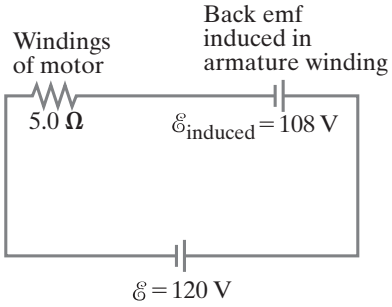

**FIGURE 29–20** Circuit of a motor showing induced back emf. Example 29–11.

**CONCEPTUAL EXAMPLE 29–12** **Motor overload.** When using an appliance such as a blender, an electric drill, or a sewing machine, if the appliance is overloaded or jammed so that the motor slows appreciably or stops while the power is still connected, the device can burn out and be ruined. Explain why this happens.

**PHYSICS APPLIED**
*Burning out a motor*

**RESPONSE** The motors are designed to run at a certain speed for a given applied voltage, and the designer must take the expected back emf into account. If the rotation speed is reduced, the back emf will not be as high as expected ($\mathcal{E} \propto \omega$, Eq. 29–4). The current will increase, and may become large enough that the windings of the motor heat up and may melt, ruining the motor.

## Counter Torque, in a Generator

In a generator, the situation is the reverse of that for a motor. As we saw, the mechanical turning of the armature induces an emf in the loops, which is the output. If the generator rotates but is not connected to an external circuit, the emf exists at the terminals but there is no current. In this case, it takes little effort to turn the armature. But if the generator *is* connected to a device that draws current, then a current flows in the coils of the armature. Because this current-carrying coil is in an external magnetic field, there will be a torque exerted on it (as in a motor), and this torque opposes the motion (use right-hand-rule-2, page 791; for the force on a wire in Fig. 29–15). This is called a **counter torque**. The greater the electrical load—that is, the more current that is drawn—the greater will be the counter torque. Hence the external applied torque will have to be greater to keep the generator turning. This makes sense from the conservation of energy principle. More mechanical energy input is needed to produce more electrical energy output.

**EXERCISE D** A bicycle headlight is powered by a generator that is turned by the bicycle wheel. (*a*) If you speed up, how does the power to the light change? (*b*) Does the generator resist being turned as the bicycle's speed increases, and if so how?

## Eddy Currents

Induced currents are not always confined to well-defined paths such as in wires. Consider, for example, the rotating metal wheel in Fig. 29–21a. An external magnetic field is applied across a limited area of the wheel as shown and points into the page. The section of wheel in the magnetic field has an emf induced in it because the conductor is moving, carrying electrons with it. The flow of induced (conventional) current in the wheel is upward in the region of the magnetic field (Fig. 29–21b), and the current follows a downward return path outside that region. Why? According to Lenz's law, the induced currents oppose the change that causes them. Consider the part of the rotating wheel labeled c in Fig. 29–21b, where the magnetic field is zero but is just about to enter a region where $\vec{\mathbf{B}}$ points into the page. To oppose this inward increase in magnetic field, the induced current is counterclockwise to produce a field pointing out of the page (right-hand-rule-1). Similarly, region d is about to move to e, where $\vec{\mathbf{B}}$ is zero; hence the current is clockwise to produce an inward field opposed to the decreasing flux inward. These currents are referred to as **eddy currents**. They can be present in any conductor that is moving across a magnetic field or through which the magnetic flux is changing.

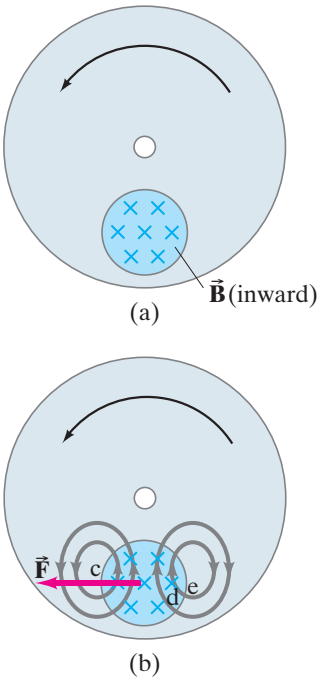

**FIGURE 29–21** Production of eddy currents in a rotating wheel. The wide gray lines in (b) indicate induced current.

In Fig. 29–21b, the magnetic field exerts a force $\vec{\mathbf{F}}$ on the induced currents it has created, and that force opposes the rotational motion. Eddy currents can be used in this way as a smooth braking device on, say, a rapid-transit railroad car. In order to stop the car, an electromagnet can be turned on that applies its field either to the wheels or to the moving steel rail below. Eddy currents can also be used to dampen (reduce) the oscillation of a vibrating system, which is referred to as **magnetic damping**.

Eddy currents, however, can be a problem. For example, eddy currents induced in the armature of a motor or generator produce heat ($P = I\mathscr{E}$) and waste energy. To reduce the eddy currents, the armatures are *laminated*; that is, they are made of very thin sheets of iron that are well insulated from one another (used also in transformers, Fig. 29–24). The total path length of the eddy currents is confined to each slab, which increases the total resistance; hence the current is less and there is less wasted energy.

**PHYSICS APPLIED**
*Metal detector*

Walk-through metal detectors (Fig. 29–22) use electromagnetic induction and eddy currents to detect metal objects. Several coils are situated in the walls of the walk-through at different heights. In one technique, the coils are given brief pulses of current, hundreds or thousands of times per second. When a person passes through the walk-through, any metal object being carried will have eddy currents induced in it, and the small magnetic field produced by that eddy current can be detected, setting off an alert or alarm.

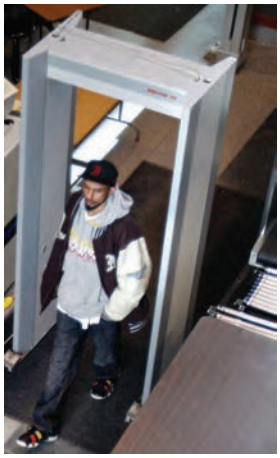

**FIGURE 29–22**
Metal detector.

# 29–6 Transformers and Transmission of Power

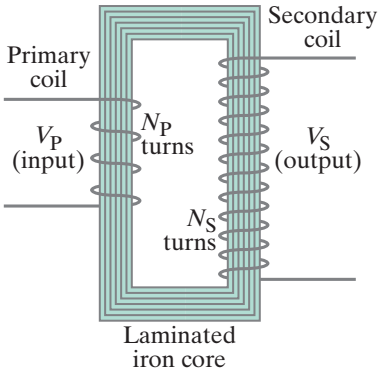
A transformer is a device for increasing or decreasing an ac voltage. Transformers are found everywhere: on utility poles (Fig. 29–23) to reduce the high voltage from the electric company to a usable voltage in houses (120 V or 240 V); in chargers for cell phones, laptops, and other electrical devices; in your car to give the needed high voltage to the spark plugs; and in many other applications. A **transformer** consists of two coils of wire known as the **primary** and **secondary** coils. The two coils can be interwoven (with insulated wire); or they can be linked by an iron core which is laminated to minimize eddy-current losses (Section 29–5), as shown in Fig. 29–24. Transformers are designed so that (nearly) all the magnetic flux produced by the current in the primary coil also passes through the secondary coil, and we assume this is true in what follows. We also assume that energy losses (in resistance and hysteresis) can be ignored—a good approximation for real transformers, which are often better than 99% efficient.

**FIGURE 29–23** Repairing a step-down transformer on a utility pole.

When an ac voltage is applied to the primary coil, the changing magnetic field it produces will induce an ac voltage of the same frequency in the secondary coil. However, the voltage will be different according to the number of "turns" or loops in each coil. From Faraday's law, the voltage or emf induced in the secondary coil is

$$V_S = N_S \frac{d\Phi_B}{dt},$$

where $N_S$ is the number of turns in the secondary coil, and $d\Phi_B/dt$ is the rate at which the magnetic flux changes through each coil.



The input primary voltage, $V_P$, is related to the rate at which the flux changes through it,

$$V_P = N_P \frac{d\Phi_B}{dt},$$

where $N_P$ is the number of turns in the primary coil. This follows because the changing flux produces a back emf, $N_P\, d\Phi_B/dt$, in the primary that exactly balances the applied voltage $V_P$ if the resistance of the primary can be ignored (Kirchhoff's rules). We divide these two equations, assuming little or no flux is lost, to find

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}. \qquad \textbf{(29–5)}$$

**FIGURE 29–24** Step-up transformer $(N_P = 4,\ N_S = 12)$.

This **transformer equation** tells how the secondary (output) voltage is related to the primary (input) voltage; $V_S$ and $V_P$ in Eq. 29–5 can be the rms values (Section 25–7) for both, or peak values for both. DC voltages don't work in a transformer because there would be no changing magnetic flux.

If the secondary coil contains more loops than the primary coil $(N_S > N_P)$, we have a **step-up transformer**. The secondary voltage is greater than the primary voltage. For example, if the secondary coil has twice as many turns as the primary coil, then the secondary voltage will be twice that of the primary voltage. If $N_S$ is less than $N_P$, we have a **step-down transformer**.

Although ac voltage can be increased (or decreased) with a transformer, we don't get something for nothing. Energy conservation tells us that the power output can be no greater than the power input. A well-designed transformer can be greater than 99% efficient, so little energy is lost to heat. The power output thus essentially equals the power input. Since power $P = IV$ (Eq. 25–6), we have

$$I_P V_P = I_S V_S,$$

or

$$\frac{I_S}{I_P} = \frac{N_P}{N_S}. \qquad \textbf{(29–6)}$$

**EXAMPLE 29–13** **Cell phone charger.** The charger for a cell phone contains a transformer that reduces 120-V (or 240-V) ac to 5.0-V ac to charge the 3.7-V battery (Section 26–4). (It also contains diodes to change the 5.0-V ac to 5.0-V dc.) Suppose the secondary coil contains 30 turns and the charger supplies 700 mA to the cell phone battery. Calculate (*a*) the number of turns in the primary coil, (*b*) the current in the primary, and (*c*) the power transformed.

**APPROACH** We assume the transformer is ideal, with no flux loss, so we can use Eq. 29–5 and then Eq. 29–6.

**SOLUTION** (*a*) This is a step-down transformer, and from Eq. 29–5 we have

$$N_P = N_S \frac{V_P}{V_S} = \frac{(30)(120\,\text{V})}{(5.0\,\text{V})} = 720\,\text{turns}.$$

(*b*) From Eq. 29–6

$$I_P = I_S \frac{N_S}{N_P} = (0.70\,\text{A})\left(\frac{30}{720}\right) = 29\,\text{mA}.$$

(*c*) The power transformed is

$$P = I_S V_S = (0.70\,\text{A})(5.0\,\text{V}) = 3.5\,\text{W}.$$

**NOTE** The power in the primary coil, $P = (0.029\,\text{A})(120\,\text{V}) = 3.5\,\text{W}$, is the same as the power in the secondary coil. This 100% efficiency in power transfer is valid only for our ideal transformer.

**EXERCISE E** How many turns would you want in the secondary coil of a transformer having $N_P = 400$ turns if it were to reduce the voltage from 120-V ac to 3.0-V ac?

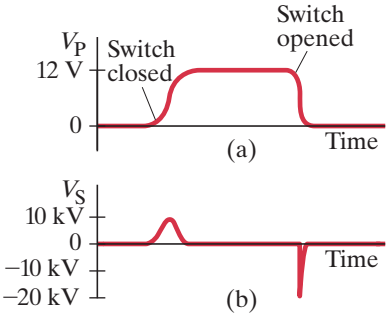


**FIGURE 29–25** A dc voltage turned on and off as shown in (a) produces voltage pulses in the secondary (b). Voltage scales in (a) and (b) are not the same.

**PHYSICS APPLIED**
*Transformers in power transmission*

A transformer operates only on ac. A dc current in the primary coil does not produce a changing flux in the secondary and therefore induces no emf. However, if a dc voltage is applied to the primary through a switch, at the instant the switch is opened or closed there will be an abrupt change in magnetic flux, and an induced voltage in the secondary. For example, if the dc is turned on and off as shown in Fig. 29–25a, the voltage induced in the secondary is as shown in Fig. 29–25b. Notice that the secondary voltage drops to zero when the dc voltage is steady. This is basically how, in the **ignition system** of an automobile, the high voltage is created to produce the spark across the gap of a spark plug that ignites the gas-air mixture in the engine cylinders. The transformer is referred to simply as an "ignition coil," and transforms the 12-V dc of the battery (when switched down from 12 V to 0 V in the primary) into a spike of as much as 30 kV in the secondary.

Transformers play an important role in the transmission of electricity. Power plants are often situated some distance from metropolitan areas, so electricity must then be transmitted over long distances (Fig. 29–26). There is always some power loss in the transmission lines, and this loss can be minimized if the power is transmitted at high voltage, using transformers, as the following Example shows.

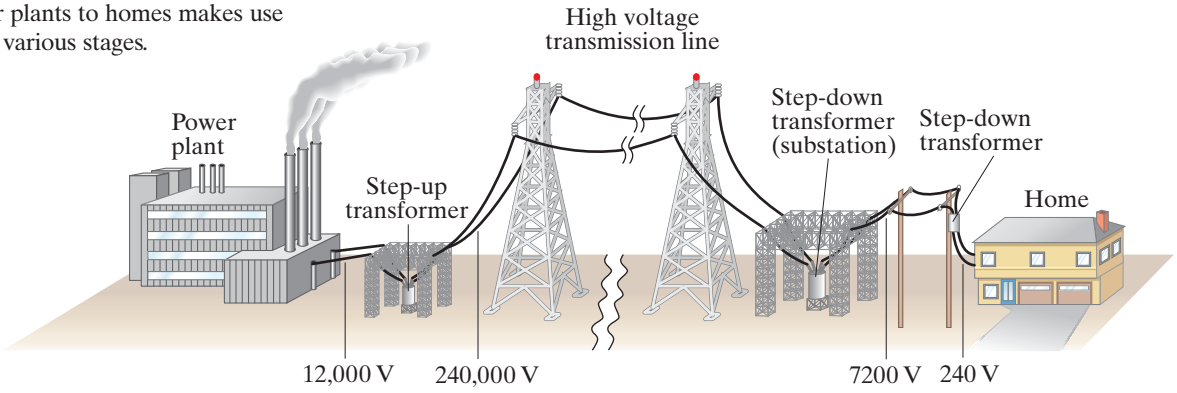

**FIGURE 29–26** The transmission of electric power from power plants to homes makes use of transformers at various stages.

**EXAMPLE 29–14** **Transmission lines.** An average of 120 kW of electric power is sent to a small town from a power plant 10 km away. The transmission lines have a total resistance of 0.40 Ω. Calculate the power loss if the power is transmitted at (*a*) 240 V and (*b*) 24,000 V.

**APPROACH** We cannot use $P = V^2/R$ because $R$ is the resistance of the transmission lines and we don't know the voltage drop along them. The given voltages are applied across the lines *plus* the load (the town). But we can determine the current $I$ in the lines $(= P/V)$, and then find the power loss from $P_L = I^2R$, for both cases (*a*) and (*b*).

**SOLUTION** (*a*) If 120 kW is sent at 240 V, the total current will be

$$I = \frac{P}{V} = \frac{1.2 \times 10^5\,\text{W}}{2.4 \times 10^2\,\text{V}} = 500\,\text{A}.$$

The power loss in the lines, $P_L$, is then

$$P_L = I^2R = (500\,\text{A})^2(0.40\,\Omega) = 100\,\text{kW}.$$

Thus, over 80% of all the power would be wasted as heat in the power lines!

(*b*) If 120 kW is sent at 24,000 V, the total current will be

$$I = \frac{P}{V} = \frac{1.2 \times 10^5\,\text{W}}{2.4 \times 10^4\,\text{V}} = 5.0\,\text{A}.$$

The power loss in the lines is then

$$P_L = I^2R = (5.0\,\text{A})^2(0.40\,\Omega) = 10\,\text{W},$$

which is less than $\frac{1}{100}$ of 1%. At high voltage we get a far better efficiency!

**NOTE** We see that the higher voltage results in less current, and thus less power is wasted as heat in the transmission lines. It is for this reason that power is usually transmitted at very high voltages, as high as 700 kV.

The great advantage of ac, and a major reason it is in nearly universal use,[†] is that the voltage can easily be stepped up or down by a transformer. The output voltage of an electric generating plant is stepped up prior to transmission—so less energy is wasted in the transmission line. Upon arrival in a city, that high voltage is stepped down in stages at electric substations prior to distribution. The voltage in lines along city streets is typically 2400 V or 7200 V, and then is stepped down to 240 V or 120 V for home use by transformers (Figs. 29–23 and 29–26).

Another use of a transformer is for fluorescent lights which require a very high voltage initially to ionize the gas inside the bulb. The high voltage is obtained using a step-up transformer, called a **ballast**, and can be replaced independently of the bulb in many fluorescent light fixtures. When the ballast starts to fail, the tube is slow to light. Replacing the bulb will not solve the problem. In newer compact fluorescent bulbs designed to replace incandescent bulbs, the ballast (transformer) is part of the bulb, and is very small.

**PHYSICS APPLIED**
*Fluorescent lightbulb ballast*

[†]DC transmission along wires does exist, and has some advantages (if the current is constant, there is no induced current in nearby conductors as there is with ac). But boosting to high voltage and down again at the receiving end requires more complicated electronics.

### Wireless Transmission of Power—Inductive Charging

**PHYSICS APPLIED**
*Charging by induction*

Many devices with rechargeable batteries, like cell phones, cordless phones, and even electric cars, can be recharged using a direct metal contact between the device and the charger. But devices can also be charged "wirelessly" by induction, without the need for exposed electric contacts. The electric toothbrush shown in Fig. 29–27 sits on a plastic base. Inside the base is a "primary coil" connected to an ac outlet. Inside the toothbrush is a "secondary coil" in which a current is induced by the changing magnetic field produced by the changing current in the primary coil. The current induced in the secondary coil charges the rechargeable batteries. (Not an option for ordinary AA or AAA batteries which are *not* rechargeable.) This is a simple transformer—except there is no iron (to contain the field lines), so you can separate the two parts (toothbrush and charger) and brush your teeth.

Inductive charging is also a possible means for recharging an electric car's batteries. A primary coil may be installed in the floor of the garage, and the secondary coil underneath the car (photo page 869).

Wireless transmission of power must be done over short distances to maintain a reasonable efficiency. Wireless transmission of signals (information) can be done over great distances (Section 31–10) because even fairly low power signals can be detected, and it is the information in the signal voltages that counts, not power.

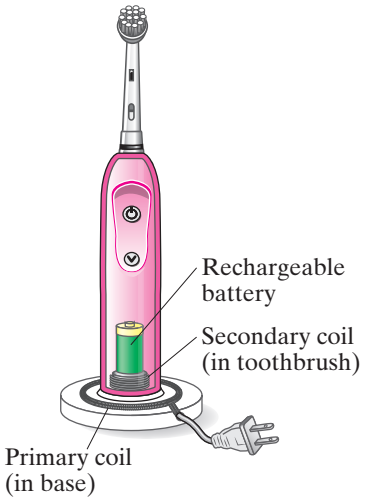

**FIGURE 29–27** This electric toothbrush contains rechargeable batteries which are being recharged as it sits on its base. Charging occurs from a primary coil in the base to a secondary coil in the toothbrush. The toothbrush can be lifted from its base when you want to brush your teeth.

## 29–7 A Changing Magnetic Flux Produces an Electric Field

We saw in Section 25–8 that when an electric current flows in a wire, there is an electric field in the wire that does the work of moving the electrons in the wire. In this Chapter we have seen that a changing magnetic flux induces a current in a wire, and that would imply that there is an *electric field* in the wire induced by the changing magnetic flux. Thus we come to the important conclusion that

**a changing magnetic flux produces an electric field.**

This result applies not only to wires and other conductors, but is a general result that applies to any region in space. Indeed, an electric field will be produced (= induced) at any point in space where there is a changing magnetic field. Such electric fields are *not static*, as are the electric fields due to electric charges at rest.

### Faraday's Law—General Form

We can put these ideas into mathematical form by generalizing our relation between an electric field $\vec{\mathbf{E}}$ and the potential difference $V_{ab}$ between two points a and b: $V_{ab} = \int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$ (Eq. 23–4a) where $d\vec{\boldsymbol{\ell}}$ is an element of displacement along the path of integration. The emf $\mathscr{E}$ induced in a circuit is equal to the work done per unit charge by the electric field, which equals the integral of $\vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$ around a closed path:

$$\mathscr{E} = \oint \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}. \qquad \textbf{(29–7)}$$

We combine this with Eq. 29–2a, to obtain a more elegant and general form of Faraday's law

*FARADAY'S LAW (general form)*

$$\oint \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = -\frac{d\Phi_B}{dt} \qquad \textbf{(29–8)}$$

which relates the changing magnetic flux to the electric field it produces. The integral on the left is taken around a path enclosing the area through which the magnetic flux $\Phi_B$ is changing. This more elegant statement of Faraday's law (Eq. 29–8) is valid not only in conductors, but in any region of space. To illustrate this, let us take an Example.

**EXAMPLE 29–15** **$\vec{\mathbf{E}}$ produced by changing $\vec{\mathbf{B}}$.** A magnetic field $\vec{\mathbf{B}}$ between the pole faces of an electromagnet is nearly uniform at any instant over a circular area of radius $r_0$ as shown in Figs. 29–28a and b. The current in the windings of the electromagnet is increasing in time so that $\vec{\mathbf{B}}$ changes in time at a constant rate $d\vec{\mathbf{B}}/dt$ at each point. Beyond the circular region $(r > r_0)$, we assume $\vec{\mathbf{B}} = 0$ at all times. Determine the electric field $\vec{\mathbf{E}}$ at any point P a distance $r$ from the center of the circular area due to the changing $\vec{\mathbf{B}}$.

**APPROACH** The changing magnetic flux through a circle of radius $r$, shown dashed in Fig. 29–28b, will produce an emf around this circle. Because all points on the dashed circle are equivalent physically, the electric field too will show this symmetry and will be in the plane perpendicular to $\vec{\mathbf{B}}$. Thus we can expect $\vec{\mathbf{E}}$ to be perpendicular to $\vec{\mathbf{B}}$ and to be tangent to the circle of radius $r$. The direction of $\vec{\mathbf{E}}$ will be as shown in Fig. 29–28b and c, since by Lenz's law the induced $\vec{\mathbf{E}}$ needs to be capable of producing a current that generates a magnetic field opposing the original change in $\vec{\mathbf{B}}$. By *symmetry*, we also expect $\vec{\mathbf{E}}$ to have the same magnitude at all points on the circle of radius $r$.

**SOLUTION** We take the circle shown in Fig. 29–28b as our path of integration in Eq. 29–8. We ignore the minus sign so we can concentrate on magnitude since we already found the direction of $\vec{\mathbf{E}}$ from Lenz's law, and obtain

$$E(2\pi r) = (\pi r^2)\frac{dB}{dt}, \qquad [r < r_0]$$

since $\Phi_B = BA = B(\pi r^2)$ at any instant. We solve for $E$ and obtain

$$E = \frac{r}{2}\frac{dB}{dt}. \qquad [r < r_0]$$

This expression is valid up to the edge of the circle $(r \le r_0)$, beyond which $\vec{\mathbf{B}} = 0$. If we now consider a point where $r > r_0$, the flux through a circle of radius $r$ is $\Phi_B = \pi r_0^2 B$. Then Eq. 29–8 gives

$$E(2\pi r) = \pi r_0^2 \frac{dB}{dt} \qquad [r > r_0]$$

or

$$E = \frac{r_0^2}{2r}\frac{dB}{dt}. \qquad [r > r_0]$$

Thus the magnitude of the induced electric field increases linearly from zero at the center of the magnet to $E = (dB/dt)(r_0/2)$ at the edge, and then decreases inversely with distance in the region beyond the edge of the magnetic field. The electric field lines are circles as shown in Fig. 29–28c. A graph of $E$ vs. $r$ is shown in Fig. 29–28d.

**EXERCISE F** Consider the magnet shown in Fig. 29–28 with a radius $r_0 = 6.0\,\text{cm}$. If the magnetic field changes uniformly from 0.040 T to 0.090 T in 0.18 s, what is the magnitude of the resulting electric field at (*a*) $r = 3.0\,\text{cm}$ and (*b*) $r = 9.0\,\text{cm}$?

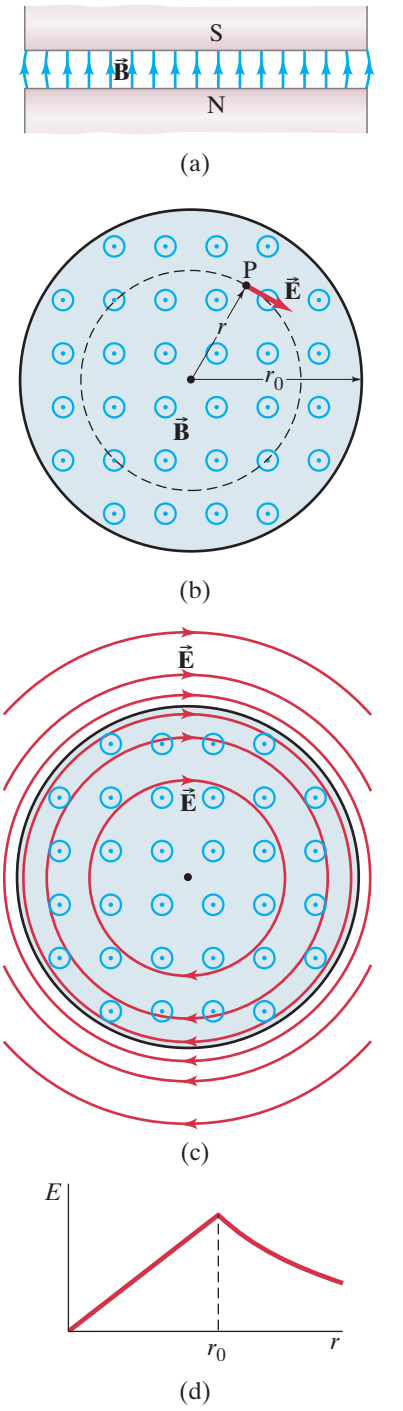

**FIGURE 29–28** Example 29–15. (a) Side view of nearly constant $\vec{\mathbf{B}}$. (b) Top view, for determining the electric field $\vec{\mathbf{E}}$ at point P. (c) Lines of $\vec{\mathbf{E}}$ produced by increasing $\vec{\mathbf{B}}$ (pointing outward). (d) Graph of $E$ vs. $r$.

## Forces Due to Changing $\vec{\mathbf{B}}$ are Nonconservative

Example 29–15 illustrates an important difference between electric fields produced by changing magnetic fields from electric fields produced by electric charges at rest (electrostatic fields). Electric field lines produced in the electrostatic case (Chapters 21 to 24) start and stop on electric charges. But the electric field lines produced by a changing magnetic field are continuous; they form closed loops. This distinction goes even further and is an important one. In the electrostatic case, the potential difference between two points is given by (Eq. 23–4a)

$$V_{ba} = V_b - V_a = -\int_a^b \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}.$$

If the integral is around a closed loop, so points a and b are the same, then $V_{ba} = 0$.

Hence the integral of $\vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}}$ around a closed path is zero:

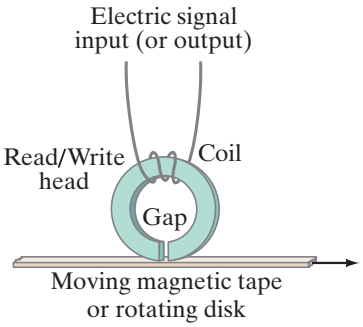
$$\oint \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = 0. \qquad \text{[electrostatic field]}$$

This followed from the fact that the electrostatic force (Coulomb's law) is a conservative force, and so a potential energy function could be defined. Indeed, the relation above, $\oint \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = 0$, tells us that the work done per unit charge around any closed path is zero (or the work done between any two points is independent of path—see Chapter 8), which is a property only of a *conservative force.* But in the nonelectrostatic case, when the electric field is produced by a changing magnetic field, the integral around a closed path is *not* zero, but is given by Eq. 29–8:

$$\oint \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = -\frac{d\Phi_B}{dt}.$$

We thus come to the conclusion that the forces due to changing magnetic fields are *nonconservative*. We are not able therefore to define a potential energy, or potential function, at a given point in space for the nonelectrostatic case. Although static electric fields are *conservative fields*, the electric field produced by a changing magnetic field is a **nonconservative field**.

# *29–8 Information Storage: Magnetic and Semiconductor



## *Magnetic Storage: Read/Write on Tape and Disks

PHYSICS APPLIED
*Hard drive*

Recording and playback on tape or disk is done by magnetic **heads**.[†] Magnetic tapes contain a thin layer of ferromagnetic oxide on a thin plastic tape. Computer **hard drives** (HD) store digital information (applications and data): they have a thin layer of ferromagnetic material on the surface of each rotating disk or platter, Fig. 29–29a. During recording of an audio or video signal on tape, or "writing" on a hard drive, the voltage is sent to the recording head which acts as a tiny electromagnet (Fig. 29–29b) that magnetizes the tiny section of tape or disk passing the narrow gap in the head at each instant. During playback, or "reading" of an HD, the changing magnetism of the moving tape or disk at the gap causes corresponding changes in the magnetic field within the soft-iron head, which in turn induces an emf in the coil (Faraday's law). This induced emf is the output signal that can be processed by the computer, or for audio can be amplified and sent to a loudspeaker (for video to a monitor or TV).

(a)

(b)

**FIGURE 29–29** (a) Photo of a hard drive showing several platters and read/write heads that can quickly move from the edge of the disk to the center. (b) Read/Write (playback/recording) head for disk or tape. In writing or recording, the electric input signal to the head, which acts as an electromagnet, magnetizes the passing tape or disk. In reading or playback, the changing magnetic field of the passing tape or disk induces a changing magnetic field in the head, which in turn induces in the coil an emf that is the output signal.

Audio and video signals may be **analog**, varying continuously in amplitude over time: the variation in degree of magnetization at sequential points reflects the variation in amplitude and frequency of the audio or video signal. In modern equipment, analog signals (say from a microphone) are electronically converted to **digital**—which means a series of **bits**, each of which is a "1" or a "0", that forms a **binary code** as discussed in Section 23–9. (Recall also, 8 bits in a row = 1 **byte**.) Computers process only digital information.

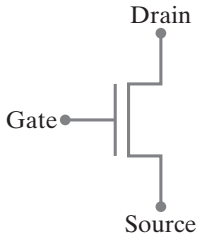
[†]CDs and DVDs are "read" by a laser light beam—an *optical drive* (Section 39–9).

## *Semiconductor Memory: DRAM, Flash

Basic to your computer is its **random access memory (RAM)**. This is where the information you are working with at any given time is temporarily stored and manipulated by you. Each data storage location can be accessed and read (or written) directly and quickly, so you don't have to wait. In contrast, hard drives, tape, flash and external devices are more permanent **storage**, and they are much slower to access because the data must be searched for, sequentially, such as along the circular tracks of hard drives (Fig. 29–29a). Programs, applications, and data that you want to use are imported by the computer into the RAM from their more permanent (and more slowly accessed) storage area.[†]

RAM is based on semiconductor technology, storing the binary bits ("0" or "1") as electric charge or voltage. Some computers may use semiconductors also for long-term storage ("flash memory") in place of a hard drive.

A common type of RAM is **dynamic random access memory** or **DRAM**, which uses arrays of transistors known as MOSFETs (metal-oxide semiconductor field-effect transistors). Transistors will be discussed in Section 40–10, but we already encountered them in Section 23–10 about TV screen addressing, Fig. 23–33, which we show again here, Fig. 29–30. A MOSFET transistor in RAM serves basically as an on-off switch: the voltage on the **gate** terminal acts to control the conductivity between the **source** and the **drain** terminals, thus allowing current to flow (or not) between them.



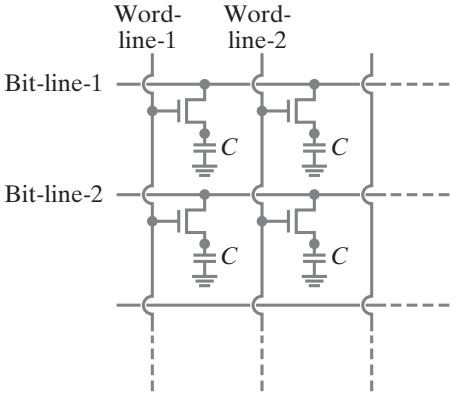


**FIGURE 29–30** Symbol for a MOSFET transistor. The gate acts to attract or repel charge, and thus open or close the connection along the semiconductor that connects source and drain.

Each memory "cell," which in DRAM consists of one transistor and a capacitor, stores one bit (= a "0" or a "1"). Each cell is extremely small physically, less than 100 nm across.[‡] Typical DRAM *chips* (integrated circuits) contain billions of these memory cells. To see how they work, we look at a tiny part, the simple four-cell array shown in Fig. 29–31. One side of each cell capacitor is grounded; the other side is connected to the transistor source. The drain of each transistor is connected to a very thin conducting wire or "line," a **bit-line**, that runs across the array of cells. Each gate is connected to a **word-line**. A particular bit is a "1" or a "0" depending on whether the capacitor of the cell is charged to a voltage $V$ (maybe 3 V) or is at zero (uncharged, or at a very small voltage).

**FIGURE 29–31** A tiny $2 \times 2$ cell, part of a simple DRAM array. The word-lines and bit-lines do not touch each other where they cross.

To **write** data, say on the upper left cell in Fig. 29–31, word-line-1 is given a high enough pulse of voltage to "turn on" the transistor: that is, the gate voltage is high and attracts charge which allows bit-line-1 and the capacitor to be connected. Thus charge can flow from bit-line-1 to the capacitor, charging it either to $V$ or to 0, depending on the bit-line-1 voltage at that moment, thus writing a "1" or a "0".

The lower left cell in Fig. 29–31 can be written at the same time by setting bit-line-2 voltage to $V$ or zero.

Now let us see a simple way to **read** a cell. In order to read the data stored ("1" or "0") on the *upper left cell*, a voltage of about $\frac{1}{2}V$ is given to bit-line-1. Then word-line-1 provides enough voltage to the gate to turn on the transistor (in fact all of them in the first column) and connect bit-line-1 to the capacitor. The capacitor, if uncharged (= "0"), will now drag charge from bit-line-1 and the bit-line voltage will drop *below* $\frac{1}{2}V$. If the capacitor is already charged to $V$ (= "1"), the connection to bit-line-1 will raise bit-line-1's voltage to *above* $\frac{1}{2}V$. A sensor at the end of bit-line-1 will detect either change in voltage (increase means it reads a "1," decrease a "0"). All cells connected to one word-line are read at the same moment. The capacitor voltage has been altered by the small charge flow during the reading process. So that cell or bit which has just been read needs to be written again, or "refreshed."

[†]Computer specifications may use "memory" for the random access (fast) memory, and "storage" for the long-term (and slower access) information on hard drives, flash drives, and related devices.

[‡]At 100 nm, $10^5$ bits can fit along a 1-cm line, $(1\text{ cm}/100\text{ nm}) = 10^{-2}\text{ m}/10^{-7}\text{ m}$. So a square, 1 cm on a side, can hold $10^5 \times 10^5 = 10^{10} = 10$ Gbits $\approx 1$ GB (gigabyte). Actually, cells are even smaller than 100 nm: a $(30\text{ nm})^2$ cell can hold $\approx$10 GB in a 1 $\text{cm}^2$ area.

The transistors are imperfect switches and allow the charge on the tiny capacitors in each cell to be "leaky" and lose charge fairly quickly, so every cell has to be read and rewritten (refreshed) many times per second. The D in DRAM stands for this "dynamic" refreshing action. If the power is turned off, the capacitors lose their charge and the data are lost. DRAM is thus referred to as being **volatile** memory. A hard drive, on the other hand, keeps its (magnetic) memory even when the electric power is off and is called **nonvolatile** memory (doesn't "evaporate").

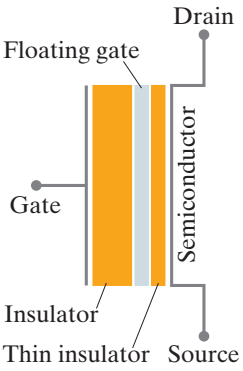

**FIGURE 29–32** A floating gate nonvolatile memory cell (NVM).

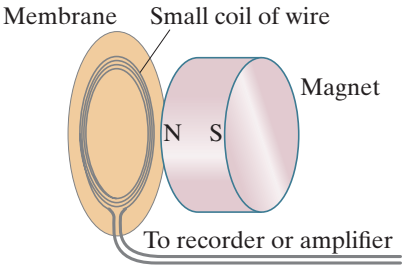
**Flash memory** is also made of semiconductor material on tiny "chips." The transistor structures are more complicated, and are able to keep the data even without power so they are nonvolatile. Each MOSFET contains a second gate (the **floating gate**) insulated on both faces, and can hold charge for many years. Charged or not corresponds to a "1" or a "0" bit. Figure 29–32 is a diagram of such an **NVM** (nonvolatile memory) cell. The floating gate is insulated from the standard gate and the semiconductor connecting source and drain. A positive voltage on the gate forces electrons in the semiconductor (at 0 V) to pass through the thin insulator into the floating gate by a process of quantum mechanical **tunneling** (discussed in Section 38–10). This charge is stored on the floating gate as a "1" bit. The erase process is done by applying the opposite voltage to force electrons to tunnel out of the floating gate, returning it to the uncharged state (= a "0" bit). The erase process is slow (milliseconds vs. ns for DRAM), so erasure is done in large blocks of memory. Flash memory[†] is slower to read or write, and is too slow to use as RAM. Instead, flash memory can be used in place of a hard drive as general storage in computers and tablets, and may be called a "solid state device" (**SSD**). Flash is also used for flash drives, memory cards (such as SD cards), thumb drives, cell phone and portable player memory, and external computer memory.



Magnetoresistive RAM (**MRAM**) is a recent development, involving (again) magnetic properties. One cell (storing one bit) consists of two tiny ferromagnetic plates (separated by an insulator), one of which is permanently magnetized. The other plate can be magnetized in one direction or the other, for a "1" or a "0", by current in nearby wires. Cell size is a bit large, but MRAM is fast and nonvolatile (no power and no refresh needed) and therefore has the potential to be used as any type of memory.

# *29–9 Applications of Induction: Microphone, Seismograph, GFCI

## *Microphone

The condenser microphone was discussed in Section 24–2. Many other types operate on the principle of induction. In one form, a microphone is just the inverse of a loudspeaker (Section 27–6). A small coil of wire attached to a membrane is suspended close to a small permanent magnet, as shown in Fig. 29–33. When sound waves strike the membrane, the coil moves in the magnetic field and this motion induces an emf in the moving wire coil. The frequency of the induced emf will be just that of the impinging sound waves, and this emf is the "signal" that can be amplified and sent to loudspeakers or a recorder.

**FIGURE 29–33** Diagram of a microphone that works by induction.

PHYSICS APPLIED
*Credit card*

## *Card Stripe Reader

Many credit cards have a semiconductor chip that is more difficult to fraudulently copy than those with a magnetic stripe on the back of the card that passes over a read head like Fig. 29–29b. The chip or magnetic stripe contains personal information about your account and connects by telephone line for approval from your credit card company.

[†]Why the name "Flash"? It may come from the erase process: large blocks erased "in a flash," and/or because the earliest floating gate memories were erased by a flash of UV light which ejected the stored electrons.

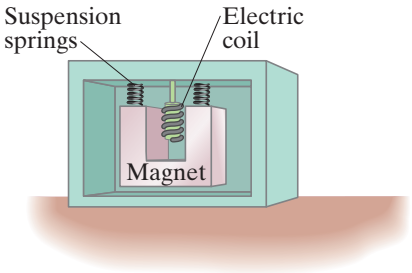


**FIGURE 29–34** One type of seismograph, in which the electric coil is fixed to the case and moves with the Earth's surface. The magnet, suspended by springs, has inertia and does not move instantaneously with the coil (and case), so there is relative motion between magnet and coil.

## *Seismograph

PHYSICS APPLIED
*Seismograph*

In geophysics, a **seismograph** measures the intensity of earthquake waves using a magnet and a coil of wire. Either the magnet or the coil is fixed to the case, and the other is inertial (suspended by a spring; Fig. 29–34). The relative motion of magnet and coil when the Earth shakes induces an emf output.

## *Ground Fault Circuit Interrupter (GFCI)

Fuses and circuit breakers (Sections 25–6 and 28–9) protect buildings from electricity-induced fire, and apparatus from damage, due to undesired high currents. But they do not turn off the current until it is very much greater than that which can cause permanent damage to humans or death ($\approx$100 mA). If fast enough, they may protect humans in some cases, such as very high currents due to short circuits. A **ground fault circuit interrupter** (GFCI) is meant above all to protect humans.

PHYSICS APPLIED
*GFCI*

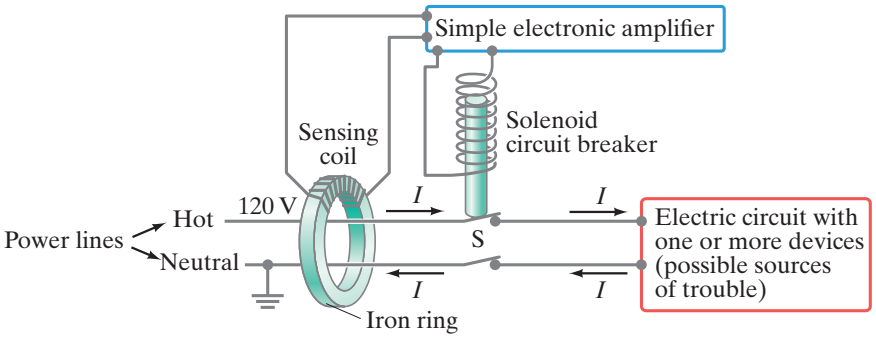

**FIGURE 29–35** A ground fault circuit interrupter (GFCI).

Electromagnetic induction is the physical basis of a GFCI. Figure 29–35 shows the two wires carrying ac current to an electrical circuit or device (red box) passing through a small iron ring. Around the ring are many loops of thin wire that serve as a sensing coil. Under normal conditions (no ground fault), the current moving in the hot power wire is exactly balanced by the returning current in the neutral wire. If something goes wrong and the hot wire touches the ungrounded metal case of the device or appliance, some of the entering current can pass through a person who touches the case and then to ground (a **ground fault**). Then the return current in the neutral wire will be less than the entering current in the hot wire, so there is a *net current* passing through the GFCI's iron ring. Because the current is ac, it is changing and that current difference produces a changing magnetic field in the iron ring, thus inducing an emf in the sensing coil wrapped around the iron. For example, if a device draws 8.0 A, and there is a ground fault through a person of 100 mA (= 0.1 A), then 7.9 A will appear in the neutral wire. The emf induced in the sensing coil by this 100-mA difference is amplified by a simple transistor circuit and sent to its own solenoid circuit breaker that opens the circuit at the switch S, thus protecting lives.

If the outer case of the faulty device is grounded, the difference is even higher when there is a fault, and the GFCI trips very quickly.

GFCIs can sense current differences as low as 5 mA and react in 1 ms ($10^{-3}$ s), saving lives. They can be small enough to fit as a wall outlet (Fig. 29–36a), or as a plug-in unit into which you plug a hair dryer or toaster (Fig. 29–36b). It is especially important to have GFCIs installed in kitchens, bathrooms, outdoors, and near swimming pools, where people are most in danger of touching ground. GFCIs always have a "test" button (to be sure the GFCI itself works) and a "reset" button (after it goes off).

**FIGURE 29–36** (a) A GFCI wall outlet. GFCIs can be recognized because they have "test" and "reset" buttons. (b) Add-on GFCI that plugs into outlet.

(a)

(b)

# Summary

The **magnetic flux** passing through a loop is equal to the product of the area of the loop times the perpendicular component of the (uniform) magnetic field: $\Phi_B = B_\perp A = BA\cos\theta$. If $\vec{\mathbf{B}}$ is not uniform, then

$$\Phi_B = \int \vec{\mathbf{B}} \cdot d\vec{\mathbf{A}}. \qquad \textbf{(29–1b)}$$

If the magnetic flux through a coil of wire changes in time, an emf is induced in the coil. The magnitude of the induced emf equals the time rate of change of the magnetic flux through the loop times the number $N$ of loops in the coil:

$$\mathscr{E} = -N\frac{d\Phi_B}{dt}. \qquad \textbf{(29–2b)}$$

This is **Faraday's law of induction**.

The induced emf can produce a current whose magnetic field opposes the original change in flux (**Lenz's law**).

It follows from Faraday's law that a straight wire of length $\ell$ moving with speed $v$ perpendicular to a magnetic field $B$ has an emf induced between its ends equal to:

$$\mathscr{E} = B\ell v. \qquad \textbf{(29–3)}$$

An electric **generator** changes mechanical energy into electric energy. Its operation is based on Faraday's law: a coil of wire is made to rotate uniformly by mechanical means in a magnetic field, and the changing flux through the coil induces a sinusoidal current, which is the output of the generator.

A motor, which operates in the reverse of a generator, acts a bit like a generator in that a **back emf** is induced in its rotating coil. Because this back emf opposes the input voltage, it can act to limit the current in a motor coil. Similarly, a generator acts somewhat like a motor in that a **counter torque** acts on its rotating coil.

A **transformer**, which is a device to change the magnitude of an ac voltage, consists of a primary coil and a secondary coil. The changing flux due to an ac voltage in the primary coil induces an ac voltage in the secondary coil. In a 100% efficient transformer, the ratio of output to input voltages $(V_S/V_P)$ equals the ratio of the number of turns $N_S$ in the secondary to the number $N_P$ in the primary:

$$\frac{V_S}{V_P} = \frac{N_S}{N_P}. \qquad \textbf{(29–5)}$$

The ratio of secondary to primary current is in the inverse ratio of turns:

$$\frac{I_S}{I_P} = \frac{N_P}{N_S}. \qquad \textbf{(29–6)}$$

Faraday's law also tells us that *a changing magnetic flux produces an electric field*. The mathematical relation is

$$\oint \vec{\mathbf{E}} \cdot d\vec{\boldsymbol{\ell}} = -\frac{d\Phi_B}{dt} \qquad \textbf{(29–8)}$$

and is the general form of Faraday's law. The integral on the left is taken around the loop through which the magnetic flux $\Phi_B$ is changing.

[*Read/write heads for computer drives and tape, as well as microphones, ground fault circuit interrupters, and seismographs, are all applications of electromagnetic induction. Computer memory and information storage can be done using magnetic drives or by semiconductor memory (RAM, flash).]

# Questions

1. What would be the advantage, in Faraday's experiments (Fig. 29–1), of using coils with many turns?
2. What is the difference between magnetic flux and magnetic field?
3. Suppose you are holding a circular ring of wire in front of you and (*a*) suddenly thrust a magnet, south pole first, away from you toward the center of the circle. Is a current induced in the wire? (*b*) Is a current induced when the magnet is held steady within the ring? (*c*) Is a current induced when you withdraw the magnet? For each yes answer, specify the direction. Explain your answers.
4. In what direction will the current flow in Fig. 29–12a if the rod moves to the left, which decreases the area of the loop?
5. (*a*) If the north pole of a thin flat magnet moves on a table toward a loop, also flat on the table (Fig. 29–37), in what direction is the induced current in the loop? Assume the magnet is the same thickness as the wire. (*b*) What if the magnet is four times thicker than the wire loop? Explain your answers.

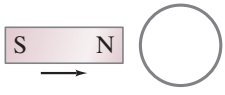

**FIGURE 29–37** Question 5.

6. Two loops of wire are moving in the vicinity of a very long straight wire carrying a steady current $I$ as shown in Fig. 29–38. Is there a force between the two loops? If so, in what direction? Explain.

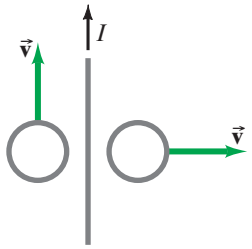

**FIGURE 29–38** Questions 6 and 7.

7. Answer Question 6 if the current $I$ in Fig. 29–38 is decreasing.
8. Suppose you are looking along a line through the centers of two circular (but separate) wire loops, one behind the other. A battery is suddenly connected to the front loop, establishing a clockwise current. (*a*) Will a current be induced in the second loop? (*b*) If so, when does this current start? (*c*) When does it stop? (*d*) In what direction is this current? (*e*) Is there a force between the two loops? (*f*) If so, in what direction?

9. The battery mentioned in Question 8 is disconnected. Will a current be induced in the second loop? If so, when does it start and stop? In what direction is this current?

10. In Fig. 29–39, determine the direction of the induced current in resistor $R_A$ (*a*) when coil B is moved toward coil A, (*b*) when coil B is moved away from A, (*c*) when the resistance $R_B$ is increased but the coils remain fixed. Explain your answers.

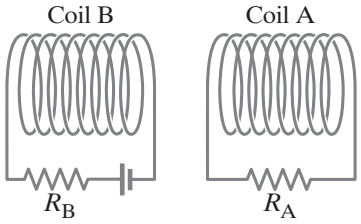

**FIGURE 29–39** Question 10.

11. What is the advantage of placing the two insulated electric wires carrying ac close together or even twisted about each other?

12. In situations where a small signal must travel over a distance, a *shielded cable* is used in which the signal wire is surrounded by an insulator and then enclosed by a cylindrical conductor (shield) carrying the return current (Fig. 28–12). Why is a "shield" necessary?

13. Use Fig. 29–15 plus the right-hand rules to show why the counter torque in a generator *opposes* the motion.

14. The use of higher-voltage lines in homes—say, 600 V or 1200 V—would reduce energy waste. Why are they not used?

15. An enclosed transformer has four wire leads coming from it. (*a*) How would you know which wires paired with which? (*b*) How could you determine the ratio of turns on the two coils without taking the transformer apart?

16. A transformer designed for a 120-V ac input will often "burn out" if connected to a 120-V dc source (but not if ac). Explain. [*Hint*: The resistance of the primary coil is usually very low.]

17. Explain why, exactly, the lights may dim briefly when a refrigerator motor starts up. When an electric heater is turned on, the lights may stay dimmed as long as the heater is on. Explain the difference.

18. Consider a large magnet whose north and south poles are close together to form a nearly uniform magnetic field, as in Fig. 27–7. If an aluminum sheet is held between the poles, it requires some force to pull it out of the magnetic field even though the sheet is not ferromagnetic and does not touch the pole faces. Explain.

19. A bar magnet is held above the floor and dropped (Fig. 29–40). In case (a), the magnet falls through a wire loop. In case (b), there is nothing between the magnet and the floor. How will the speeds of the magnets compare? Explain.

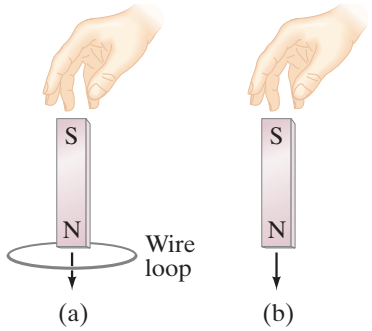

**FIGURE 29–40** Question 19 and MisConceptual Question 5.

20. Will an eddy current brake (Fig. 29–21) work on a copper or aluminum wheel, or must the wheel be ferromagnetic? Explain.

21. Eddy currents can be used to sort solid waste for **recycling**. The waste is first ground into tiny pieces and iron removed with a magnet. The waste then is allowed to slide down an incline over permanent magnets. How will this aid in the separation of nonferrous metals (Al, Cu, Pb, brass) from nonmetallic materials?

22. The pivoted metal bar with slots in Fig. 29–41 falls much more quickly through a magnetic field than does a solid bar. Explain.

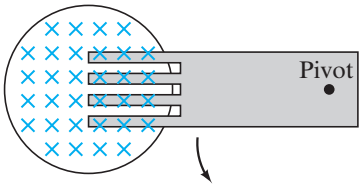

**FIGURE 29–41** Question 22.

23. A metal bar, pivoted at one end, oscillates freely in the absence of a magnetic field; but in a magnetic field, its oscillations are quickly damped out. Explain. (This **magnetic damping** is used in a number of practical devices.)

*24. A bar magnet falling inside a vertical metal tube reaches a terminal velocity even if the tube is evacuated so that there is no air resistance. Explain.

*25. Since a magnetic microphone is basically like a loudspeaker, could a loudspeaker (Section 27–6) actually serve as a microphone? That is, could you speak into a loudspeaker and obtain an output signal that could be amplified? Explain. Discuss, in light of your response, how a microphone and loudspeaker differ in construction.

# MisConceptual Questions

**1.** A coil of wire rests in the plane of the page while a magnetic field is directed into the page. A clockwise current is induced
(*a*) when the magnetic field gets stronger.
(*b*) when the size of the coil decreases.
(*c*) when the coil is moved sideways across the page.
(*d*) when the magnetic field is tilted so it is no longer perpendicular to the page.

**2.** A wire loop moves at constant velocity without rotation through a constant magnetic field. The induced current in the loop will be
(*a*) clockwise.
(*b*) counterclockwise.
(*c*) zero.
(*d*) We need to know the orientation of the loop relative to the magnetic field.

**3.** A square loop moves to the right from an area where $\vec{\mathbf{B}} = 0$, completely through a region containing a uniform magnetic field directed into the page (Fig. 29–42), and then out to $\vec{\mathbf{B}} = 0$, after point L. A current is induced in the loop
(*a*) only as it passes line J.
(*b*) only as it passes line K.
(*c*) only as it passes line L.
(*d*) as it passes line J or line L.
(*e*) as it passes all three lines.

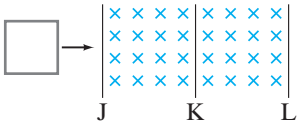

**FIGURE 29–42**
MisConceptual Question 3.

**4.** Two loops of wire are moving in the vicinity of a very long straight wire carrying a steady current (Fig. 29–43). Find the direction of the induced current in each loop.

For C:
(*a*) Clockwise.
(*b*) Counterclockwise.
(*c*) Zero.
(*d*) Alternating (ac).

For D:
(*a*) Clockwise.
(*b*) Counterclockwise.
(*c*) Zero.
(*d*) Alternating (ac).

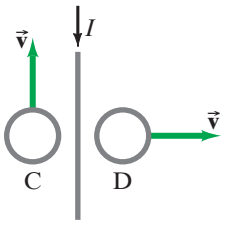

**FIGURE 29–43**
MisConceptual Question 4.

**5.** If there is induced current in Question 19 (see Fig. 29–40), wouldn't that cost energy? Where would that energy come from in case (a)?
(*a*) Induced current doesn't need energy.
(*b*) Energy conservation is violated.
(*c*) There is less kinetic energy.
(*d*) There is more gravitational potential energy.

**6.** A nonconducting plastic hoop is held in a magnetic field that points out of the page (Fig. 29–44). As the strength of the field increases,
(*a*) an induced emf will be produced that causes a clockwise current.
(*b*) an induced emf will be produced that causes a counterclockwise current.
(*c*) an induced emf will be produced but no current.
(*d*) no induced emf will be produced.

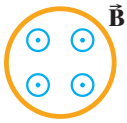

**FIGURE 29–44**
MisConceptual Question 6

**7.** A long straight wire carries a current $I$ as shown in Fig. 29–45. A small loop of wire rests in the plane of the page. Which of the following will *not* induce a current in the loop?
(*a*) Increasing the current in the straight wire.
(*b*) Moving the loop in a direction parallel to the wire.
(*c*) Rotating the loop so that it becomes perpendicular to the plane of the page.
(*d*) Moving the loop farther from the wire without rotating it.
(*e*) Moving the loop farther from the wire while rotating it.

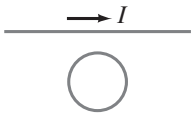

**FIGURE 29–45**
MisConceptual Question 7.

**8.** When a generator is used to produce electric current, the resulting electric energy originates from which source?
(*a*) The generator's magnetic field.
(*b*) Whatever rotates the generator's axle.
(*c*) The resistance of the generator's coil.
(*d*) Back emf.
(*e*) Empty space.

**9.** Which of the following will *not* increase a generator's voltage output?
(*a*) Rotating the generator faster.
(*b*) Increasing the area of the coil.
(*c*) Rotating the magnetic field so that it is more closely parallel to the generator's rotation axis.
(*d*) Increasing the magnetic field through the coil.
(*e*) Increasing the number of turns in the coil.

**10.** Two separate but nearby coils of wire are mounted along the same axis. A power supply controls the flow of current in the first coil, and thus the magnetic field it produces. The second coil is connected only to an ammeter. The ammeter will indicate that a current is flowing in the second coil
(*a*) whenever a current flows in the first coil.
(*b*) only when a steady current flows in the first coil.
(*c*) only when the current in the first coil changes.
(*d*) only if the second coil is connected to the power supply by rewiring it to be in series with the first coil.

**11.** Which of the following can a good transformer accomplish?
(*a*) Changing voltage but not current.
(*b*) Changing current but not voltage.
(*c*) Changing power.
(*d*) Changing both current and voltage.

**12.** The alternating electric current at a wall outlet is most commonly produced by
(*a*) a connection to rechargeable batteries.
(*b*) a coil that is rotating in a magnetic field.
(*c*) accelerating electrons between oppositely charged capacitor plates.
(*d*) using an electric motor.
(*e*) alternately heating and cooling a wire.

**13.** Which of the following statements about transformers is false?
(*a*) Transformers work using ac current or dc current.
(*b*) If the current in the secondary is higher, the voltage is lower.
(*c*) If the voltage in the secondary is higher, the current is lower.
(*d*) If no flux is lost, the product of the voltage and the current is the same in the primary and secondary coils.

# Problems

## 29–1 and 29–2 Faraday's Law of Induction

**1.** (I) The magnetic flux through a coil of wire containing two loops changes at a constant rate from −68 Wb to +48 Wb in 0.42 s. What is the emf induced in the coil?

**2.** (I) The rectangular loop shown in Fig. 29–46 is pushed into the magnetic field which points inward. In what direction is the induced current?

**FIGURE 29–46**
Problem 2.

**3.** (I) A 22.0-cm-diameter round loop of wire is initially oriented perpendicular to a 1.5-T magnetic field. The loop is rotated so that its plane is parallel to the field direction in 0.35 s. What is the average induced emf in the loop?

**4.** (II) A 22.0-cm-diameter coil consists of 36 turns of circular copper wire 2.6 mm in diameter. A uniform magnetic field, perpendicular to the plane of the coil, changes at a rate of $8.65 \times 10^{-3}$ T/s. Determine (*a*) the current in the loop, and (*b*) the rate at which thermal energy is produced.

**5.** (II) A 16-cm-diameter circular loop of wire is placed in a 0.65-T magnetic field. (*a*) When the plane of the loop is perpendicular to the field lines, what is the magnetic flux through the loop? (*b*) The plane of the loop is rotated until it makes a 35° angle with the field lines. What is the angle $\theta$ in Eq. 29–1a for this situation? (*c*) What is the magnetic flux through the loop at this angle?

**6.** (II) A fixed 10.8-cm-diameter wire coil is perpendicular to a magnetic field 0.48 T pointing up. In 0.14 s, the field is changed to 0.25 T pointing down. What is the average induced emf in the coil?

**7.** (II) If the solenoid in Fig. 29–47 is being pulled away from the loop shown, in what direction is the induced current in the loop? Explain.

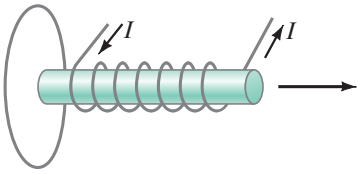

**FIGURE 29–47**
Problem 7.

**8.** (II) (*a*) If the resistance of the resistor in Fig. 29–48 is slowly increased, what is the direction of the current induced in the small circular loop inside the larger loop? (*b*) What would it be if the small loop were placed outside the larger one, to the left? Explain your answers.

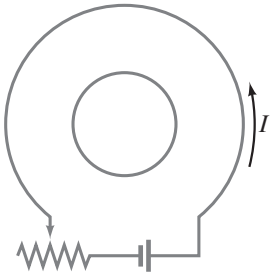

**FIGURE 29–48**
Problem 8.

**9.** (II) A circular loop in the plane of the paper lies in a 0.65-T uniform magnetic field pointing into the paper. The loop's diameter changes from 20.0 cm to 8.0 cm in 0.50 s. What is (*a*) the direction of the induced current, (*b*) the magnitude of the average induced emf, and (*c*) the average induced current if the coil resistance is 2.5 Ω?

**10.** (II) Part of a single rectangular loop of wire with dimensions shown in Fig. 29–49 is situated inside a region of uniform magnetic field of 0.650 T. The total resistance of the loop is 0.250 Ω. Calculate the force required to pull the loop from the field (to the right) at a constant velocity of 3.40 m/s. Neglect gravity.

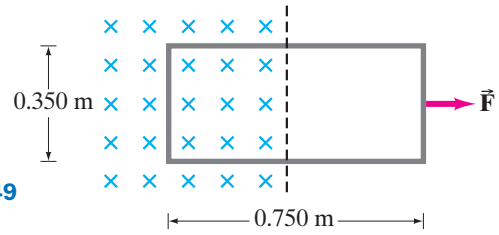

**FIGURE 29–49**
Problem 10.

**11.** (II) What is the direction of the induced current in the circuit loop due to the current shown in each part of Fig. 29–50? Explain why.

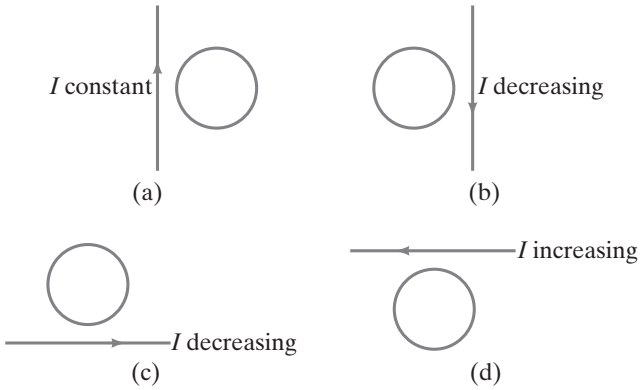

**FIGURE 29–50** Problem 11.

**12.** (II) A circular wire loop of radius $r = 12$ cm is in a uniform magnetic field $B = 0.400$ T with its plane perpendicular to the direction of the field. If the field magnitude begins to decrease at a rate of $-0.010$ T/s, at what rate should $r$ be increasing at this instant so that the induced emf within the loop is zero?

**13.** (II) The magnetic flux through each loop of a 75-loop coil is given by $(9.6t - 0.51t^3) \times 10^{-2}\ \text{T} \cdot \text{m}^2$, where the time $t$ is in seconds. (*a*) Determine the emf $\mathcal{E}$ as a function of time. (*b*) What is $\mathcal{E}$ at $t = 1.0$ s and $t = 4.0$ s?

**14.** (II) A 25-cm-diameter circular loop of wire has a resistance of 135 Ω. It is initially in a 0.40-T magnetic field, with its plane perpendicular to $\vec{\mathbf{B}}$, but is removed from the field in 120 ms. Calculate the electric energy dissipated in this process.

**15.** (II) The area of an elastic circular loop decreases at a constant rate, $dA/dt = -3.50 \times 10^{-2}\ \text{m}^2/\text{s}$. The loop is in a magnetic field $B = 0.35$ T whose direction is perpendicular to the plane of the loop. At $t = 0$, the loop has area $A = 0.285\ \text{m}^2$. Determine the induced emf at $t = 0$, and at $t = 2.00$ s.

**16.** (II) Suppose the radius of the elastic loop in Problem 15 increases at a constant rate, $dr/dt = 3.75$ cm/s. Determine the emf induced in the loop at $t = 0$ and at $t = 1.00$ s.

**17.** (II) The magnetic field perpendicular to a single 13.2-cm-diameter circular loop of copper wire decreases uniformly from 0.760 T to zero. If the wire is 2.25 mm in diameter, how much charge moves past a point in the coil during this operation?

**18.** (II) A single circular loop of wire is placed inside a long solenoid with its plane perpendicular to the axis of the solenoid. The area of the loop is $A_1$ and that of the solenoid, which has $n$ turns per unit length, is $A_2$. A current $I = I_0 \cos \omega t$ flows in the solenoid turns. What is the induced emf in the small loop?

**19.** (II) We are looking down on an elastic conducting loop with resistance $R = 2.0\ \Omega$, immersed in a magnetic field. The field's magnitude is uniform spatially, but varies with time $t$ according to $B(t) = \alpha t$, where $\alpha = 0.60\ \text{T/s}$. The area $A$ of the loop also increases at a constant rate, according to $A(t) = A_0 + \beta t$, where $A_0 = 0.50\ \text{m}^2$ and $\beta = 0.70\ \text{m}^2/\text{s}$. Find the magnitude and direction (clockwise or counterclockwise, when viewed from above the page) of the induced current within the loop at time $t = 2.0\ \text{s}$ if the magnetic field (*a*) is parallel to the plane of the loop to the right; (*b*) is perpendicular to the plane of the loop, down.

**20.** (III) A power line carrying a sinusoidally varying current with frequency $f = 60\ \text{Hz}$ and peak value $I_0 = 125\ \text{A}$ runs at a height of 7.0 m across a farmer's land (Fig. 29–51). The farmer, not appreciating this eyesore, decides to strike back and constructs a vertical 2.0-m-high 2000-turn rectangular wire coil below the power line. The farmer hopes to use the induced voltage in this coil to power 120-V electrical equipment, which requires a sinusoidally varying voltage with frequency $f = 60\ \text{Hz}$ and peak value $V_0 = 170\ \text{V}$. Estimate the length $\ell$ of the coil needed. Would this be stealing?

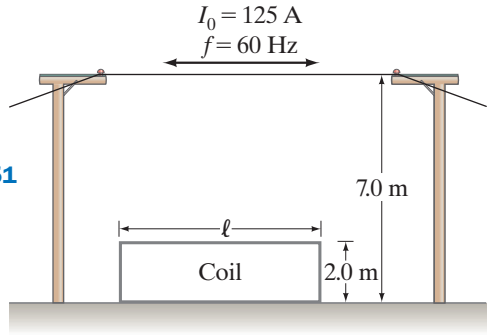

**FIGURE 29–51**
Problem 20.

**21.** (III) (*a*) Determine the magnetic flux through a square loop of side $a$ (Fig. 29–52) if one side is parallel to, and a distance $b$ from, a straight wire that carries a current $I$. (*b*) If the loop is pulled away from the wire at speed $v$, what emf is induced in it? (*c*) Does the induced current flow clockwise or counterclockwise? (*d*) Determine the force $F$ required to pull the loop away.

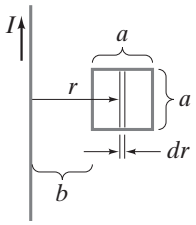

**FIGURE 29–52**
Problems 21 and 22.

**22.** (III) Determine the emf induced in the square loop in Fig. 29–52 if the loop stays at rest and the current in the straight wire is given by $I(t) = (15.0\ \text{A}) \sin(2200\, t)$ where $t$ is in seconds. The distance $a$ is 12.0 cm, and $b$ is 15.0 cm.

## 29–3 Motional EMF

**23.** (I) The moving rod in Fig. 29–12b is 15.6 cm long and generates an emf of 120 mV while moving in a 0.90-T magnetic field. What is its speed?

**24.** (I) The moving rod in Fig. 29–12b is 12.0 cm long and is pulled at a speed of 15.0 cm/s. If the magnetic field is 0.650 T, calculate the emf developed.

**25.** (II) In Fig. 29–12a, the rod moves with a speed of 1.6 m/s on rails 30.0 cm apart. The rod has a resistance of 2.5 Ω. The magnetic field is 0.35 T, and the resistance of the U-shaped conductor is 24.0 Ω at a given instant. Calculate (*a*) the induced emf, (*b*) the current in the U-shaped conductor, and (*c*) the external force needed to keep the rod's velocity constant at that instant.

**26.** (II) If the U-shaped conductor in Fig. 29–12a has resistivity $\rho$, whereas that of the moving rod is negligible, derive a formula for the current $I$ as a function of time. Assume the rod starts at the bottom of the U at $t = 0$, and moves with uniform speed $v$ in the magnetic field $B$. The cross-sectional area of the rod and all parts of the U is $A$.

**27.** (II) In Fig. 29–12, the moving rod has a resistance of 0.25 Ω and moves on rails 20.0 cm apart. The stationary U-shaped conductor has negligible resistance. When a force of 0.350 N is applied to the rod, it moves to the right at a constant speed of 1.30 m/s. What is the magnetic field?

**28.** (II) Suppose that the U-shaped conductor and connecting rod in Fig. 29–12a are oriented vertically (but still in contact) so that the rod is falling due to the gravitational force. Find the terminal speed of the rod if it has mass $m = 3.6$ grams, length $\ell = 18$ cm, and resistance $R = 0.0013\ \Omega$. It is falling in a uniform horizontal field $B = 0.080\ \text{T}$. Neglect the resistance of the U-shaped conductor, and friction.

**29.** (II) A conducting rod rests on two long frictionless parallel rails in a magnetic field $\vec{\mathbf{B}}$ ($\perp$ to the rails and rod) as in Fig. 29–53. (*a*) If the rails are horizontal and the rod is given an initial push, will the rod travel at constant speed even though a magnetic field is present? (*b*) Suppose at $t = 0$, when the rod has speed $v = v_0$, the two rails are connected electrically by a wire from point a to point b. Assuming the rod has resistance $R$ and the rails have negligible resistance, determine the speed of the rod as a function of time. Discuss your answer.

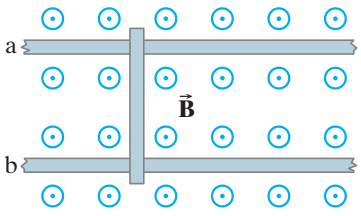

**FIGURE 29–53**
Problems 29 and 30.

**30.** (III) Suppose a conducting rod (mass $m$, resistance $R$) rests on two frictionless and resistanceless parallel rails a distance $\ell$ apart in a uniform magnetic field $\vec{\mathbf{B}}$ ($\perp$ to the rails and to the rod) as in Fig. 29–53. At $t = 0$, the rod is at rest and a source of emf is connected to the points a and b. Determine the speed of the rod as a function of time if (*a*) the source puts out a constant current $I$, (*b*) the source puts out a constant emf $\mathscr{E}_0$. (*c*) Does the rod reach a terminal speed in either case? If so, what is it?

31. (III) A short section of wire, of length $a$, is moving with velocity $\vec{\mathbf{v}}$, parallel to a very long wire carrying a current $I$ as shown in Fig. 29–54. The near end of the wire section is a distance $b$ from the long wire. Assuming the vertical wire is very long compared to $a + b$, determine the emf between the ends of this short section. Assume $\vec{\mathbf{v}}$ is ($a$) in the same direction as $I$, ($b$) in the opposite direction to $I$.

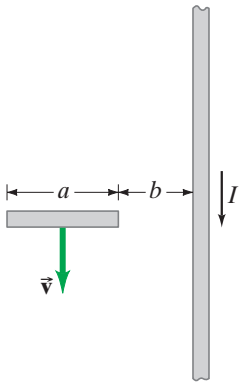

**FIGURE 29–54**
Problem 31.

## 29–4 Generators

32. (I) A simple generator is designed to generate a peak output voltage of 24.0 V. The square armature consists of windings that are 5.15 cm on a side and rotates in a field of 0.380 T at a rate of 60.0 rev/s. How many loops of wire should be wound on the square armature?
33. (II) The generator of a car idling at 875 rpm produces 12.4 V. What will the output be at a rotation speed of 1850 rpm assuming nothing else changes?
34. (II) A simple generator has a 440-loop square coil 22.0 cm on a side. How fast must it turn in a 0.550-T field to produce a 120-V peak output?
35. (II) A 280-loop circular armature coil with a diameter of 10.0 cm rotates at 120 rev/s in a uniform magnetic field of strength 0.45 T. ($a$) What is the rms voltage output of the generator? ($b$) What would you do to the rotation frequency in order to double the rms voltage output?
36. (II) A generator rotates at 85 Hz in a magnetic field of 0.030 T. It has 950 turns and produces an rms voltage of 150 V and an rms current of 60.0 A. ($a$) What is the peak current produced? ($b$) What is the area of each turn of the coil?
37. (II) Calculate the peak output voltage of a simple generator whose square armature windings are 5.50 cm on a side; the armature contains 125 loops and rotates in a field of 0.200 T at a rate of 120 rev/s.
38. (III) A simple generator has a square armature 6.0 cm on a side. The armature has 85 turns of 0.65-mm-diameter copper wire and rotates in a 0.65-T magnetic field. The generator is used to power a lightbulb rated at 12.0 V and 25.0 W. At what rate should the generator rotate to provide 12.0 V to the bulb? Consider the resistance of the wire on the armature.

## 29–5 Back EMF, Counter Torque; Eddy Current

39. (I) The back emf in a dc motor is 72 V when operating at 1400 rpm. What would be the back emf at 2500 rpm if the magnetic field is unchanged?
40. (I) A dc motor has an armature resistance of 2.65 Ω. If it draws 7.20 A when running at full speed and connected to a 120-V line, how large is the back emf?
41. (II) What will be the current in the motor of Example 29–11 if the load causes it to run at half speed?
42. (II) The back emf in a dc motor is 85 V when the motor is operating at 1400 rpm. How would you change the motor's magnetic field if you wanted to reduce the back emf to 75 V when the motor was running at 2300 rpm?
43. (II) A dc generator is rated at 16 kW, 250 V, and 56 A when it rotates at 1200 rpm. The resistance of the armature windings is 0.40 Ω. ($a$) Calculate the "no-load" voltage at 1200 rpm (when there is no circuit hooked up to the generator). ($b$) Calculate the full-load voltage (i.e., at 56 A) when the generator is run at 750 rpm. Assume that the magnitude of the magnetic field remains constant.

## 29–6 Transformers

[Assume 100% efficiency, unless stated otherwise.]

44. (I) A transformer is designed to change 117 V into 13,500 V, and there are 172 turns in the primary coil. How many turns are in the secondary coil?
45. (I) A transformer has 330 primary turns and 1120 secondary turns. The input voltage is 120 V and the output current is 15.0 A. What are the output voltage and input current?
46. (I) A transformer has 680 turns in the primary coil and 85 in the secondary coil. What kind of transformer is this, and by what factor does it change the voltage? By what factor does it change the current?
47. (I) Neon signs require 12 kV for their operation. To operate from a 240-V line, what must be the ratio of secondary to primary turns of the transformer? What would the voltage output be if the transformer were connected in reverse?
48. (II) A model-train transformer plugs into 120-V ac and draws 0.35 A while supplying 6.5 A to the train. ($a$) What voltage is present across the tracks? ($b$) Is the transformer step-up or step-down?
49. (II) If 75 MW of power at 45 kV (rms) arrives at a town from a generator via transmission lines of total resistance 3.0 Ω, calculate ($a$) the emf at the generator end of the lines, and ($b$) the fraction of the power generated that is wasted in the lines.
50. (II) Assume a voltage source supplies an ac voltage of amplitude $V_0$ between its output terminals. If the output terminals are connected to an external circuit, and an ac current of amplitude $I_0$ flows out of the terminals, then the equivalent resistance of the external circuit is $R_{eq} = V_0/I_0$. ($a$) If a resistor $R$ is connected directly to the output terminals, what is $R_{eq}$? ($b$) If a transformer with $N_P$ and $N_S$ turns in its primary and secondary, respectively, is placed between the source and the resistor as shown in Fig. 29–55, what is $R_{eq}$? [Transformers can be used in ac circuits to alter the apparent resistance of circuit elements, such as loudspeakers, in order to maximize transfer of power.]

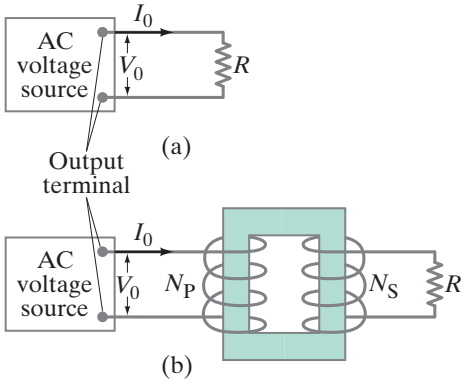

**FIGURE 29–55**
Problem 50.

51. (II) For the transmission of electric power from power plant to home, as depicted in Fig. 29–26, where the electric power sent by the plant is 100 kW, about how far away could the house be from the power plant before power loss is 50%? Assume the wires have a resistance per unit length of $4 \times 10^{-5}\ \Omega/\text{m}$.

**52.** (II) For the electric power transmission system shown in Fig. 29–26, what is the ratio $N_S/N_P$ for (*a*) the step-up transformer, (*b*) the step-down transformer next to the home?

**53.** (III) Design a dc transmission line that can generate 625 MW of electricity and transmit it 485 km with only a 2.0% loss. The wires are to be made of aluminum and the voltage is 660 kV.

**54.** (III) Suppose 785 kW is to arrive at a shopping mall over two 0.100-Ω lines. Estimate how much power is saved if the voltage is stepped up from 120 V to 1200 V and then down again, rather than simply transmitting at 120 V. Assume the transformers are each 99% efficient.

### 29–7 Changing $\Phi_B$ Produces $\vec{E}$

**55.** (III) In a circular region, there is a uniform magnetic field $\vec{\mathbf{B}}$ pointing into the page (Fig. 29–56). An *xy* coordinate system has its origin at the circular region's center. A free positive point charge $+Q = 1.0\,\mu C$ is initially at rest at a position $x = +10\,cm$ on the *x* axis. If the magnitude of the magnetic field is now decreased at a rate of $-0.10\,T/s$, what force (magnitude and direction) will act on $+Q$?

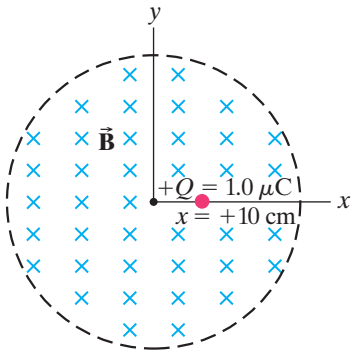

**FIGURE 29–56** Problem 55.

**56.** (III) The **betatron**, a device used to accelerate electrons to high energy, consists of a circular vacuum tube placed in a magnetic field (Fig. 29–57), into which electrons are injected. The electromagnet produces a field that (1) keeps the electrons in their circular orbit inside the tube, and (2) increases the speed of the electrons when *B* changes. (*a*) Explain how the electrons are accelerated. (See Fig. 29–57.) (*b*) In what direction are the electrons moving in Fig. 29–57 (give directions as if looking down from above)? (*c*) Should *B* increase or decrease to accelerate the electrons? (*d*) The magnetic field is actually 60-Hz ac; show that the electrons can be accelerated only during $\frac{1}{4}$ of a cycle $\left(\frac{1}{240}\,s\right)$. (During this time they make hundreds of thousands of revolutions and acquire very high energy.)

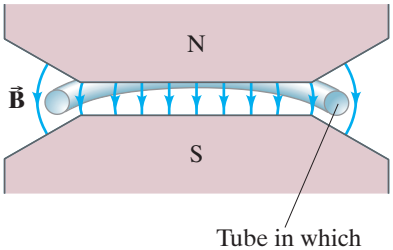

**FIGURE 29–57**
Problems 56 and 57.

**57.** (III) Show that the electrons in a betatron, Problem 56 and Fig. 29–57, are accelerated at constant radius if the magnetic field $B_0$ at the position of the electron orbit in the tube is equal to half the average value of the magnetic field $(B_{avg})$ over the area of the circular orbit at each moment: $B_0 = \frac{1}{2}B_{avg}$. (This is the reason the pole faces have a rather odd shape, as indicated in Fig. 29–57.)

**58.** (III) Find a formula for the net electric field in the moving rod of Problem 30 as a function of time for each case, (*a*) and (*b*).

## General Problems

**59.** A square loop 27.0 cm on a side has a resistance of 8.80 Ω. It is initially in a 0.755-T magnetic field, with its plane perpendicular to $\vec{\mathbf{B}}$, but is removed from the field in 40.0 ms. Calculate the electric energy dissipated in this process.

**60.** Power is generated at 24 kV at a generating plant located 75 km from a town that requires 65 MW of power at 12 kV. Two transmission lines from the plant to the town each have a resistance of 0.10 Ω/km. What should the output voltage of the transformer at the generating plant be for an overall transmission efficiency of 98.5%, assuming a perfect transformer?

**61.** A circular loop of area $12\,m^2$ encloses a magnetic field perpendicular to the plane of the loop; its magnitude is $B(t) = (8.0\,T/s)t$. The loop is connected to a 7.5-Ω resistor and a 6.5-pF capacitor in series. When fully charged, how much charge is stored on the capacitor?

**62.** The primary windings of a transformer which has an 85% efficiency are connected to 110-V ac. The secondary windings are connected across a 2.4-Ω, 75-W lightbulb. (*a*) Calculate the current through the primary windings of the transformer. (*b*) Calculate the ratio of the number of primary windings of the transformer to the number of secondary windings of the transformer.

**63.** A pair of power transmission lines each have a 0.80-Ω resistance and carry 680 A over 9.0 km. If the rms input voltage is 42 kV, calculate (*a*) the voltage at the other end, (*b*) the power input, (*c*) power loss in the lines, and (*d*) the power output.

**64.** Show that the power loss in transmission lines, $P_L$, is given by $P_L = (P_T)^2 R_L/V^2$, where $P_T$ is the power transmitted to the user, *V* is the delivered voltage, and $R_L$ is the resistance of the power lines.

**65.** A high-intensity desk lamp is rated at 35 W but requires only 12 V. It contains a transformer that converts 120-V household voltage. (*a*) Is the transformer step-up or step-down? (*b*) What is the current in the secondary coil when the lamp is on? (*c*) What is the current in the primary coil? (*d*) What is the resistance of the bulb when on?

**66.** Two parallel resistanceless rails are 32 cm apart on a 6.0° ramp. They are joined at the bottom by a 0.60-Ω resistor. At the top a copper bar of mass 0.040 kg (ignore its resistance) is laid across the rails. Assuming a vertical 0.65-T magnetic field, what is the terminal (steady) velocity of the bar as it slides frictionlessly down the rails?

**67.** A coil with 160 turns, a radius of 5.0 cm, and a resistance of 12 Ω surrounds a solenoid with 230 turns/cm and a radius of 4.5 cm (Fig. 29–58). The current in the solenoid changes at a constant rate from 0 to 2.0 A in 0.10 s. Calculate the magnitude and direction of the induced current through the resistor in the outer coil.

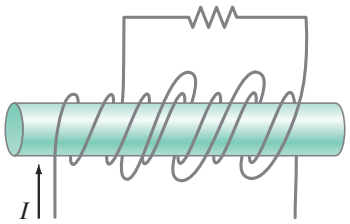

**FIGURE 29–58** Problem 67.

**68.** A **search coil** for measuring $B$ (also called a **flip coil**) is a small coil with $N$ turns, each of cross-sectional area $A$. It is connected to a so-called **ballistic galvanometer**, which is a device to measure the total charge $Q$ that passes through it in a short time. The flip coil is placed in the magnetic field to be measured with its face perpendicular to the field. It is then quickly rotated 180° about a diameter. Show that the total charge $Q$ that flows in the induced current during this short "flip" time is proportional to the magnetic field $B$. In particular, show that $B$ is given by

$$B = \frac{QR}{2NA}$$

where $R$ is the total resistance of the circuit, including that of the coil and that of the ballistic galvanometer which measures the charge $Q$.

**69.** A ring with a radius of 3.0 cm and a resistance of 0.035 Ω is rotated about an axis through its diameter by 90° in a magnetic field of 0.23 T perpendicular to that axis. What is the largest number of electrons that would flow past a fixed point in the ring as this process is accomplished?

**70.** A flashlight can be made that is powered by the induced current from a magnet moving through a coil of wire. The coil and magnet are inside a plastic tube that can be shaken by your hand causing the magnet to move back and forth through the coil. Assume the magnet has a maximum field strength of 0.05 T. Make reasonable assumptions and specify the size of the coil and the number of turns necessary to light a standard 1-watt, 3-V flashlight bulb.

**71.** Conceptual Example 29–12 states that an overloaded motor may burn out due to high currents. Suppose you have a blender with an internal resistance of 3.0 Ω. (*a*) At 120 V, what is the initial current through the blender? (*b*) The blender is rated at 2.0 A for continuous use. What is the back emf of the blender? (*c*) At what rate is heat dissipated in the blender during normal use? (*d*) If the blender jams and stops turning, at what rate is heat dissipated in the motor coils?

**72.** While demonstrating Faraday's law to her class, a physics professor inadvertently moves the gold ring on her finger from a location where a 0.60-T magnetic field points along her finger to a zero-field location in 45 ms. The 1.5-cm-diameter ring has a resistance and mass of 55 μΩ and 15 g, respectively. (*a*) Estimate the thermal energy produced in the ring due to the flow of induced current. (*b*) Find the temperature rise of the ring, assuming all of the thermal energy produced goes into increasing the ring's temperature. The specific heat of gold is 129 J/kg · C°.

**73.** Suppose you are looking at two wire loops in the plane of the page as shown in Fig. 29–59. When the switch S is closed in the left-hand coil, (*a*) what is the direction of the induced current in the other loop? (*b*) What is the situation after a "long" time? (*c*) What is the direction of the induced current in the right-hand loop if that loop is quickly pulled horizontally to the right? (*d*) Suppose the right-hand loop also has a switch like the left-hand loop. The switch in the left-hand loop has been closed a long time when the switch in the right-hand loop is closed. What happens in this case? Explain each answer.

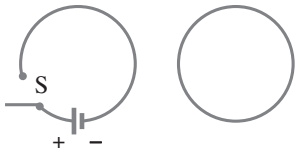

**FIGURE 29–59**
Problem 73.

**74.** A small electric car overcomes a 250-N friction force when traveling 35 km/h. The electric motor is powered by ten 12-V batteries connected in series and is coupled directly to the wheels whose diameters are 58 cm. The 320 armature coils are rectangular, 12 cm by 15 cm, and rotate in a 0.54-T magnetic field. (*a*) How much current does the motor draw to produce the required torque? (*b*) What is the back emf? (*c*) How much power is dissipated in the coils? (*d*) What percent of the input power is used to drive the car?

**75.** What is the energy dissipated as a function of time in a circular loop of 18 turns of wire having a radius of 10.0 cm and a resistance of 2.0 Ω if the plane of the loop is perpendicular to a magnetic field given by

$$B(t) = B_0 e^{-t/\tau}$$

with $B_0 = 0.50$ T and $\tau = 0.10$ s?

**76.** A thin metal rod of length $\ell$ rotates with angular velocity $\omega$ about an axis through one end (Fig. 29–60). The rotation axis is perpendicular to the rod and is parallel to a uniform magnetic field $\vec{\mathbf{B}}$. Determine the emf developed between the ends of the rod.

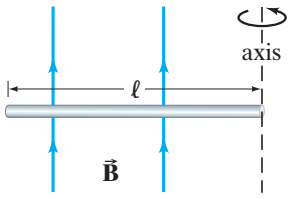

**FIGURE 29–60**
Problem 76.

**77.** The magnetic field of a "shunt-wound" dc motor is produced by field coils placed in parallel with the armature coils. Suppose that the field coils have a resistance of 32.0 Ω and the armature coils 3.00 Ω. The back emf at full speed is 105 V when the motor is connected to 115 V dc. (*a*) Draw the equivalent circuit for the situations when the motor is just starting and when it is running full speed. (*b*) What is the total current drawn by the motor at start up? (*c*) What is the total current drawn when the motor runs at full speed?

**78.** Apply Faraday's law, in the form of Eq. 29–8, to show that the static electric field between the plates of a parallel-plate capacitor cannot drop abruptly to zero at the edges, but must, in fact, fringe. Use the path shown dashed in Fig. 29–61. [*Hint*: Assume the contrary: that there is no fringing. Show that this assumption leads to a contradiction.]

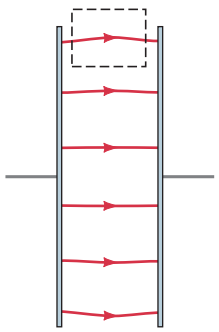

**FIGURE 29–61**
Problem 78.

**79.** A circular metal disk of radius $R$ rotates with angular velocity $\omega$ about an axis through its center perpendicular to its face. The disk rotates in a uniform magnetic field $B$ whose direction is parallel to the rotation axis. Determine the emf induced between the center and the edges of the disk.

**80.** What is the magnitude and direction of the electric field at each point in the rotating disk of Problem 79?

**81.** A circular-shaped circuit of radius $r$, containing a resistance $R$ and capacitance $C$, is situated with its plane perpendicular to a spatially uniform magnetic field $\vec{\mathbf{B}}$ directed into the page (Fig. 29–62). Starting at time $t = 0$, the voltage difference $V_{ba} = V_b - V_a$ across the capacitor plates is observed to increase with time $t$ according to $V_{ba} = V_0(1 - e^{-t/\tau})$, where $V_0$ and $\tau$ are positive constants. Determine $dB/dt$, the rate at which the magnetic field magnitude changes with time. Is $B$ becoming larger or smaller as time increases?

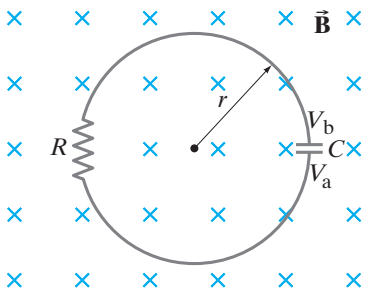

**FIGURE 29–62**
Problem 81.

**82.** In a certain region of space near Earth's surface, a uniform horizontal magnetic field of magnitude $B$ exists above a level defined to be $y = 0$. Below $y = 0$, the field abruptly becomes zero (Fig. 29–63). A vertical square wire loop has resistivity $\rho$, mass density $\rho_m$, diameter $d$, and side length $\ell$. It is initially at rest with its lower horizontal side at $y = 0$ and is then allowed to fall under gravity, with its plane perpendicular to the direction of the magnetic field. (*a*) While the loop is still partially immersed in the magnetic field (as it falls into the zero-field region), determine the magnetic "drag" force that acts on it at the moment when its speed is $v$. (*b*) Assume that the loop achieves a constant terminal velocity $v_T$ before its upper horizontal side exits the field. Determine a formula for $v_T$. (*c*) If the loop is made of copper and $B = 0.80$ T, find $v_T$.

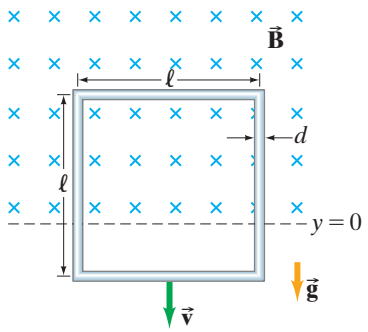

**FIGURE 29–63**
Problem 82.

**83.** A single, square loop of wire just fits inside a long, conventional solenoid of radius $R$ with $n$ turns per unit length. The plane of the square loop is perpendicular to the axis of the solenoid and far from the ends. The current through the solenoid is given by the expression $I(t) = I_0 \cos(\omega t)$ where $I_0$ is the maximum current and $\omega$ is the applied angular frequency. What is the maximum emf developed by the square loop?

**84.** Magnetic flux passes through a stationary loop of wire with resistance $R$ and this flux varies from $t = 0$, to $t = T/2$ such that $\Phi(t) = b \sin(2\pi t/T)$ where $b$ is a given constant. Estimate the energy dissipated in the loop during that time.

**85.** In an experiment, a coil was mounted on a low-friction cart that moved through the magnetic field $B$ of a permanent magnet. The speed of the cart $v$ and the induced voltage $V$ were simultaneously measured, as the cart moved through the magnetic field, using a computer-interfaced motion sensor and a voltmeter. The Table below shows the collected data:

| | | | | | |
|---|---|---|---|---|---|
| Speed, $v$ (m/s) | 0.367 | 0.379 | 0.465 | 0.623 | 0.630 |
| Induced voltage, $V$ (V) | 0.128 | 0.135 | 0.164 | 0.221 | 0.222 |

(*a*) Make a graph of the induced voltage, $V$, vs. the speed, $v$. Determine a best-fit linear equation for the data. Theoretically, the relationship between $V$ and $v$ is given by $V = BN\ell v$ where $N$ is the number of turns of the coil, $B$ is the magnetic field, and $\ell$ is the average of the inside and outside widths of the coil. In the experiment, $B = 0.126$ T, $N = 50$, and $\ell = 0.0561$ m. (*b*) Find the % error between the slope of the experimental graph and the theoretical value for the slope. (*c*) For each of the measured speeds $v$, determine the theoretical value of $V$ and find the % error of each.

## ANSWERS TO EXERCISES

**A:** (*e*).
**B:** (*a*) Counterclockwise; (*b*) clockwise; (*c*) zero; (*d*) counterclockwise.
**C:** Electrons flow clockwise (conventional current counterclockwise).
**D:** (*a*) Increase (brighter light); (*b*) yes; resists more (counter torque).
**E:** 10 turns.
**F:** (*a*) $4.2 \times 10^{-3}$ V/m; (*b*) $5.6 \times 10^{-3}$ V/m.
